Mechanical Operation - CVHF

Overview

THE FOLLOWING DESCRIPTION APPLIES TO THE TRANE MODEL CVHF CENTRIFUGAL CHILLER ONLY. Refer to the appropriate operation manual for refrigeration cycle descriptions of other models.

Each CVHF unit is composed of 5 basic components:

-- the evaporator
-- 2 stage compressor
-- water-cooled condenser
-- single-stage economizer
-- related interconnecting piping

A heat-recovery or auxiliary condenser can be factory-added to the basic unit assembly to provide a heat-recovery cycle.

Figure 5 illustrates the general component layout of a typical CVHF chiller.

CVHF cooling-only and heat recovery modes of operation are described in the following sections. A pressure/enthalpy diagram is provided in Figure 6 to further illustrate unit operation.

Cooling-Only Cycle

When the CVHF is functioning in the cooling mode, liquid refrigerant is distributed along the length of the evaporator and sprayed through small holes in a distributor (i.e., running the entire length of the shell) to uniformly coat each evaporator tube. Here, the liquid refrigerant absorbs enough heat from the system water circulating through the evaporator tubes to vaporize.

The gaseous refrigerant is then drawn through the eliminators (which remove droplets of liquid refrigerant from the gas), first-stage variable inlet guide vanes, and into the first-stage impeller.

Note: Inlet guide vanes are designed to modulate the flow of gaseous refrigerant to meet system capacity requirements; they also prerotate the gas allowing it to enter the impeller at an optimal angle that maximizes efficiency at all load conditions.

Compressed gas from the first-stage impeller is discharged through the second-stage variable guide vanes and into the second-stage impeller. Here, the refrigerant gas is again compressed, and then discharged into the condenser.

Baffles within the condenser shell distribute the compressed refrigerant gas evenly across the condenser tube bundle. Cooling tower water, circulated through the condenser tubes, absorbs heat from the refrigerant, causing it to condense. The liquid refrigerant then flows out of the bottom of the condenser, passing through an orifice plate and into the economizer.

The economizer reduces the energy requirements of the refrigerant cycle by eliminating the need to pass all gaseous refrigerant through both stages of compression. See Figure 7. Notice that some of the liquid refrigerant flashes to a gas because of the pressure drop created by the orifice plate, thus further cooling the liquid refrigerant. This flash gas is then drawn directly from the economizer into the second-stage impellers of the compressor. All remaining liquid refrigerant flows out of the economizer, passes through another orifice plate and into the evaporator.

Note: See Figure 8 for a unit with Refrigerant pump.

Figure 5
General CVHF Components

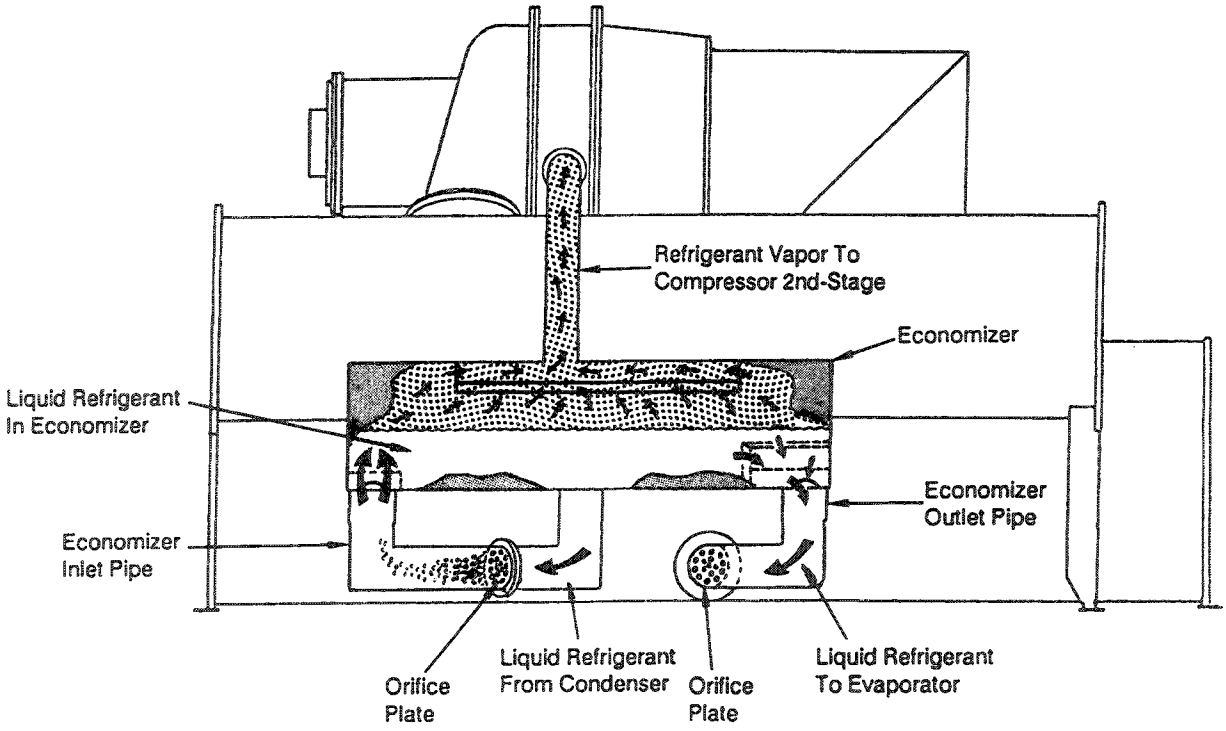
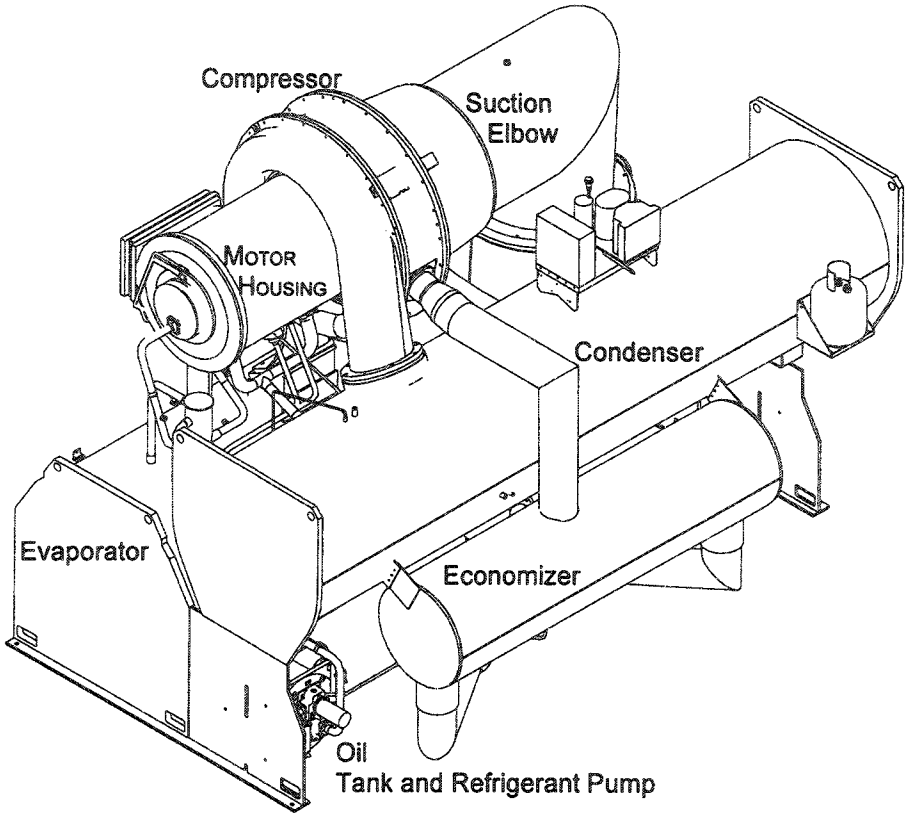
CVHF Economizer Operation





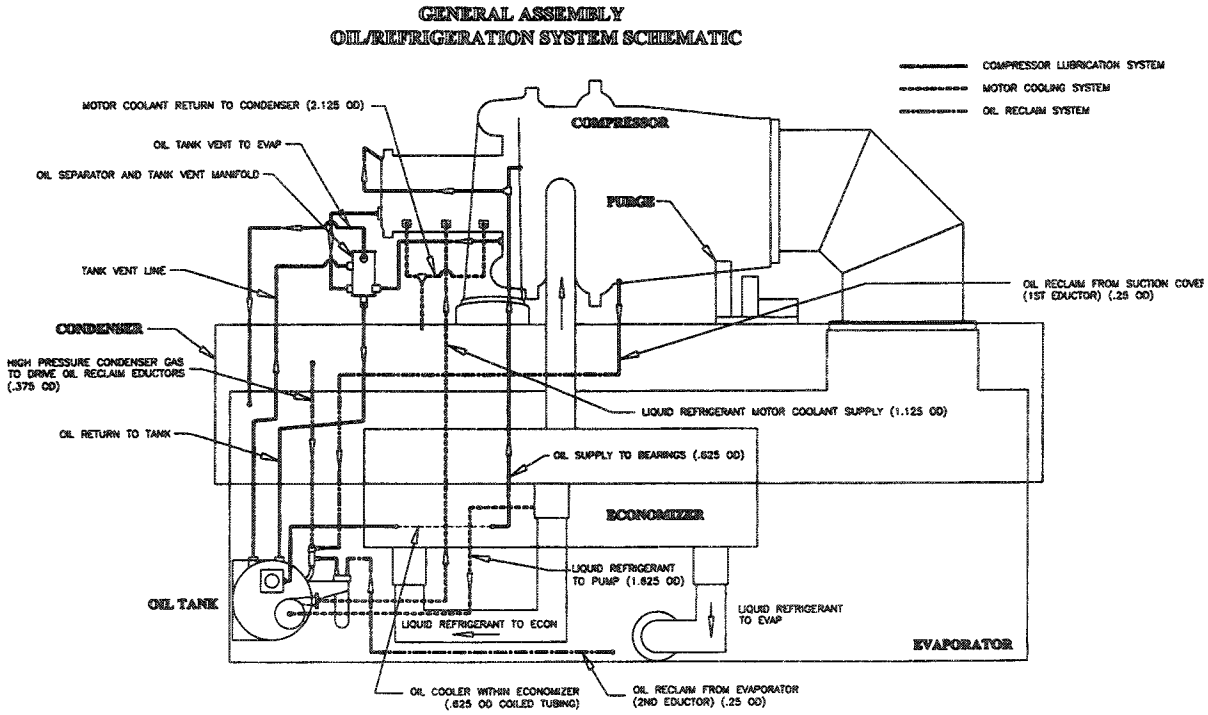


Figure 8 - CVHF Unit With Refrigerant Pump

CVHF Units With Refrigerant Pump

Compressor Lubrication System - CVHF

A schematic diagram of the compressor Refrigerant/Oil lubrication system is illustrated in Figure 8 for the CVHF.

Oil is pumped from the oil tank through an oil pressure regulating valve designed to maintain a net oil pressure of 18 to 22 psid. It is then filtered and sent to the oil cooler and on to the bearings.

From the bearings, the oil drains back to the manifold under the motor and then on to the oil tank.

⚠ WARNING

SURFACE TEMPERATURES MAY EXCEED 150 F. USE CAUTION WHILE WORKING ON CERTAIN AREAS OF THE UNIT, FAILURE TO DO SO MAY RESULT IN DEATH OR PERSONAL INJURY.

To ensure proper lubrication and prevent refrigerant from condensing in the oil tank, a 750 watt heater is immersed in the oil tank and is used to warm the oil while the unit is off. When the unit starts, the oil heater is de energized. This heater energizes as needed to maintain 140 F to 145 F (60 to 63 C) when the chiller is not running.

When the chiller is operating, the temperature of the oil tank is typically 115 F to 160 F (46 to 72 C). The oil return lines from the thrust and journal bearings, transport oil and some seal leakage refrigerant. The oil return lines are routed into a manifold under the motor. Gas flow exits the top of the manifold and is vented to the Evaporator. A vent line solenoid is not needed with the refrigerant pump. Oil exits the bottom of the manifold and returns to the tank. Separation of the seal leakage gas in the manifold keeps this gas out of the tank.

A dual eductor system is used to reclaim oil from the suction cover and the evaporator, and deposit it back into the oil tank. These eductors use high pressure condenser gas to draw the oil from the suction cover and evaporator back to the eductors and then discharged into the oil tank. The evaporator eductor line has a shut off valve mounted by the evaporator and ships with two turns open.

Liquid refrigerant is used to cool the oil supply to both the Thrust bearing and Journal bearing on larger units (360 ton and larger). On refrigerant pump units the oil cooler is located inside the economizer and uses refrigerant passing from the condenser to evaporator to cool the oil. Oil leaves the oil cooler and flows to both the thrust and journal bearings.

Motor Cooling System

Compressor motors are cooled with liquid refrigerant, See Figure 8.

The refrigerant pump is located on the front of the oil tank (motor inside the oil tank). The refrigerant pump inlet is connected to the well at the bottom of the condenser. The connection is on the side where a weir assures a preferential supply of liquid. Refrigerant is delivered to the motor via the pump and delivered to the same connection as used on units without the refrigerant pump. Motor refrigerant drain lines are routed to the condenser.

Free Cooling Cycle CVHE, CVHF and CVHG

Based on the principle that refrigerant migrates to the coldest area in the system, the free cooling option adapts the basic chiller to function as a simple heat exchanger. However, it does not provide control of the leaving chilled water temperature.

If condenser water is available at a temperature lower than the required leaving chilled water temperature, the operator manually stops the compressor and starts the free cooling cycle by enabling the Free cooling mode in the "Operator Settings" Group of the Human Interface.

Several components must be factory-supplied or field-installed to equip the unit for free cooling operation:

-- options module 1U5

-- a refrigerant gas line, including an electrically-actuated shutoff valve, between the evaporator and condenser;

-- a valve liquid return line, including an electrically-actuated shutoff valve, between the condenser sump and the evaporator;

-- a liquid refrigerant storage vessel; and,

-- additional refrigerant.

When the chiller operator initiates changeover to the free cooling mode, the compressor will shut down if running, the shutoff valves in the liquid and gas lines open; UCP (i.e., unit control panel) control logic prevents the compressor from energizing during free cooling. Liquid refrigerant then drains (by gravity) from the storage tank into the evaporator and floods the tube bundle.

Since the temperature and pressure of the refrigerant in the evaporator are higher than in the condenser (i.e., because of the difference in water temperature), the refrigerant in the evaporator vaporizes and travels to the condenser. Cooling tower water causes the refrigerant to condense, and it flows (again, by gravity) back to the evaporator.

This compulsory refrigerant cycle is sustained as long as a temperature differential exists between condenser and evaporator water. The actual cooling capacity provided by the free cooling cycle is determined by the difference between these temperatures which, in turn, determines the rate of refrigerant flow between the evaporator and condenser shells.

If the system load exceeds the available free cooling capacity, the operator must manually initiate changeover to the mechanical cooling mode by disabling the free cooling mode in the "Operator Settings" Group of the Human Interface. The gas and liquid line valves then close and compressor operation begins. Refrigerant gas is drawn out of the evaporator by the compressor, where it is then compressed and discharged to the condenser.

Most of the condensed refrigerant initially follows the path of least resistance by flowing into the storage tank. This tank is vented to the economizer sump through a small bleed line; when the storage tank is full, liquid refrigerant must flow through the bleed line restriction. Because the pressure drop through the bleed line is greater than that of the orifice flow control device, the liquid refrigerant flows normally from the condenser through the orifice system and into the economizer.

Note: During changeover from free cooling to mechanical cooling, the refrigerant transfer process is completed within three minutes. The micro-computer-based control system prevents carry-over by not allowing the unit to load for a period of two minutes.

Heat Recovery Cycle

"Heat recovery" is designed to salvage the heat that is normally rejected to the atmosphere through the cooling tower, and put it to beneficial use.

For example, a high-rise office building may require simultaneous heating and cooling during the winter months. With the addition of a heat recovery cycle, heat removed from the building cooling load can be transferred to areas of the building that require heat. (Keep in mind that the heat recovery cycle is only possible if a cooling load exists to act as a heat source.)

To provide a heat recovery cycle, a heat-recovery condenser is added to the unit; see Figure 2. Though physically identical to the standard cooling condenser, the heat-recovery condenser is piped into a heat circuit rather than to the cooling tower.

During the heat recovery cycle, the unit operates just as it does in the "cooling only" mode except that the cooling load heat is rejected to the heating water circuit rather than to the cooling tower water circuit.

When hot water is required, the heating water circuit pumps energize. Water circulated through the heat-recovery (or auxiliary) condenser tube bundle by the pumps absorbs cooling-load from the compressed refrigerant gas discharge by the compressor. The heated water is then used to satisfy heating requirements.

Auxiliary Condensers

Unlike the heat-recovery condenser (which is designed to satisfy comfort heating requirements), the auxiliary condenser serves a preheat function only, and is used in those applications where hot water is needed for use in kitchens, lavatories, etc. While the operation of the auxiliary condenser is physically identical to that of the heat-recovery condenser, it is comparatively smaller in size, and its heating capacity is not controlled.

Trane does not recommend operating the auxiliary condenser alone because of its small size.

Ice Machine Control

UCP2 provides a service level "Enable/Disable" menu entry for the Ice Building feature when the Ice Building option is installed. UCP2 will accept either an isolated contact closure (J3, 7 & 8 on the options module) or a remote communicated input (Tracer) to initiate the ice building mode where the unit runs fully loaded at all times. Ice building will be terminated either by opening the contact or based on entering evaporator water temperature. UCP2 will not permit the Ice Building mode to be entered again until the unit is switched to the Non-ice building mode and back into the ice building mode. It is not acceptable to reset the chilled water setpoint low to achieve a fully loaded compressor.

When entering ice-building the compressor will be loaded at its maximum rate and when leaving ice building the compressor will be unloaded at its maximum rate. While loading and unloading the compressor, all surge detection will be ignored.

While in the ice building mode, current limit setpoints less than the maximum will be ignored. Ice Building can be terminated by one of the following means:

1. Opening the external Ice Contacts/Remote communicated input (Tracer).

2. Satisfying an evaporator entering water temperature setpoint.

3. Surging for 15 minutes at full open IGV.

Base Loading

Tracer Base Loading:

Current Setpoint Range:
(20 - 100) % RLA

The tracer commands the chiller to enter the base load mode by setting the base load mode request bit to 1. If the chiller is not running, it will start regardless of the differential to start (either chilled water or hot water). If the chiller is already running, it will continue to run regardless of the differential to stop (either chilled water or hot water), using the base load control algorithm. While the unit is running in base loading, it will report that status back to the tracer by setting "Base Load Status = true" in the Tracer Status Byte. When the tracer removes the base load mode request (sets the bit to 0). The unit will continue to run, using the normal chilled or hot water control algorithm, and will turn off, only when the differential to stop has been satisfied.

External Base Loading:

Current Setpoint Range:
(20 - 100) % RLA

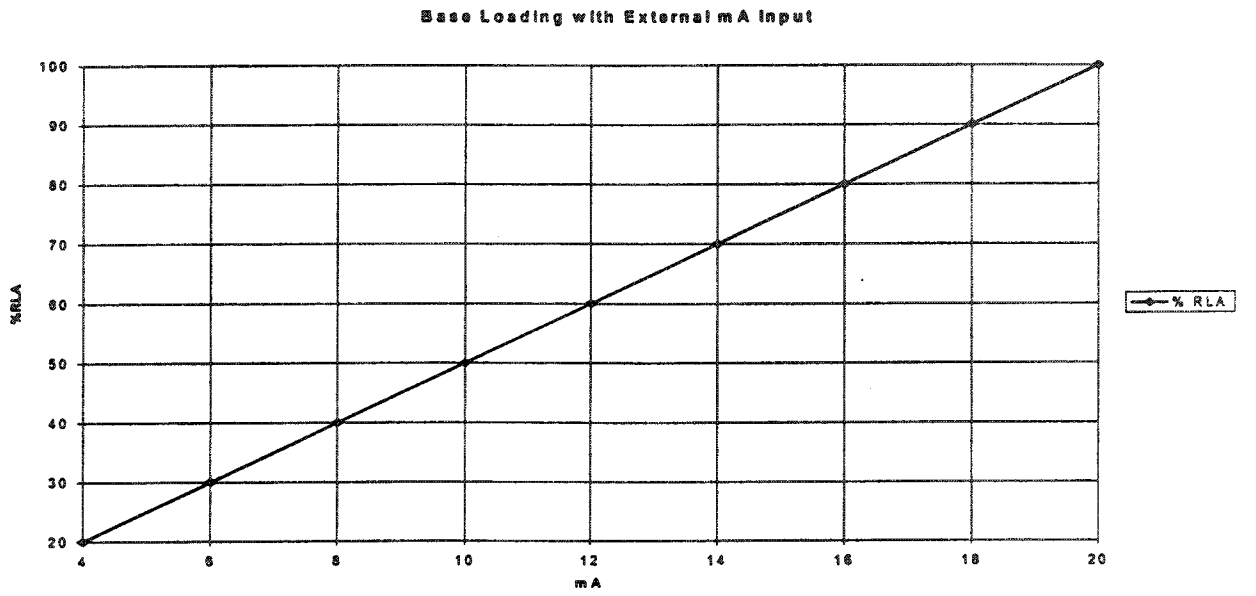
The chiller module accepts 2 inputs to work with external base loading. The first input is on chiller module terminals J7-1 and J7-2. This input looks for a switch closure to enter the base-loading mode. The second input is found on chiller module terminals J7-11 and J7-12. This input selects the base loading setpoint, and can be controlled by either a 2-10Vdc or 4-20ma Signal. To use a 2-10Vdc input, dip switch 2-1 should be in the 'OFF' position. To use a 4-20mA input, dip switch 2-1 should be in the 'ON' Position. You must also set the correct input type in the Machine Configuration menu. This menu is titled "External Setpoints Input". The graphs in Figure 9 show the relationship between input and % RLA.

While in base loading the active current limit setpoint is set to the tracer or external base load setpoint, providing that the base load setpoint is not equal to 0 (or out of range). If it is out of range, the front panel current limit setpoint is used. During base loading, all limits are enforced with the exception of current limit. The human interface displays the message "Unit is Running Base Loaded". Hot Gas Bypass is not run during base loading. If base loading and ice making are commanded simultaneously, ice making takes precedence.

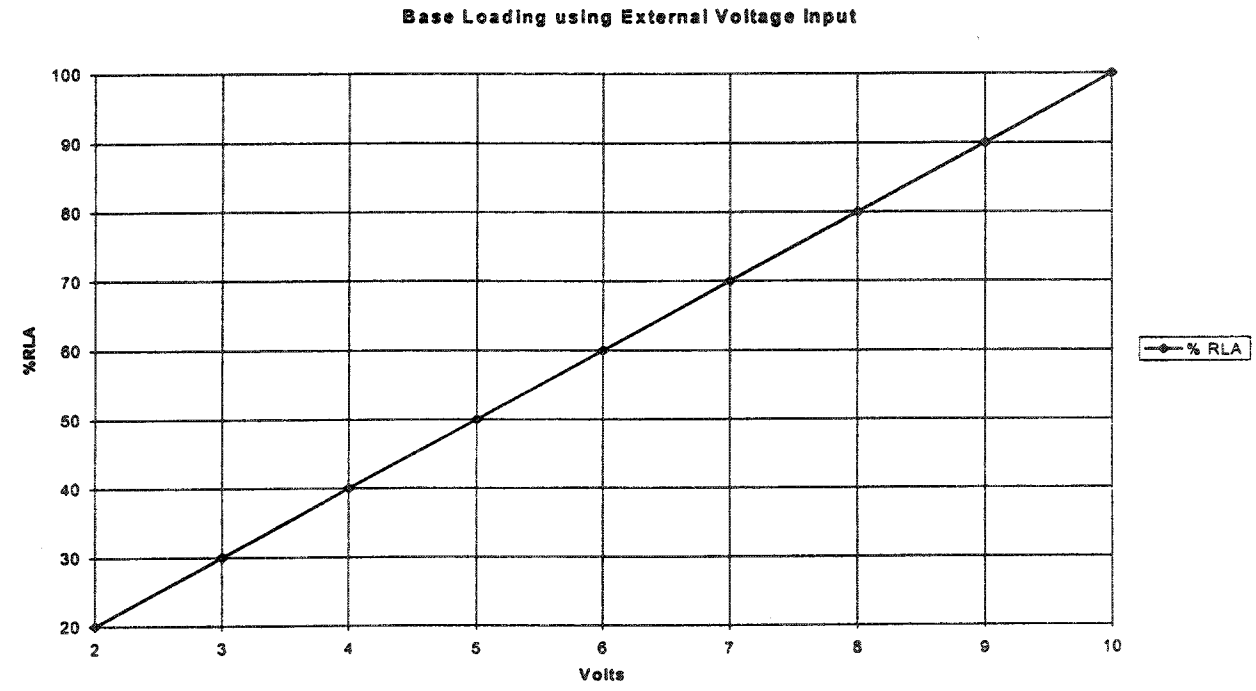
Base Loading Control

Algorithm:

Base Loading Control is basically a variation of the current limit algorithm. During base loading, the leaving water control algorithm provides a 1250 step load command every 5 seconds. The current limit routine limits the loading when the current is below setpoint. When the current is within the deadband of the setpoint the current limit algorithm holds against this loading command. If the current exceeds the setpoint, the current limit algorithm unloads. The "Capacity Limited By High Current" message normally displayed while the current limit routine is active is suppressed while base loading.



Unit Mounted Refrigerant Monitor



Refer to RMWD-IOM-1D or the most current revision. This can be obtained from the nearest Trane office in your area.

Unit Mounted Adaptive Frequency™ Drive

The AFDB, is a water-cooled pulse width modulated inverter. The function of the inverter is to change a DC input voltage to a symmetrical AC output voltage of desired magnitude and frequency. It is designed for 460/480-volt application. Circuit breakers, surge capacitors and ground faults are standard on all AFDB units. The CTV unit control panel has full control of the AFDB unit operation, including the start/stop functions. AFDB-OM-1C (or most recent revision) covers the features and specifications of the Trane Adaptive Frequency drive.

Figure 9
Base Loading with External mA Input and with External Voltage Input

Unit Control Panel

The UCP2 control, see Figure 10, consists of a modular design partitioned by major function or group of functions. All modules communicate with each other through the IPC circuit.

Major components within each of these control groups are described below.

Unit-mounted temperature sensors, pressure transducers and functional switches provide analog and binary inputs to the various modules.

The "microcomputer-based" modules are described below. All wiring to the modules are to pluggable terminal blocks.

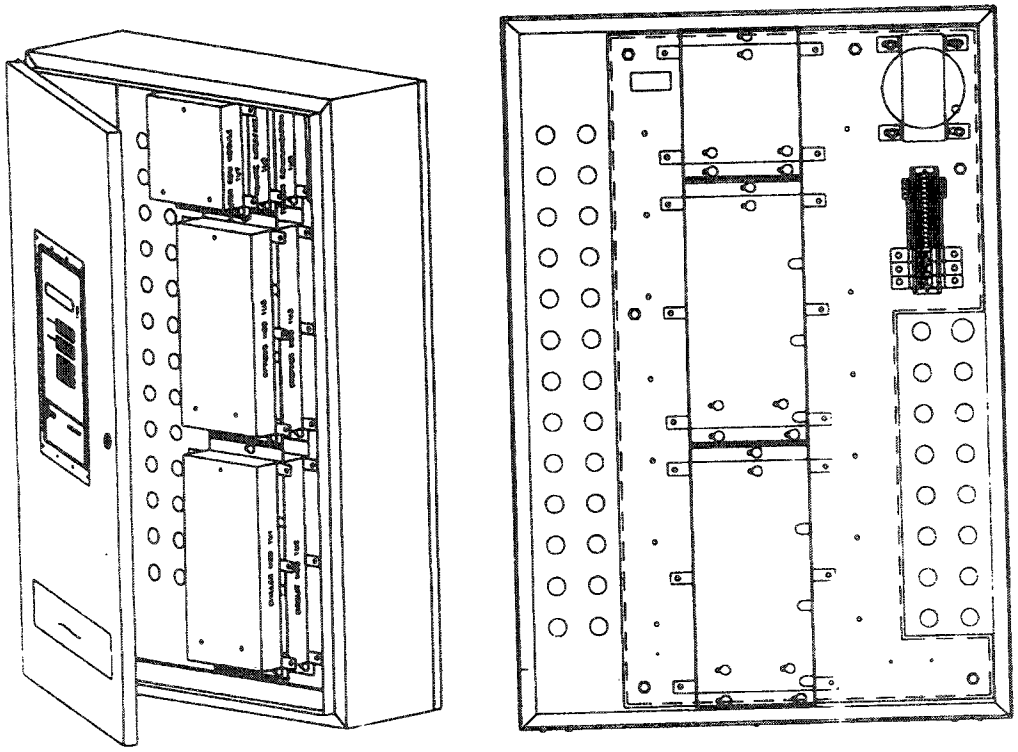
Chiller Module (1U1)

The Chiller Module, located in the UCP2 control panel, is the "Master" of the chiller communicating commands to other modules and collecting data, status and diagnostic information from the other modules over the IPC (Inter Processor Communications) link. The Chiller Module performs the Leaving Chilled Water Temperature and Limit Control Algorithms arbitrating capacity against any operating limit the chiller may find itself working against. The Chiller module contains non-volatile memory both checking for valid set points and retaining them on any power loss.

Inputs and outputs are chilled water system level inputs and outputs including evaporator and condenser water temperatures, outdoor air temperature, evaporator and condenser water pump control, status and alarm relays, external auto-stop, emergency stop, evaporator and condenser water pressure drops and evaporator and condenser water flow switches. Connection points of standard and optional inputs and outputs for the chiller module (1U1) are shown in Figure 11.

For more information regarding the UCP2 control module screens, refer to CVHE-CLD-1A or later revision, which is the Clear Language Display manual that ships with CVHE, CVHF and CVHG units from the factory. This manual also may be obtained from the nearest Trane office.

Figure 10
UCP2 Control Panel



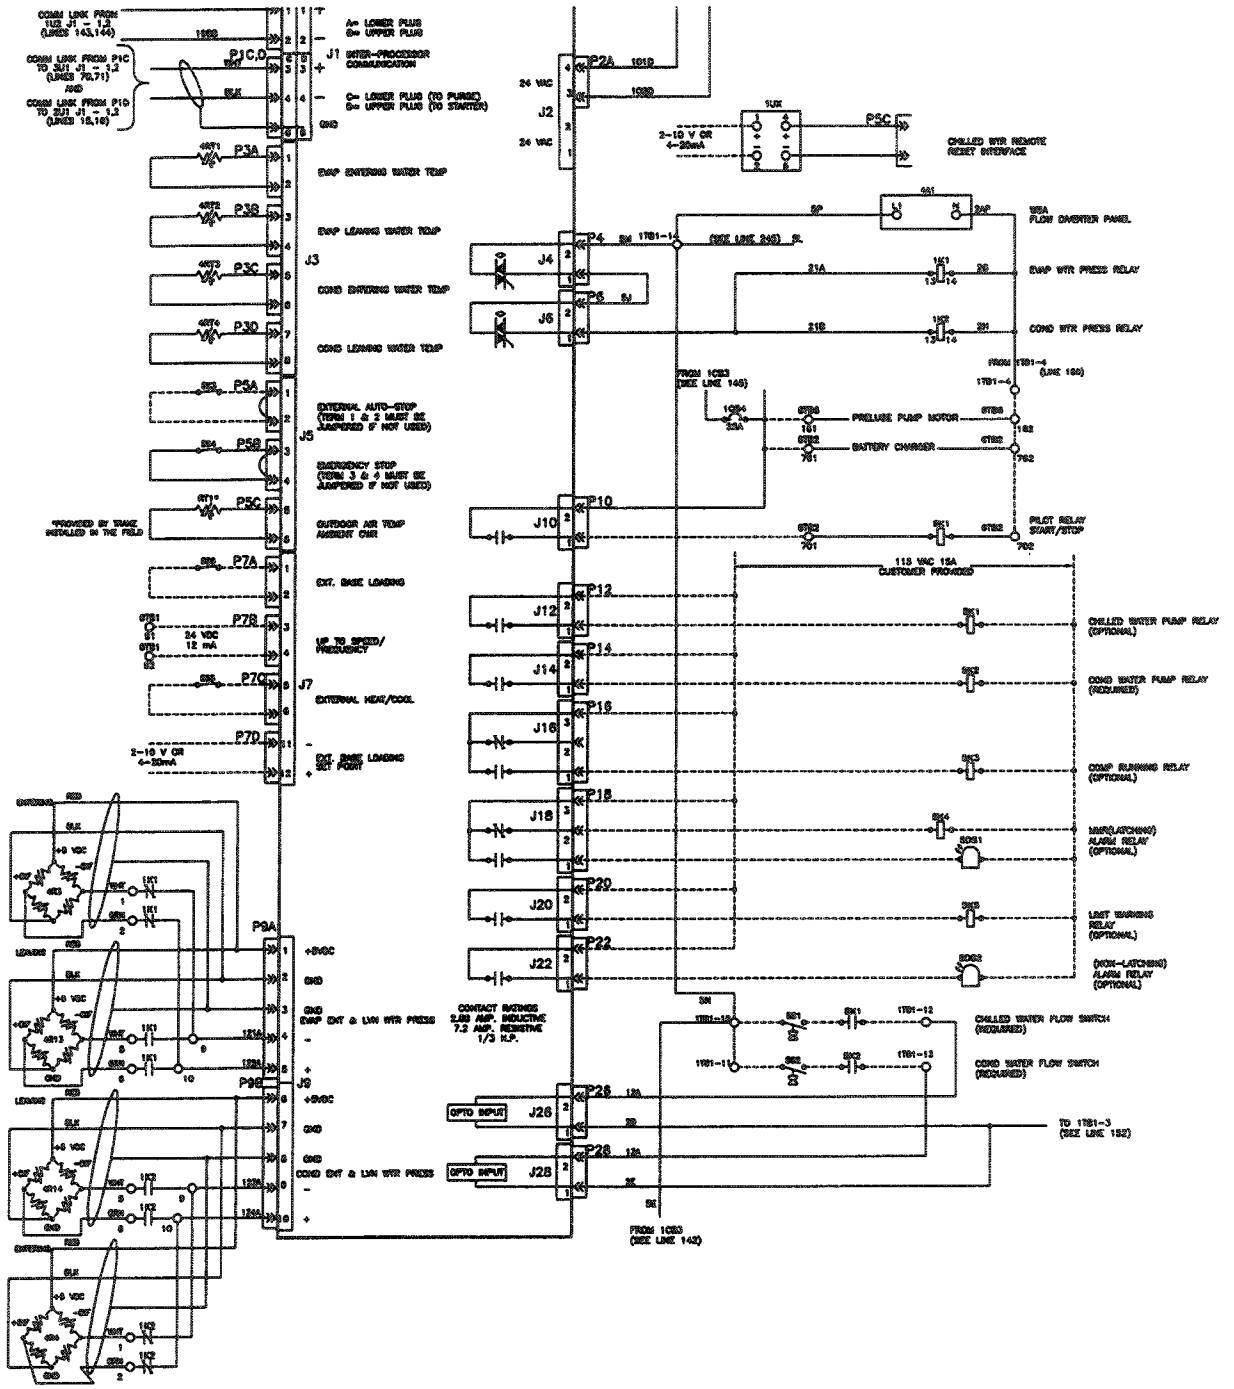


Figure 11 - Chiller Module (1U1) - CVHE, CVHF and CVHG

Circuit Module (1U2)

The Circuit Module serves as an input/output expander and has inputs and outputs associated with motor, refrigerant and lubrication functions. These include, motor winding temperatures, oil temperature, refrigerant monitor connection, optional condenser refrigerant pressure, oil sump pressure, oil pump discharge pressure, vent line valve operation, oil tank heater operation, oil pump and oil pump/refrigerant pump on units with the refrigerant pump.

Note: The oil heater no longer needs to run when the unit is running. When the unit is OFF, the heater will be ON.

You will notice that the oil sump may run colder when the unit is running and the oil heater is OFF. The oil sump temperature will operate at oil saturated evaporator temp plus 30° F (16.6°C).

Connection points of inputs and outputs for the Circuit Module (1U2) are shown in Figure 18.

Figure 18 shows Circuit Module with a Refrigerant Pump.

Stepper Module (1U3)

Note: The CVHF 1470/1720 Stepper Module drives two actuators, one for each compressor stage. The Stepper Module determines the direction and distance to drive the second actuator based on the Chiller Module's command to drive the First Actuator.

The Stepper Module drives the stepper motor inlet guide vane actuator on CenTraVac® Chillers. The Stepper Module receives from the Chiller Module the direction and distance to drive the inlet guide vanes and then generates the appropriate signals to operate the stepper motor.

The Stepper Module has inputs and outputs used to support functions on the module. These include saturated evaporated refrigerant temperature, bearing temperatures, compressor discharge temperature, inlet guide vane binary position indicator (B.P.I.), and saturated condenser refrigerant temperature.

Connection points of inputs and outputs of the Stepper Module (1U3) are shown in Figure 12 and include CVHF 1470 and 1720.

Clear Language Display Module (1U4)

The Clear Language Display Module, located on the UCP2 control panel door, provides display of chiller data and access to operator/serviceman controls, set points and chiller setup information. All information is stored in non-volatile memory in the Chiller Module. The Clear Language Display and the Chiller Module work together to display and store information requiring non-volatility. The connections to the Clear Language Display Module (1U4) are shown in Figure 13. The front face of the Clear Language Display Module consists of a LCD Display, a LED, and a keypad. The LCD Display presents the operating status of the unit, operating set points, operating conditions, unit configurations, purge operating conditions, diagnostics, unit configuration, and service test in a clear language display.

The LED is red in color and will only be "ON" when a manual reset is required to restore the unit to full operation. The keypad has 16 keys arranged in a 4 c 4 matrix. See CVHE-CLD-1A or latest revision for operation and set-ups on the Clear Language Display.

Options Module (1U5)

The Options Module provides control or interface requirements for a number of options. Features supported by the Options Module include Ice-Making, Heat Recovery, External Chilled Water Setpoint, External Current Limit Setpoint, Free Cooling, Evaporator Differential Water Pressure Drop, Condenser Differential Water, Pressure Drop Percent RLA of Compressor, Tracer Temperature Sensor, Head Relief Request, Maximum Capacity Relay, and Tracer Controlled Relay. Connection points of inputs and outputs of the Options Module (1U5) are shown in Figure 14.

Starter Module (2U1)

The Starter Module located in the Compressor Motor Starter Panel provides control of the starter when starting, running and stopping the motor. The Starter Module provides interface to and control of the Y-Delta, X-Line, P-Reactor, A-Transformer and Solid State Starters; interface to and control of Adjustable Speed Drives is also supported.

The Starter Module also provides protection to both the motor and the compressor in the form of starting and running overload, phase reversal, phase loss, phase unbalance, momentary power loss and compressor surge. Typical wiring connections to the Starter Module are shown in Figures 16 and 17.

Purge Module (3U1)

The Purge Module provides control of the Purge used on CVHE, CVHF and CVHG units. The Purge Module provides all the inputs and Outputs to control the purge, optimizing both purge and chiller efficiency. The Purge Module resides in the purge control panel and communicates with the Chiller Module over the IPC (Inter-Processor Communications Link) uploading setpoints and down loading data and diagnostics. Connection points of the input and outputs to the Purge Module are shown in Figure 15.

UCP2 Board Dip Switch Settings

Several of the UCP2 modules have dip switch settings on them, used to set up the board for 2-10 VDC or 4-20 MA signal inputs and or outputs of the boards. The following are the various switch settings.

Chiller Module

External Vane Position	Switch	2-10V	4-20 MA
	SW2-1	OFF	ON (SW2-2 and SW2-3 are not used).

Options Module

External Current Limit External Chilled Water	Switch	2-10V	4-20 MA
	SW2-1	OFF	ON (SW2-2 and SW2-3 are not used).
	SW3-1	OFF	ON (SW2-3 not used)

TCI/IPC Modules

Tracer COM3	Switch	-1	-2	-3
	SW1	OFF	OFF	OFF

Tracer COM4	Switch	-1	-2	-3
	SW1	OFF	ON	OFF

IPC BUFFER	Switch	-1	-2	-3
	SW1	OFF	OFF	ON

PRINTER	Switch	-1	-2	-3
	SW1	OFF	OFF	ON

Setup for External Current Limit Setpoint

The External Current Limit is an option that allows the current limit setpoint to be changed from a remote location. The External Limit Setpoint is found on Option Module terminals J7-11 and J7-12.

UCP2 shall accept either a 2-10 Vdc or 4-20 analog input suitable for customer connection to set the unit external current limit setpoint. 2-10 vdc and 4-20 ma shall each correspond to a 40 to 120% RLA range. CTV UCP2 will limit the maximum ECLS to 100%.

The following must be "SET":

1. SW2-1-OFF for 2-20 Vdc On for 4-20 ma.
2. Current Limit Setpoint Source: External
3. External Current Limit Setpoint: Installed
4. Setpoint Type: 2-10 Vdc or 4-20 ma

The user must also specify the type of External Setpoint Input (4-20 ma or 2-10 VDC) in the Machine Configuration Menu.

Setup for External Chilled Water Setpoint

The External Chilled Water Setpoint allows the chilled water setpoint to be changed from a remote location. The External Chilled Water Setpoint is found on Options Module terminals J9-4 and J9-5.

UCP2 shall accept either a 2-10 Vdc or 4-20 ma analog input suitable for customer connection to set the unit leaving chilled water setpoint. 2-10 vdc and 4-20 ma shall each correspond to a 0 to 65 F (-17.8 to 18.3 C) CWS range.

The following must be "SET":

1. SW3-1 OFF for 2-10 VDC. ON for 4-20 MA.
2. Chilled Water Reset Type: Disable - Operator Settings Group
3. Chilled Water Setpoint : Source External - Operator Settings Group
4. Setpoint Source Override: None - Operator Settings Group
5. External Chilled Water Setpoint: Installed - Service Settings Group - Machine Configuration
6. Setpoint Type: 2-10 Vdc or 4-20 ma. - Service Setting Group-Machine Configuration

Refrigerant Monitor Input

Analog type input 4-20ma input signal to the Circuit module J5-5 and J5-6. This represents 0-100 ppm.

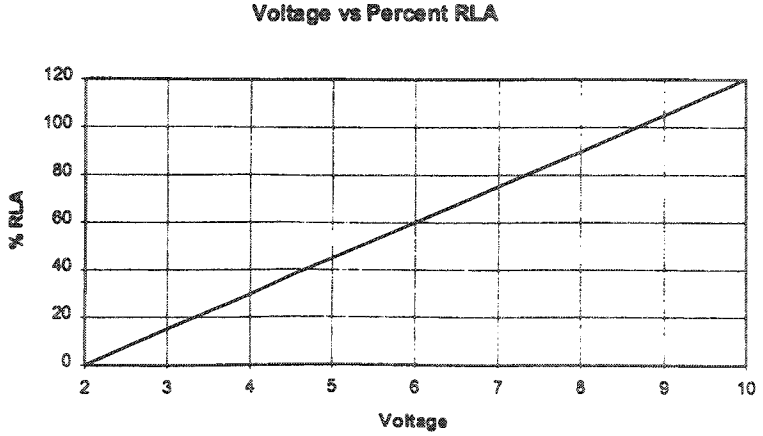
Under Machine Configuration "Refrigeration Monitor Type". Direct communication to the CLD via the IPC.

Under Machine Configuration "Refrigeration Monitor Type" " 02" for IPC Monitor.

Also allows monitor calibration and setup. Please note that the monitor cannot have a local display, and communicate with the UCP2. If the customer requires a local display, he can connect an RMWD style monitor up like the analog type previously described. See Figure 19 for the Refrigerant Monitor Module (4U1).

Load Indication Output

Option Modules J7-3, --4



2-10 Vdc

As an option, the UCM shall provide a 0-10 Vdc analog output to indicate % RLA. The transfer function shall be 2 to 10 Vdc corresponding to 0 to 120% RLA.

Percent RLA Output:

UCP2 provides a 2-10 Vdc analog output to indicate Percent RLA. The transfer function shall be 2 to 10 Vdc corresponding to 0 to 120% RLA. With a resolution of 0.146%.

The following graph illustrates the output:

The Percent RLA Output is found on the Options Module terminals J7-3 and J4.

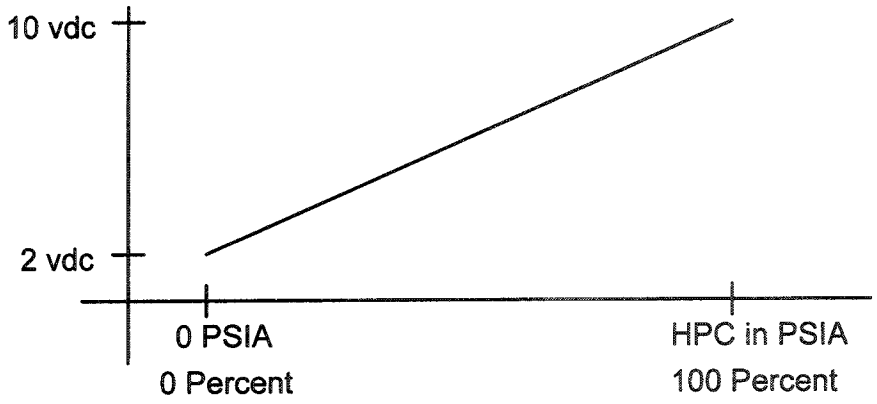
The Percent RLA Output is polarity sensitive.

J7-3 is +
J7-4 is -

The Percent RLA Output's maximum source capability is 30mA.

Percent Condenser Pressure Output:

The transfer function is 2 to 10 Vdc corresponding to 0 Psia to the HPC setting (psig) plus the local atmospheric pressure setting or, 0 Psia to HPC in Psia. The Percent Condenser Pressure Indication Output is based on the Condenser Refrigerant Pressure sensor if the Condenser Pressure Option is selected as "installed" at the CLD. The Percent Condenser Pressure Indication Output is based on the Saturated Condenser Refrigerant Temperature sensor if the Condenser Pressure Option is selected as "Not Installed" at the CLD.



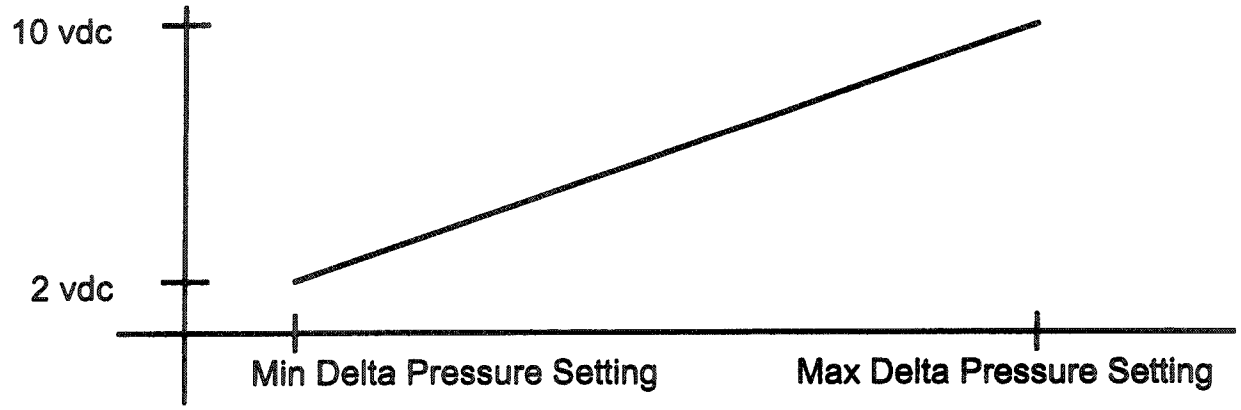
When a Temperature Sensor Only is used and a Temperature to Pressure Conversion is made:

If the Condenser Saturated Temperature goes out of range due to an open or short, a pressure sensor diagnostic will be called and the output will also go to the respective out of range value. That is, for an out of range low on the sensor, the output will be limited to 2.0 VDC. For an out of range high on the sensor, the output will be limited to 10.0 VDC.

When a Condenser Pressure Sensor is used (Optional): If the Condenser Pressure sensor goes out of range due to an open or short, a pressure sensor diagnostic will be called and the output will go to end of range low. That is, for an out of range low on the sensor, the output will be limited to 2.0 VDC. For an out of range high on the sensor, the output will be limited to 2.0 VDC.

When a Temperature Sensor Only is used (Optional): If the Temperature Sensor (or Condenser Pressure sensor) goes out of range due to an open or short, a Temperature Sensor (or Pressure Sensor) diagnostic will be called and the output will go to end of range low. That is, for an out of range low on the sensor, the output will be limited to 2.0 VDC. For an out of range high on the sensor, the output will be limited to 2.0 VDC.

Or:



Refrigerant Differential Pressure Indication Output:

(Selectable in Service Settings - Field Start-up Group) The Transfer function is 2 to 10 VDC corresponding to the menu entered "Min Delta Pressure Calibration" setting to the menu entered "Max Delta Pressure Calibration" setting.

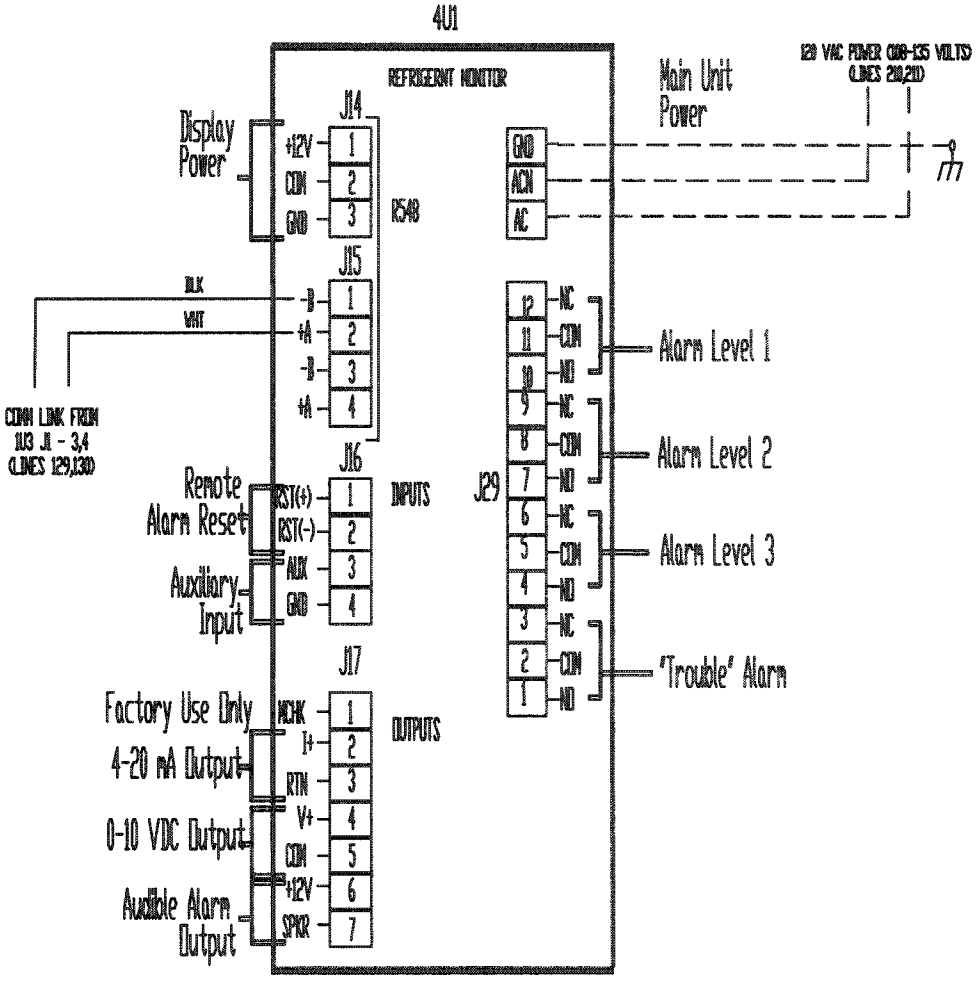
The transfer function is 2 to 10 Vdc corresponding to the menu entered "Min Delta Pressure Calibration" setting to the menu entered "Max Delta Pressure Calibration" setting. The Min Delta Pressure Calibration setting shall have a range of 0-400 psid (0-2758 kPa) in increments of 1 psid (1kPa).

The Max Delta Pressure Calibration setting shall have a range of 1-400 psid (7-2758 kPa) in increments of 1 psid (1kPa). The condenser refrigerant pressure shall be based on the Condenser Refrigerant Temperature sensor if the Condenser Pressure Option is selected as "Not Installed" at the CLD.

The evaporator refrigerant pressure shall be based on the Saturated Evaporator Refrigerant Temperature Sensor.

The Percent Condenser Pressure/ Refrigerant Differential Pressure Indication Output is located on the Circuit Module at J7-1, 2.

If the saturated condenser temperature is used to determine condenser pressure, it takes about 11.5 seconds for UCP2's Percent Condenser Pressure Output to respond to a step change in saturated condenser temperature.



The Percent Condenser Pressure Output can source a maximum of 30mA of current.

The maximum recommended length to run this signal is included in Table 1.

Table 1 - Recommended Length to Run Percent Condenser Pressure Output

Gauge	Ohms/Foot	Max Length (Ft)	Max Length (M)
14	0.002823	1062.7	324.0
16	0.004489	668.3	203.8
18	0.007138	420.3	128.1
20	0.01135	264.3	80.6
22	0.01805	166.3	50.7
24	0.0287	104.5	31.9
26	0.04563	65.7	20.0
28	0.07255	41.4	12.6
Note: the above table is for copper conductors only.			

Figure 19 - Refrigerant Monitor (4U1) CVHE, CVHF and CVHG

Electrical Sequence of Operation

Overview

This section will acquaint the operator with the control logic , governing CVHE, CVHF and CVHG chillers equipped with UCP2 based control systems. When reviewing the step-by-step electrical sequences of operation, refer to the typical wiring schematics shown in the installation manual or wiring manual which are shipped with the chiller.

Note: The typical wiring diagrams are representative of standard units and are provided only for general reference. They may not reflect the actual wiring of your unit. For specific electrical schematic and connection information, always refer to the wiring diagrams that shipped with the chiller.

With the supply power disconnect switch or circuit breaker (2CB1) closed, 120-volt control power transformer 2T5 and a 30-amp starter panel fuse (2F4) to terminal 1TB1-1 in the UCP2 control panel. From this point, control voltage flows to:

Circuit Breaker 1CB1, supplying power to starter module (2U1) via terminal 2TB1-6 for starter contactors operation and the high condenser pressure switch 3S1.

Circuit Breaker 1CB2, supplying power to the purge module (3U1) and the 24 volt supply transformer 3T1 for the purge module (3U1).

Circuit Breaker 1CB3, Supplying power to:

1. The I/O module (1U10) will operate the Hot Gas Bypass valve, the Oil Heater (4R1), and the oil pump motor through Fuse 1F2.

2. The chiller module (1U1) will operate evaporator (4L2) and condenser (4L3) water pressure transducer solenoids and to the chilled water (5S1) and condenser water (5S2) flow switch circuits.

The starter module (2U1) receives 24 volt power from control power transformer 2T4 in the starter panel.

The Clear Language Display (1U4), Stepper (1U3), Circuit (1U2), Options (1U5), Chiller (1U1), and COMM (1U6), (1U7), (1U8) & (U10) modules obtain 24 volt power from control power transformer 1T1 in the control panel.

Chilled and Condenser Water Flow Interlock Circuits

Proof of chilled water flow for the evaporator is made by the closure of flow switch 5S1 and the closure of auxiliary contacts 5K1 on terminals 1TB1-11 and 1TB1-12.

Proof of condenser water flow for the condenser is made by the closure of flow switch 5S2 and the closure of auxiliary contacts 5K2 on terminals 1TB1-11 and 1TB1-13.

UCP2 and Wye-Delta Starter Control Circuits

Logic Circuits within the various modules will determine the starting, running, and stopping operation of the chiller. If operation of the chiller is required and the chiller mode is set at "Auto", then the Chiller Module's logic decides to start the chiller based on the differential to start setpoint.

The chiller water pump relay (5K1) is energized by the Chiller Module (1U1-J12) and chilled water flow must be verified within 3 minutes by the Chiller Module (1U1-J26).

Circuit Module (1U2-J22) and the condenser water pump relay (5K2) Based on the restart inhibit timer and the differential to start setpoint, oil pump and refrigerant pump (4B3) will be energized by the will be energized by the Chiller Module (1U2-J14) when the restart inhibit timer is at 30 seconds or less. The oil pressure must be at least 9 Psid for 30 continuous seconds and condenser water flow verified within 3 minutes by the Chiller Module (1U1-J28) for the compressor start sequence to be initiated.

When less than 5 seconds remain before compressor start, a starter test is conducted to verify contactor states prior to starting the compressor. The following test/start sequence is conducted for "Wye-Delta" starters: Also refer to Figure 21 in this manual.

A. Test for transition complete contact open (2K2 AUX at 2U1-J4) - 160 to 240 msec. An MMR diagnostic will be generated if the contact is closed.

B. Delay time - 20 msec.

C. Close start contactor (2K1) and check for no current - 500 msec. If currents are detected, the MMR diagnostic "Starter Fault Type I" is generated.

D. Stop relay (2U1-J6) closes for 1 second for test "C" above.

E. Delay time - 200 msec.(Opens 2K1).

F. Close shorting contactor, (2K3) and check for no current - 1 sec. If currents are detected the MMR diagnostic "Starter Fault Type II" is generated. (Starter Integrity test)

G. If no diagnostics are generated in the above tests, the Stop Relay (2U1-J6) is closed for 2 seconds and the Start Relay (2U1-J8) is closed to energize the start contactor (2K1). The shorting contactor (2K3) has already been energized from (F) above. The compressor motor (4B1) starts in the "Wye" configuration, an auxiliary contact (2K1-AUX) locks in the start contactor (2K1) coil.

H. After the compressor motor has accelerated and the maximum phase current has dropped below 85% of the chiller nameplate RLA for 1.5 seconds, the starter transition to the "Delta" configuration is initiated.

J. The transition contactor (2K4) is closed through relay 2U1-J14, placing the transition resistors (2R1, 2R2, and 2R3) in parallel with the compressor motor windings.

K. The shorting contactor (2K3) is opened through the opening of relay 2U1-J12 100 msec after the closure of the transition relay 2U1-J14.

L. The run contactor (2K2) is closed through relay 2U1-J10 shorting out the transition resistors 260 msec after the opening of the shorting relay 2U1-J12. This places the compressor motor in the "Delta" configuration and the micro waits to look for this transition for 2.35 seconds through the closure of the transition complete contacts (2K2-AUX) at 2U1-J4.

M. The micro must now confirm closure of the transition complete contact (2K2-AUX) within 2.32 to 2.38 seconds after the run relay (2U1-J10) is closed. Finally, the transition relay (2U1-J14) is opened de-energizing the transition contactor (2K4) and the compressor motor starting sequence is complete. An MMR diagnostic will be generated if the transition complete contacts (2K2-AUX) do not close. A diagram of this test/start sequence is shown in Figure 21.

Now that the compressor motor (4B1) is running in the "Delta" configuration, the inlet guide vanes will modulate, opening and closing to the chiller load variation by operation of the stepper vane motor actuator (4B2) to satisfy chilled water setpoint. The chiller continues to run in its appropriate mode of operation: Normal, Softload, Limit Mode, etc.

If the chilled water temperature drops below the chilled water set point by an amount set as the "differential to stop" setpoint, a normal chiller stop sequence is initiated as follows:

1. The inlet guide vanes are driven closed for 50 seconds.

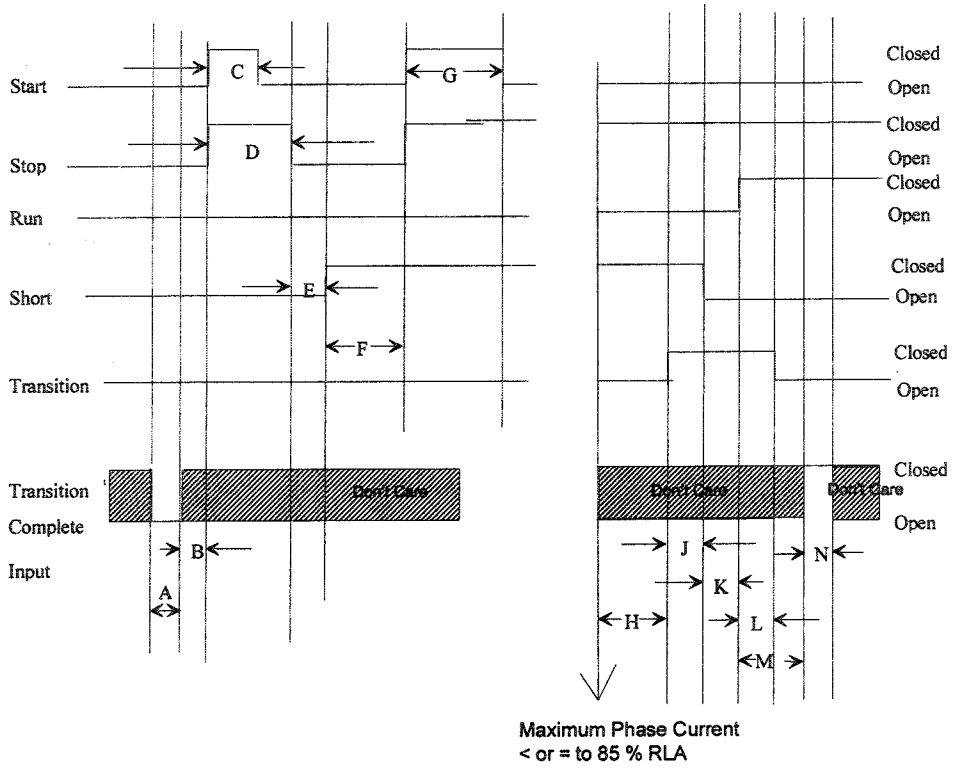
2. After the 50 seconds has elapsed, the stop relay (2U1-J6) and the condenser water pump relays (1U1-J14) open to turn off the compressor motor (4B3) will continue to run for 2 minutes post lube while the compressor coasts to a stop. The chilled water pump will continue to run while the chiller module (1U1) monitors leaving chilled water temperature preparing for the next compressor motor start based on the "differential to start" setpoint.

If the STOP key is pressed on the human interface, the chiller will follow the same stop sequence as above except the chilled water pump relay (1U1-J12) will also open and stop the chilled water pump after the chilled water pump delay timer has timed out after compressor shut down.

If the STOP key is pressed twice in rapid succession, twice within 5 seconds, a "panic stop" is initiated which follows the same stop sequence as pressing the STOP key once except the inlet guide vanes are not sequence closed and the compressor motor is immediately turned off.

Vane Actuator Control

The 1U3 Stepper Module pulses a DC voltage to the windings of the 4B2 Stepper Module Vane Actuator and 4B4 for CVHF 1470 and 1720 to control inlet guide vane position.



While operation of this stepper motor is automatic, manual control is possible by going to the Vane Control Status/Vane Position Commands screen in the Service Tests Menu and changing the "Target" value.

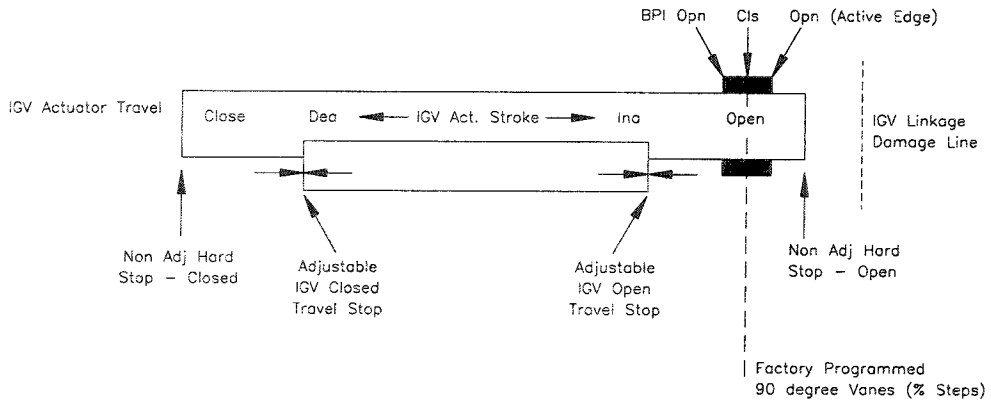
Note: If the chiller is operating in a limit mode (i.e. current limit, condenser limit, evaporator limit, etc.) the limit operation has priority over all manual modes of operation.

On each UCP power-up, the inlet guide vanes are driven full closed to recalibrate the zero position (Steps) of the Stepper motor vane actuator. An inlet guide vane stroke test is conducted for BPI (Binary Position Indicator) position on all resets (hardware and software) if there has not been a Momentary Power Loss.

Figure 21
UCP2 Test/Start Timing Sequence

Timing requirements to operate the "Stop", "Start", "Short", "Transition", and "Run" contact closure outputs are shown below. Prior to closing the "Short" contact, the transition complete input shall be verified to be open, otherwise an MMR diagnostic shall be generated.

Interval	Minimum	Maximum	Units	Actual Design
A (Test for transition complete input open)				160 to 240 msec
B (Just delay time)				20 msec
C (Close 1M (2K1) Contactor and test for no current.)(Starter integrity test)				500 msec
D-(Hold 1M (2K1) Contactor and test for no current.)(Starter integrity test)				1 sec
E- (Open 1M (2K1) Delay time				200 msec
F- (Close Shorting Contactor (2K3) and and test for no current, then wait for Start command.) (Starter integrity test)	100 (1)		msec	1 sec (Min)
G (Close 1M (2K1)	2.0		sec	2 sec
H- (Wait 1.5 sec after phase currents drop to 85%)	1	2	sec	1.5 sec
J - (Begin Transition sequence)	85	100	msec	100 msec
K- (Open S (Shorting) Contactor)	250	300	msec	260 msec
L- (Close 2M (2K2) Contactor				140 msec
M- (Wait to look for Transition complete)	(2)		msec	2.32 to 2.38 sec
N (Filtering time on Transition complete input)	(2)		msec	160 to 240 msec



This is also done if there is a call for cooling or heating condition and it has been 24 hours or more since the last BPI test and there has not been a Momentary Power Loss for 5 minutes. See Figure 22 for BPI operation.

Note: The closed range of the BPI must straddle the factory programmed 90 degree Vane Position.

Circuit Breaker 1CB3 Oil Pump and Refrigerant/Oil Pump

Circuit Breaker 1CB3 115-volt control power from control power transformer 2T5 flows through branch circuit breaker 1CB3 and terminal 1TB1-6 to a 15 amp fuse (1F2) Fuse which protects the refrigerant/oil pump motor (4B3) from over amperage conditions.

Figure 22
CVHE, CVHF, CVHG IGV/Actuator Operation and BPI Switch

Current passing through fuse 1F2 reaches 3 normally open parallel sets of contacts: those of refrigerant/oil pump relay (1K5), 1U2-J22 relay and the start contactor 2K1-aux.

Note: While the 1U2-J22 relay automatically is closed by 1U2 as a part of the start sequence. It can also be closed manually by changing the oil pump status to "ON" in the service test mode.

Closure of the 1U2-J22 or 2k1 auxiliary contacts also allows current to pass through the coil of the refrigerant pump starter relay (1K5) closing the contact 1K5, to the start windings of the refrigerant pump. When motor 4B3 first starts, current draw is high: This causes current sensing relay 4K8 to close its normally open contacts and pull in of pump Capacitor 4C1. Increasing motor speed and related decreasing current through the main winding and relay coil reduce the magnetic force and the armature "Drips out". To open the start contacts and disconnect the start windings and capacitor. Current now flows to the Run windings of the oil pump motor or refrigerant/oil pump motor.

Restart Inhibit

A Restart Inhibit Timer is used to prevent high frequent chiller ON-OFF cycling and subsequent motor overheating.

The Restart Inhibit (RI) timer is set based on a Background Timer (BT) that is incremented by (XX) minutes at every start and is timed out from the new total only while the chiller is running and is based on the equation: RI = BT-50.

The value of XX is based on nominal compressor size to include the motor heating constant as listed in the Table 2 on this page.

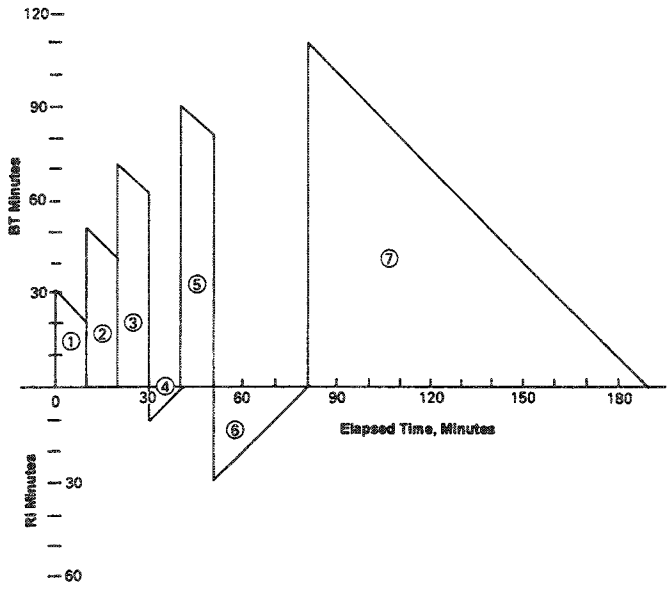
This value of the motor heating constant (XX) must be set in the Machine Configuration Group of the Service Settings Menu based on the unit NTON and motor frequency.

On any UCM Reset (either hardware (e.g. powerup or software), the RI Timer is reset to 30 seconds if the motor winding temperature is less than or equal to 165°F. The maximum value of the RI Timer is 60 minutes, and is adjustable from 25 to 60 minutes in the Field Startup Group of the Service Settings menu.

See Figure 23 for an example of how the RI Timer functions.

Any other pre-start system timers, e.g. prelube = 60 seconds, overlap the RI Timer to anticipate its time out and permit start of the compressor at or shortly after the RI. If the RI Timer value ever reaches 45 minutes an IFW diagnostic is generated.

The RI Timer can be cleared to 30 seconds in the Service Settings Menu.



If the RI Timer is the overriding criteria holding the chiller off, this mode will be displayed along with the remaining time, counting down, prior to the chiller starting.

Table 2 - NTON/BT Information

NTON	BT
230-320	30
360-500	35
560-800	40
890 - 1280	50
1470-1720	65

Figure 23
CVHE, CVHF and CVHG - UCP2 Restart Inhibit Timer

Parameter	CVHE/CVHF
Background Timer Increment on Start (Motor Heating Constant)	Adjustable, 25 Min. Fac. Dflt.
General RI Timer Setting	RI = BT -50 Minutes
Minimum RI Timer Setting	30 Seconds
Maximum RI Timer Setting	60 Minutes
Adjustment Range of Maximum RI Timer Setting	30 to 60 Minutes
Winding Temperature Decision Point/RI Timer Above this Temp. after Reset	165 F (73.8C)/15 Minutes
IFW Diagnostic Threshold	RI Timer = 45 Minutes

1. Unit started and ran 10 min., BT incremented 30 Min., and decreased by 10 min. RI = (30-10) - 50 = -30.
2. Unit restarted RI = -30, BT incremented another 30 min., unit ran 10 min. and BT decreased by 10 min. RI = (50-10) - 50 = -10
3. Unit restarted RI = -10, BT incremented another 30 min., unit ran 10 min. and BT decreased by 10 min., RI = (70-10) - 50 = 10.
4. Unit Restart Inhibit is 10 min. from (3).
5. Unit restarted after 10 min. RI in (4), BT incremented another 30 min., unit ran 10 min. and BT decreased by 10 min. RI = (90-10) -50 = 30.
6. Unit restart is 30 min. from (5).
7. Unit restarted after 30 minute RI min, (6), BT incremented another 30 min., and unit ran for 110 min., and BT goes to zero.

Notes:
1. 30 second/15 minute restart inhibit due to motor winding temperature not included.
2. Example for Motor Heating Constant = 30
3. If calculated RI is negative then RI = 0.

Controls Chilled Water Reset (CWR)

Chilled water reset is designed for those applications where the design chilled water temperature is not required at partload. In these cases, the leaving chilled water temperature setpoint can be reset upward using the CWR features.

When the CWR function is based on return water temperature, the CWR feature is standard.

When the CWR function is based on outdoor air temperature, the CWR feature is an option requiring an outdoor temperature sensor and the Options Module installed in the UCP2 panel.

The type of CWR is selected in the Operator settings Menu along with the Reset Ratio, Start Reset Setpoint, and the Max Reset Setpoint.

The following equations and parameters apply for CWR.

Return Water

CWS' = CWS + RATIO (START RESET - TWE - TWL) and CWS' > or = CWS' and CWS - CWS < or = Maximum Reset.

Outdoor Air Temperature

CWS' = CWS + RATIO (START RESET - TOD) and CWS' > or = CWS' and CWS - CWS < or = Maximum Reset.

Where

CWS is the new chilled water setpoint.

CWS is the active chilled water setpoint before any reset has occurred RESET RATIO is a user adjustable gain.

START RESET is a user adjustable reference.

TWE is entering evap. water temperature.

MAXIMUM RESET is a user adjustable limit providing the maximum amount of reset. For all types of reset, CWS - CWS < or = Maximum Reset.

The values for "Start Reset" for each of the reset types are shown in Table 3.

Both Return and Outdoor Reset do not apply to Heat Pump Mode where the UCP2 is controlling the Leaving Water Temperature.

Constant Return Reset will reset the leaving water temperature setpoint so as to provide a constant entering water temperature. The Constant Return Reset equation is the same as the Return Reset equation except on selection of Constant Return Reset, the UCP2 shall automatically set RATIO, START RESET, and MAXIMUM RESET to the following:

The RATIO = 100%
The START RESET = Design Delta Temp.
The MAXIMUM RESET = Design Delta Temp.

The equation for Constant Return is as follows:

Table 3 - Values for Start Reset Types

The values for "RESET RATIO" for each of the reset types are:				
Reset	Reset	Increment	Increment	Factory
Type	Ratio	English	SI Units	Default
	Range	Units		Value
Return	10 to 120%	1%	1%	50%
Outdoor	80 to -80%	1%	1%	10%
The values for "START RESET " for each of the reset types are:				
Reset	Start	Increment	Increment	Factory
Type	Reset	English	SI Units	Default
	Range	Units		Value
Return	4 to 30 F	1 F	0.1 C	10 F (5.6C)
	(2.2 to 16.7C)	1 F	0.1 C	90 F (32.2C)
The values for "MAXIMUM RESET" for each of the reset types are:				
Reset	Maximum	Increment	Increment	Factory
Type	Reset	English	SI Units	Default
	Range	Units		Value

Constant Return

CWS' = CWS ÷ 100% (Design Delta Temp.) - (TWE-TWL) and CWS > or = CWS and CWS - CWS < or = Maximum Reset

Notice that Constant Return is nothing more than a specific case of Return Reset offered for operator convenience.

When any type of CWR is enabled, the UCP2 will step the CWS toward the desired CWS (based on the above equations and setup parameters) at a rate of 1°F every 5 minute until the Active CWS equals the desired CWS'. This applies when the chiller is both running and not running.

The chiller will start at the Differential to Start value above a fully reset CWS or CWS for both Return and Outdoor Reset.

The graph on the next page, shows the reset function for Outdoor Air Temp: **Note:** This graph assumes that Maximum Reset is set to 20 degrees.

Using the Equation for calculating CWR for Outdoor Air Temp

Equation:

Degrees of Reset = Reset Ratio*(Start Reset - TOD)

Degrees of Reset:

Degrees of Reset = Active CWS - Front Panel CWS
or
Degrees of Reset = CWS' - CWS

To obtain Active CWS from Degrees of Reset :
Active CWS = Degrees of Reset + Front Panel CWS

Reset Ratio:

The Reset Ratio on the CLD is displayed as a percentage. To use it in the above equation it must be converted to it's decimal form.

Reset Ratio percent /100 = Reset Ratio decimal

Example of converting Reset Ratio:

If the Reset Ratio displayed on the CLD is 50% then use (50/100)=.5 in the equation

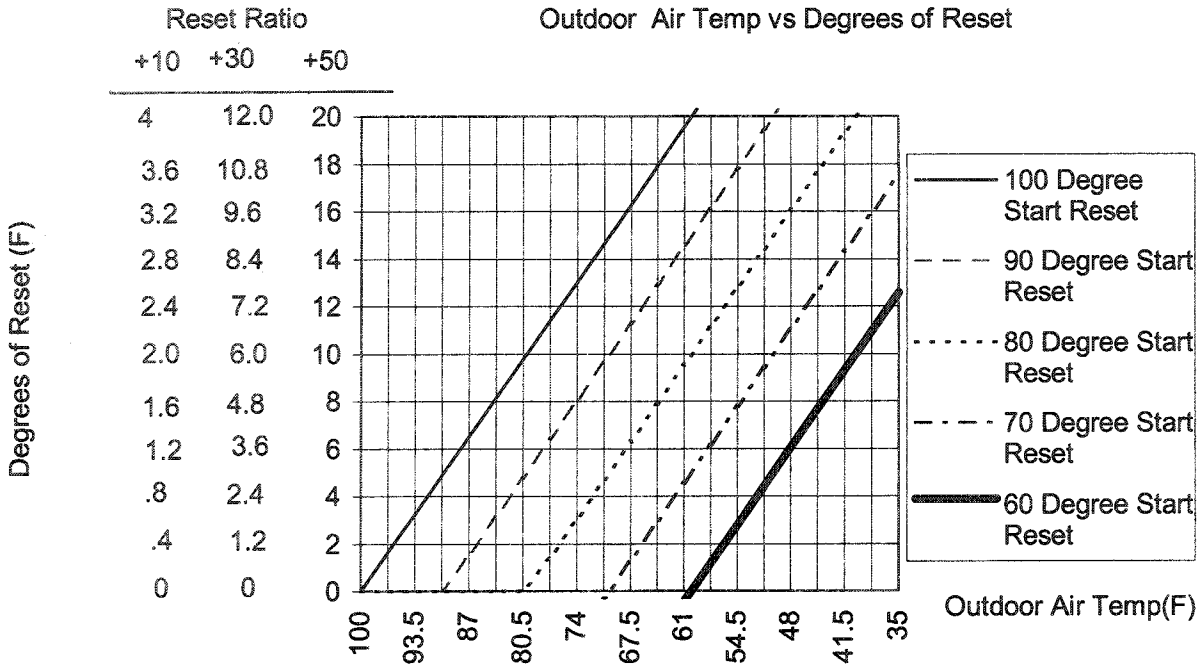
TOD = Outdoor Air Temp

Start Reset = Outdoor Air Start Reset

Example of Calculating Reset for Outdoor Air Temp:

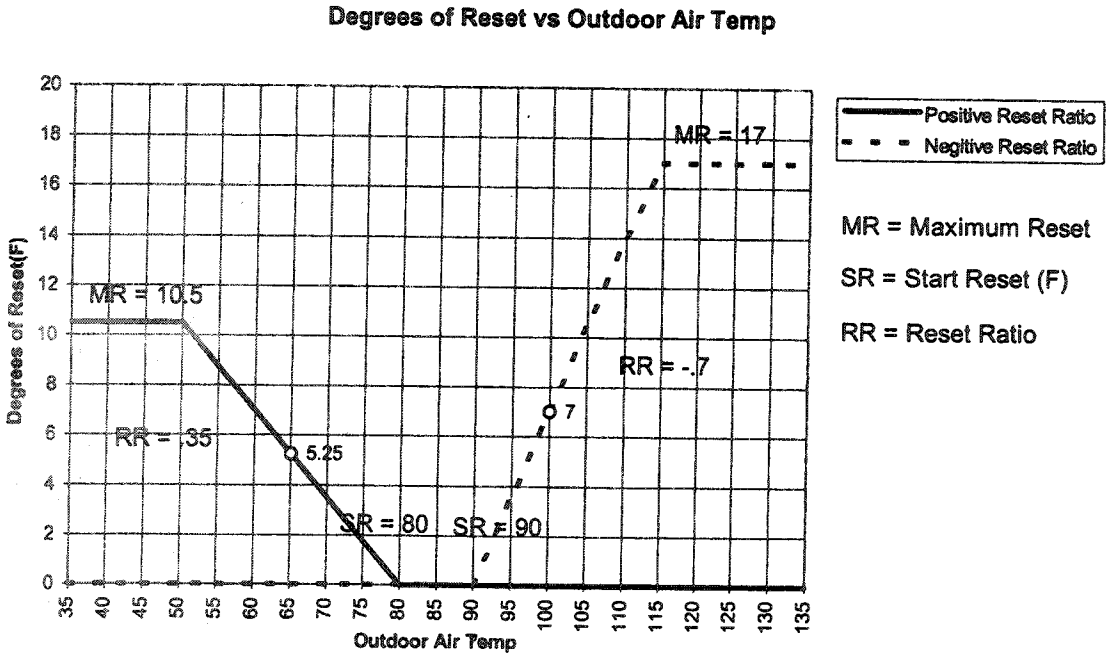
If:
Reset Ratio = 35%
Start Reset = 80
TOD = 65
Maximum Reset = 10.5

How many Degrees of Reset will there be?



Degrees of Reset = Reset Ratio*(Start Reset - TOD)
Degrees of Reset = .35*(80-65)
Degrees of Reset = 5.25

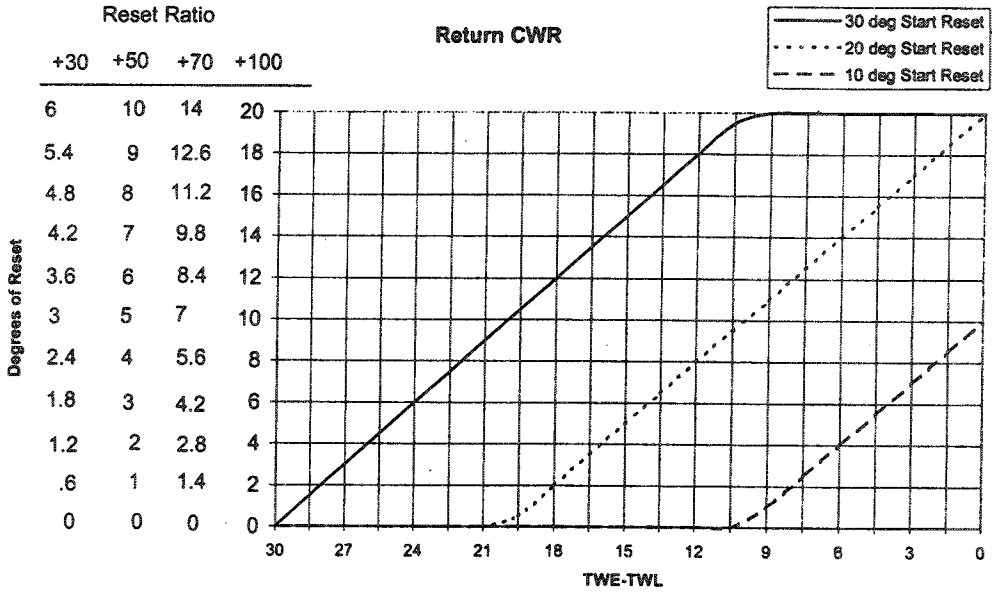
If:
Reset Ratio = -70%
Start Reset = 90
TOD = 100
Maximum Reset = 17



How many Degrees of Reset will there be?

Degrees of Reset = Reset Ratio*(Start Reset - TOD)
Degrees of Reset = -.7*(90-100)
Degrees of Reset = 7

Electrical Sequence of Operation



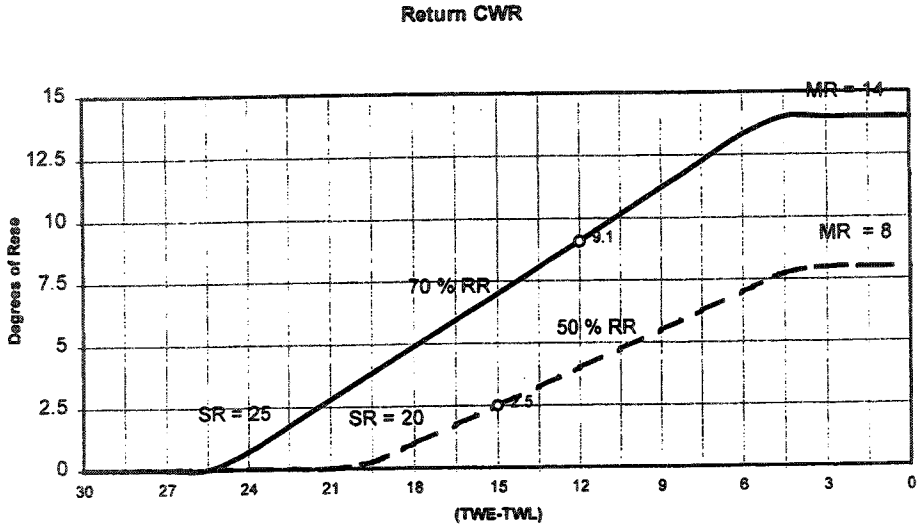
The following graph illustrates the reset functions of the above examples:

The following graph shows the reset function for Return CWR:

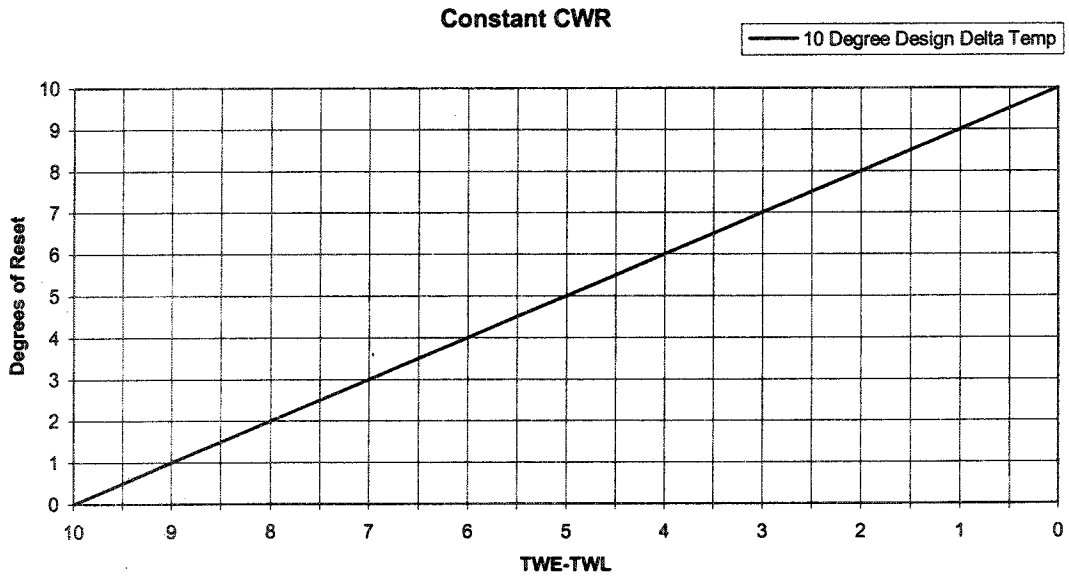
The following graph shows the reset function for Return CWR:

Note: This graph assumes Maximum Reset is set to 20 degrees.
Example of Calculating Return Reset:

If:
Reset Ratio = 50%
Start Reset = 25
TWE = 65
TWL = 45
Maximum Reset = 8



How many Degrees of Reset will there be?



Degrees of Reset = Reset Ratio*(Start Reset - (TWE-TWL))
Degrees of Reset = .5*(25-(65-45))
Degrees of Reset = 2.5

If:
Reset Ratio = 70%
Start Reset = 20
TWE = 60
TWL = 53
Maximum Reset = 14

How many Degrees of Reset will there be?

Degrees of Reset = Reset Ratio*(Start Reset - (TWE-TWL))
Degrees of Reset = .7*(20-(60-53))
Degrees of Reset = 9.1

The following graph illustrates the Reset Actions of the above examples:

Differential to Start/Stop

The Differential to Start setpoint is adjustable from 1 to 10°F (0.5 to 5.55 C) and the Differential to Stop setpoint adjustable from 1 to 10°F (0.5 to 5.55C). Both setpoints are with respect to the Active Chilled Water Setpoint and are set in the Service Settings menu.

When the chiller is running and the LWT reaches the Differential to Stop setpoint the chiller will go through its shutdown sequence to AUTO.

Leaving Water Temperature Cutout

Leaving water temperature cutout is a safety control that protects the chiller from damage caused by water freezing in the evaporator. The cutout setpoint is adjustable in the Service Settings Menu.

For freeze protection from low leaving water temperatures the UCP2 provides a low leaving water temperature cutout based on leaving water temperature. The "Leaving Water Temperature Cutout Setpoint" is independently adjustable from the chilled water setpoint and factory set. Shutdown of the compressor due to violation of the Leaving Water Temperature Cutout results in an automatically resettable diagnostic (MAR).

The UCP2 indicates when the "Leaving Water Temperature Cutout Setpoint" conflicts with the chilled water temperature setpoint by a message on the display. The "Leaving Water Temperature Cutout Setpoint" and chilled water setpoint, both active and front panel, are separated by a minimum of 1.7°F.

See Cutout Strategy, Figure 24. When either difference is violated, the UCP2 does not permit the above differences to be violated and the display exhibits a message to that effect and remains at the last valid setpoint.

When the chilled water setpoint, both active and front panel, is adjusted downward, it does not violate the above minimum differences and the "Leaving Water Temperature Cutout Setpoint" remains at its current setting. When the "Leaving Water Temperature Cutout Setpoint" is adjusted upward, the above minimum difference is not violated and as the "Leaving Water Temperature Cutout Setpoint" is setpoint, both active and front panel, is raised to maintain the minimum difference.

After violation of the "Leaving Water Temp. Cutout Setpoint" for 30°F seconds the chiller will shutdown and indicate a diagnostic.

Low Refrigerant Temperature Cutout

This is a safety function that prevents water in the evaporator from freezing due to low evaporator refrigerant temperatures. When the trip point is violated, the chiller will shut down and display a latching diagnostic (MMR) indicating the violation. The cutout setpoint is adjustable in the Service Settings Menu.

The UCP2 indicates when the "Low Refrigerant Temp. Cutout Setpoint" conflicts with the chilled water temperature setpoint by a message on the display.

The "Low refrigerant Temp Cutout Setpoint" and chilled water setpoint, both active and front panel, are separated by a minimum of 6°F. See Figure 24.

When either difference is violated, the UCP2 does not permit the above differences to be violated and the display exhibits a message to that effect and remains at the last valid setpoint.

When the chilled water setpoint, both active and front panel, is adjusted downward, it does not violate the above minimum differences, and the "Low Refrigerant Temperature Cutout Setpoint is adjusted upward, the above minimum difference is not violated, and as the "Low Refrigerant Temperature Cutout Setpoint" is adjusted upward, the chilled water setpoint, both active and front panel, are raised to maintain the minimum difference.

After violation of the "Low Refrigerant Temp. Cutout Setpoint" for 30°F - seconds, the chiller will shutdown and indicate a diagnostic.

Enhanced Condenser Limit Control

When the chiller is running Condenser Limit Mode or in Surge Mode, the head relief request relay on the Options Module (1U5-J12) will be energized and can be used to control or signal for a reduction in the entering condenser water temperature.

Designed to prevent high refrigerant pressure trip-outs during critical periods of chiller operation, this UCP2 option consists of:

1. Condenser refrigerant Pressure Transducer (3R3).

2. The Options Module (1U5) with the head relief request relay (1U5-J12).

3. Interconnecting Wiring.

If the unit is not equipped with the Enhanced Condenser Limit Option (3R31U5) the unit will use the condenser refrigerant temperature sensor (input converted to saturated refrigerant pressure) to perform the Standard Condenser Limit function, without the head relief request relay, by limiting inlet guide vane stroke and chiller capacity.

Keep in mind that the UCP2 Condenser Limit Control supplements the protection provided by the condenser pressure high pressure cutout switch 3S1.

Free Cooling

To enable Free Cooling Mode:

1. "Install" Free Cooling in the Machine Configuration Menu.

2. Enable the Free Cooling mode in the Operator Settings Menu to "ON" while the chiller is in "AUTO", or

3. Close the external binary input switch to the Options Module 1U5-J3-5 and -6 if so equipped while the chiller is in "AUTO".

Free Cooling can not be entered if the chiller is in "STOP".

If the chiller is in "AUTO" and not running, the condenser water pump will start. After condenser water flow is proven, relays at 1U5-J16, 1U5-J20, and 1U5-J24 will energize operating the Free Cooling Valves 4B12 and 4B13. The Free Cooling Valves End Switches must open within 3 minutes, or an MMR diagnostic will be generated. Once the Free Cooling Valves End Switches open, the unit is in the Free Cooling mode.

If the chiller is in "AUTO" and running powered cooling, the chiller will do a friendly shut down first, (Run: Unload, Post Lube, and drive vanes closed). After the vanes have been overdriven, closed and condenser water proven, the Free Cooling relays will be energized.

To disable Free Cooling and return to Powered Cooling, either disable the Free Cooling Mode in the Operators Settings menu if used to enable Free Cooling or "OPEN" the external binary input switch to the Options Module if it was used to enable Free Cooling.

Once Free Cooling is disabled, the Free Cooling relays 1U5-J16, and 1U5-J20 and 1U5-J24 will de-energize allowing the Free Cooling valves to close. The Free Cooling valves end switches must close within 3 minutes or an MMR diagnostic is generated.

Once the end switches close the chiller will return to "AUTO" and powered cooling will resume if there is a call for cooling based on the differential to start.

Once powered cooling has resumed and the compressor has started, the inlet guide vanes will be held closed for 3 minutes to allow for temperature/pressure stabilization.

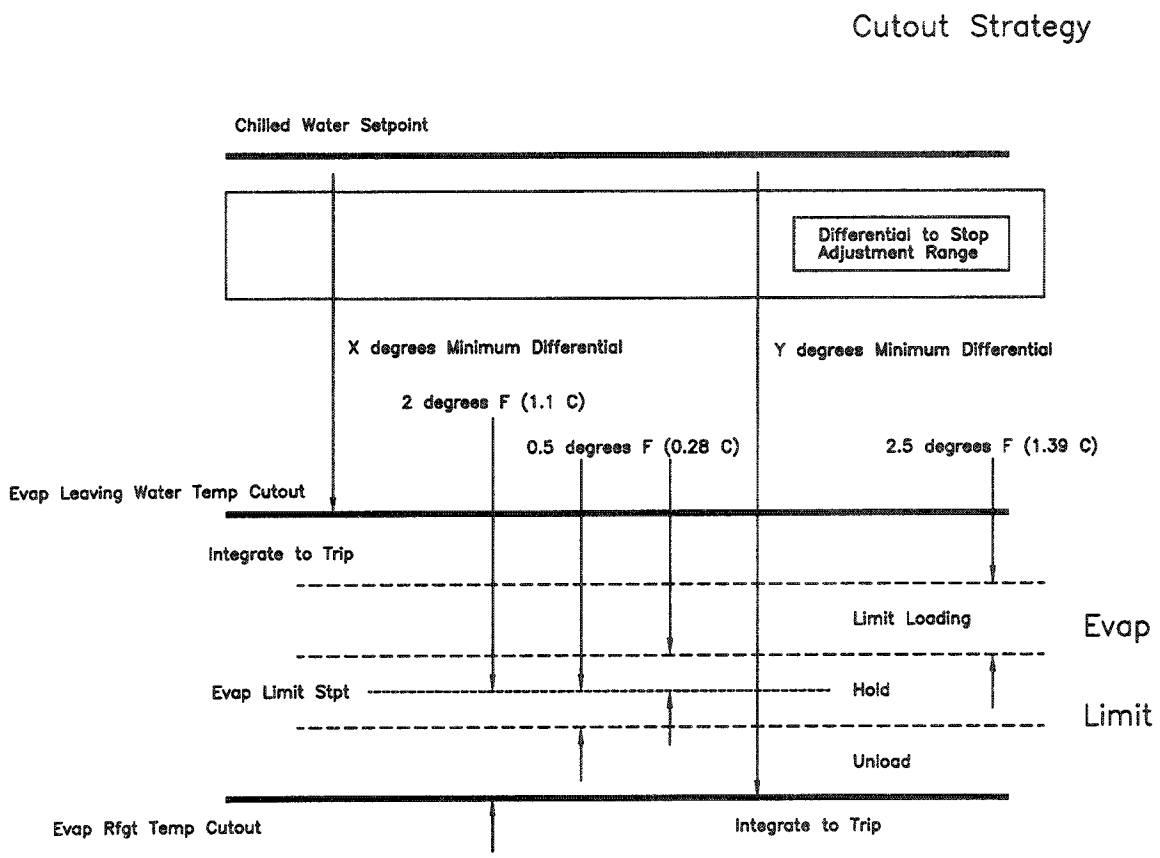
Note: The manual control of the inlet guide vanes is disabled while in the Free Cooling Mode and the compressor is prevented from starting by the control logic.

Note: The relay at 1U5-J20 is a FC auxiliary relay and can be used as required.

Hot Gas Bypass

The hot gas bypass (HGBP) control option is designed to minimize machine cycling by allowing the chiller to operate stably under minimum load conditions. In these situations, the inlet guide vanes are "locked" at a preset minimum position, and unit capacity is governed by the HGBP valve actuator.

Control circuitry is designed to allow both the inlet guide vanes and the HGBP valve to close for unit shutdown.



HGBP is enabled in the Field Startup Group of the Service Settings Menus by enabling the option and setting the HGBP Cut-In Vane Position in the same menu.

After a chiller starts and is running the inlet guide vanes will pass through the HGBP Cut-In-Vane position as the chiller starts to load. As the chiller catches the load and starts to unload, the inlet guide vanes will close to the HGBP Cut-In Vane position. At this point the movement of the inlet guide vanes is frozen and further unloading of the chiller is controlled by the opening of the HGBP Valve 4B5 by the 1U10 module. The 1U10 module modulates the HGBP valve at low loads.

When the control algorithm determines the chiller to be shut down, the inlet guide vanes will be driven fully closed, and the HGBP valve will be driven closed. After the inlet guide vanes are fully closed the chiller will shut down in the Friendly mode.

Chillers with HGBP have a discharge temperature sensor (4RT6) monitoring the discharge gas temperature from the compressor. If this temperature exceeds 200°F, the chiller will shut off on a MAR diagnostic. The chiller will reset automatically when this temperature drops 50°F below the trip-point.

Figure 24
Cutout Strategy

Ice Machine Control

UCP2 provides a service level "Enable/Disable" menu entry for the Ice Building feature when the Ice Building option is installed.

UCP2 will accept either an isolated contact closure (J3, 7 & 8 on the options module) or a remote communicated input (Tracer) to initiate the ice building mode where the unit runs fully loaded at all times. Ice building will be terminated either by opening the contact or based on entering evaporator water temperature. UCP2 will not permit the Ice Building mode to be entered again until the unit is switched to the NON-Ice Building mode and back into the Ice Building mode. It is not acceptable to reset the chilled water setpoint low to achieve a fully loaded compressor.

While in the Ice Building mode, current limit setpoints less than the maximum will be ignored.

Ice Building can be terminated by one of the following means:

1. Operating the external ice contacts and remote communicated input (Tracer).

2. Satisfying an evaporator entering water temperature setpoint.

3. Surging for 15 minutes at full open IGV.

Unit Start-Up Procedures

Daily Unit Start-Up

1. Verify the chilled water pump and condenser water pump starter are in "ON" or "AUTO".

2. Verify the cooling tower is in "ON" or "AUTO".

Note: Refer to Figure 25 for UCP Start-Run-Shutdown sequence and UCP timing functions.

3. Check the oil tank oil level; the level must be visible in or above the lower sight glass. Also, be sure to check the oil tank temperature; normal oil tank temperature before start-up is 140°F to 145°F (60 to 63 C).

Note: The oil heater is energized during the compressor off cycle. During unit operation, the oil tank heater is de-energized.

4. If the chiller is equipped with the free cooling option, ensure that the free cooling option is disabled in the Operator Settings menu.

5. Check the chilled water setpoint and readjust it, if necessary, in the Operator Settings menu.

6. If necessary, readjust the current limit setpoint in the Operators Setting menu.

7. Press "AUTO".

The UCP also checks compressor motor winding temperature, and a minimum 30 second delay is initiated if the winding temperature is less than 165°F. If it is greater than 165°F, however, a 15-minute delay period begins. The chilled water pump relay is energized and evaporator water flow is proven.

Next, the UCP checks the leaving evaporator water temperature and compares it to the chilled water setpoint. If the difference between these values is less than the start differential setpoint, cooling is not needed.

If the UCP determines that the difference between the evaporator leaving water temperature and chilled water setpoint exceeds the start differential setpoint, the unit enters the initiate Start Mode and the oil pump/Refrigerant pump and the condenser water pump are started. If condenser water flow is not proven (i.e. flow switch 5S3 does not close) within 3 minutes, the unit is locked out on a MMR Diagnostic.

Oil pressure must be verified within 3 minutes or a MMR diagnostic is generated.

When less than 5 seconds remain on the restart inhibit, the pre-start starter test is conducted on Y-Delta starters. If faults are detected, the unit's compressor will not start, and a MMR Diagnostic will be generated.

If the compressor motor starts and accelerates successfully, "Unit is Running" appears on the display. At this time the purge unit will start operating on "Automatic" and will continue to operate as long as chiller compressor is running.

Note: Whenever the UCP detects a MMR diagnostic condition during start-up, unit operation is locked out, and manual reset is required before the start-up sequence can begin again. If the fault condition has not cleared, the UCP will not permit restart.

When the cooling requirement is satisfied, the UCP originates a "Shutdown" signal. The inlet guide vanes are driven closed for 50 seconds, and the unit enters a 3-minute post-lube period. The compressor motor and condenser water pump starter are de-energized immediately, but the oil pump continues to run during this 3-minute interval; the evaporator pump will continue to run.

Once the post-lube cycle is done, the unit returns to auto mode.

Electrical Sequence of Operation

Seasonal Unit Start-Up

Note: Refer to Figure 25 for UCP Start-Run-Shutdown sequence and UCP timing functions.

1. Close all drain valves, and re-install the drain plugs in the evaporator and condenser headers.

2. Service the auxiliary equipment according to the start-up/ maintenance instructions provided by the respective equipment manufacturers.

3. Vent and fill the cooling tower, if used, as well as the condenser and piping. At this point, all air must be removed from the system (including each pass). Then close the vents in the condenser water boxes.

4. Open all of the valves in the evaporator chilled water circuit.

5. If the evaporator was previously drained, vent and fill the evaporator and chilled water circuit. When all air is removed from the system (including each pass), close the vent valves in the evaporator water boxes.

6. Lubricate the external vane control linkage as needed.

7. Check the adjustment and operation of each safety and operating control.

8. Close all disconnect switches.

⚠ WARNING

USE CARE WHEN MEASUREMENTS, ADJUSTMENTS, OR OTHER SERVICE-RELATED WORK IS PERFORMED WITH POWER ON. Failure to do so can result in injury or death due electrical shock or contact with moving parts.

9. Perform instructions listed in "Daily Unit Start-up" section.

⚠ CAUTION

PROPER SAFEGUARDS SHOULD BE TAKEN TO ENSURE THE EVAPORATOR WATER PUMP DOES NOT CONTINUE TO RUN LONGER THAN 30 MINUTES AFTER CHILLER SHUTDOWN. Failure to avoid excessive operation of the evaporator water pump with chiller off may cause rupture disc failure and loss of refrigerant charge.

⚠ WARNING

IF THE CHILLED WATER LOOP IS USED IN A HEATING MODE, ENSURE THAT THE EVAPORATOR IS ISOLATED FROM THE HOT WATER LOOP BEFORE CHANGEOVER TO HEADING MODE. Failure to do so may cause rupture disc failure and loss of refrigerant charge.

Unit Shutdown Procedures

Daily Unit Shutdown

Note: Refer to Figure 25 for UCP Start-Run Shutdown sequence and UCP timing functions.

1. Press STOP.

2. After compressor shutdown turn Pump Contactors to OFF or open pump disconnects.

Seasonal Unit Shutdown

⚠ CAUTION

CONTROL POWER DISCONNECT MUST REMAIN CLOSED TO ALLOW OIL SUMP HEATER OPERATION. Failure to do this will allow refrigerant to condense in the oil pump.

3. Open all disconnect switches except the control power disconnect switch.

4. Drain the condenser piping and cooling tower, if used.

5. Remove the drain and vent plugs from the condenser headers to drain the condenser.

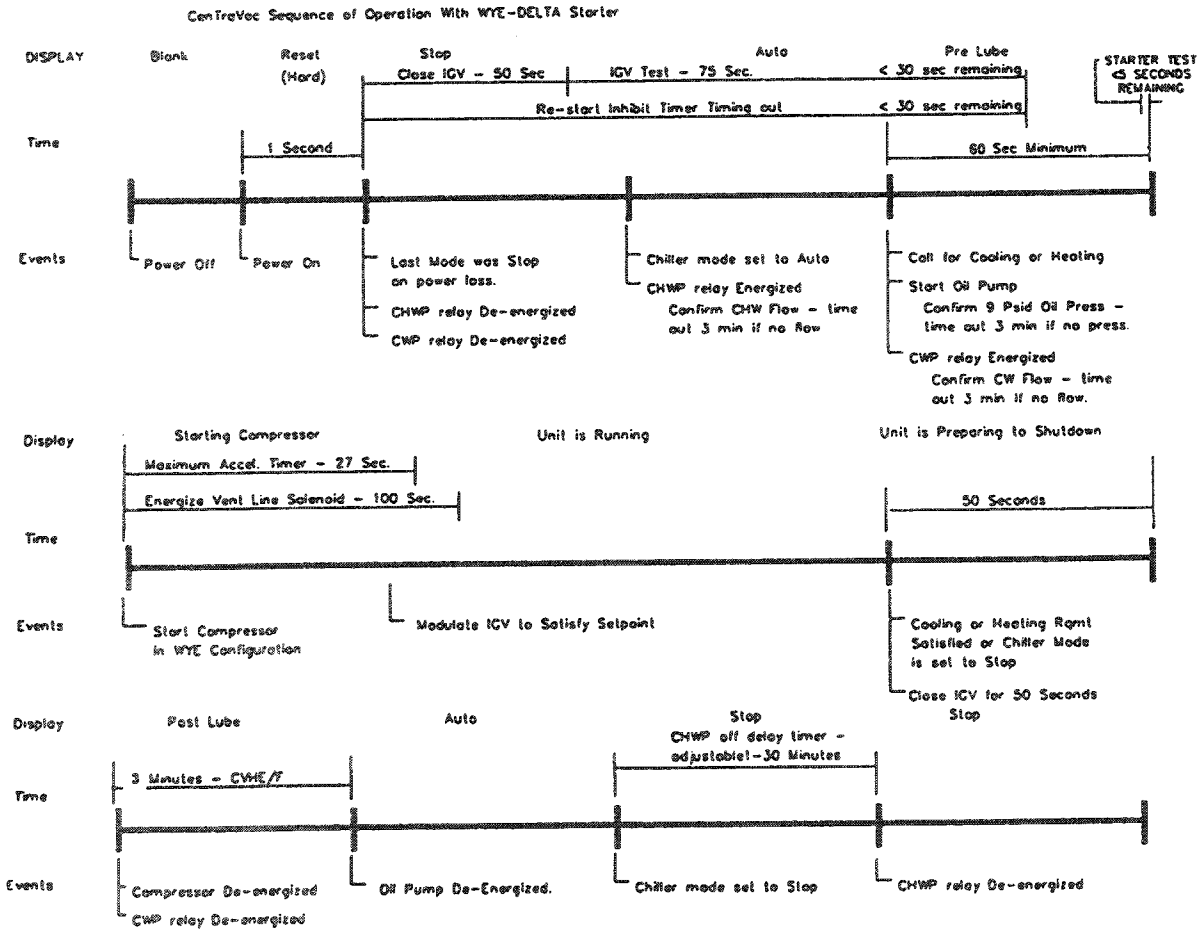
6. Once the unit is secured for winter, the maintenance procedures described under "Annual Maintenance" in the Periodic Maintenance section of this manual should be performed by qualified Trane service technicians.

Note: During extended shutdown, be sure to operate the purge unit for a 2-hour period every two weeks. This will prevent the accumulation of air and non-condensables in the machine. To start the purge, change the purge mode to ON in the Operator Settings Menu. Refer to CVHE-CLD-1A or latest revision. Remember to turn the purge mode to AUTO after the 2-hour run time.

⚠ WARNING

DO NOT ALLOW THE CHILLER TO INCREASE IN TEMPERATURE PRESSURE TO A TEMPERATURE ABOVE 110°f (43C) WHILE THE UNIT IS OFF. Failure to do so will cause the rupture disk to relieve and discharge the refrigerant from the machine. Continuous running of pumps while the machine is off may cause this condition to occur. The rupture disk is designed to relieve and discharge the refrigerant from the unit if the pressure in the evaporator exceeds 15 PSIG causing bodily harm and possible death to anyone in contact with refrigerant discharge.

Electrical Sequence of Operation



⚠ WARNING
TO ALLOW OIL SUMP HEATER OPERATION, CONTROL POWER MUST REMAIN CLOSED DURING ENTIRE SHUTDOWN PERIOD. Failure to do so will allow refrigerant to condense in the oil sump.

⚠ WARNING
DO NOT ALLOW CHILLER TO INCREASE IN TEMPERATURE OR PRESSURE WHILE THE UNIT IS OFF. Continuous running of pumps while the chiller is off can increase the temperature or pressure and will result in premature release of refrigerant causing bodily harm and possible death to anyone in contact with refrigerant discharge.

Trouble Analysis

If the RED light on the control panel is flashing, an MMR diagnostic has occurred. Refer to CVHE-CLD-1A or the latest revision. See the Diagnostic section for trouble shooting information.

Figure 25
CVHE, CVHF and CVHG - UCP Start-Run-Shutdown Sequence and UCP Timing Functions

Procedure for Selecting Current Overload Settings for UCP2

1. Determine the design condition Rated Load Amps (RLA) from the Unit Nameplate or sales order information.

2. Refer to Table 4 or Table 5 as follows:

   Select Table 4 if any of the following conditions are met:

   a. The unit has a Trane supplied starter (unit or remote mounted) and is less than 600 v.
   b. The starter has a single CT per phase, wired directly to the Starter module

   Select Table 5 if any of the following conditions are met:

   a. The unit has a starter that was not supplied by Trane.
   b. The unit voltage is 600 v higher.
   c. The starter has two CTs per phase wired to the Starter module.

3. Using Table 4 or Table 5 (determined in Step 2), determine the CT Meter Scale Rating based on the the RLA from Step 1.

4. Calculate the CT factor using one of the following two equations:

   If Table 4 was used: (Single CT per phase)

   CT Factor = (Motor RLA/CT Meter Scale Rating) x 100

   If Table 5 was used: (Two CTs per phase)

   CT Factor = (Motor RLA/CT Meter Scale Rating) x 139

5. Refer to Table 6. Determine Current Overload Settings #1 and #2 based on the CT Factor that was calculated in Step 4 above.

Enter and verify the correct Current Overload Setting #1 and Current Overload Setting #2 in the unit control menus.

Table 4
CT Factor = (Motor RLA/CT Meter Scale Rating) x 100

Current Transformer Selection Table for Single CT/Phase Systems

Periodic Maintenance

Overview

This section describes the basic chiller preventive maintenance procedures, and recommends the intervals at which these procedures should be performed. Use of a periodic maintenance program is important to ensure the best possible performance and efficiency from a CenTraVac® chiller.

Recommended purge maintenance procedures for the Purifier Purge unit are covered by PRG-OM-6A or the latest revision which can be obtained at the nearest Trane office.

Record Keeping Forms

An important aspect of the chiller maintenance program is the regular completion of records. Provided at the end of this manual are copies of the "Annual Inspection Check List and Report", "CenTraVac with UCP2 Commissioning Checklist and "Start-Up Test Log", a "Start-Up Test Log for Water Cooled CenTraVacs with UCP2 Control Panels" and "UCP2 "Settings Group" Menu Record". When filled out accurately by the machine operator, the completed logs can be reviewed to identify any developing trends in the chiller's operating conditions.

For example, if the machine operator notices a gradual increase in condensing pressure during a month's time, he can systematically check, then correct the possible cause (s) of this condition (e.g., fouled condenser tubes, non-condensable in the system, etc.)

Daily Maintenance and Checks

[ ] Check the chiller's evaporator and condenser pressures, oil tank pressure, differential oil pressure and discharge oil pressure. Compare the readings with the values provided in Table 7.

IMPORTANT: *IT IS HIGHLY RECOMMENDED THAT THE OPERATING LOG BE COMPLETED ON A DAILY BASIS.*

CAUTION

IF FREQUENT PURGING IS REQUIRED, MONITOR PURGE PUMPOUT RATE, IDENTIFY AND CORRECT SOURCE OF AIR OR WATER LEAK AS SOON AS POSSIBLE. Failure to do so can shorten chiller life expectancy, due to moisture contamination caused by leakage.

[ ] Check the oil level in the chiller oil sump using the 2 sight glasses provided in the oil sump head. When the unit is operating, the oil level should be visible in the lower sight glass.

Weekly Maintenance

[ ] Complete all recommended daily maintenance procedures and checks. Complete logs on a daily basis.

WARNING

WHEN SERVICING, LOCK UNIT DISCONNECT SWITCH IN OPEN POSITION. Failure to do so, may result in death or injury due to electrical shock or contact with moving parts.

Every 3 Months

[ ] Complete all recommended weekly maintenance procedures. Refer to the previous sections for details.

[ ] Clean all water strainers in the CenTraVac water piping system.

Every 6 Months

WARNING

WHEN SERVICING, LOCK UNIT DISCONNECT SWITCH IN OPEN POSITION. Failure to do so, may result in death or injury due to electrical shock or contact with moving parts.

Table 7
Normal Chiller Operating Characteristcs

Operating Characteristic	Normal Reading
Evaporator Pressure	12" to 18" Hg (Vacuum)
Condenser Pressure (See Notes 1 and 2)	2 to 12 PSIG (Standard Condensers)
Oil Sump Temperature:	
Unit Not Running	140 to 145 F
	(60 to 63)
Unit Running	62° F to 162° F
	(16.7°C to 72°C)
Differential Oil Pressure	18 to 22 psid

[ ] Complete all recommended quarterly maintenance procedures.

[ ] Lubricate the vane control linkage bearings, ball joints, and pivot points; as needed a few drops of light machine oil (e.g., SAE-20) is sufficient.

[ ] Lubricate first stage vane operator tang "O" rings by removing the setscrew and adding several drops of Trane Oil 0022. Replace setscrew. On CVHF 1470/1720 compressors remove fill and vent hole setscrews. Add grease (Rheolube 434a) until excess appears in vent hole. Replace setscrews.

[ ] Lubricate the oil filter shutoff valve "O" rings by removing the pipe plug and adding several drops of Trane Oil 0022. Replace plug.

[ ] Drain the contents of the rupture disc/purge discharge ventline drip-leg, into an evacuated waste container minimally and more often if the purge is operated excessively.

Also, apply 1 or 2 drops of oil on the vane operator shaft and spread it into a very light film; this will protect the shaft from moisture and rust.

Off-Season Maintenance

During those periods of time when the chiller is not operated, be sure the control panel is energized. This is to keep the purge operational, the oil heater warm and will also keep air out of the machine.

Annual Maintenance

Shut down the chiller once each year to check the items listed ; a more detailed inspection checklist is provided on the "Model CVHE, CVHF and CVHG CenTraVac Annual Inspection Checklist and Report" illustrated in this manual.

[ ] Perform the annual maintenance procedures referred to in the Maintenance Section of the purge manual.

[ ] Use an ice water bath to verify that the accuracy of the evaporator refrigerant temperature sensor (4RT5) is still within tolerance (i.e., + or - 2.0° at 32°F).

If the evaporator refrigerant temperature displayed on the UCP's read-out is outside this 4-degree tolerance range, replace the sensor.

Note: If the sensor is exposed to temperature extremes outside its normal operating range (0°F to 90°F) (-18°C to 32°C), check its accuracy at 6-month intervals.

Compressor Oil Change on CVHE, CVHF, CVHG

After the first six months of operation it is recommended to have the oil analyzed.

After 1000 hours and one year of operation it is recommended to change the oil and filter and have the removed waste oil analyzed.

Note: Use only Trane Oil 0022. A full oil change is 9 gallons of Oil 0022 with refrigerant pump and 7-1/2 gallons without refrigerant pump.

Beyond the first year, recommendations are to subscribe to an annual oil analysis program rather than change the oil automatically every year. This program will reduce the chiller's overall lifetime oil consumption and minimize refrigerant emissions. The oil analysis should be done by a qualified laboratory experienced in refrigerant/oil chemistry and the servicing of Trane centrifugal chillers.

In conjunction with other diagnostics performed by a qualified service technician, oil analyses can provide valuable information on the performance of the chiller to help minimize operating and maintenance costs and maximize it's operating life. A drain fitting is installed in the oil filter top, after the oil filter, for obtaining oil samples.

Oil Change Procedure

When oil analysis indicates the need to change compressor oil, use the following procedure for removing oil.

⚠ CAUTION
BE SURE TO OPEN CONTROL PANEL DISCONNECT SWITCH BEFORE DRAINING THE SUMP. Failure to do so could possibly burn out the oil sump heater.

[ ] Draw the oil from the chiller through the oil charging valve on the chiller oil sump into an approved, evacuated tank; or,

[ ] Pump the oil from the chiller through the oil charging valve into an air-tight resealable container, using a magnetically-driven auxiliary pump.

Forcing the oil from the oil sump by pressurizing the chiller (i.e. by raising chiller temperature or adding nitrogen) is not recommended.

Refrigerant dissolved in the oil can be removed and returned to the chiller by using an appropriate

deep-vacuum recovery unit and heating/agitating the oil container. Follow all Federal, State and Local regulations with regard to disposal of waste oil.

Replacing Oil Filter

Replace oil filter: (1) annually, (2) at each oil change, (3) or if erratic oil pressure is experienced during chiller operation.

Oil Filter Replacement

Use the following procedure to service the oil filter. Refer to Figure 26.

1. Run the oil pump for two to three minutes to insure that the oil filter is warmed up to the oil sump temperature.

2. Turn the oil pump motor off.

3. Pull the "D" handle on the rotary valve locking pin out of its detent and rotate the valve to the "DRAIN" position. An offset pointer is located on top of the valve with wrench flats to allow turning. the spring force on the locking pin should allow the pin to drop into a detent at this position.

4. Allow at least 15 minutes for the oil to drain from the filter back into the oil sump.

5. Pull the "D" handle to unlock the pin and rotate the valve to the "Change Filter" position. This isolates the filter from the unit. The locking pin should drop into a detent in this position.

6. Remove and replace the filter as quickly as possible. Tighten filter 2/3 to 3/4 turn per instructions written on the filter. Place the used filter in a reusable container. Follow all local, state and federal regulations to dispose of the filter.

Pull the "D" handle to unlock the pin and rotate the valve to the "RUN" position. The locking pin should drop into a detent in this position. The chiller is now ready for operation.

Other Maintenance Requirements

Compressors using new seal technology will not use O-rings. The O-ring has been replaced by Loctite 515 applied at a minimum film thickness of .010 applied across the width of the flange. The current jack bolt holes remain for disassembly.

⚠ CAUTION:
USE CARE WHEN APPLYING LOCTITE ON A JOINT. Failure to do so could result in Loctite getting into the chiller which may cause problems with the Oil supply system and eductor system.

[ ] Inspect the condenser tubes for fouling; clean if necessary.

[ ] Measure the compressor motor winding resistance to ground; a Qualified Service Technician should conduct this check to ensure that the findings are properly interpreted.

Contact a qualified service organization to leak-test the chiller; this procedure is especially important if the system requires frequent purging.

[ ] Use a nondestructive tube test to inspect the condenser and evaporator tubes at 3-year intervals.

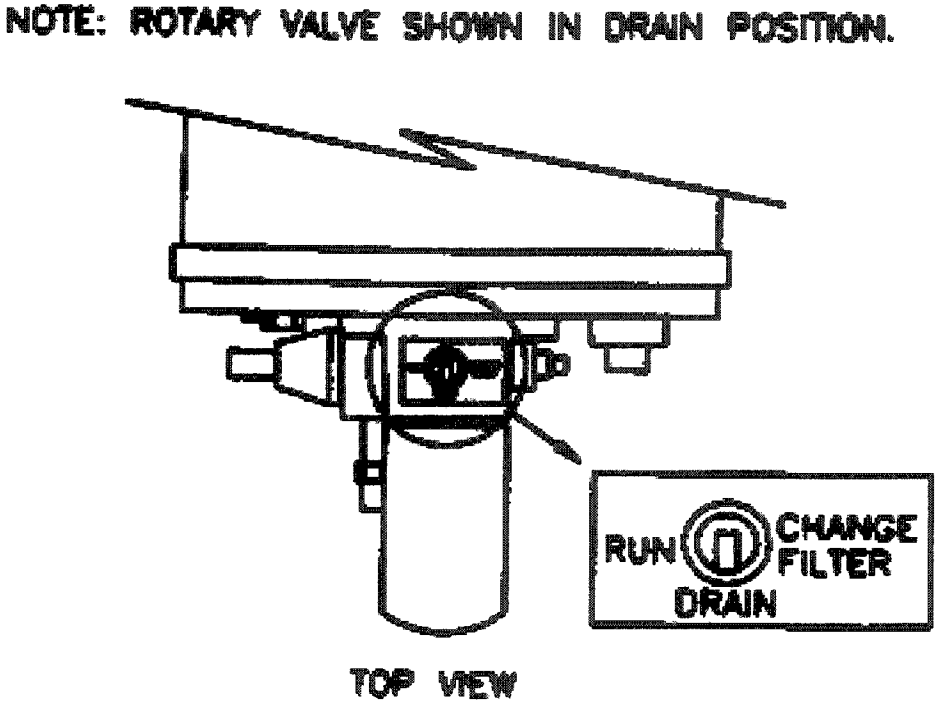
Note: It may be desirable to perform tube tests on these components at more frequent intervals, depending upon chiller application. This is especially true of critical process equipment.

[ ] Depending on chiller duty, contact a qualified service organization to determine when to conduct a complete examination of the unit to discern the condition of the compressor and internal components.

Note: (a) Chronic air leaks, which can cause acidic conditions in the compressor oil and result in premature bearing wear; and, (b) Evaporator or condenser water tube leaks. Water mixed with the compressor oil can result in bearing pitting, corrosion, or excessive wear.

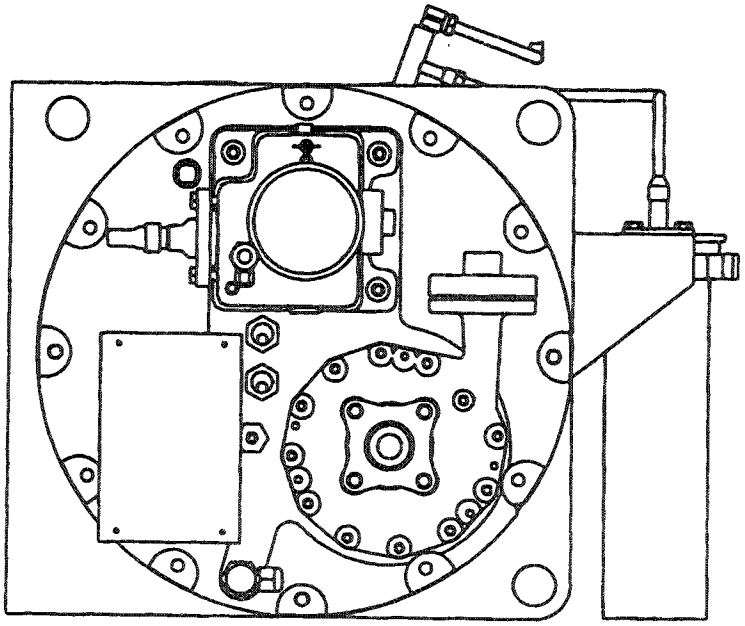
[ ] Submit a sample of the compressor oil to a Trane qualified laboratory for comprehensive analysis on an annual basis; this analysis determines system moisture content, acid level and wear metal content of the oil, and can be used as a diagnostic tool.

Lubrication



The only CVHE, CVHF and CVHG chiller component that requires periodic lubrication is the external vane linkage assembly and Rotary oil valve.

Lubricate the vane linkage shaft bearings and rod end bearings as needed with a few drops of light-weight machine oil.



Lubricate the 1st Stage IGV actuator O-Rings, by removing the pipe plug and adding several drops of Trane Oil 0022. Be sure and reinstall pipe plug.

The oil valve block rotary valve uses dual O'Rings to seal to atmosphere. These should be manually lubricated by removing the pipe plug at the valve lubrication port and placing a few drops of Trane Oil 0022 in the cavity. Be sure to reinstall the pipe plug when lubrication is completed.

Figure 26
Rotary Valve in Drain Position

Front View with Refrigerant Pump

Periodic Maintenance

Refrigerant Charge

⚠ WARNING

CERTAIN PROCEDURES COMMON TO REFRIGERANT SYSTEM SERVICE MAY EXPOSE OPERATING AND/OR SERVICING PERSONNEL TO LIQUID AND/OR VAPOROUS REFRIGERANT. CLOSELY FOLLOW ALL SAFETY PROCEDURES DESCRIBED IN THE MATERIAL SAFETY DATA SHEET FOR THE REFRIGERANT CONTAINERS. Failure to do so could result in death or injury due to inhalation of, or skin exposure to refrigerant.

The refrigerant charging procedure for Trane centrifugal chillers is:

1. If water is present in the tubes, break machine vacuum with refrigerant vapor, or circulate water, to avoid tube damage.

2. Always use refrigerant compatible hoses or copper-tubing with self-sealing connections or shut-off valves.

3. Transfer the refrigerant using one of the following (listed in order of preference):

   a. An approved Trane low-pressure refrigerant recovery/recycle unit.

   b. The available pressure differential.

   c. Gravity. (Use a return vent line to refrigerant drums to equalize pressure.)

5. Do not use dry nitrogen to push refrigerant into the chiller as was common practice in the past. This will contaminate the charge and require excessive purging, which will result in unnecessary release of refrigerant.

6. Weigh in the proper charge.

7. Use recovery/recyle unit or vacuum pump to evacuate hoses; discharge outdoors.

8. If refrigerant is supplied in new returnable cylinders, be sure and refer to General Service Bulletin CVHE-SB-48B for information on returning cylinders. This service bulletin is available at the nearest Trane office.

Depending on the chiller duty, contact a qualified service organization to determine when to conduct a complete examination of the unit to discern the condition of the compressor and internal components.

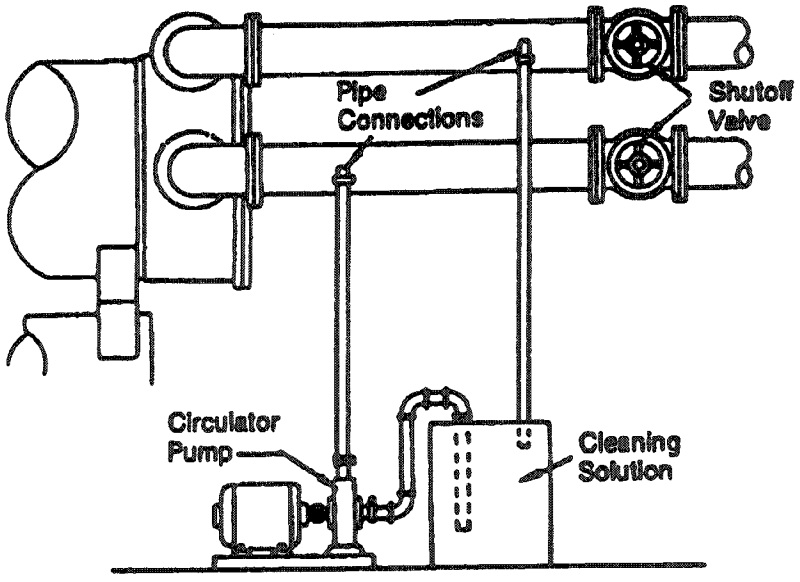
Note: If your chiller is covered by a Trane extended warranty, the terms of that warranty may require that the procedures listed in the Periodic Maintenance section of this manual be followed for your extended warranty to remain in force. The terms may also require that the chiller be inspected by a Trane authorized warranty agent every 4 years or 40,000 operating hours, whichever occurs first. This inspection will include, at a minimum, a review of the annual inspection checklists and the daily operating logs, as well as performance of a leak test and a general inspection of the chiller. The owner is then required to follow the recommendations made as a result of this inspection at the owners expense.

Recovery and Recycle Connections

To facilitate refrigerant removal and replacement, newer-design CVHE, CVHF and CVHG units are provided with a 3/4-inch vapor fitting with shutoff valve on the chiller suction and with a 3/4-inch liquid connection with shutoff valve at the bottom of the evaporator shell.

Leak Testing

To leak-test a chiller containing full refrigerant charge, raise chiller pressure using a controlled hot water or electric-resistance system to a maximum of 8 psig. Do not use nitrogen, which will cause excessive refrigerant discharge by the purge system.



Cleaning the Condenser

CAUTION

DO NOT USE UNTREATED OR IMPROPERLY TREATED WATER. Failure to follow this caution could result in damaged equipment.

See Figure 27 which shows a Typical Chemical Cleaning Setup.

Figure 27
Typical Chemical Cleaning Setup

Condenser tube fouling is indicated when the approach temperature (the difference between the condensing refrigerant temperature and the leaving condenser water temperature) is higher than predicted.

If the annual condenser tube inspection indicates that the tubes are fouled, two cleaning methods, mechanical and chemical, can be used to rid the tubes of contaminants.

Use the mechanical cleaning method to remove sludge and loose material from smooth-bore tubes.

(To clean other types of tubes including internally-enhanced types, consult a qualified service organization for recommendations).

1. Remove the retaining nuts and bolts from the water box covers at each end of the condenser. Use a hoist to lift the covers off the water box. (A threaded connection is provided on each water box cover to allow insertion of an eyebolt).

2. Work a round nylon or brass bristled brush (attached to a rod) in and out of each of the condenser water tubes to loosen the sludge.

3. Thoroughly flush the condenser water tubes with clean water.

Scale deposits are best removed by chemical means. Be sure to consult any qualified chemical house in the area (i.e., one familiar with the local water supply's chemical mineral content) for a recommended cleaning solution suitable for the job. Remember, a standard condenser water circuit is composed solely of copper, cast iron and steel.

⚠ CAUTION

USE CARE WHEN CHEMICAL CLEANING THE UNIT. Failure to do so can damage the unit.

IMPORTANT: *ALL OF THE MATERIALS USED IN THE EXTERNAL CIRCULATION SYSTEM, THE QUANTITY OF THE SOLUTION, THE DURATION OF THE CLEANING PERIOD, AND ANY REQUIRED SAFETY PRECAUTIONS SHOULD BE APPROVED BY THE COMPANY FURNISHING THE MATERIALS OR PERFORMING THE CLEANING.*

REMEMBER, HOWEVER, THAT WHENEVER THE CHEMICAL TUBE CLEANING METHOD IS USED, IT MUST BE FOLLOWED UP WITH MECHANICAL TUBE CLEANING, FLUSHING AND INSPECTION.

Cleaning the Evaporator

Since the evaporator is typically part of a closed circuit, it does not accumulate appreciable amounts of scale or sludge. Normally, cleaning every 3 years is sufficient. However, on open CVHE, CVHF and CVHG systems, such as air washers, periodic inspection and cleaning is recommended.

Control Settings and Adjustments

A list of CVHE, CVHF and CVHG time delays and safety control cutout settings is provided in Table 1 in the Chiller Control System section of this manual. For control calibration and check-out, contact a Trane qualified service organization.

Purge System

Because some sections of the chiller's refrigeration system operate at less-than-atmospheric pressure, the possibility exists that air and moisture may leak into the system. If allowed to accumulate, these non-condensibles become trapped in the condenser; this increases condensing pressure and compressor power requirements, and reduces the chiller's efficiency and cooling capacity.

The Trane Purifier Purge is the only purge system available for the CVHE, CVHF and CVHG chiller. The purge is designed to remove non-condensable gases and water from the refrigeration system. Purifier Purge unit operation, maintenance and trouble shooting is covered by a separate operation and maintenance manual, PRG-OM-6A or the latest issue, which may be obtained from the nearest Trane office.

Installed Unit Extended Storage

Overview

This section describes extended storage requirements for UCP2 installed CVHE, CVHF and CVHG chillers to be removed from service for an undetermined length of time.

Unit Preparation

The following steps are necessary in order to properly prepare a unit for storage.

1. Remove all liquid refrigerant if the unit is charge.

⚠ WARNING

TO AVOID INJURY OR DEATH DUE TO INHALATION OF, OR SKIN EXPOSURE TO REFRIGERANT, CLOSELY FOLLOW ALL SAFETY PROCEDURES DESCRIBED IN THE MATERIAL SAFETY DATA SHEET. Failure to do so may expose operating and/or servicing personnel to liquid and/or vaporous refrigerant.

2. After the liquid refrigerant is removed, using a recovery/recycle unit or vacuum pump, pull a vacuum to remove remaining refrigerant vapor from the unit.

3. After all traces of refrigerant are out of the unit, a positive nitrogen charge should be put into the unit (6 to 8 psig). This positive pressure must be checked monthly to insure no noncondensibles get into the unit. Use a pressure gage on the evaporator shell to verify that the 6 to 8 psig dry nitrogen holding charge is still in the chiller. If this charge has escaped, contact a qualified service organization and the Trane sales engineer that handled the order.

4. The refrigerant charge should be stored in proper refrigerant containers. Due to possible leakage, do not store in used drums.

5. Maintain control power to the control panel. This will maintain oil temperature in the oil sump and the capability of the control panel to present report information. The Chiller, Refrigerant and Compressor Reports should be viewed once a week for normal readings. Any abnormal observation must be reported to the Trane Sales Engineer that handled the order.

⚠ WARNING

USE CARE WHEN MEASUREMENTS, ADJUSTMENTS OR OTHER SERVICE-RELATED OPERATIONS ARE PERFORMED WITH POWER ON. Failure to do so could result in death due to electrical shock or contact with moving parts.

6. Remove the factory installed jumper or the field installed wiring on terminals J5-1 and J5-2 on the 1U1 Chiller Module in the unit control panel. This will prevent unwanted chiller operation.

7. Set the purge operating mode to OFF on UCP2 chillers.

8. The oil can be left in the unit.

9. The water side should not cause a problem if shut down and drained. There may be slight scaling inside the tubes, but not enough to cause a problem. Customer should inspect and clean tubes before the unit is returned to service.

IMPORTANT: *DO NOT USE UNTREATED OR IMPROPERLY TREATED WATER, OR EQUIPMENT DAMAGE MAY OCCUR.*

IMPORTANT: *SCALE DEPOSITS ARE BEST REMOVED BY CHEMICAL MEANS. BE SURE TO CONSULT ANY QUALIFIED CHEMICAL HOUSE IN THE AREA (I.E., ONE FAMILIAR WITH THE LOCAL WATER SUPPLY'S CHEMICAL MINERAL CONTENT) FOR A RECOMMENDED CLEANING SOLUTION SUITABLE FOR THE JOB.*

10. Motor bearings: If the motor sits for a long time the bearings could take a set and cause bearing problems/replacement later. Once every six months the chiller oil pump must be started and the compressor motor bump started to rotate the shaft. Contact a qualified service organization to perform this task. If the compressor motor cannot be bump started, then the shaft must be rotated manually by a qualified service organization.

11. Obtain an oil analysis initially after 6 months of storage, and once each succeeding year. If no oil breakdown is evident do not change the oil. If breakdown is evident, the oil must be replaced.

12. If the unit is stored for more than five years, and the storage is expected to be indefinite, the unit should be examined for leaks every five years from the initial storage date.

13. When the unit is to be returned to service, the services of a qualified service organization should be obtained to conduct all activities associated with the startup of a new chiller.

Annual Inspection Check List and Report: CenTraVacs® w/UCP2 Control Panels

Compressor Motor

[ ] Motor continuity check
Good [ ] Open [ ]

[ ] Check and tighten motor terminals

[ ] Meg motor
Phase 1 [ ] Phase 2 [ ] Phase 3 [ ]

[ ] Check nameplate rating
Amps [ ]

Starter

[ ] Check condition of starter contacts
Good [ ] Fair [ ] Replace [ ]

Oil Sump

[ ] Change oil
If oil analysis, refer to program procedures
[ ] Gallons (7) required

[ ] Oil pump motor ground check
Good [ ] Open [ ]

[ ] Check motor terminals

[ ] Change oil filter

Condenser

[ ] Visually inspect for scaling in tubes:
note findings and make recommendations

Control Circuits

[ ] Low refrigerant temperature sensor check-out
__ F set point __ F trip point (ice water)

[ ] Leaving Evaporator water temperature sensor check-out
__ F set point __ F trip point (ice water)

[ ] Condenser High Pressure Switch check-out
__ psig set point
__ psig trip point

[ ] Check Net Oil Pressure

[ ] Check adjustment and operation of inlet guide vane actuator stepper motor. The stroke of the actuator motor is 10,000 steps/in and approximately 46,000 to 54, 000 steps full stroke. (**Note**: each machine is unique and must have the 90° number of steps input.)

Leak Test Chiller

Refrigerant and oil analysis for acid content.

[ ] Sample refrigerant and oil for laboratory analysis (attach copy of analysis to next monthly inspection report)

Purge Unit

[ ] Perform the purge system control check described in"Control Circuit Diagnostics" in the "Troubleshooting" section of the most current Purge operation and maintenance manual.

Note: This form is suggested for your use.

TRANE®

CenTraVac®
Checksheet and Request for Serviceman

To: _____ Trane Service Company

S.O. No.: _____ Serial No.: _____

Job/Project Name: _____

The following items are being installed and will be complete by _____

1. CenTraVac
In place and piped. Do not insulate CenTraVac or adjacent piping. The contractor is responsible for any foreign material left in the unit. .....☐

2. Piping
Chilled water piping connected to:
- CenTraVac .....☐
- Air handling units.....☐
- Pumps .....☐

Condenser and heat recovery condenser (as applicable) piping connected to:
- CenTraVac .....☐
- Pumps .....☐
- Cooling tower.....☐
- Heating loop .....☐

Make-up water connected to cooling tower .....☐
Water supply connected to filling system .....☐
Systems filled .....☐
Pumps run, air bled from system.....☐
Strainers cleaned.....☐

3. Flow Balancing Valves Installed
Leaving chilled water .....☐
Leaving condenser water .....☐
Heat recovery condenser leaving water .....☐

4. Wiring
Compressor motor starter has been furnished by or approved by The Trane Company, La Crosse, WI.....☐
Power available .....☐
Interconnecting wiring, starter to control panel..☐
External interlock (flow switches, water pump aux., etc.) .....☐

Motors connected on:
- CenTraVac* .....☐
- Chilled water pump.....☐

Cooling tower fan rotation checked .....☐
Condenser water pump .....☐
Heat recovery condenser water pump (as applicable) .....☐
Power available for vacuum pump .....☐
(115V AC).....☐
All controls installed and connected .....☐
All magnetic starters installed and connected ...☐

*NOTE: Do not make final connections to compressor motor until requested by Trane Service Representative.

5. Testing
Dry nitrogen available for pressure testing .....☐
Trace gas amounts of Refrigerant-22 available for leak testing, if necessary.....☐

6. Refrigerant On Job Site .....☐

7. Gauges, Thermometers and Air Vents
Installed on both sides of evaporator.....☐
Installed on both sides of condenser and heat recovery condenser (as applicable).....☐

8. System Can Be Operated Under Load Conditions.....☐

9. Electrician, Control Man and Contractor's Representative Are Available to Evacuate, Charge and Test the CenTraVac under Serviceman's Supervision.....☐

In accordance with your quotation and our purchase order number _____

We will therefore require your serviceman on the job by** _____

This is to certify that the CenTraVac(s) has been properly and completely installed and the applicable items listed above have been completed.

**Advance notification is required to allow scheduling of the start-up as close to the requested date as possible.

Compliance To ASHRAE Standard 15

Yes	No	1. Is this an outdoor installation? If yes, skip to "Owner Awareness of Safe Refrigerant Handling Procedures".
Yes	No	2. Does the equipment room have a refrigerant monitor/sensor capable of monitoring and alarming within the acceptable exposure level (AEL) of the refrigerant?
Yes	No	3. Does the equipment room have an audible or visual alarm (other than the light on the monitor) which is controlled by the monitor?
Yes	No	4. Does the equipment room have mechanical ventilation?†
Yes	No	5. Is a self-contained breathing apparatus required by local building code? If no, go to question 7.
Yes	No	6. Is a self-contained breathing apparatus available in close proximity of the equipment room?
Yes	No	7. Are the purge discharge and the rupture disk piped to the outdoors?

† The mechanical ventilation consists of two flow requirements i.e., a two-speed fan where the high speed is sized by the formula Cfm = 100 x the square root of the pounds of refrigerant of the largest chiller, and low speed is 0.5 Cfm per square foot of the equipment room space. (This requirement is for chillers located within the building which is the most common.)

Owner Awareness Of Safe Refrigerant Handling Procedures

Yes	No	1. Has the owner been fully instructed on the proper use of refrigerant 123?
Yes	No	2. Was the owner given a copy of the MSDS for HCFC-123?
Yes	No	3. Was the owner given a copy of Trane publication "CFC-GUIDE-2, Refrigerant Handling Guidelines"?

Additional time required to complete the start-up and adjustment due to incompleteness of the installation will be invoiced at prevailing rates.

TRANE	CENTRAVAC WITH UCP2 COMMISSIONING CHECKLIST & START-UP TEST LOG

Job name _____ **Location** _____
Model # _____ **Serial #** _____
Sales Order # _____ **Start-up Date** _____

NOTE: The Unit Installation, Operation and Maintenance Manuals, Submittals, and Design Specifications must be used in conjunction with this checklist. **(INCLUDING WARNINGS AND CAUTIONS)**

I. PRECOMMISIONING PROCEDURES

A. Obtain Installation Check Sheet
This must be prepared by installer for a particular unit, verifying the unit is ready for commissioning.

B. Obtain Design (order) Specification Data
This indicates the design criteria of the particular unit. A unit cannot be properly commissioned unless this data is known. It is the responsibility of the selling office to furnish this data.

C. Obtain Wiring Diagrams
The "as-wired" electrical diagram should be compatible with the recommended Trane submittals and diagrams. Are customer added external/remote control circuits compatible? ☐ Yes ☐ No

D. General Installation Observations

☐ 1. Is there any apparent shipping or rigging damage? ☐ Yes ☐ No

☐ 2. Record the pressure on the shipping gauge_____PSIG. If there is no pressure on the gauge, A leak test will have to be done before the unit can be evacuated and charged.

☐ 3. Is the water piping correctly installed? ☐Yes ☐No
Flow Switches ☐ Yes ☐ No Pressure Gauges ☐ Yes ☐ No
Isolations Valves ☐ Yes ☐ No Flow Balancing Valves ☐ Yes ☐ No
Thermometer Wells ☐ Yes ☐ No Vent Cocks and Drains ☐ Yes ☐ No

☐ 4. Have proper clearances around the unit been maintained per submittal and/or installation Are there Manual guidelines available? ☐ Yes ☐ No

☐ 5. Is power wiring of adequate ampacity and correct voltage? ☐Yes ☐No
Are fuses or circuit breakers of the correct value or type? ☐Yes ☐No

☐ 6. Is the unit base acceptable, level, and is the unit on isolators (rubber as supplied by Trane or spring type)? ☐ Yes ☐ No

☐ 7. Have the micro (less than 30 volts) circuits been properly isolated from the higher voltage control and power circuits? ☐ Yes ☐ No

E. Comments_____
_____
_____

1

II. COMMISSIONING PROCEDURES

A. Pre-start Operations

1. Holding Charge

☐ _____ PSIG. Must be positive pressure or leak test must be done.
☐ Before relieving the holding charge, calibrate the H.P.C. high-pressure control. This is a check of pressure to the H. P. C. as well as calibration of the control. Disconnect and cap the flare. Calibrate H.P.C. reconnect flare.
☐ Relieve the holding charge.

2. Calibration of High Pressure Cutout

☐ Calibrate the HPC to cut out when 15 PSIG is exceeded. The cut in value is approximately 10 PSIG. CUT OUT____PSIG, CUT IN____PSIG.

3. Meggar the Motor (500 volt Meggar)

☐ Compressor motor Megohms -- refer to temp/resistance chart for acceptable values. Remove surge suppressors before Megging. Never Meg test with the unit in a vacuum.

T1 to Earth____	T4 to Earth____T1 to T2____	T1 to T4____
T2 to Earth____	T5 to Earth____T1 to T3____	T2 to T5____
T3 to Earth____	T6 to Earth____T2 to T3____	T3 to T6____

4. Evacuation

☐ Connect the vacuum pump to start evacuation. Use a 2-stage pump with at least 5 CFM capacity Connect to the evaporator-charging valve with a hose no smaller than ¾ inch ID.

5. Condenser

☐ Isolation and flow valves installed.

☐ Calibrated thermometers and pressure gauges installed in/out condenser on machine side of any valve or elbow.

☐ If condenser pump controlled by UCP2, is field wiring correct and complete?

☐ Condenser pump(s) run, system and strainers properly cleaned and/or flushed.

☐ Condenser water strainer in close proximity to entering connection of condenser.

☐ Previsions installed to properly maintain water treatment additives.

☐ Initial water treatment added to system.

☐ Flow or differential pressure switch installed and wired in series with auxiliary of pump motor starter. Operation of circuit verified.

☐ Condenser water flow balance. Ft H2O PD design ____, Ft H2O actual____
GPM design_____ GPM actual____

6. Evaporator

- ☐ ____PSIG. Must be positive pressure or leak test must be done.
- ☐ Calibrated thermometers and pressure gauges installed in/out of evaporator on machine side of any valve or elbow.
- ☐ If evaporator pump controlled by UCP2, is field wiring correct and complete?
- ☐ Evaporator pump(s) run 24 hrs. System and strainers properly cleaned and/or flushed.
- ☐ Evaporator water strainer in close proximity to entering connection of evaporator.
- ☐ Provisions installed to properly maintain water treatment additives.
- ☐ Initial water treatment added to system.
- ☐ Flow or differential pressure switch installed and wired in series with auxiliary of pump motor starter. Operation of circuit verified.
- ☐ Evaporator water flow balanced. Ft H2P PD design____, Ft H2O PD actual____
  GPM design____ GPM actual_____

7. Electrical and Controls

a. Motor starter panel

- ☐ All terminals tightened.
- ☐ Wiring free from abrasion, kinks and sharp corners.
- ☐ Contactors and relays have freedom of movement.
- ☐ All contacts are free of corrosion or dirt. Panel is free of dust, debris etc.
- ☐ Check the ratio of the current transformers. Record the part #s on the start-up log.
- ☐ Use only twisted shielded pair for the IPC circuit between the starter and the UCP2 on remote starters. Recommended wire is Belden 8760, 18 AWG. Polarity is critical.
- ☐ The low voltage IPC link (< 30 volts) must be in a separate conduit from the 115-volt wiring.
- ☐ IPC link routing within the starter panel must stay a minimum of 6 inches from higher voltages.
- ☐ Remote starter to UCP2 connections are complete and comply with Trane requirements.

☐ Check the correctness of the power connections from the starter to the motor.

☐ Check the wiring to the starter for size, voltage and correct phase rotation (A-L1, B-L2, and C-L3).

- ☐ Check the equal phase representation in each power-wiring conduit.

b. Control panel

☐ All terminals tightened.

☐ Wires free from abrasion, kinks and sharp corners.

☐ Low voltage wires are isolated from high voltage wires.

☐ Panel is free of debris, dust etc.

☐ "Power up" the control panel.

1. Starter disconnect locked open.
2. Fuse 2F4 must be removed from the starter.'
3. Connect auxiliary 115VAC-power cord to Terminals 1TB1-1 and 1TB1-2 in the control panel. **MAKE SURE OF THE POLARITY. THE 'HOT' SIDE MUST BE CONNECTED TO TERMINAL 1TB1-1 AND THE 'NEUTRAL' SIDE TO 1TB1-2.**
4. Plug in cord to 115VAC-power source. Control panel is now energized.

☐ Record the settings found in the Operator Settings, Service Settings Field Start-up Group, and Machine Configuration Menus in the UCP2.

☐ Using the CVHE Operation and Maintenance manual and the order specification, double check and reset, if required, the settings of Current Overload Setting #1 and Current Overload Setting #2 found in the Machine Configuration menu of the UCP2.

NOTE: DO NOT FORGET TO ADJUST THE RLA RATING TO MATCH THE ACTUAL JOBSITE VOLTAGE IF IT DIFFERS FROM THE DESIGN VOLTAGE.

☐ If Evaporator and/or condenser water pumps are controlled by the UCP2, use the Service Test Menu of the UCP2 to manually start and test the control of the pumps.

☐ Check the setting of the oil pressure-regulating valve.

1. Use the Service Tests menu of the UCP2 to manually start the oil pump.
2. Proceed to the Compressor Report menu of the UCP2 and observe the Differential Oil Pressure
3. Adjust the oil pressure-regulating valve to maintain 12 to 18 psid. The oil pressure-regulating valve may require adjustment as the unit is started.
4. This procedure also checks to ensure correct sensing of oil pressure. The Oil Pressure Cutout setting is a non-adjustable 9 psid within the logic of the UCP2.
5. Return Oil Pump control to 'auto'.

☐ Check vane operator and vanes.

1. Use the Service Tests menu of the UCP2 to manually override the vane control.
2. Enter targets from 0% to 100% and observe vane operation. At minimum and maximum travel the operator should not exert any force on the vane assembly, adjust as required.
3. Vane movement is smooth to open/close.
4. Vane movement is reported back to the UCP2.
5. Return Vane control to 'auto'.

☐ Dry run the starter
1. Make sure the starter disconnect is safely locked open.
2. Use the Service Tests menu of the UCP2 to initiate the Starter Dry Run.
3. Observe correct operation of starter contactors.
4. Observe correct operation of transition complete signal (if required).
5. Disable Starter Dry Run when complete.

☐ Disconnect and remove the temporary power cord.

B. Preparation for Start-up.

1. Evacuation and charging

☐ Evacuation leak test. When vacuum has been drawn down to .5-1 MM Hg, (500-1000 microns) secure the vacuum pump. Wait for 12 hours for a valid vacuum leak test. If the rise in vacuum is less .5 mm (500 microns) per 12 hours, start-up may proceed.

☐ Charge refrigerant. **MAKE SURE THE CHILLED WATER IS FLOWING THROUGH THE EVAPORATOR.** Charge the prescribed amount of refrigerant through the liquid charging valve at the liquid inlet to the evaporator. Check that all drums contain a full amount of refrigerant. Amount charged_____lbs/kg.

2. Electrical

☐ Disconnect all temporary power cords, replace all fuses, connect motor leads, make final electrical inspection.

☐ Power up the motor starter. Check for control voltage at control panel terminals 1TB1-1 and 1TB1-2. _____volts.

☐ Check current to the oil sump heater. ____amperes

☐ As the oil heats up, finish any operations not yet completed in preparation for starting the unit.

C. Chiller Start-up

1. Make all preliminary checks.

☐ Oil temp, oil level, chilled water flow, chilled water load available (cooling units on) etc.

2. Start the unit.

☐ If the phase rotation of the electrical power has not been positively confirmed, the actual rotation of the motor must be checked. Observe the rotation of the motor shaft through the sight glass on the end of the motor at the moment of start-up. Rotation must be CLOCKWISE. If the phase sequence is incorrect, confirmed by observation of the Phase Reversal diagnostic on the UCP2, then L1 and L3 power leads to the starter must be reversed.

☐ As the unit starts and runs, observe closely all operating conditions.

☐ Adjust the oil pressure regulator if necessary to 18 to 22 psi net.

- ☐ In the Operator Settings menu of the UCP2, place the Purge Operating Mode to 'on' to allow the removal of non-condensables. It may also be necessary to increase the length of the Purge Service Override timer found in the Field Startup Group menu.

- ☐ After the unit has the system down to design leaving chilled water temp and is under control, and the purge is no longer relieving non-condensables, begin taking the start-up test log. Log the unit a minimum of 3 times at 15-minute intervals.

- ☐ In the Operator Settings menu of the UCP2, return the purge-operating mode to 'Adaptive'.

- ☐ When the logging is complete, shut the chiller down. Allow the unit to sit idle for 5-10 minutes. Attach a piece of clear plastic hose between the ½ inch valve at the bottom of the evaporator and the ¼ inch valve near the top of the evaporator. Open the valves and record or mark permanently the refrigerant level in the hose. Record this level – it is very important! At some later time, the refrigerant charge can be easily checked and verified.

- ☐ Restart the chiller and carefully observe the starting and loading sequence.

3. Instructions to the Chiller Operator.

   - ☐ Instructions for starting, operating, and shutting down.

   - ☐ Instructions for logging the unit.

   - ☐ Instructions for periodic maintenance.

D. After 2 weeks of operation. (International Units Only)

1. Remove the water box covers on both the evaporator and condenser. Mechanically brush clean all the tubes. This is to assure there is no debris blocking any of the tubes. A piece of debris partially blocking a tube may cause that tube to fail prematurely.

2. Replace the oil filter with the spare oil filter included in the control panel at time of shipment.

START-UP PROCEDURES
TRANE LIQUI-FLO VARIABLE FREQUENCY DRIVE
PRE START-UP CHECKLIST AND SERVICE REQUEST

Use this form to check for proper installation of the Rockwell Automation Liqui-Flo VFD. For start-up service, please fax this completed form to: **Rockwell Automation -- LaCrosse, WI FAX: 1-608-781-7182** to schedule start-up. Please allow three weeks to arrange for start-up services.

JOB LOCATION_____INSTALLING CONTRACTOR_____

STREET_____CONTRACTOR CONTACT_____

CITY_____CONTACT PHONE_____

PRE START-UP CHECKLIST

PRIOR TO ROCKWELL AUTOMATION BEING ON SITE, CONFIRM THAT THE FOLLOWING ACTIONS HAVE BEEN COMPLETED (OR WILL BE COMPLETED PRIOR TO THE SCHEDULED START-UP):

	YES
1. The Trane Liqui-Flo VFD is mounted and wired per the CVHE-OM-8 Operation & Maintenance manual and/or wiring diagram (if separately supplied).	☐
2. The A-C primary line voltage is the proper voltage.	☐
3. The Trane chiller is ready to start and operate under load conditions. All preliminary start-up checks have been completed as detailed in the appropriate Installation Operation Maintenance manual, such as (evacuation, charging, all wiring & electrical work, chiller and AFD control settings checked, etc...).	☐
4. The Personnel have been selected to assist the Rockwell Automation service representative with the operation of the equipment and the facility layout.	☐

REQUEST FOR SERVICE REPRESENTATIVE

I acknowledge that all four of the above items have been completed. I understand that if upon job inspection these requirements are not met, no start-up work will be performed and travel time and mileage will be charged at current hourly rates.

Warnings and Cautions

Warnings and Cautions
Notice that warnings and cautions appear at appropriate intervals throughout this manual. Warnings are provided to alert installing contractors to potential hazards that could result in personal injury or death, while cautions are designed to alert personnel to conditions that could result in equipment damage.

Your personal safety and the proper operation of this machine depend upon the strict observance of these precautions.

NOTICE:

Warnings and Cautions appear at appropriate sections throughout this manual. Read these carefully.

⚠ **WARNING** – Indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

⚠ **CAUTION** – Indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury. It may also be used to alert against unsafe practices.

CAUTION – Indicates a situation that may result in equipment or property-damage-only accidents.

General Information

Literature change
Applicable to CVHE, CVHF, CVHG

About this manual
Operation and maintenance information for models CVHE, CVHF and CVHG are covered in this manual. This includes both 50 and 60 Hz. CVHE, CVHF and CVHG centrifugal chillers equipped with the Tracer CH530 Chiller Controller system. Please note that information pertains to all three chiller types unless differences exist in which case the sections are broken down by Chiller type as applicable and discussed separately.

By carefully reviewing this information and following the instructions given, the owner or operator can successfully operate and maintain a CVHE, CVHF or CVHG unit.

If mechanical problems do occur, however, contact a qualified service organization to ensure proper diagnosis and repair of the unit.

Note: The CH530 controller was first applied to CVHE with Design Sequence "3K", and to CVHF with Design Sequence "1W".

Unit Nameplate

The unit nameplate is located on the left side of the unit control panel. The following information is provided on the unit nameplate.

1. Serial Number
The unit serial number provides the specific chiller identity. Always provide this serial number when calling for service or during parts identification..

2. Service Model Number
The service model represents the unit as built for service purposes . It identifies the selections of variable unit features required when ordering replacements parts or requesting service.

Note: Unit-mounted starters are identified by a separate number found on the starter.

3. Product Coding Block
The CVHE, CVHF and CVHG models are defined and built using the product definition and selection (PDS) system. This system describes the product offerings in terms of a product coding block which is made up of feature categories and feature codes. An example of a typical product code block is given on this page. The coding block precisely identifies all characteristics of a unit.

4. Identifies unit electrical requirements

5. Correct operating charges and type of refrigerant

6. Unit Test Pressures and Maximum Operating Pressures

7. Identifies unit Installation and Operation and Maintenance manuals

8. Drawing numbers for Unit Wiring Diagrams

- C = Six Lead Medium Voltage
- S = Special

General Information

Commonly Used Acronyms

For convenience, a number of acronyms are used throughout this manual. These acronyms are listed alphabetically below, along with the "translation" of each:

AFD = Adaptive Frequency Drive

ASME = American Society of Mechanical Engineers

ASHRAE = American Society of Heating, Refrigerating and Air Conditioning Engineers

BAS = Building Automation System

CABS = Auxiliary Condenser Tube-Bundle S

CDBS = Condenser Bundle Size

CDSZ = Condenser Shell Size

CH530 = Tracer CH530 Controller

DV = DynaView™ Clear Language Display, also know as the Main Processor (MP)

CWR = Chilled Water Reset

CWR' = Chilled Water Reset Prime

DTFL = Design Delta-T at Full Load (i.e., the difference between entering and leaving chilled water temperatures)

ELWT = Evaporator Leaving Water Temperature

ENT = Entering Chilled Water Temperature

FC = Free Cooling

GPM = Gallons-per-minute

HGBP = Hot Gas Bypass

HVAC = Heating, Ventilating, and Air Conditioning

IE = Internally-Enhanced Tubes

IPC = Interprocessor Communication

LBU = La Crosse Business Unit

LCD = Liquid Crystal Display

LED = Light Emitting Diode

MAR = Machine Shutdown Auto Restart (Non-Latching where chiller will restart when condition corrects itself.)

MMR = Machine Shutdown Manual Restart (Latching where chiller must be manually reset.)

MP = Main Processor

PFCC = Power Factor Correction Capacitor

PSID = Pounds-per-Square-Inch (differential pressure)
PSIG = Pounds-per-Square-Inch (gauge pressure)

UCP = Unit Control Panel

LLID = Low Level Intelligent Device (Sensor, Pressure Transducer, or Input/output UCP module)

RLA = Rated Load Amps

RTD = Resistive Temperature Device

Tracer CH530= Controls Platform utilized on this Chiller

TOD = Temperature Outdoor

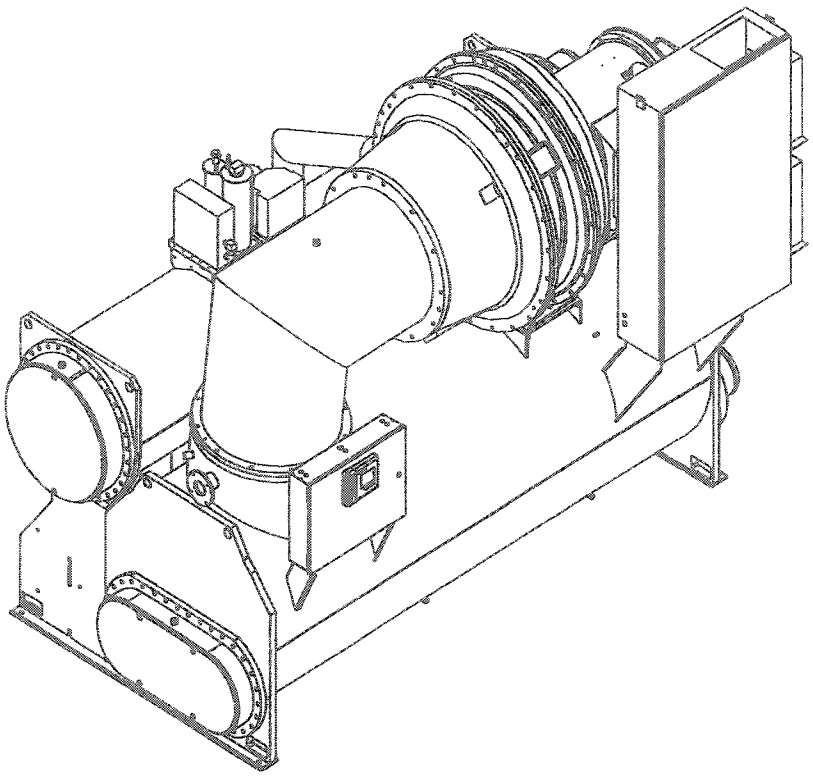
General Information

Overview

CVHE, CVHG, CVHF

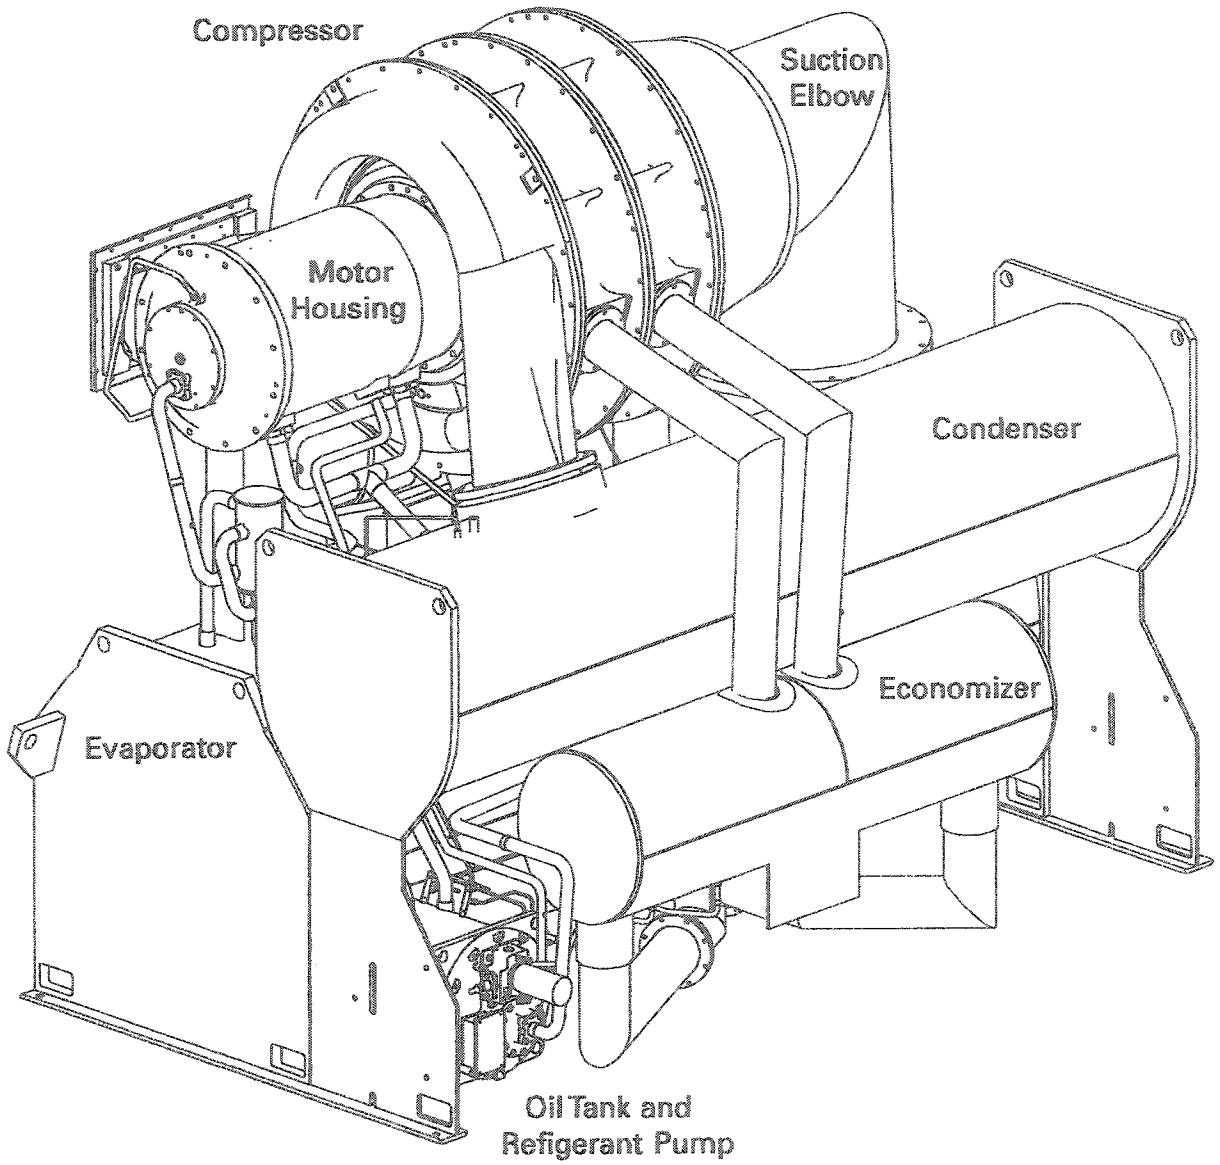
Each CVHE, CVHG, or CVHF unit is composed of 5 basic components.



- the evaporator,
- 3-stage compressor on CVHE, CVHG or 2 stage compressor on CVHF,
- 2-stage economizer on CVHE, CVHG, or single economizer on CVHF,

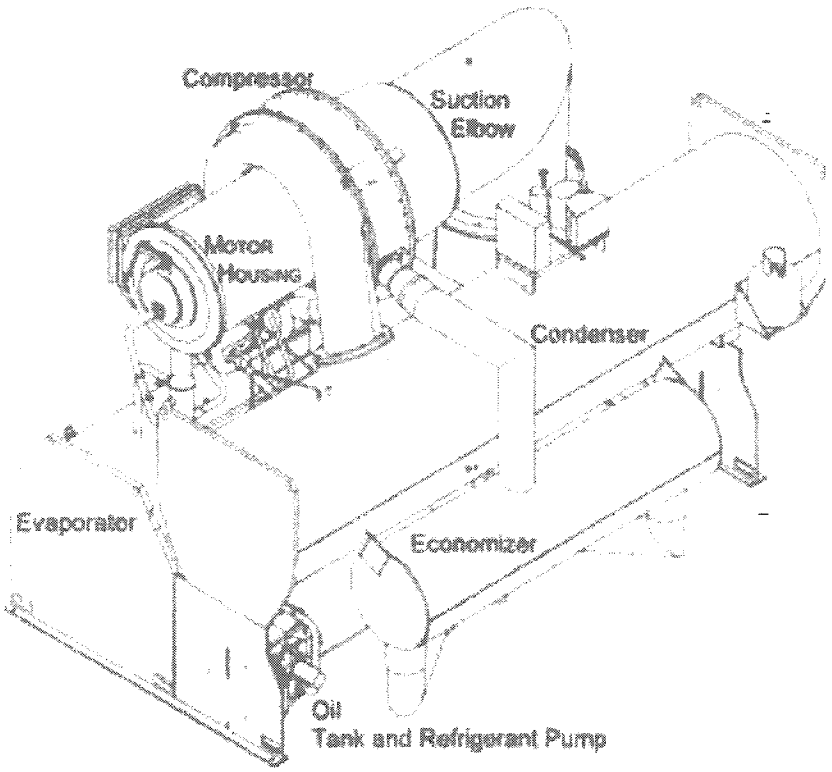
See Figure 1 for Typical CVHE and CVHG, and Figure 2 for Typical CVHF major components.

A heat-recovery or auxiliary condenser can be factory-added to the basic unit assembly to provide a heat-recovery cycle.



- water-cooled condenser,
- related interconnecting piping.

Figure 1. General CVHE and CVHG unit components



General Information

General Information

Figure 2. Illustrates the general component layout of a typical CVHF chiller

General Information

Cooling Cycle

CVHE, CVHG, CVHF

When in the cooling mode, liquid refrigerant is distributed along the length of the evaporator and sprayed through small holes in a distributor (i.e., running the entire length of the shell) to uniformly coat each evaporator tube. Here, the liquid refrigerant absorbs enough heat from the system water circulating through the evaporator tubes to vaporize.

The gaseous refrigerant is then drawn through the eliminators (which remove droplets of liquid refrigerant from the gas) and first-stage variable inlet guide vanes, and into the first stage impeller.

Note: Inlet guide vanes are designed to modulate the flow of gaseous refrigerant to meet system capacity requirements; they also prerotate the gas, allowing it to enter the impeller at an optimal angle that maximizes efficiency at all load conditions.

CVHE, CVHG Compressor

Compressed gas from the first-stage impeller flows through the fixed, second-stage inlet vanes and into the second-stage impeller.

Here, the refrigerant gas is again compressed, and then discharged through the third-stage variable guide vanes and into the third stage impeller.

Once the gas is compressed a third time, it is discharged into the condenser. Baffles within the condenser shell distribute the compressed refrigerant gas evenly across the condenser tube bundle. Cooling tower water circulated through the condenser tubes absorbs heat from the refrigerant, causing it to condense. The liquid refrigerant then passes through orifice plate "A" and into the economizer.

The economizer reduces the energy requirements of the refrigerant cycle by eliminating the need to pass all gaseous refrigerant through three stages of compression. See Figure 3. Notice that some of the liquid refrigerant flashes to a gas because of the pressure drop created by the orifice plates, thus further cooling the liquid refrigerant. This flash gas is then drawn directly from the first (Chamber A) and second (Chamber B) stages of the economizer into the third-and second-stage impellers of the compressor, respectively.

All remaining liquid refrigerant flows through another orifice plate "C" to the evaporator.

CVHF Compressor

Compressed gas from the first-stage impeller is discharged through the second-stage variable guide vanes and into the second-stage impeller. Here, the refrigerant gas is again compressed, and then discharged into the condenser.

Baffles within the condenser shell distribute the compressed refrigerant gas evenly across the condenser tube bundle. Cooling tower water, circulated through the condenser tubes, absorbs heat from the refrigerant, causing it to condense. The liquid refrigerant then flows out of the bottom of the condenser, passing through an orifice plate and into the economizer.

The economizer reduces the energy requirements of the refrigerant cycle by eliminating the need to pass all gaseous refrigerant through both stages of compression. See Figure 6. Notice that some of the liquid refrigerant flashes to a gas because of the pressure drop created by the orifice plate, thus further cooling the liquid refrigerant. This flash gas is then drawn directly from the economizer into the second-stage impellers of the compressor.

All remaining liquid refrigerant flows out of the economizer, passes through another orifice plate and into the evaporator.

General Information

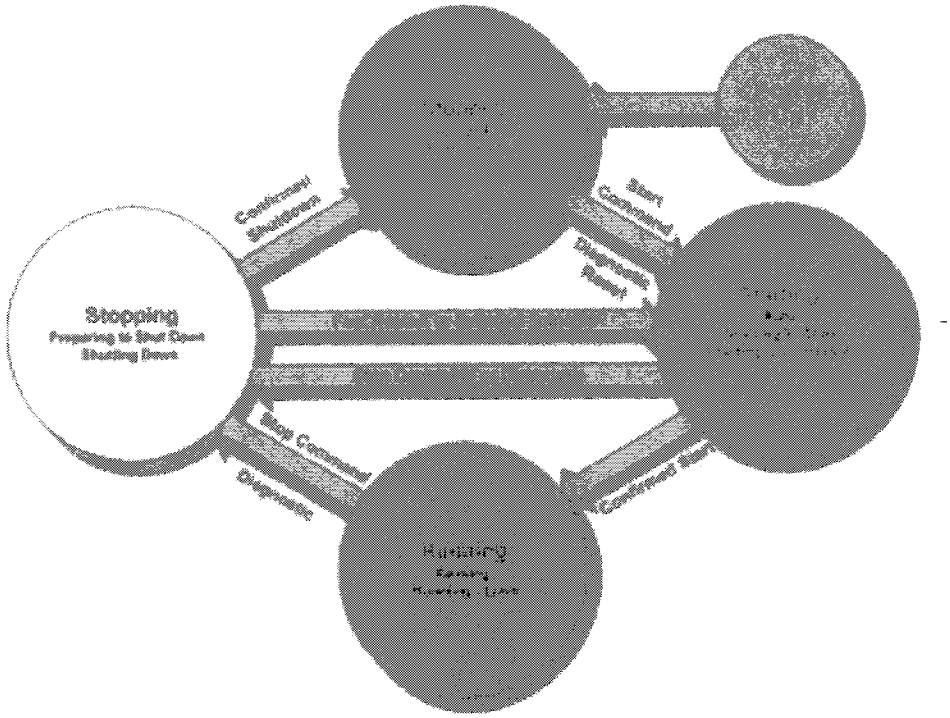
Overview

Controls Operator Interface
Information is tailored to operators, service technicians and owners

When operating a chiller, there is specific information you need on a day-to-day basis — setpoints, limits, diagnostic information, and reports.



When servicing a chiller, you need different information and a lot more of it — historic and active diagnostics, configuration settings, and customizable control algorithms, as well as operation settings.

By providing two different tools – one for daily operation and one for periodic service — everyone has easy access to pertinent and appropriate information.

DynaView™ Human Interface
— For the operator
Day-to-day operational information is presented at the panel. Up to seven lines of data (English or SI units) are simultaneously displayed on the ¼ VGA touch-sensitive screen. Logically organized groups of information — chiller modes of operation, active diagnostics, settings and reports put information conveniently at your fingertips. See Operator Interface Section for details.

TechView™ Chiller Service Tool
— For the service technician or advanced operator
All chiller status, machine configuration settings, customizable limits, and up to 60 active or historic diagnostics are displayed through the service tool interface. Without changing any hardware, we give you access to the latest and greatest version of Tracer CH530! A new level of serviceability using the innovative TechView™ chiller service tool, a technician can interact with an individual device or a group of devices for advanced troubleshooting. LED lights and their respective TechView™ indicators visually confirm the viability of each device. Any PC that meets the system requirements may download the service interface software and Tracer CH530 updates. For more information on TechView™ visit your local Trane Service company, or The Trane Company's website at www.trane.com.

General Information

Oil and Refrigeration Pump

Compressor Lubrication System - A schematic diagram of the compressor lubrication system is illustrated in Figure 12.

Oil is pumped from the oil tank (by a pump and motor located within the tank) through an oil pressure-regulating valve designed to maintain a net oil pressure of 18 to 22 psid. It is then filtered and sent to the oil cooler located in the economizer and on to the bearings. From the bearings, the oil drains back to the manifold under the motor and then on to the oil tank.

CAUTION

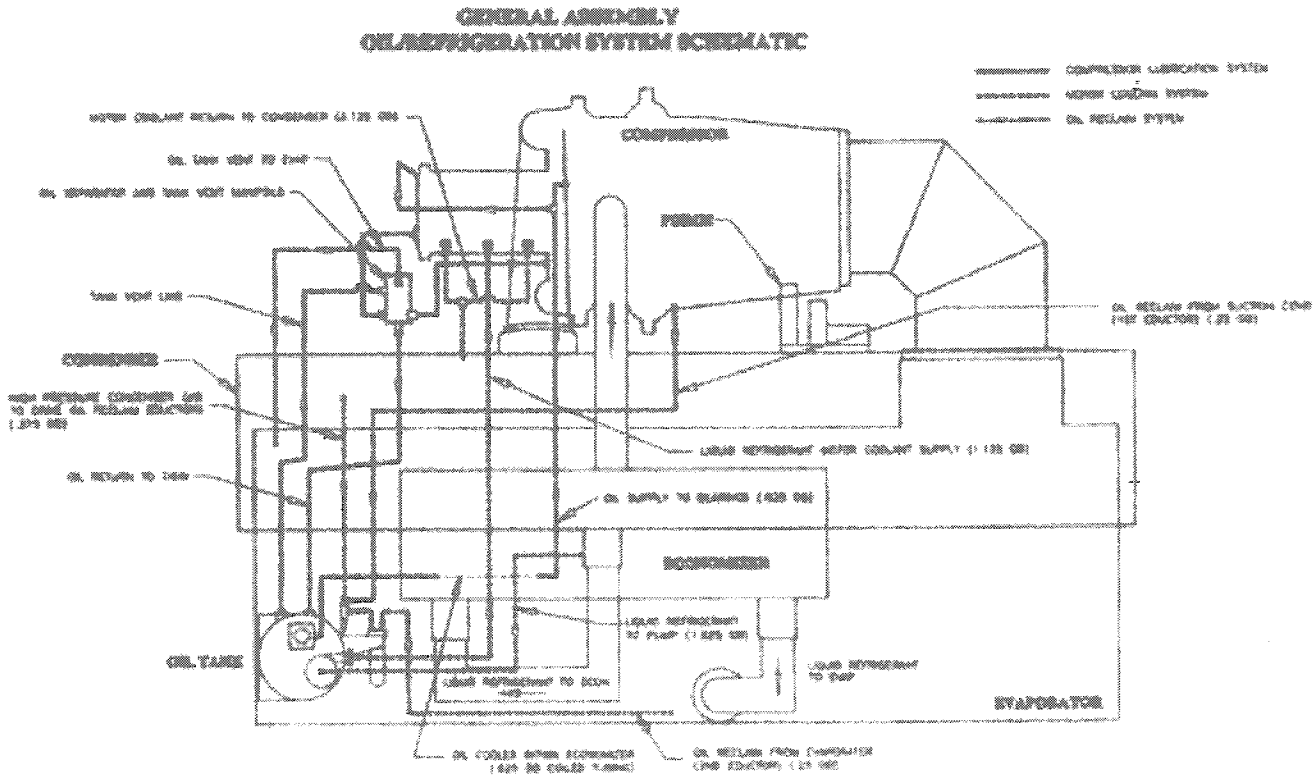
Surface Temperatures!

MAY EXCEED 150°F. Use caution while working on certain areas of the unit, failure to do so may result in minor or moderate injury.

To ensure proper lubrication and prevent refrigerant from condensing in the oil tank, a 750-watt heater is immersed in the oil tank and is used to warm the oil while the unit is off. When the unit starts, the oil heater is de-energized. This heater energizes as needed to maintain 140° to 145° F (60-63°C) when the chiller is not running.

When the chiller is operating, the temperature of the oil tank is typically 115° to 160°F (46-72°C). The oil return lines from the thrust and journal bearings, transport oil and some seal leakage refrigerant. The oil return lines are routed into a manifold under the motor. Gas flow exits the top of the manifold and is vented to the Evaporator. A vent line solenoid is not needed with the refrigerant pump. Oil exits the bottom of the manifold and returns to the tank. Separation of the seal leakage gas in the manifold keeps this gas out of the tank.

A dual eductor system is used to reclaim oil from the suction cover and the evaporator, and deposit it back into the oil tank. These eductors use high pressure condenser gas to draw the oil from the suction cover and evaporator to the eductors and then discharged into the oil tank. The evaporator eductor line has a shut off valve mounted by the evaporator and ships closed. Open two turns if necessary.



Liquid refrigerant is used to cool the oil supply to both the thrust bearing and journal bearings. On refrigerant pump units the oil cooler is located inside the economizer and uses refrigerant passing from the condenser to evaporator to cool the oil. Oil leaves the oil cooler and flows to both the thrust and journal bearings.

Motor Cooling System
Compressor motors are cooled with liquid refrigerant, see Figure 12.

The refrigerant pump is located on the front of the oil tank (motor inside the oil tank). The refrigerant pump inlet is connected to the well at the bottom of the condenser. The connection is on the side where a weir assures a preferential supply of liquid. Refrigerant is delivered to the motor via the pump. Motor refrigerant drain lines are routed to the condenser.

General Information

Figure 12. Oil refrigerant pump

General Information

Base Loading Control Algorithm:

This feature allows an external controller to directly modulate the capacity of the chiller. It is typically used in applications where virtually infinite sources of evaporator load and condenser capacity are available and it is desirable to control the loading of the chiller. Two examples are industrial process applications and cogeneration plants. **Industrial process applications** might use this feature to impose a specific load on the facility's elecrical system. **Cogeneration plants** might use this feature to balance the system's heating, cooling and electrical generation.

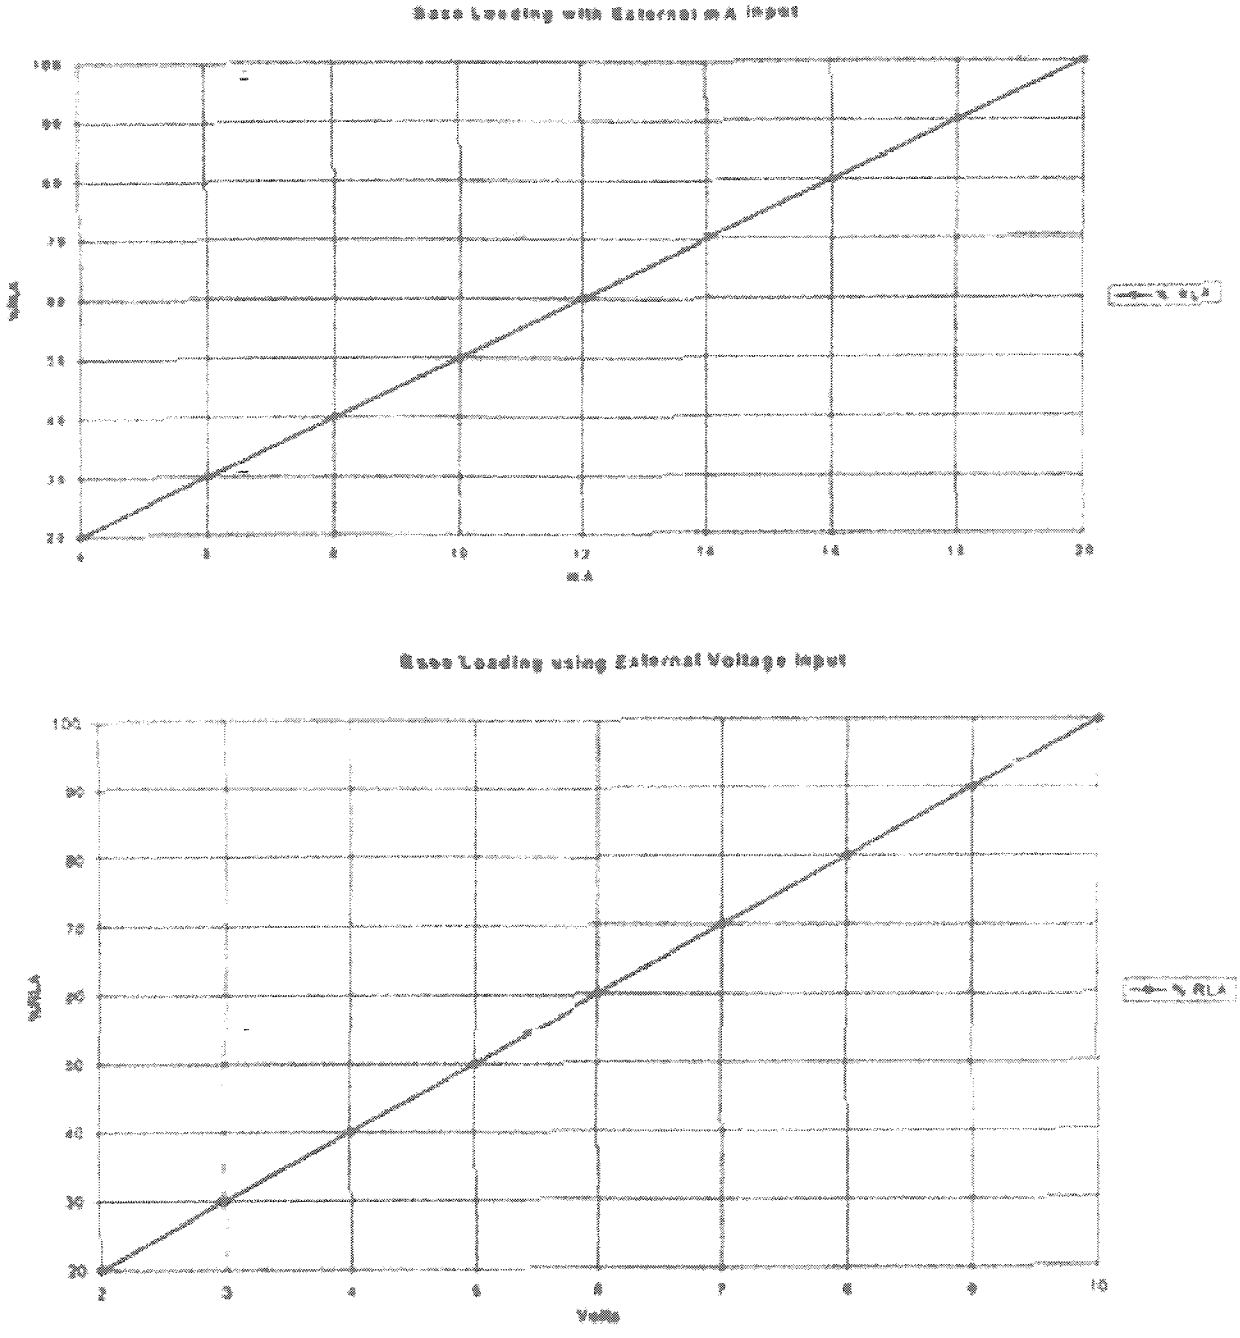
All chiller safeties and adaptive control functions are in full effect when Base Loading control is enabled. If the chiller approaches full current, the evaporator temperature drops too low, or the condenser pressure rises too high, Tracer CH530 Adaptive Control logic limits the loading of the chiller to prevent the chiller from shutting down on a safety limit. These limits may prevent the chiller from reaching the load requested by the Base Loading signal.

Base Loading Control is basically a variation of the current limit algorithm. During base loading, the leaving water control algorithm provides a load command every 5 seconds. The current limit routine may limit the loading when the current is below setpoint. When the current is within the deadband of the setpoint the current limit algorithm holds against this loading command. If the current exceeds the setpoint, the current limit algorithm unloads. The "Capacity Limited By High Current" message normally displayed while the current limit routine is active is suppressed while base loading.

Base loading can occur via Tracer, External signal, or front panel.

Tracer Base Loading:
Current Setpoint Range:
(20 - 100) percent RLA
Requires Tracer and Optional Tracer Communications Module (LLID)

The Tracer commands the chiller to enter the base load mode by sending the base load mode request. If the chiller is not running, it will start regardless of the differential to start (either chilled water or hot water). If the chiller is already running, it will continue to run regardless of the differential to stop (either chilled water or hot water), using the base load control algorithm. While the unit is running in base loading, it will report that status back to the Tracer by setting "Base Load Status = true" in the Tracer Status Byte. When the Tracer removes the base load mode request (sets the bit to 0). The unit will continue to run, using the normal chilled or hot water control algorithm, and will turn off, only when the differential to stop has been satisfied.



External Base Loading:
Current Setpoint Range:
(20 - 100) percent RLA

The UCP accepts 2 inputs to work with external base loading. The binary input is at 1A18 Terminals J2-1 and J2-2 (Ground) which acts as a switch closure input to enter the base-loading mode. The second input, an analog input, is at 1A17 terminals J2 – 1 and 3 (Ground) which sets the external base loading setpoint, and can be controlled by either a 2-10Vdc or 4-20ma Signal. At startup the input type is configured. The graphs in Figure 13 show the relationship between input and percent RLA. While in base loading the active current limit setpoint is set to the Tracer or external base load setpoint, providing that the base load setpoint is not equal to 0 (or out of range). If it is out of range, the front panel current limit setpoint is used. During base loading, all limits are enforced with the exception of current limit. The human interface displays the message "Unit is Running Base Loaded". Hot Gas Bypass is not run during base loading. If base loading and ice making are commanded simultaneously, ice making takes precedence.

An alternative and less radical approach to Base Loading indirectly controls chiller capacity. Artifically load the chiller by setting the chilled water setpoint lower than it is capable of achieving. Then, modify the chiller's load by adjusting the current limit setpoint. This method provides greater safety and control stability in the operation of the chiller because it has the advantage of leaving the chilled water temperature control logic in effect. The chilled water temperature control logic responds quicker to dramatic system changes, and can limit the chiller loading prior to reaching an Adaptive Control limit point.

General Information

Figure 13. Base loading with external mA input and with external voltage input

General Information

Ice Machine Control

The control panel provides a service level "Enable or Disable" menu entry for the Ice Building feature when the Ice Building option is installed. Ice Building can be entered 1) from the "Front Panel", 2) if hardware is specified, will accept either an isolated contact closure (1A19 Terminals J2-1 and J2-2 (Ground)) 3), a remote communicated input (Tracer) to initiate the ice building mode where the unit runs fully loaded at all times. Ice building will be terminated either by opening the contact or based on entering evaporator fluid temperature. UCP will not permit the Ice Building mode to be entered again until the unit is switched to the Non-ice building mode and back into the ice building mode. It is not acceptable to reset the chilled water setpoint low to achieve a fully loaded compressor. When entering ice-building the compressor will be loaded at its maximum rate and when leaving ice building the compressor will be unloaded at its maximum rate. While loading and unloading the compressor, all surge detection will be ignored. While in the ice building mode, current limit setpoints less than the maximum will be ignored. Ice Building can be terminated by one of the following means:

1. Front Panel Disable, or
2. Opening the external Ice. Contacts/ Remote communicated input (Tracer), or
3. Satisfying an evaporator entering fluid temperature setpoint (Default to 27°F).
4. Surging for 7 minutes at full open IGV.

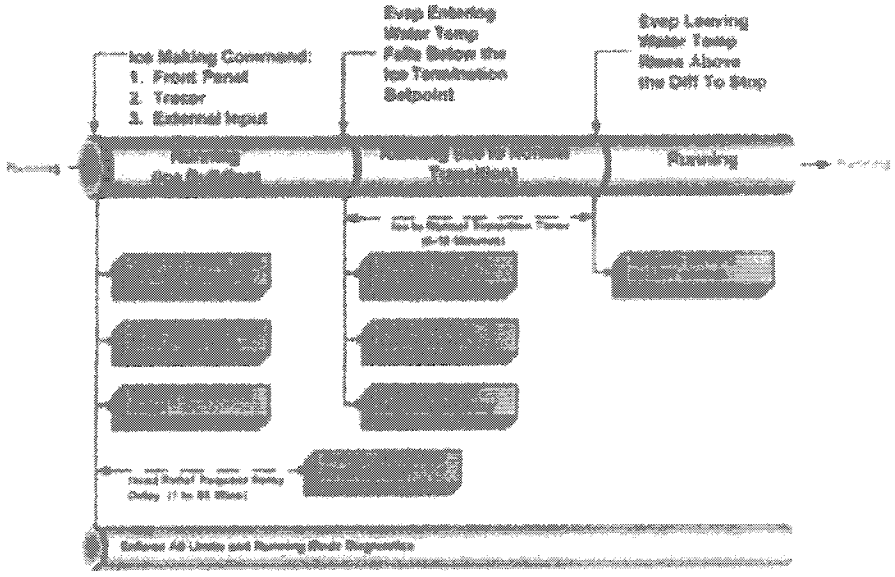

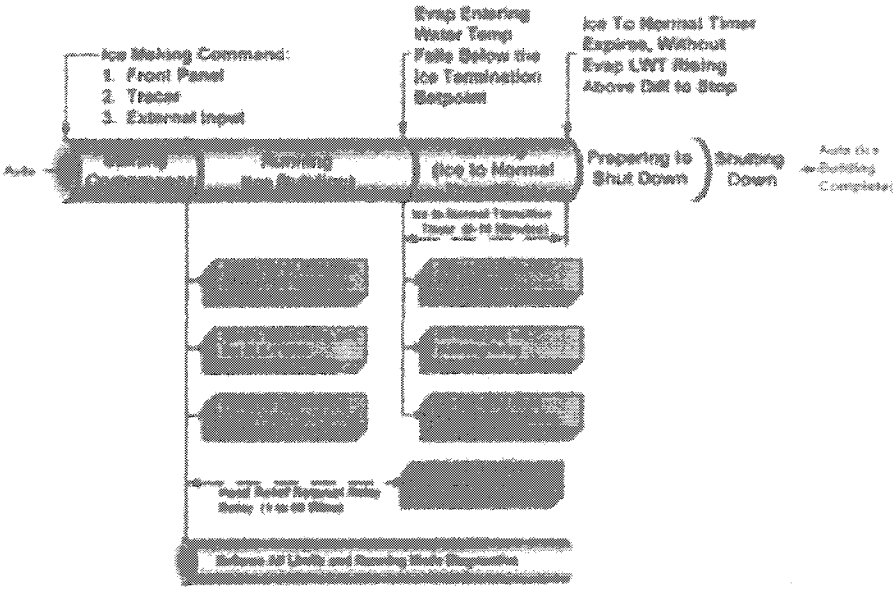

Figure 15. CVHE, CVHF and CVHG sequence of operation: ice making: stopped to ice to ice building complete

General Information

Free Cooling Cycle

Based on the principle that refrigerant migrates to the coldest area in the system, the free cooling option adapts the basic chiller to function as a simple heat exchanger. However, it does not provide control of the leaving chilled water temperature.

If condenser water is available at a temperature lower than the required leaving chilled water temperature, the operator interface must remain in "AUTO" and the operator starts the free cooling cycle by enabling the Free cooling mode in the "DynaView™ Feature Settings" group of the operator interface, or by means of a Tracer request.

Several components must be factory-installed or field-installed to equip the unit for free cooling operation:

- a refrigerant gas line, and electrically-actuated shutoff valve, between the evaporator and condenser;
- a valve liquid return line, and electrically-actuated shutoff valve, between the condenser sump and the evaporator;
- a liquid refrigerant storage vessel (larger economizer); and,
- additional refrigerant.

When the chiller is changed over to the free cooling mode, the compressor will shut down if running, the shutoff valves in the liquid and gas lines open; unit control logic prevents the compressor from energizing during free cooling. Liquid refrigerant then drains (by gravity) from the storage tank into the evaporator and floods the tube bundle. Since the temperature and pressure of the refrigerant in the evaporator are higher than in the condenser (i.e., because of the difference in water temperature), the refrigerant in the evaporator vaporizes and travels to the condenser. Cooling tower water causes the refrigerant to condense, and it flows (again, by gravity) back to the evaporator.

This compulsory refrigerant cycle is sustained as long as a temperature differential exists between condenser and evaporator water. The actual cooling capacity provided by the free cooling cycle is determined by the difference between these temperatures which, in turn, determines the rate of refrigerant flow between the evaporator and condenser shells.

If the system load exceeds the available free cooling capacity, the operator must manually initiate changeover to the mechanical cooling mode by disabling the free cooling mode of operation. The gas and liquid line valves then close and compressor operation begins. (See Figure 8 beginning at "Auto" mode.) Refrigerant gas is drawn out of the evaporator by the compressor, where

General Information

it is then compressed and discharged to the condenser. Most of the condensed refrigerant initially follows the path of least resistance by flowing into the storage tank. This tank is vented to the economizer sump through a small bleed line; when the storage tank is full, liquid refrigerant must flow through the bleed line restriction. Because the pressure drop through the bleed line is greater than that of the orifice flow control device, the liquid refrigerant flows normally from the condenser through the orifice system and into the economizer.

Free Cooling FRCL

To enable Free Cooling Mode:

1. Free Cooling must first be installed and commissioned.
2. Enable the Free Cooling mode in the DynaView™ Settings Menu
3. Press "AUTO", and if used, close the external binary input switch (connected to 1A20 J2- 1 to 2) while the chiller is in "AUTO".

Free Cooling cannot be entered if the chiller is in "STOP".

If the chiller is in "AUTO" and not running, the condenser water pump will start. After condenser water flow is proven, Relay Module 1A11 will energize operating the Free Cooling Valves 4B12 and 4B13. The Free Cooling Valves End Switches must open within 3 minutes, or an MMR diagnostic will be generated. Once the Free Cooling Valves End Switches open, the unit is in the Free Cooling mode. If the chiller is in "AUTO" and running powered cooling, the chiller will do a friendly shut down first, (Run: Unload, Post Lube, and drive vanes closed). After the vanes have been overdriven, closed and condenser water proven, the Free Cooling relays will be energized. To disable Free Cooling and return to Powered Cooling, either disable the Free Cooling Mode in the DynaView™ settings menu if used to enable Free Cooling or "OPEN" the external binary input switch to the 1A20 Module if it was used to enable Free Cooling. Once Free Cooling is disabled, the Free Cooling relays Relay Module 1A11 will de-energize allowing the Free Cooling valves to close. The Free Cooling valves end switches must close within 3 minutes or an MMR diagnostic is generated. Once the end switches close the chiller will return to "AUTO" and powered cooling will resume if there is a call for cooling based on the differential to start.

Note: The manual control of the inlet guide vanes is disabled while in the Free Cooling Mode and the compressor is prevented from starting by the control logic.

Note: The relay at 1A11-J-2-4 to 6 is a FC auxiliary relay and can be used as required.

General Information

Hot Gas Bypass

The hot gas bypass (HGBP) control option is designed to minimize machine cycling by allowing the chiller to operate stably under minimum load conditions. In these situations, the inlet guide vanes are "locked" at a preset minimum position, and unit capacity is governed by the HGBP valve actuator. Control circuitry is designed to allow both the inlet guide vanes and the HGBP valve to close for unit shutdown.

After a chiller starts and is running the inlet guide vanes will pass through the HGBP Cut-In-Vane position as the chiller starts to load. As the chiller catches the load and starts to unload, the inlet guide vanes will close to the HGBP Cut-In Vane position. At this point the movement of the inlet guide vanes is frozen and further unloading of the chiller is controlled by the opening of the HGBP Valve 4M5 and module modulates the HGBP valve at low loads. When the control algorithm determines the chiller to be shut down, the inlet guide vanes will be driven fully closed, and the HGBP valve will be driven closed. After the inlet guide vanes are fully closed the chiller will shut down in the Friendly mode. Chillers with HGBP have a discharge temperature sensor (4R16) monitoring the discharge gas temperature from the compressor. If this temperature exceeds 200°F, the chiller will shut off on a MAR diagnostic. The chiller will reset automatically when this temperature drops 50°F below the trip-point.

HGBP is enabled in the Features menu settings Group of the DV Menus by enabling the option. The setting the HGBP Cut-In Vane Position is setup at unit commissioning via the service tool.

General Information

Hot Water control

Occasionally CTV chillers are selected to provide heating as a primary mission. With hot water temperature control, the chiller can be used as a heating source or cooling source. This feature provides greater application flexibility. In this case the operator selects a hot water temperature and the chiller capacity is modulated to maintain the hot water setpoint. Heating is the primary mission and cooling is a waste product or is a secondary mission. This type of operation requires an endless source of evaporator load (heat), such as well or lake water. The chiller has only one condenser.

Note: Hot water temperature control mode does not convert the chiller to a heat pump. Heat pump refers to the capability to change from a cooling-driven application to a heating-driven application by changing the refrigerant path on the chiller. This is impractical for centrifugal chillers as it would be much easier to switch over the water side.

This is NOT heat recovery. Although this feature could be used to recover heat in some form, there is a second heat exchanger on the condenser side.

The DynaView™ Main Processor provides the hot water temperature control mode as standard. The leaving condenser water temperature is controlled to a hot water setpoint between 80 and 140°F (26.7 to 60°C) The leaving evaporator water temperature is left to drift to satisfy the heating load of the condenser. In this application the evaporator is normally piped into a lake, well, or other source of constant temperature water for the purpose of extracting heat.

In hot water temperature control mode all the limit modes and diagnostics operate as in normal cooling with one exception; The leaving condenser water temperature sensor is an MMR diagnostic when in hot water temperature control mode. (It is an informational warning in the normal cooling mode.)

In the hot water temperature control mode the differential-to-start and differential-to-stop setpoints are used with respect to the hot water setpoint instead of with the chilled water setpoint.

UCP provides a separate entry at the DV to set the hot water setpoint. Tracer is also able to set the hot water setpoint. In the hot water mode the external chilled water setpoint is the external hot water setpoint; that is, a single analog input is shared at the 1A16–J2-1 to J2-3 (ground)

An external binary input to select external hot water control mode is on the EXOP OPTIONAL module 1A18 terminals J2-3 to J2-4 (ground). Tracer also has a binary input to select chilled water control or hot water temperature control.

There is no additional leaving hot water temperature cutout; the HPC and condenser limit provide for high temperature and pressure protection.

In hot water temperature control the softloading pulldown rate limit operates as a softloading pullup rate limit. The setpoint for setting the temperature rate limit is the same setpoint for normal cooling as it is for hot water temperature control.

The hot water temperature control feature is not designed to run with HGBP, AFD, free cooling, or ice making.

The factory set PID tuning values for the leaving water temperature control are the same settings for both normal cooling and hot water temperature control.

General Information

Heat Recovery Cycle

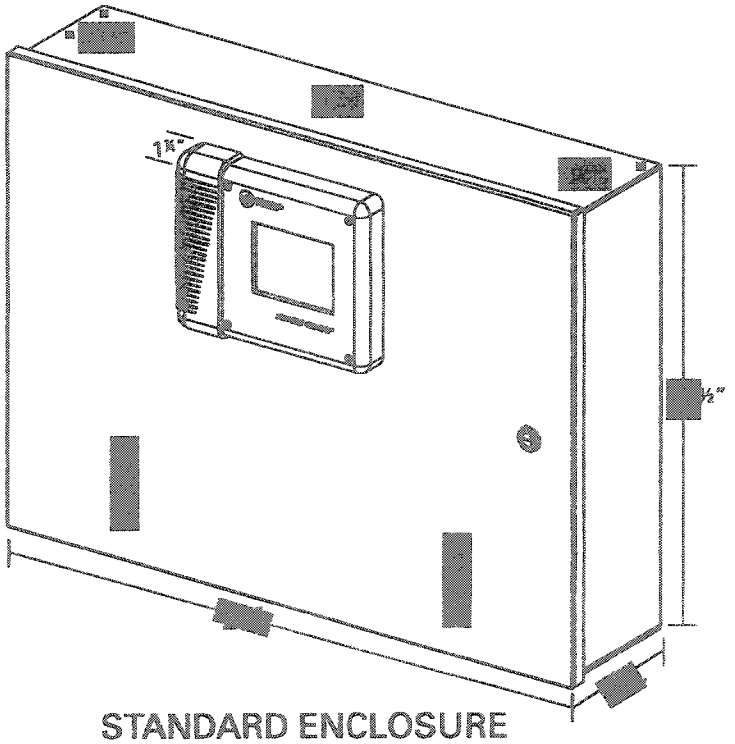
"Heat recovery" is designed to salvage the heat that is normally rejected to the atmosphere through the cooling tower, and put it to beneficial use. For example, a high-rise office building may require simultaneous heating and cooling during the winter months. With the addition of a heat recovery cycle, heat removed from the building cooling load can be transferred to areas of the building that require heat. (Keep in mind that the heat recovery cycle is only possible if a cooling load exists to act as a heat source.)

To provide a heat recovery cycle, a heat-recovery condenser is added to the unit; see Figure 2. Though physically identical to the standard cooling condenser, the heat-recovery condenser is piped into a heat circuit rather than to the cooling tower. During the heat recovery cycle, the unit operates just as it does in the "cooling only" mode except that the cooling load heat is rejected to the heating water circuit rather than to the cooling tower water circuit. When hot water is required, the heating water circuit pumps energize. Water circulated through the heat-recovery (or auxiliary) condenser tube bundle by the pumps absorbs cooling-load from the compressed refrigerant gas discharge by the compressor. The heated water is then used to satisfy heating requirements.

Auxiliary Condensers

Unlike the heat-recovery condenser (which is designed to satisfy comfort heating requirements), the auxiliary condenser serves a preheat function only, and is used in those applications where hot water is needed for use in kitchens, lavatories, etc. While the operation of the auxiliary condenser is physically identical to that of the heat-recovery condenser, it is comparatively smaller in size, and its heating capacity is not controlled.

Trane does not recommend operating the auxiliary condenser alone because of its small size.



Unit Control Panel (UCP)

Control Panel Devices and Unit Mounted Devices

Unit Control Panel (UCP)
Safety and operating controls are housed in the unit control panel, the starter panel and the purge control panel. The UCP 's operator interface and main processor is called the DynaView™ (DV) and is located on the UCP door. (See Operators interface section for detailed information)

The UCP houses several other controls modules called panel mounted LLID (Low Level Intelligent Device), power supply, terminal block, fuse, circuit breakers, and transformer. The IPC (Interprocessor communication) bus allows the communications between LLID's and the main processor. Unit mounted devices are called frame mounted LLID's and can be temperature sensors or pressure transducers. These and other functional switches provide analog and binary inputs to the control system.

Figure 16. Control panel and approximate dimensions

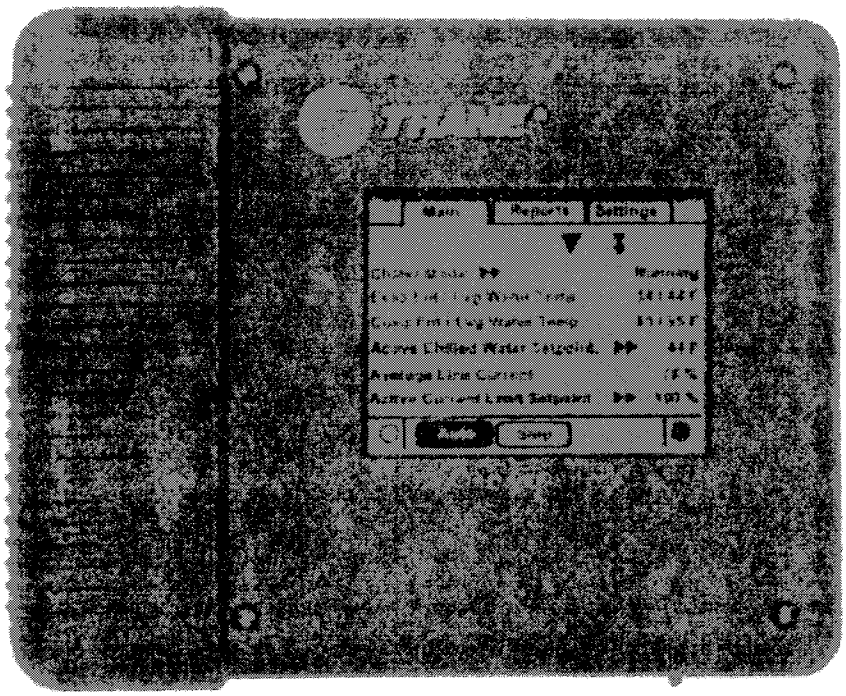
STANDARD ENCLOSURE

Unit Control Panel (UCP)

Tracer CH530 Chiller Controller
Revolutionary control of the chiller, chilled water system, and your entire building with unprecedented accuracy, reliability, efficiency, and support for maintenance using the chiller's PC-based service tool. Chiller reliability is all about producing chilled water and keeping it flowing, even when facing conditions that ordinarily would shut down the chiller — conditions that often happen when you need cooling the most.

Tracer CH530's Main Processor, DynaView™, is fast and keeps the chiller online whenever possible. Smart sensors collect three rounds of data per second, 55 times the data collection speed of its predecessor. Each device (a sensor) has its own microprocessor that simultaneously converts and accurately calibrates its own readings from analog to digital.

Because all devices are communicating digitally with the DynaView™ main processor, there is no need for the main processor to convert each analog signal one at a time. This distributed logic allows the main processor to focus on responding to changing conditions — in the load, the machine, its ancillary equipment, or its power supply. Tracer CH530 constantly receives information about key data parameters, temperatures and current. Every five seconds then a multiple objective algorithm compares each parameter to its programmed limit. The chiller's Adaptive Control™ capabilities maintain overall system performance by keeping its peak efficiency. Whenever the controller senses a situation that might trigger a protective shutdown, it focuses on bringing the critical parameter back into control. When the parameter is no longer critical, the controller switches its objective back to controlling the chilled water temperature, or to another more critical parameter should it exist.



Variable water flow through the evaporator
Chilled-water systems that vary water flow through chiller evaporators have caught the attention of engineers, contractors, building owners, and operators. Varying the water flow reduces the energy consumed by pumps, while requiring no extra energy for the chiller. This strategy can be a significant source of energy savings, depending on the application. With its faster and more intelligent response to changing conditions, Tracer CH530 reliably accommodates variable evaporator water flow and its effect on the chilled water temperature. These improvements keep chilled water flowing at a temperature closer to its setpoint.

User-defined language support
DynaView™ is capable of displaying English text or one of the two alternate languages that are stored in DynaView™ at one time. Switching languages is simply accomplished from a settings menu.

Similarly, TechView™ accommodates a primary and a secondary language from the same list of available languages.

Operator Interface

Figure 17. DynaView™ main processor

The DynaView™ (DV) Operator Interface contains the "Main Processor (MP)" and is mounted on the unit control panel front door where it communicates commands to other modules, collecting data, status and diagnostic information from the other modules over the IPC (Inter Processor Communications) link. The Main Processor (MP) software controls water flows by starting pumps and sensing flow inputs, establishes a need to heat or cool, performs pre-lube, performing post-lube, starts the compressor(s), performs water temperature control, establishes limits, and pre-positions the inlet guide-vanes.

The MP contains non-volatile memory both checking for valid set points and retaining them on any power loss. System data from modules (LLID) can be viewed at the DynaView™ operator interface. Such as evaporator and condenser water temperatures, outdoor air temperature, evaporator and condenser water pump control, status and alarm relays, external auto-stop, emergency stop, evaporator and condenser water pressure drops and evaporator and condenser water flow switches.

DynaView™ presents three menu tabs across the top which are labeled "MAIN, REPORTS, and SETTINGS".

The **Main screen** provides an overall high level chiller status so the operator can quickly understand the mode of operation of the chiller.

The Chiller Operating Mode will present a top level indication of the chiller mode (Auto, Running, Inhibit, Run Inhibit, etc.) The "additional info" icon will present a subscreen that lists in further detail the subsystem modes. (See Machine Operating Modes.)

Main screen content can be viewed by selecting the up or down arrow icons. The Main screen is the default screen and after an idle time of 30 minutes.

Operator Interface

DynaView™ (DV) is the **operator interface** of the Tracer CH530 control system utilized on the CTV machine. The DynaView™ enclosure is 9.75" wide, 8" high and 1.6" deep. The DynaView™ display is approximately 4" wide by 3" high. Features of the display include a touch screen and long life LED backlight. This device is capable of operating in 0 - 95 percent relative humidity (non-condensing), and is designed and tested with UV considerations consistent with an outdoor application in direct sunlight. The enclosure includes a weather tight connection means for the RS232 service tool connection.

Touch screen key functions are determined completely in the software and change depending upon the subject matter currently being displayed. The user operates the touch sensitive buttons by touching the button of choice. The selected button is darkened to indicate it is the selected choice. The advantage of touch sensitive buttons is that the full range of possible choices as well as the current choice is always in view.

Spin values (up or down) are a graphical user interface model used to allow a continuously variable setpoint, such as leaving water setpoint to be changed. The value changes by touching the increment or decrement arrows.

Action buttons are buttons that appear temporarily and provide the operator with a choice such as **Enter** or **Cancel**. The operator indicates his choice by touching the button of choice. The system then takes the appropriate action and the button typically disappears.

DynaView™ consists of various screens, each meant to serve a unique purpose of the machine being served. **Tabs** are shown row across the top of the display. The user selects a screen of information by touching the appropriate tab. The folder that is selected will be brought to the front so it's contents are visable

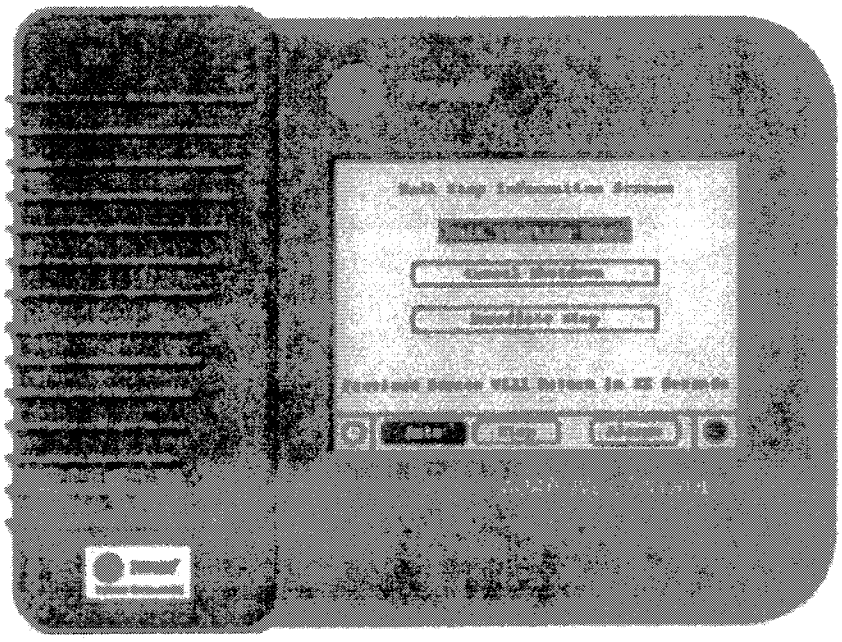
The main body of the screen is used for description text, data, setpoints, or **keys** (touch sensitive areas) The **double up arrows** cause a page by page scroll either up or down. The **single arrow** causes a line by line scroll to occur. At the end of the screen, the appropriate scroll buttons will disappear. Wrap around will not occur.

The bottom of the screen is the persistent area. It is present in all screens and performs the following functions. The **left circular area** is used to reduce the contrast and viewing angle of the display. The **right circular area** is used to increase the contrast and viewing angle of the display. The contrast control will be limited to avoid complete "light" or complete "dark", which would potentially confuse an unfamiliar user to thinking the display was malfunctioning.

Operator Interface

The **Auto** and **Stop** keys are used to put the unit into the auto or stop modes. Key selection is indicated by being darkened (reverse video).

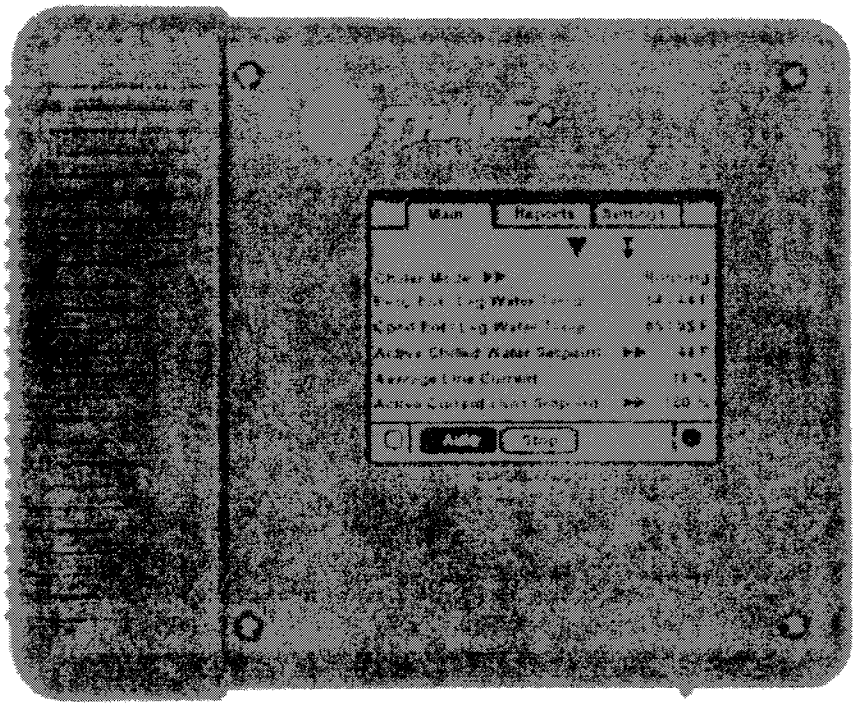
The **Alarms** button is to the right of the **Stop** key. The **Alarms** button appears only when alarm information is present. The alarm blinks to draw attention to the shutdown diagnostic condition. Blinking is defined as normal versus reverse video. Pressing on the **Alarms** button takes you to the corresponding screen.



Persistent keys, horizontal at the bottom of the display, are those keys that must be available for operation regardless of the screen currently being displayed. These keys are critical for machine operation. The **Auto and Stop** keys will be presented as radio buttons within the persistent key display area. The selected key will be dark. The chiller will stop when the **Stop** key is touched, entering the stop sequence. Pressing the "Immediate Stop" button will cause the chiller to stop right away.

The AUTO and STOP, take precedence over the ENTER and CANCEL keys. (While a setting is being changed, AUTO and STOP keys are recognized even if ENTER or CANCEL has not been pressed. Selecting the Auto key will enable the chiller for active cooling (if no diagnostic is present.)

Chiller Stop Prevention/Inhibit Feature
A new chiller "Stop prevention/ inhibit" feature allows a user to prevent an inadvertent chiller stop from the DynaView screen for those chillers which are solely controlled by the CH530.



How It Works
This new feature will be activated after the service tech sets a variable shut down timer in TechView to be greater that 0 seconds and up to 20 seconds (i.e. 0 < Timer ± 20). Then, when the user presses the 'STOP' button on the DynaView display and initiates a chiller shutdown, a window will now appear that displays the "Unit Stop Information Screen" as shown below.

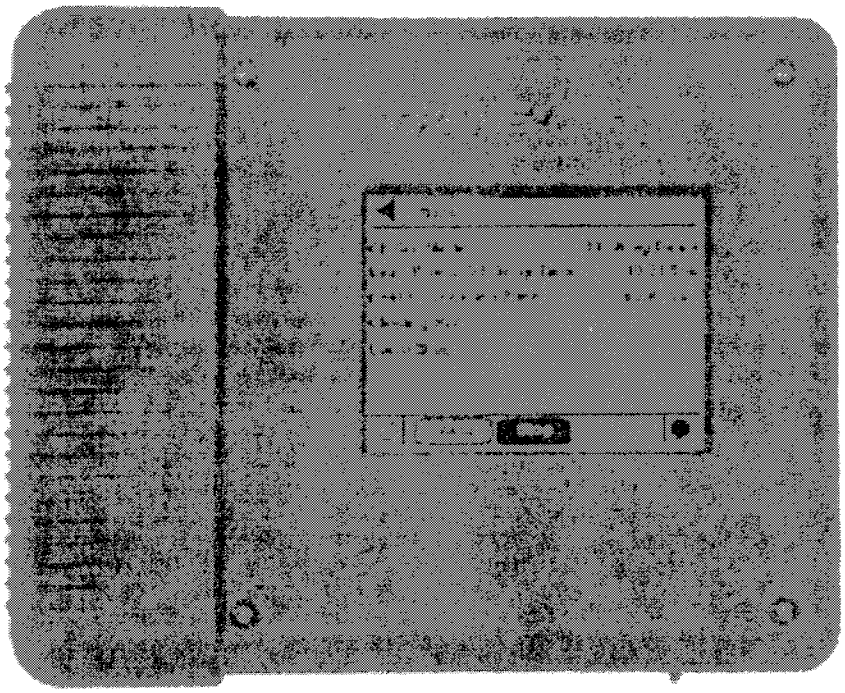
TechView service tool is utilized to enable this feature.

Operator Interface

Figure 18

A general description of the top level modes is show in the following table.

Top Level Mode	Description
Stopped	Unit inhibited from running and will require user action to go to Auto.
Run Inhibit	Unit inhibited from running by Tracer, External BAS, or an Auto Reset diagnostic.
Auto	Unit determining if there is a need to run.
Waiting To Start	Unit waiting for tasks required prior to compressor start to be completed.
Starting Compressor	Unit is starting compressor.
Running	Compressor is running with no limits in effect.
Running – Limit	Compressor is running with limit in effect.
Preparing To Shutdown	Unit is closing inlet guide vanes prior to compressor shutdown.
Shutting Down	Compressor has been stopped and unit is performing shutdown tasks.
Free Cooling	Unit is in Free Cooling mode and will not run the compressor.



The **machine-operating mode** indicates the operational status of the chiller. A subscreen with additional mode summary information will be provided. When the user scrolls down the screen the Machine Operation Mode will remain stationary

On DynaView™, the user will be presented with a single line of text that represents the 'top-level' operating state of the machine. These top-level modes are shown in the table below. Additional information (if it exists) regarding the machine operating state will be available to the user by selecting the "additional information" button (double right arrow) next to the top-level operating mode. These sub-level modes are shown in the table at left.

The TOP LEVEL MODE is the text seen on the single top level chiller system operating mode line. The SUB LEVEL MODE is the text seen on the operating mode sub-menu. The operating mode sub-menu may have up to six (6) lines of text displayed. The BAS CODE is the code that will be sent via COMM4 to the Tracer Summit system as the chiller system mode. Note that each top level mode may contain multiple sub level modes. In general, the BAS CODE will reflect the top level mode and not the sub level mode.

Operator Interface

Operator Interface

Diagnostic Screen

The **diagnostic screen** is accessible by touching the **Alarms** enunciator.

When an alarm is present, the alarm enunciator is present next to the Stop key. A flashing "alarm" indicates a machine shutdown and a non flashing "alarm" indicates an informational message.

Machine shutdowns can be of two types:

Latching - Machine Shutdown Manual Reset Required (MMR)

or

Non-Latching - Machine Shutdown Auto Reset (MAR)

Latching (MMR) require corrective action and manual reset.

Non-Latching (MAR) will restart automatically when condition corrects itself.

There are over 200 potential messages, too numerous to incorporate in this manual.

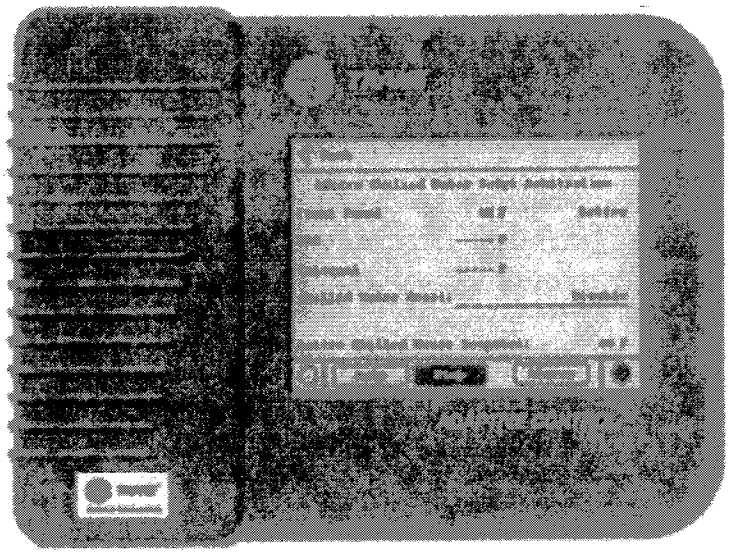
Up to ten active diagnostics can be displayed if required.

The reason for all diagnostic must be determined and corrected. Do not reset and restart the chiller as this can cause a repeat failure. Contact local Trane Service for assistance as necessary.

After corrective action, the chiller can be reset and/or restarted. In the case of "Unit Shutdown - Reset Required" diagnostic types, the chiller will have to be manually reset through the Diagnostics alarm menu.

When reset they become historic and viewable via the service tool TechView.

Performing a **Reset All Active Diagnostics** will reset all active diagnostics regardless of type, machine or refrigerant circuit.



A **Manual Override** indicator (shares space with the Alarms key) alerts the operator to the presence of a manual override. An Alarm will take precedence of the Manual, until the reset of active alarms, at which point the Manual indicator would reappear if such an override exists.

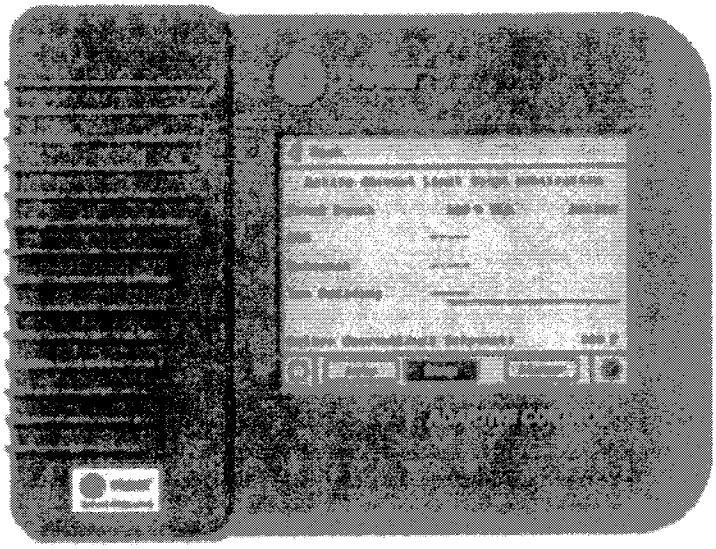
Temperature settings can be expressed in F or C, depending on Display Units settings.

Dashes ("----") appearing in a temperature or pressure report, indicates that the value is invalid or not applicable.

The **languages** for DynaView™ will reside in the main processor. The main processor will hold three languages, English, and two alternate languages. The service tool (TechView™) will load the main processor with user selected languages from a list of available translations. Whenever possible, complete words will be used on the persistent keys as described.

Operator Interface

The **active chilled water setpoint** is the setpoint that is currently in use. It will be displayed to 0.1 degrees Fahrenheit or Celsius. Touching the **double arrow** to the left of the Active Chilled Water Setpoint will take the user to the active chilled water setpoint arbitration sub-screen.



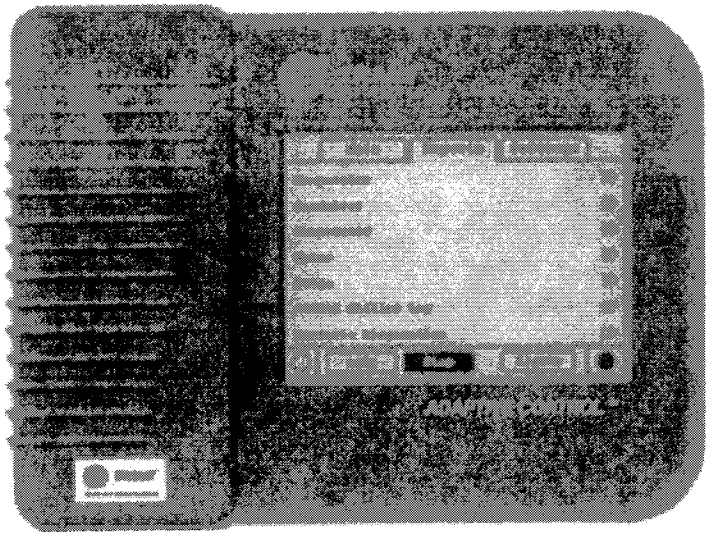
The Active Chilled Water Setpoint the result of arbitration between the front panel, BAS, and external setpoints,

The **chilled water reset status** area in the right most column will display one of the following messages: Return, Constant Return, Outdoor, None

The left column text "Front Panel", "BAS", "External", Chilled Water Reset, and "Active Chilled Water Setpoint" will always be present regardless of installation or enabling those optional items. In the second column "- - - -" will be shown if that option is Not Installed, otherwise the current setpoint from that source will be shown.

The **"Back" button** provides navigation back to the chiller screen.

Operator Interface



The **active current limit setpoint** is the current limit setpoint that is currently in use. It will be displayed in percent RLA. Touching the double arrow to the left of the Active Current Limit Setpoint will take the user to the active current limit setpoint sub-screen. The active current limit setpoint is that setpoint to which the unit is currently controlling. It is the result of arbitration between the front panel, BAS, and external setpoints.

The left column text "Front Panel", "BAS", "External", and "Active Current Limit Setpoint" will always be present regardless of installation or enabling those optional items. In the second column "----" will be shown if that option is Not Installed, otherwise the current setpoint from that source will be shown. The "Back" button provides navigation back to the chiller screen.

Note: This is the same for other setpoints in the "Main" menu.

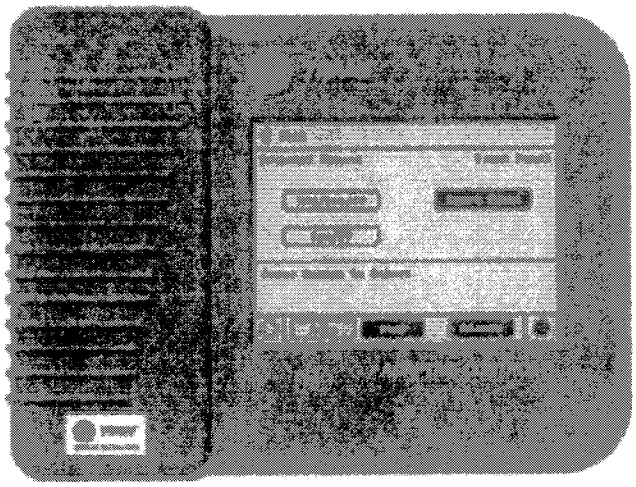
(1) Temperatures will be adjustable to 0.1 degree F or C. The Main Processor provides the minimum and maximum allowable value.
(2) Adjustable to the nearest whole number percent. The Main Processor provides the minimum and maximum allowable value.
(3) Terminates with 10 minutes if inactivity
(4) The Date and Time setup screen formats deviate slightly from the standard screens defined above. See the time and date section for further details.
(5) Enables a DynaView™ Lockout screen. All other screens timeout in 30 minutes to this screen when enabled. The DynaView™ Lockout Screen displays a 0-9 keypad to permit the user to exit the lockout with a fixed password (1-5-9 + Enter). See lockout setion for further details.
(6) Language choices are dependent on what has been setup in the Main Processor. Language selections will include English and qty 2 alternate as loaded by TechView™. Language shall always be the last setting listed on the Display Settings menu. This will allow a user to find language selection if looking at an unrecognizable language.
(7) Manual Compressor Control allows an operator to override the Auto Control and manually control the compressor while in operation. This is not active during Stop mode.

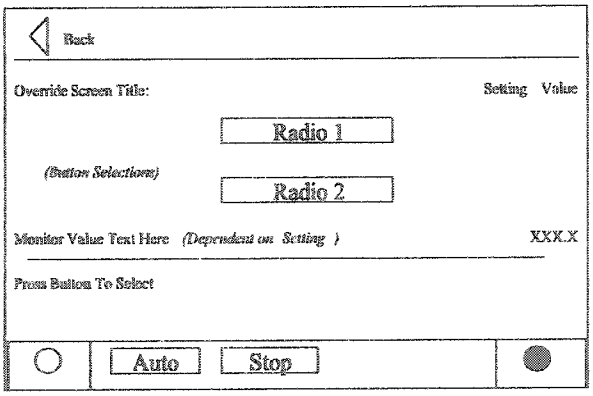
Operator Interface

Each Settings Sub screen consists of a setpoints list and the current value. The operator selects a setpoint to change by touching either the description or setpoint value. Doing this causes the screen to switch to the Analog Settings Subscreen shown below.



Analog Settings Subscreen displays the current value of the chosen setpoint in the upper ½ of the display. It is displayed in a changeable format consistent with its type. Binary setpoints are considered to be simple two state enumeration and will use buttons. Analog setpoints are displayed as spin buttons. The lower half of the screen is reserved for help screens. To change the setpoint the ENTER key must be touched, otherwise the new setting is cancelled.

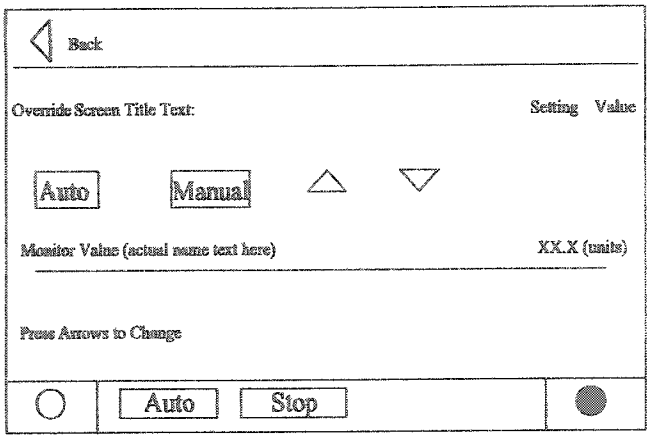
Note: Spin buttons used to change setpoint value.



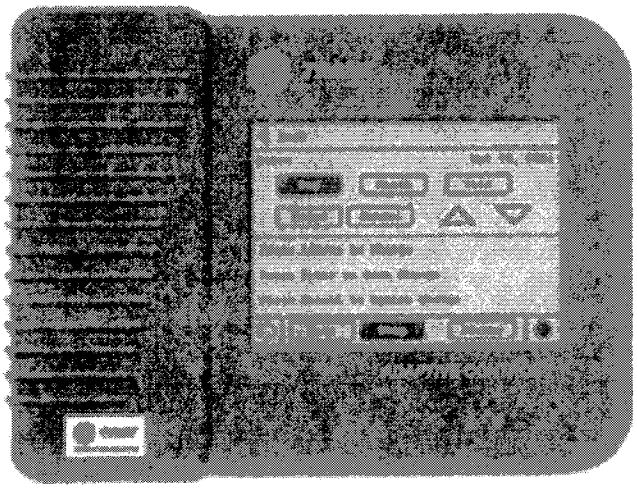
Operator Interface

Settings with buttons only [screen has no cancel or enter key] do accept the new selection immediately.

Note: Radio 1 and Radio 2 refer to "touch sensitive buttons." The labels depend upon the setting being controlled.



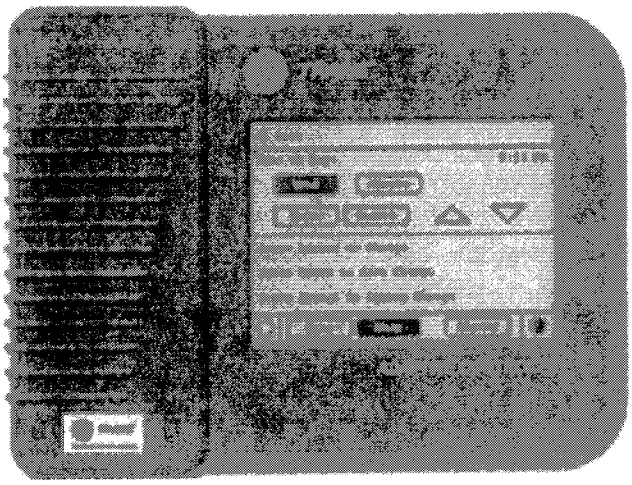
Mode Override for Enumerated Settings is shown below:

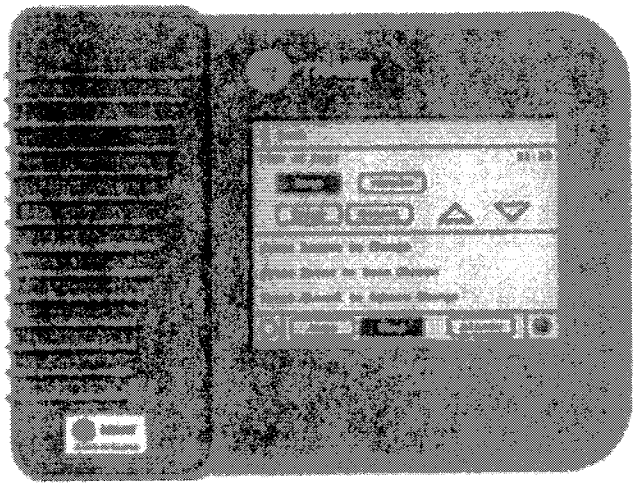


Operator Interface

The mode override analog setting subscreen is similar but offers an Auto or Manual radio button and value setting. An Auto or Manual selection is necessary set to the mode to override. An Enter and Cancel Key will allow the user to Enter or Cancel the entry.

Mode Override for Analog Settings is shown below:

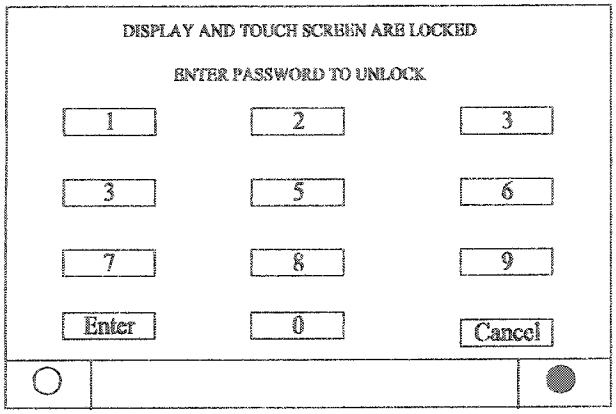




The date setpoint screen for setting up the is shown below: The user must select Day, Month, or Year and then use the up or down arrows to adjust.

Operator Interface

The **time setpoint screen** with a 12-hour format is shown below: The user must select **Hour**, or **Minute** and then use the up or down arrows to adjust. Adjusting hours will also adjust am and pm.



Note: The 24-hour format setpoint screen is similar with the am and pm not shown.

Operator Interface

The DynaView™ Display Touch Screen Lock screen is shown below. This screen is used if the Display and Touch Screen Lock feature is Enabled. 30 minutes after the last key stroke this screen will be displayed and the Display and Touch Screen will be locked out until "159enter" is entered.
Until the proper password is entered there will be no access to the DynaView™ screens including all reports, all setpoints, and Auto and Stop and Alarms and Interlocks. The password "159" is not programmable from either DynaView™ or TechView™.

If the Display and Touch Screen Lock feature is Disabled, the following screen will be automatically shown if the MP temperature is below 32°F (0°C) and it has been 30 minutes after the last key stroke. *Note: the main processor is equipped with an on-board temperature sensor which enables the ice protection feature.*

Interprocessor Communication

Inter Processor Communications IPC3

When using Tracer CH530, you will not be required to know all the details about the structure of the IPC3 bus. However this page gives detailed information about the system for those of you that are really interested in how it works. The IPC3 protocol is based on RS485 signal technology. IPC3 was designed to be very efficient. It communicates at 19.2 Kbaud. This data rate will allow for three rounds of data per second on a 64 device network. A typical CVHE control network will have less than 50 devices. IPC3 allows for a maximum of 255 devices per network.

IPC3 Definitions:

Bus Management:
The DynaView™ provides the bus management having the task of restarting the link, or filling in for missing nodes when the normal communication has been degraded. This involves reassigning node addresses and filling in for nodes that are off-line. The DynaView™ always has a node number of 01.

Node Assignment:
When a unit is factory commissioned, the LLIDS must have their node addresses assigned to them for storage in non-volatile memory. The node addresses are normally assigned sequentially during factory commissioning.

Node Zero:
Node number zero is is a special node assignment that is reserved for devices that are service selected. A LLID communicating on node address zero will also communicate on an assigned node address. A LLID will only communicate on node address zero if it is service selected.

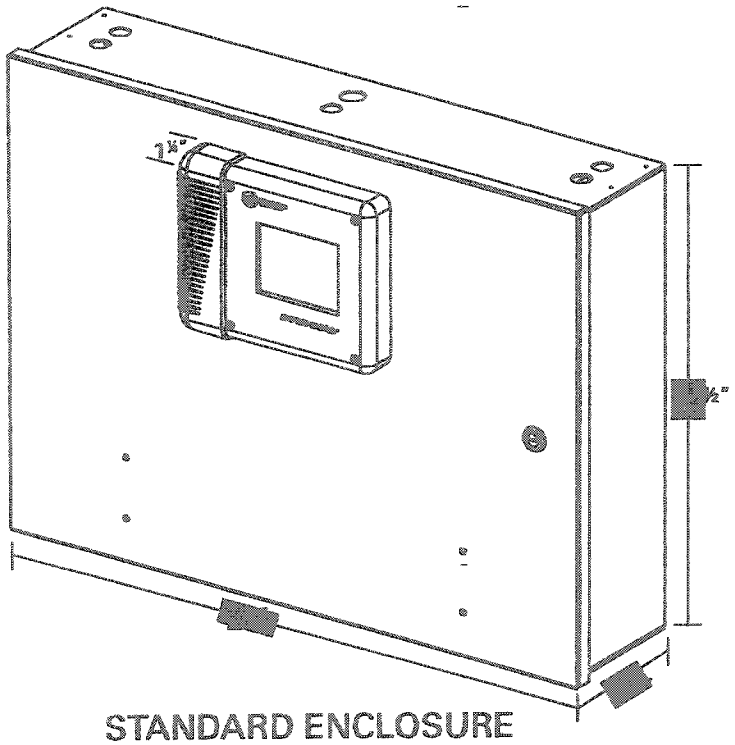
Binding:
Binding is the process of assigning a node number and functional IDs to a LLID. Binding is a simple process:

1. Service selecting the LLID with a magnet.
2. Assigning functional IDs to that LLID with TechView™.

Functional Identification:
When each LLID on the bus is bound, its inputs and outputs are given a functional ID. The Frame LLIDS have only one functional ID, but most Panel LLIDs have more than one functional ID. A dual high voltage binary input will have two functional IDs, a quad relay output has four functional IDs.

The DynaView™ Main Processor with its IPC3 Bus communicates to the control panel devices, unit mounted devices, and any remote devices on the IPC3 bus network. The various devices are discussed in the upcoming sections.

Control System Components



Control Panel Internally mounted devices

For visual identification Internal Control Panel mounted devices are identified by their respective schematic designation number. Control panel items are marked on the inner back panel in the control panel. Figure 20 illustrated below, identifies these devices. The Control Panel Devices table corresponds to the same device designators (see right hand column). Optional controls are present when a specific optional controls package is specified, as listed in the second column. Optional controls packages are; OPST Operating Status, GBAS Generic Building Systems, EXOP Extended operation, CDRP Condenser Pressure, TRMM Tracer communications, WPSR Water Flow Pressure sensing, FRCL Free Cooling, HGBP Hot Gas Bypass , and EPRO Enhanced Protection

Figure 20 illustrates the Control Panel Components Layout.

Modules 1A1, 1A3, 1A4, 1A5, 1A6, 1A7, and 1A13 are standard and present in all configurations. Other Modules vary depending on machine optional devices.

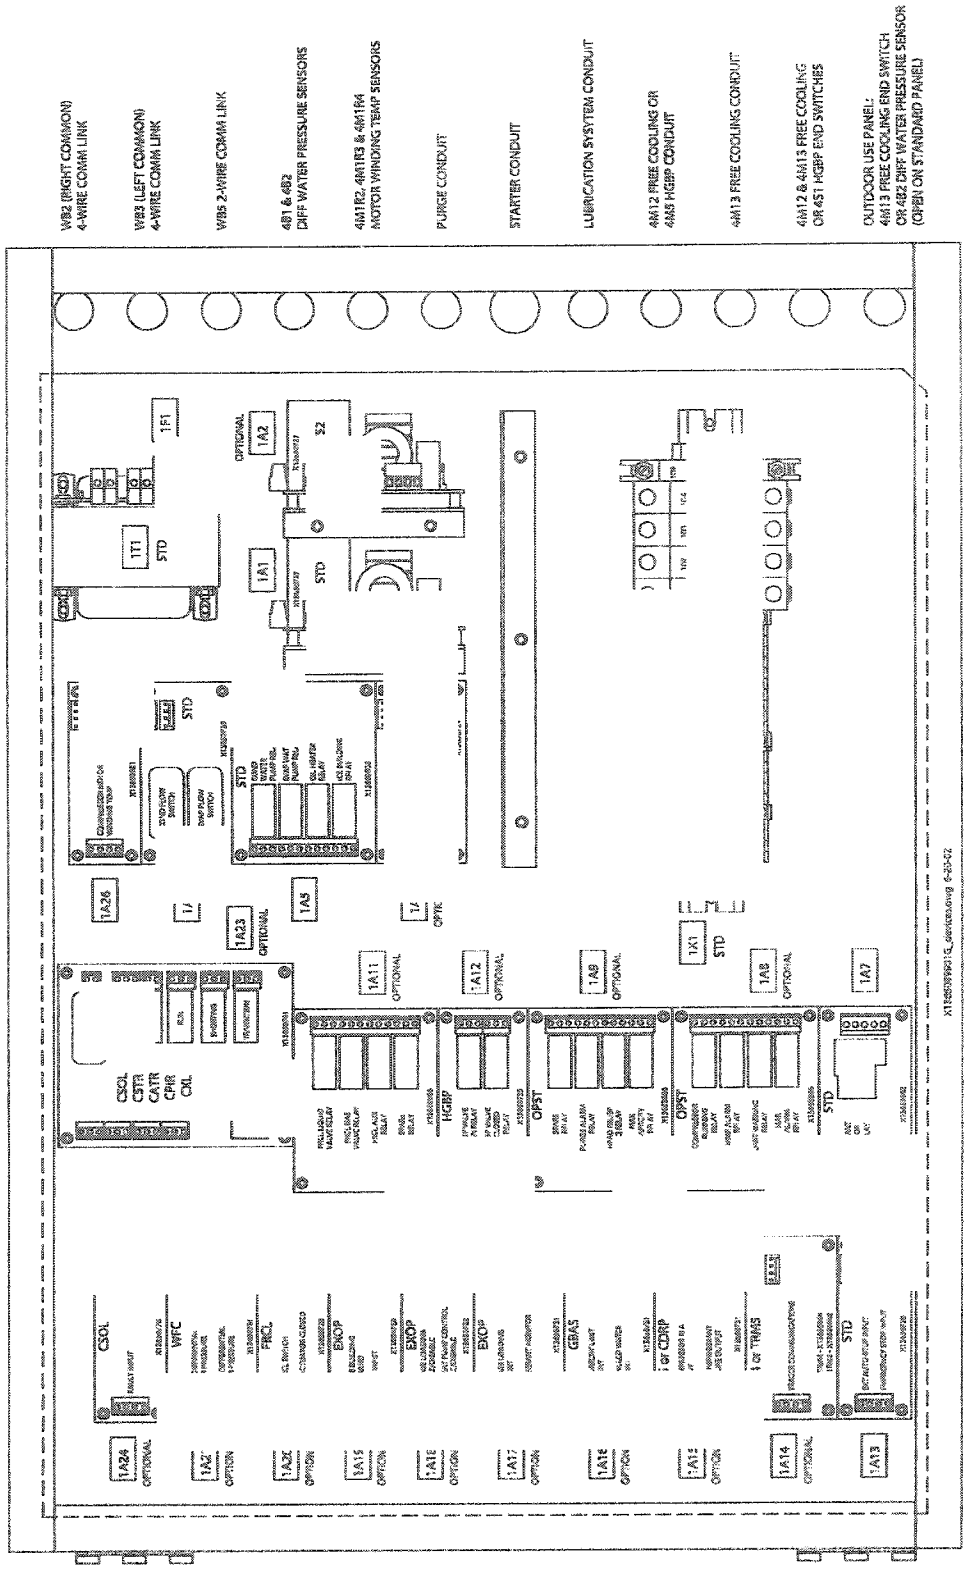


Figure 20. Control panel components layout and approximate dimensions

Control System Components

Chilled and Condenser Water Flow Interlock Circuits

Proof of chilled water flow for the evaporator is made by the closure of flow switch 5S1 and the closure of auxiliary contacts 5K1 on terminals 1X1-5 and 1A6-J3-2. Proof of condenser water flow for the condenser is made by the closure of flow switch 5S2 and the closure of auxiliary contacts 5K2 on terminals 1X1-6 and 1A6-J2-2.

OPST Operation Status Option
Relay output modules 1A8 and 1A9 provide relay outs as shown:

1A8 Optional Quad Relay Output Status	OPST	Relay #1	Compressor running relay,	J2-10 NO, J2-11 NC, J2-12 common
1A8 Optional Quad Relay Output Status	OPST	Relay #2	MMR Alarm Relay, (Latching)	J2-7 NO, J2-8 NC, J2-9 common
1A8 Optional Quad Relay Output Status	OPST	Relay #3	Limit Warning Relay,	J2-4 NO, J2-5 NC, J2-6 common
1A8 Optional Quad Relay Output Status	OPST	Relay #4	MAR Alarm Relay (Non-Latching)	J2-1 NO, J2-2 NC, J2-3 common
1A9 Optional Quad Relay Output Status	OPST	Relay #2	Purge Alarm Relay	J2-7 NO, J2-8 NC, J2-9 common
1A9 Optional Quad Relay Output Status	OPST	Relay #3	Head Relief Request Relay	J2-4 NO, J2-5 NC to J2-6 common
1A9 Optional Quad Relay Output Status	OPST	Relay #4	Maximum Capacity Relay	J2-1 NO, J2-2 NC, to J2-3 common

Head Relief Request Output

When the chiller is running in Condenser Limit Mode or in Surge Mode, the head relief request relay (1 minute default) on the 1A9–J2-6 to J2-4 will be energized and can be used to control or signal for a reduction in the entering condenser water temperature. Designed to prevent high refrigerant pressure trip-outs during critical periods of chiller operation.

If the unit is not equipped with the CDPR Enhanced Condenser Limit Option the unit will use the condenser refrigerant temperature sensor (input converted to saturated refrigerant pressure) to perform the Standard Condenser Limit function, without the head relief request relay, by limiting inlet guide vane stroke and chiller capacity.

Keep in mind that Condenser Limit Control supplements the protection provided by the condenser pressure high pressure cutout switch 3S1.

Compressor Motor Winding Temp Sensor Module

The motor temperature module 1A26 connects via unit wiring to the three motor winding temperature sensors.

Maximum Capacity Relay (TechView adjustable)

When the chiller has been operating at maximum capacity for 10 minutes (TechView adjustable 1 to 60 min.) this relay will activate. Also upon being less than maximum capacity for 10 minutes this relay will deactivate.

Compressor Running Relay

Relay activates while compressor is running.

Machine Shutdown Manual Reset (MMR)

Limit warning machine shutdown auto reset relays will activate with such conditions for remote status indication.

Control System Components

EXOP Extended Operation Option
The following modules (1A17, 1A18, and 1A19) are provide when this control package is specified.

1A5 Quad Relay Output modules*	EXOP	Relay #4	Ice Building Relay	J2-10 NO, J2-11 NC, J2-12 common
1A17 Optional Dual Analog Input/Output Module	EXOP	Signal #1	External Base Loading Setpoint input	J2-1 Output #1, J2-3 Ground
1A17 Optional Dual Analog Input/Output Module	EXOP	Signal #2	Refrigerant monitor inputs	J2-4 Output #2, J2-6 Ground
1A18 Optional Dual LV Binary input module	EXOP	Signal #1	External Base Loading Enable or Disable input, points	J2-1 Binary Input Signal #1, J2-2 Ground
1A18 Optional Dual LV Binary input module	EXOP	Signal #2	External Hot Water Control Enable or Disable input	J2-3 Binary Input Signal #2, J2-4 Ground
1A19 Optional Dual LV Binary input module	EXOP	Signal #1	Ice Building Control Enable or Disable input point	J2-1 Binary Input Signal #1, J2-2 Ground

*previously was 1A10

Refrigerant Monitor Input 1A17

Analog type input 4-20ma input signal to the 1A17 J2-4 to J2-6 (ground). This represents 0-100 ppm.

Control System Components

FRCL (Free Cooling Option)

1A11 Optional Quad Relay Output Status	FRCL	Relay #1	Free Cooling Relay 1,	J2- 4 NO to J2-6 common
1A20 Optional Dual LV Binary input module	FRCL	Signal #1	External Free Cooling Switch,	J2-1 Binary Input Signal #1, J2-2 Ground
1A20 Optional Dual LV Binary input module	FRCL	Signal #2	Free Cooling Valves closed	Not for field use

HGBP (Hot Gas Bypass Option)

*CDRP (Condenser Refrigerant Pressure Output)**

1A15 Optional Dual Analog Input/output Module	CDRP or GBAS	Signal #2	Condenser Refrigerant Pressure output	J2-4 Output #2, J2-6 Ground

EPRO (Enhanced Protection)

4R22	EPRO	Condenser Refrigerant Pressure Transducer
4R16	EPRO	Compressor Discharge Refrigerant Temperature Sensor. (This is also included with H6BP).
4R1	EPRO	Inboard Bearing Temperature Sensor
4R2	EPRO	Outboard Bearing Temperature Sensor

*See CTV-PRB006-EN for "Condenser Water Temperature Control".

Control System Components

CDRP Refrigerant Pressure Output Option 1A15:

Refrigerant Pressure Output can be configured at commissioning to correspond to either A) the absolute condenser pressure, or B) the differential pressure of the evaporator to condenser pressures.

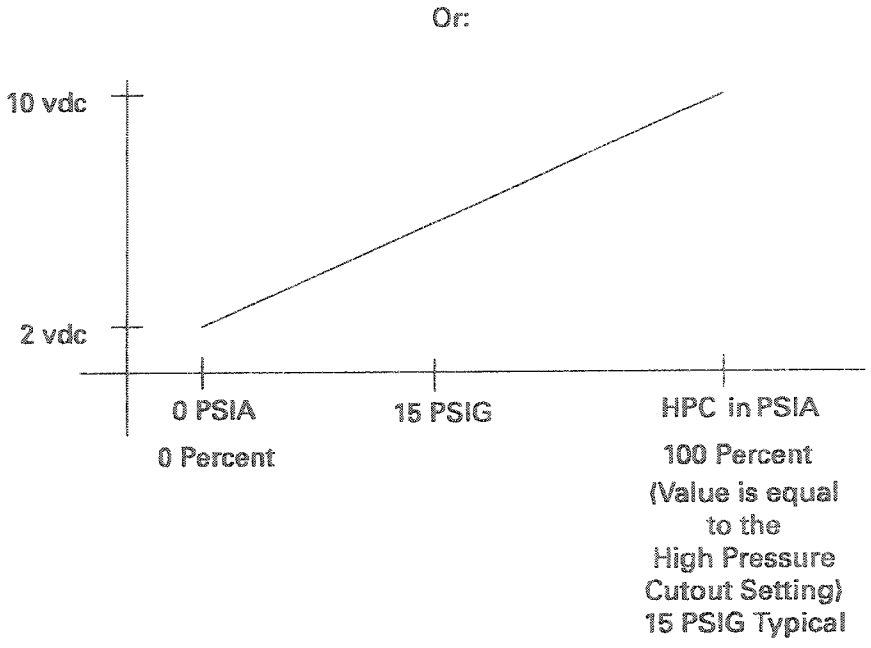
This vdc output is located at 1A15 – J2 – 4 (+) to J2-6 (Ground)

The Voltage DC Output can source a maximum of 22 mA of current.

This output is Voltage DC only, 4-20mA is not supported.

A) Condenser Pressure Output.
2 to 10 Vdc corresponds to 0 Psia to the HPC (in Psia) setting.

Note: Controls allow Delta Pressure or condenser pressure output, but not both.



Temperature based
On standard machines the Percent Condenser Pressure Indication Output is based on the Saturated Condenser Refrigerant and a temperature to pressure conversion is made.

If the Condenser Saturated Temperature goes out of range due to an open or short, a pressure sensor diagnostic will be called and the output will also go to the respective out of range value. That is, for an out of range low on the sensor, the output will be limited to 2.0 VDC. For an out of range high on the sensor, the output will be limited to 10.0 VDC.

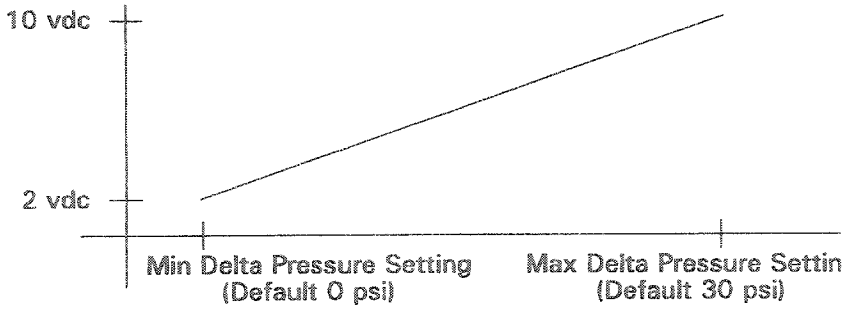
Pressure based
With the Enhanced Protection EPRO option, a condenser pressure transducer is installed and the pressure is measured.

If the Condenser Pressure sensor goes out of range due to either an open or short, a pressure sensor diagnostic will be called and the output will go to end of range low. That is, for an out of range low on the sensor, the output will be limited to 2.0 VDC. For an out of range high on the sensor, the output will be limited to 2.0 VDC.

Figure 21. Condenser pressure based output

Control System Components

B) Refrigerant Differential Pressure Indication Output:
A 2 to 10 VDC analog output is provided instead of the previous condenser pressure output signal. This signal corresponds to a predetermined minimum and maximum pressure settings setup at commissioning of this feature. This relationship can be altered using the service tool if required.



The "Minimum Delta Pressure " is typically set to 0 psi and will then correspond to 2 vdc. The "Maximum Delta Pressure " is typically set to 30 psi and corresponds to 10 vdc.

The Minimum Delta Pressure Calibration setting has a range of 0-400 psid (0-2758 kPa) in increments of 1 psid (1kPa). The Maximum Delta Pressure Calibration setting has a range of 1-400 psid (7-2758 kPa) in increments of 1 psid (1kPa). The condenser refrigerant pressure is based on the Condenser Refrigerant Temperature sensor if the Condenser Pressure Option is selected as "Not Installed" at the display.

The evaporator refrigerant pressure is based on the Saturated Evaporator Refrigerant Temperature Sensor.

See CTV-PRB006-EN for additional information about condenser water temperature control.

Figure 22. Delta pressure setting - differential pressure based output (Defaults shown)

In this example, 2 vdc corresponds to 0 psi differential and 10 vdc corresponds to 30 psi differential. The min value of 0 psi, and the max value of 30 psi are individually adjustable via the service tool.

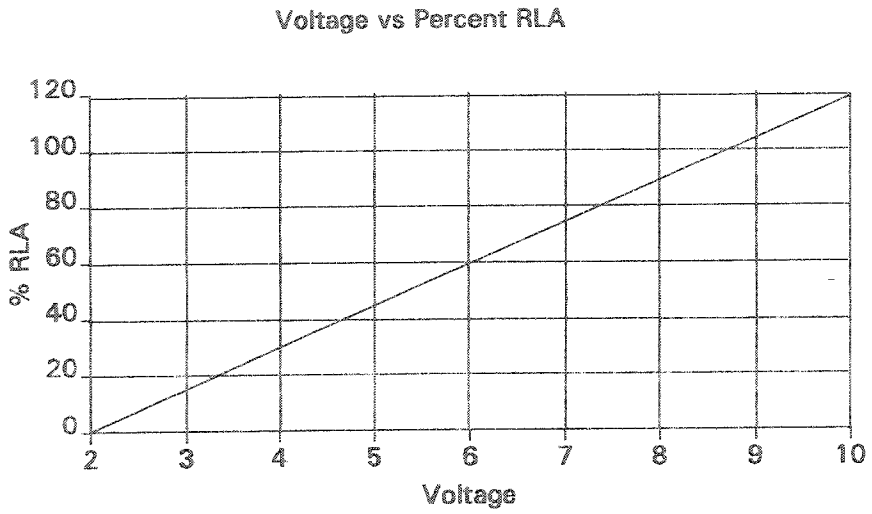
Note: Typical settings for CVHE, F, G with refrigerant pumps are as follows.

- Min pressure 0 psid (= 2 vdc)
- Max pressure 6 psid (= 10 vdc)
- Target tower control at 4 psid

Control System Components

GBAS (Generic Building Automation System)

1A15 Optional Dual Analog Input/ output Module	GBAS or CDRP	Signal #1	Percent RLA Compressor Output	J2-1 Output #1, J2-3 Ground
1A16 Optional Dual Analog Input/ output Module	GBAS	Signal #1	External Current limit Setpoint	J2-2 Input #1, J2-3 Ground
1A16 Optional Dual Analog Input/ output Module	GBAS	Signal #2	Chilled Water Reset input, or External Chiller Water Setpoint	J2-5 Input #2, J2-6 Ground



Percent RLA Output
2 to 10 Vdc corresponding to 0 to 120% RLA. With a resolution of 0.146%. The Percent RLA Output connections are on the terminals 1A15 –J2-1 (+) to J2-3 (Ground). The Percent RLA Output is polarity sensitive.

The following graph illustrates the output:

Notes: 0% RLA = 2 vdc
120% RLA = 10 vdc

Example: If RLA is 500 amps then 10 vdc = 600 amps.

Figure 23. Voltage versus percent RLA

Control System Components

External Chilled Water Setpoint (ECWS)

The External Chilled Water Setpoint allows the chilled water setpoint to be changed from a remote location. The External Chilled Water Setpoint is found on 1A16 J2-5 to J2-6 (Ground). 2-10 vdc and 4-20 ma correspond to a 34°F to 65°F (-17.8 to 18.3°C) CWS range. Default 34°F to 65°F, adjustable via service tool.

External Current Limit Setpoint

The External Current Limit is an option that allows the current limit setpoint to be changed from a remote location. The External Limit Setpoint is found on 1A16 J2-2 to J2-3 (ground), 2-10 vdc and 4-20 ma each correspond to a 40 to 100 percent RLA range. UCP limits the maximum ECLS to 100 percent. Default 40 to 100%, adjustable via service tool.

Note: To use external inputs, the setpoint source setting on DynaView must be set to "Ext/FP."

The ECWS or ECLS LLID will report either a very low or very high value when there is either an open or short in the system.

When an open or short is detected (or the signal is severely beyond the valid range) on the 2-10 VDC or 4-20mA ECLS input and when the ECLS option is installed, an informational diagnostic shall be generated. The active current limit set point will default to the panel (or next priority) current limit set point. Open and short criteria will be set as close to the end of the range values as possible and still reliably detect an open and short.

WPSR (WFC Water Pressure Sensing Option)

1A21 Optional Dual Analog Input or output Module	WPSR = WFC	Signal #1	Evaporator Differential Water Pressure	Not for field use
1A21 Optional Dual Analog Input or output Module	WPSR = WFC	Signal #2	Condenser Differential Water Pressure	Not for field use

Module Characteristics

1A1, 1A2 Power Supply :
Unit Control Power Supply Module Converts 27 vac to 24 vdc.

Power Input Voltage: 23VRMS minimum, 27VRMS Nominal, 30VRMS maximum

Frequency: 50-60 Hz

Current: Full load 27 VAC – 4.30 A (RMS)

Inrush 27 VAC (RMS) ~ 30A (RMS)

Power Output: Class II Voltage 24 VDC, Rated Current 2.44 Amps. Fused @ 3 amps. (FUS01513)

1A3, 1A5, 1A10 Dual Relay Output modules :
Relay #1 J2-1 NO, J2-2 NC, J2-3 common

Relay #2 J2 4 NO, J2-5 NC, J2-6 common

Relay Outputs at 120 VAC: 7.2 Amps resistive, 2.88 Amps pilot duty, 1/3 HP, 7.2 FLA at 240 VAC: 5 Amps general purpose, 14 - 26 AWG with a maximum of two 14 AWG.

Power, 24 +/- 10 percent VDC, 60 mA maximum, Trane IPC3 protocol. J1-1 +24VDC, J1-2 Ground, J1-3 COMM + J1-4 COMM -

1A4, 1A6 Dual High Voltage Binary input module:
Binary Input Signal #1 J2-1 to 2

Binary Input Signal #2 J3-1 to 2

High Voltage Binary Input: Off Voltage: 0 to 40 VAC RMS , On Voltage: 70 to 276 VAC RMS

Input is not polarity sensitive (Hot and neutral can be switched), Input impedance 130K to 280K ohms

14 - 26 AWG with a maximum of two 14 AWG

Power, 24 +/- 10 percent VDC, 20 mA maximum. Trane IPC3 protocol. J1-1 +24VDC, J1-2 Ground, J1-3 COMM +, J1-4 COMM -

1A7 High Power Relay
Relay output contacts at 120 VAC: 16.0 Amps resistive, 6.4 Amps pilot duty, 1 HP, 16.0 FLA

J2 14-26 AWG with a maximum of two 14 AWG J2-1 NO, J2-2 NO, J2-3 NC, J2-4 COM, J2-5 COM.

Power, 24 +/- 10% VDC, 60 mA max. Communications, RS485 Physical layer, 19.2 Kbaud, Trane IPC3 protocol.

J1: J1-1 +24 VDC, J1-2 GND, J1-3 COMM +, J1-4 COMM -
J11: J11-1 +24 VDC, J11-2 GND, J11-3 COMM +, J11-4 COMM -

Control System Components

1A8, 1A9, 1A11, 1A12 Quad Relay Output Status:
Relay #1 J2-1 NO, J2-2 NC, J2-common

Relay #2 J2-4 NO, J2-5 NC, J2-6 common

Relay #3 J2-7 NO, J2-8 NC, J2-9 common

Relay #4 J2-10 NO, J2-11 NC, J2-12 common

Relay Outputs: at 120 VAC: 7.2 Amps resistive, 2.88 Amps pilot duty, 1/3 HP, 7.2 FLA, at 240 VAC: 5 Amps general purpose 14-26 AWG, two 14 AWG Maximum Power, 24 +/-10 percent VDC, 100 ma maximum. Trane IPC3 protocol.

1A13, 1A18, 1A19, 1A20 Dual Binary input module:
J2-1 Binary Input Signal #1, J2-2 Ground, J2-3 Binary Input Signal #2, J2-4 Ground

Binary Input: Looks for a dry contact closure. Low Voltage 24V 12 mA.

14 - 26 AWG with a maximum of two 14 AWG

Power, 24 +/- 10 percent VDC, 40 mA maximum Trane IPC3 protocol.

1A14 Communication interface Module
Power, 24 +/- 10 percent VDC, 50 mA maximum. Trane IPC3 protocol.

J1-1	+24 VDC	J2-1 COMM +.	J11-1 +24 VDC
J1-2	Ground	J2-2 COMM -	J11-2 Ground
J1-3	COMM +	J2-3 COMM +	J11-3 COMM +
J1-4	COMM -	J2-4 COMM -	J11-4 COMM -

Control System Components

1A15, 1A16, 1A17, 1A21 Dual Analog Input/output Module;
Analog Output: The Analog Output is a voltage only signal. 2-10 Vdc at 22mA

J2: 14 - 26 AWG with a maximum of two 14 AWG

J2-1 Output #1 to J2-3 (Ground), J2-4 Output #2 to J2-6 (Ground).

UCP provides a 2-10 Vdc analog signals as Outputs. The Output's maximum source capability is 22mA. The maximum recommended length to run this signal is included in the table below.

Recommended Length to Run external Output signals

Gauge	Ohms per Feet	Length (Feet)	Maximum Length (Meters)
14	0.00 2823	1062.7	324
16	0.004489	668.3	203.8
18	0.007138	420.3	128.1
20	0.01135	264.3	80.6
22	0.01805	166.3	50.7
24	0.0287	104.5	31.9
26	0.04563	65.7	20
28	0.07255	41.4	12.6

Note: the above table is for copper conductors only.

Analog Input:
The analog input can be software switched between a voltage input or a current input. When used as a current input a 200 Ohm load resistor is switched in.

2-12 Vdc or 4 to 20 mA Analog Inputs
UCP accepts either a 2-10 Vdc or 4-20 analog input suitable for customer external control. The type is determined at unit commissioning during feature installation.
J2: 14 - 26 AWG with a maximum of two 14 AWG
J2-2 Input #1 to
J2-3 (Ground).
J2-5 Input #2 to
J2-6 (Ground).
Power, 24 +/- 10 percent VDC, 60 mA maximum, Trane IPC3 protocol.

Control System Components

Unit mounted devices

Vane Actuator Control
The Stepper Module within the stepper vane actuator (4M2) (and 4M4 extended capacity) pulses a DC voltage to the windings of the Stepper Motor Actuator(s) to control inlet guide vane position. While operation of this stepper motor is automatic, manual control is possible by going to the Mode Overrides settings menu within the DynaView™. Compressor Control Signal allow the operator to manually increase or decrease the compressor load by adjusting the compressor control signal.

Note: If the chiller is operating in a limit mode (current limit, condenser limit, evaporator limit, etcetera.) The limit operation has priority over all DynaView™ manual modes of operation.

On each UCP power-up, the inlet guide vanes are driven full closed to recalibrate the zero position (Steps) of the Stepper motor vane actuator.

Temperature sensors,
Evaporator sensors 4R6 and 4R7, and condenser sensors 4R8, 4R9 entering and leaving, bearing temperature sensors 4R1, 4R2, oil temperature sensor 4R5, outdoor air temperature 4R13, and evaporator 4R10 and condenser 4R11 saturated refrigerant temperature sensors.

Probe Operating Temperature Range - 40 to 250°F (-40 to 121°C)
Accuracy +/- 0.25°C over the range -4 to 122°F (-20 to 50°C), +/- 0.50°C over the range -40 to 250°F (-40 to 121°C)
Power and Communications and Terminations Power 24 +/- 10% VDC, 20 mA maximum.
Trane IPC3 protocol Communications.

Pressure sensors
Oil tank sump 4R4 and oil pump discharge 4R3, evaporator and condenser refrigerant pressure 4R22,
Working Pressure Range: 0 to 50 Psia
Accuracy: ± 0.3% of full scale output at 68°F (20°C)
Power and Communications and Terminations
Power 24 +/- 10% VDC, 20 mA maximum.
Communications, RS485 Physical Layer, 19.2 Kbaud, Trane IPC3 protocol.

Starter Module
In the hierarchy of modules the Starter module 2A1 (1A23 when customer supplied starter specified) is second only to the DynaView™. The starter module is present in all starter selections (except AFD) .This includes Wye Delta, Across the Line, Solid State whether remote unit mounted or supplied by others. The starter module provides the logic to provide the motor protection for Current overload, phase reversal, phase loss, phase imbalance, and momentary power loss. These functions are discussed in the motor protection section of this manual.

Relay outputs @ 120 vac: 7.2 amps resistive 2.88 amps Pilot Duty 1/3 hp, 7.2 FLA.

Relay outputs @ 240 vac: 5 amps 6 general purpose.

EarthWise™ Purge
Trane has also revolutionized its controller-integrated purge, which features an automatic regeneration system for high-efficiency, maintenance-free refrigerant containment. Air and noncondensables are pumped out faster, and the lower temperature refrigeration system enhances the base purge efficiency. See EarthWise purge operation and maintenance manual for details.

Unit-mounted medium - voltage starter
Take advantage of Tracer CH530's new starter and save space in your equipment room. There is no need for a remote or floor-mounted starter with our new, exclusive unit-mounted medium - voltage starter from Cutler-Hammer.

Adaptive Frequency™ motor drive
Tracer CH530 complements Trane's Adaptive Frequency motor drive (AFD) system for chillers better than ever before. Brand new control logic allows safe, more efficient inlet vane and motor speed control operation to maximize part-load performance and, when necessary, limit the starting current.

When equipped with the Trane Adjustable Frequency Drive (AFD) the Unit Control Panels DynaView™ also provides the Operator interface to the AFD control. The Service Tool, TechView™ is also utilized for setting service items. See the Adjustable Frequency drive operation maintenance manual that ships with the chiller for details .

Control Sequence of Operation

Electrical Sequence

This section will acquaint the operator with the control logic governing CVHE, CVHF and CVHG chillers equipped with Tracer CH530 UCP based control systems. When reviewing the step-by-step electrical sequences of operation, refer to the typical wiring schematics for Unit mounted Wye Delta starter shown in the installation manual shipped with the chiller.

Note: The typical wiring diagrams are representative of standard units and are provided only for general reference. They may not reflect the actual wiring of your unit. For specific electrical schematic and connection information, always refer to the wiring diagrams that shipped with the chiller.

With the supply power disconnect switch or circuit breaker (2Q1 or 2K3) closed, 115-volt control power transformer 2T5 and a 40-amp starter panel fuse (2F4) to terminal (2X1-1) starter panel to terminal 1X1-1 in the control panel. From this point, control voltage flows to:

1. Circuit Breaker 1Q1 which provides power to the starter module (2A1) relay outputs and the High Pressure Cutout switch (3S1).
2. Circuit Breaker 1Q2 which provides power to the Purge circuitry.
3. Circuit Breaker 1Q3 which provides power to Transformer (1T1) which steps down the 115 Vac to 24 Vac. This 24 Vac then powers the 24 Vdc power supply 1A1, and 1A2 if present. The 24 vdc is then connected to all modules via the Interprocessor communications Bus providing module power.

   1Q3 also provides power to the external chiller water proof of flow device connected between terminal block 1X1-5 to 1A6-J3-2, and condenser water proof of flow device connected at 1X1-6 to 1A6-J2-2.
4. Circuit Breaker 1Q4 which provides power to the Oil Heater 4HR1 circuit and to Circuit Breaker 1Q5 oil and refrigerant pump circuits.
5. The DynaView™ display module 1A22, receives 24 vdc power from the IPC bus.

UCP and Wye-Delta Starter Control Circuits

Logic Circuits within the various modules will determine the starting, running, and stopping operation of the chiller. When operation of the chiller is required the chiller mode is set at "Auto". Using customer supplied power, the chilled water pump relay (5K1) is energized by the 1A5 Module output at 1A5-J2-4, and chilled water flow must be verified within 4 minutes 15 seconds by the 1A6 Module. The main processors logic decides to start the chiller based on the differential to start setpoint. With the differential to start criteria met module 1A5 then energizes condenser water pump relay (5K2) via customer supplied power at 1A5 J2-1.

Based on the restart inhibit function and the differential to start setpoint, oil and refrigerant pump (4M3) will be energized by 1A7 Module (1A7-J1). The oil pressure must be at least 9 Psid for 60 continuous seconds and condenser water flow verified within 4 minutes 15 seconds minutes for the compressor start sequence to be initiated.

Control Sequence of Operation

When less than 2.5 seconds remain before compressor start, a starter test is conducted to verify contactor states prior to starting the compressor. The following test or start sequence is conducted for "Wye-Delta" starters: Also refer to Figure 24.

A. Test for transition complete contact open (2A1-J12-2) –160 to 240 msec. An MMR diagnostic will be generated if the contact is closed.

B. Delay time - 20 msec.

C. Close start contactor (2K1) and check for no current - 500 msec. If currents are detected, the MMR diagnostic "Starter Fault Type I" is generated.

D. Stop relay (2A1-J10-3 to 1) closes for one second for test "C" above.

E. Delay time - 200 msec. (Opens 2K1).

F. Close shorting contactor, (2K3) and check for no current - one second. If currents are detected the MMR diagnostic "Starter Fault Type II" is generated. (Starter Integrity test)

G. If no diagnostics are generated in the above tests, the Stop Relay (2A1-J10) is closed for 2 seconds and the Start Relay (2A1-J8) is closed to energize the start contactor (2K1). The shorting contactor (2K3) has already been energized from (F) above. The compressor motor (4M1) starts in the "Wye" configuration, an auxiliary contact (2K1-AUX) locks in the start contactor (2K1) coil.

H. After the compressor motor has accelerated and the maximum phase current has dropped below 85 percent of the chiller nameplate RLA for 1.5 seconds, the starter transition to the "Delta" configuration is initiated.

J. The transition contactor (2K4) is closed through relay 2A1-J2, placing the transition resistors (2R1, 2R2, and 2R3) in parallel with the compressor motor windings. The run relay (2A1-J6-3 to 1) is closed.

K. The shorting contactor (2K3) is opened through the opening of relay 2A1-J4 100 msec after the closure of the transition relay 2A1-J2, and the run relay 2A1-J6.

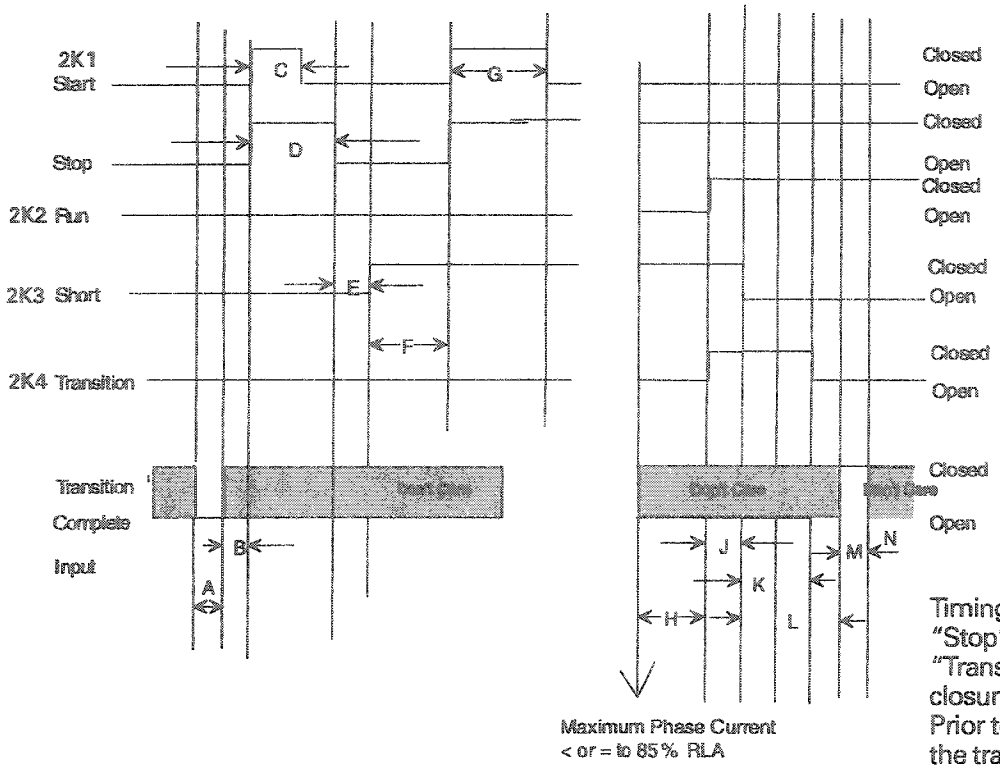
L. The run contactor (2K2) is closed through auxillary contacts on the shorting contactor (2K3), shorting out the transition resistors. This places the compressor motor in the "Delta" configuration and the starter module waits to look for this transition for about 2.3 seconds through the closure of the transition complete contacts 2K2-Aux at module 2A1-J12 input)

M. The starter module must now confirm closure of the transition complete contact (2K2-AUX) within 2.5 seconds after the shorting relay (2A1-J4) is opened. Finally, the transition relay (2A1-J2) is opened de-energizing the transition contactor (2K4) and the compressor motor starting sequence is complete. An MMR diagnostic will be generated if the transition complete contacts (2K2-AUX) do not close. A diagram of this test or start sequence is shown in Figure 24.

Control Sequence of Operation

Now that the compressor motor (4M1) is running in the "Delta" configuration, the inlet guide vanes will modulate, opening and closing to the chiller load variation by operation of the stepper vane motor actuator (4M2) to satisfy chilled water setpoint. The chiller continues to run in its appropriate mode of operation: Normal, Softload, Limit Mode, etcetera.

If the chilled water temperature drops below the chilled water set point by an amount set as the "differential to stop" setpoint, a normal chiller stop sequence is initiated as follows: (Refer to Figure 10.)



1. The inlet guide vanes are driven closed up to 50 seconds.
2. After the inlet guide vanes are closed, the stop relay (2A1-J10) and the condenser water pump relays (1A5-J2) open to turn off. The oil and refrigerant pump motor (4B3) will continue to run for 3 minutes post lube while the compressor coasts to a stop. The chilled water pump will continue to run while the Main processor module (1A22) monitors leaving chilled water temperature preparing for the next compressor motor start based on the "differential to start" setpoint.

If the STOP key is pressed on the operator interface, the chiller will follow the same stop sequence as above except the chilled water pump relay (1A5-J2) will also open and stop the chilled water pump after the chilled water pump delay timer has timed out after compressor shut down.

If the "Immediate Stop" is initiated, a panic stop occurs which follows the same stop sequence as pressing the STOP key once except the inlet guide vanes are not sequence closed and the compressor motor is immediately turned off.

Control Sequence of Operation

Figure 24. Test and start timing sequence

Timing requirements to operate the "Stop", "Start", "Short", "Transition", and "Run" contact closure outputs are shown below. Prior to closing the "Short" contact, the transition complete input shall be verified to be open, otherwise an MMR diagnostic shall be generated.

Steps A to F: Starter Integrity Test.
Steps F to N: Starter Timing

Interval	Minimum	Maximum	Units	Actual Design
A. (Test for transition complete input open)				160 to 240 milliseconds
B. (Just delay time)				20 milliseconds
C. (Close 1M (2K1) Contactor and test for no current.) (Starter integrity test)				500 milliseconds
D. (Hold 1M (2K1) Contactor and test for no current.) (Starter integrity test)				1 second
E. (Open 1M (2K1) Delay time				200 milliseconds
F. (Close Shorting Contactor (2K3) and and test for no current, then wait for Start command.) (Starter integrity test)	100		milliseconds	1 second (Minimum)
G. (Close 1M (2K1)	2.0		second	2 second
H. (Wait 1.5 seconds after phase currents drop to 85 percent)	1	2	second	1.5 second
J. (Begin Transition sequence)	85	100	milliseconds	100 milliseconds
K. (Open S (Shorting) Contactor)	250	300	milliseconds	260 milliseconds
L. (Close 2M (2K2) Contactor				140 milliseconds
M. (Wait to look for Transition complete)			milliseconds	2.32 to 2.38 second
N. (Filtering time on Transition complete input)			milliseconds	160 to 240 milliseconds

Control Sequence of Operation

Current passing through fuse 1F2 reaches 2 normally open parallel sets of contacts: those of refrigerant and oil pump relay (1A7-J2-5 to 1), and the start contactor 2K1-aux. Connecter at module 1A7-J2-2 to 4.

Note: While the (1A7-J2-5 to 1) relay automatically is closed by the main processor 1A22 as a part of the start sequence. It can also be closed manually by changing the oil pump status to "ON" in the manual over ride mode menu of DynaView™.

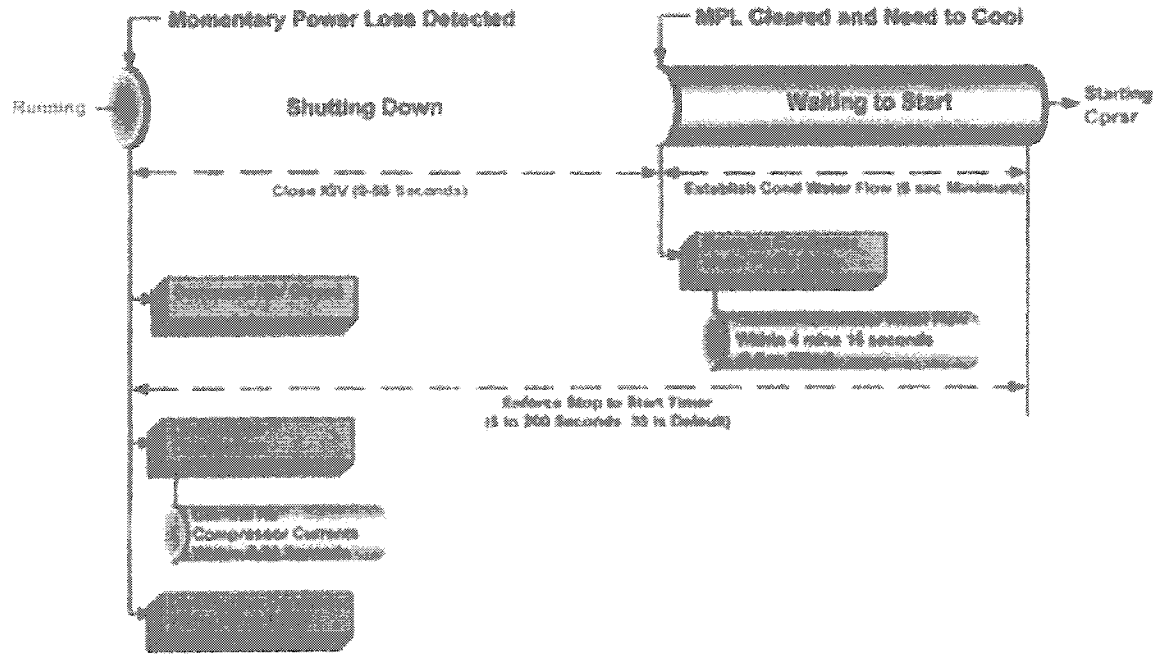
Closure of the (1A7-J2-5 to 1), or 2K1 auxiliary contacts also allows current to pass through the coil of the refrigerant pump starter relay (4K8),

Maximum Acceleration Timer Setting by Starter Type	
Wye-Delta	27 Seconds
Auto-Transformer	16
Primary Reactor	16
Across the Line	6
Solid State	25
AFD	30

to the start windings of the refrigerant pump. When motor 4M3 first starts, current draw is high: This causes current sensing relay 4K8 to close its normally open contacts and pull in pump Capacitor 4C1. Increasing motor speed and related decreasing current through the main winding and relay coil reduce the magnetic force and the armature "Drops out" to open the start contacts and disconnect the start windings and capacitor. Current now flows only to the Run windings of the oil pump motor or refrigerant and oil pump motor.

Machine Protection and Adaptive Control

Momentary Power Loss (MPL) Protection.



Improved power measurement and protection algorithms allow the unit to accommodate more power anomalies than ever. If the chiller must shut down, faster restarts get the machine up and running as soon as possible.

Momentary power loss (MPL) detects the existence of a power loss to the compressor motor and responds by initiating the disconnection of the compressor motor from the power source. Power interruptions of less than 30 line-cycles are defined as momentary power losses. Tests have shown that these short-term power interruptions can be damaging to the motor and compressor if the chiller is reconnected to the line while the motor and line phases do not match. The chiller will be shut down when a MPL is detected and will display a non-latching diagnostic indicating the failure. The oil pump will be run for the post-lube time period when power returns. The compressor and compressor motor are protected from damage from large torques and inrush currents resulting from reconnecting the compressor motor to the power source following a momentary loss of power.

MPL's greater than 2 or 3 cycles are detected resulting in unit shut down. Disconnection from the line is initiated within 6 line cycles of the power loss. MPL protection is active anytime the compressor is in the running mode. (The transition complete input has been satisfied).

MPL is enabled however can be disabled, if required via the service tool.

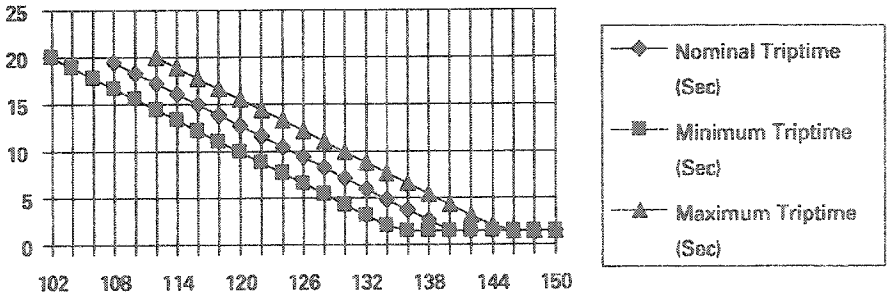
Figure 25. CVHE, CVHF, and CVHG sequence of operation: momentary power loss, (DynaView™ and Starter module remain powered)

Machine Protection and Adaptive Control

Current Overload Protection

Motor currents are continuously monitored for over current protection and locked rotor protection. This protects the Chiller itself from damage due to current overload during starting and running modes but is allowed to reach full load amps. This overload protection logic is independent of the current limit. The overload protection will ultimately shut the unit down anytime the highest of the three phase currents exceeds the time-trip curve. A manual reset diagnostic describing the failure will be displayed.

Overload protection for the motor starts based on the Maximum Time to Transition permitted for a particular motor .



Running Over Current Protection

In the run mode, a "time-to-trip" curve is looked at to determine if a diagnostic should be called. The UCP continuously monitors compressor line currents to provide running over current and locked rotor protection. Over current protection is based on the line with the highest current. It triggers a manually resettable diagnostic shutting down the compressor when the current exceeds the specified time-trip curve. The compressor overload time trip curve is expressed as a percent of the Rated Load Amps of the compressor and is not adjustable:

Overload Must Hold = 102 Percent RLA.
Overload Must Trip in 20 (+0 -3) seconds = 112 Percent RLA
(Note the above gives a nominal 20 second must trip point of 107 Percent RLA.)
Overload Must Trip in 1.5 seconds = 140 Percent RLA (Nominal)

The linear time-trip curve is as follows:

Figure 26. Overload trip time versus percent RLA

The Maximum Acceleration Time Setting and Current Transformer Setting are factory set however can be set with the service tool;

Machine Protection and Adaptive Control

Current Limit Protection

Current Limit Protections exist to avoid motor current overload and damage to the compressor motor during starting and running. Compressor motor current is continuously monitored and current is controlled via a limit function that to prevent running into over current diagnostic trips.

The current limit control logic attempts to prevent the motor from shutting down on a diagnostic trip by limiting compressor current draw relative to an adjustable current limit DynaView™ Current Limit Setpoint. This setpoint can also be lowered to provide electrical demand limiting on the unit as required. This could also be set to allow the Chiller to continue to run at a lower load to avoid tripping off via a diagnostic.

The Current Limit function uses a PID algorithm (Similar to the Leaving Water Temperature control) that allows the chiller to run at the Current Limit Setpoint. At machine startup, or with any setpoint change the new current limit setpoint reached after the is filtered setpoint time elapses. The minimum current limit setpoint is default set to 40 percent RLA (20-100 percent). The filtering time is default set to 10 minutes (0-120 minutes), however these can be altered via the service tool. This filtered setpoint allows for stable control if the Current Limit setpoint is adjusted during a run.

The Current Limit Setpoint (CLS) can be changed from: Front Panel, External Analog input (with GBAS option), or Tracer (Tracer option). However, if present Tracer current setpoint has the highest priority, unless disabled in the DynaView™ Setpoint source override menu. The External CLS has second priority, and will be used if Tracer is disabled or not installed. The Front Panel Setpoint has the lowest priority, and will be used if Tracer and the External CLS are both disabled.

Phase Loss Protection

Loss of phase detection protects the chiller motor from damage due to a single-phasing condition. The controls will shut down the chiller if any of the three phase currents feeding the motor are lost. The shutdown will result in a latching diagnostic indicating the failure. The motor is protected from over-current during a single-phase condition by the Current Overload Protection feature. Phase Loss Protection provides redundant protection and a diagnostic that more accurately describes the fault.

Reverse Rotation Protection

This function protects the compressor from being driven in the reverse direction. Incorrect phase rotation detection results in a manually resettable diagnostic. Phase Reversal protection is default to Enable, however can be disabled via the service tool.

Phase Imbalance Protection

CH530 provides phase imbalance protection based on the average three-phase current. The three phase currents supplied to the motor are monitored for unequal amperage draw. Motor overload is not considered to be a problem since each phase of the motor is monitored for overcurrent. In addition, since each phase is monitored for loss of current, the motor will be protected against single phasing.

Under and Over Voltage Protection

Under/over voltage protection can be enabled (default) or disabled via TechView.

If Disabled : No effect.

If Enabled :

and an Overvoltage condition occurs:

-Diagnostic called when the average of the three line voltages is greater than 112.5% of the unit line voltage set point for 60 seconds.

-Diagnostic cleared when the average of the three line voltages is 110% or less of the unit line voltage set point.

and an Undervoltage condition occurs:

-Diagnostic called when the average of the three line voltages is less than 87.5% of the unit line voltage set point for 60 seconds.

-Diagnostic cleared when the average of the three line voltages is 90% or greater of the unit line voltage set point.

Machine Protection and Adaptive Control

Differential to Start or Stop

The Differential to Start setpoint is adjustable from 1 to 10°F (0.55 to 5.55°C) and the Differential to Stop setpoint adjustable from 1 to 10°F (0.55 to 5.55°C). Both setpoints are with respect to the Active Chilled Water Setpoint. When the chiller is running and the LWT (Leaving Water Temperature) reaches the Differential to Stop setpoint the chiller will go through its shutdown sequence to AUTO. (Refer to Figure 10.)

SoftLoading

Softloading stabilizes the startup control during the initial chiller pulldown. Soft loading is used to bring the building loop temperature from its start value to the Chilled Water or Hot Water Setpoint in a controlled manner. Without soft loading, the chiller controls will load the chiller rapidly and use the full chiller capacity to bring the loop temperature to setpoint. Although the start temperature of loop may have been high, the actual system load may be low. Thus, when the setpoint is met the chiller must unload quickly to the system load value. If it is not able to unload quickly enough, the supply water temperature will drop below setpoint and may even cause the chiller to cycle off. Soft loading prevents the chiller from going to full capacity during the pulldown period. After the compressor has been started, the starting point of the filtered setpoint is initialized to the value of the Evaporator Leaving Water temperature and the percent RLA.

There are three independent Softload setpoints:

- Capacity Control Softload Time (default to 10 minutes, 0-120 minutes) This setting controls the time constant of the Filtered Chilled Water Setpoint.
- Current Limit Control Softload Time (default 10 minutes; 0-120 minutes) This Setting controls the time constant of the Filtered Current Limit Setpoint.
- Current Limit Softload Starting Percent (default is 40 percent RLA; 20-100 percent): This setting controls the Starting point of the Filtered Current Limit Setpoint

Service tool provides access to these three setpoints, if it is determined necessary to change from the defaults.

Softloading is not active during Ice Making or during the Ice To normal Transition. Softloading will be enabled after the Ice to normal Transition timer has expired.

Softloading is not active during Free Cooling, The softloading is active during the transition from Free Cooling to Powered operation.

Softloading times can be active during Hot Gas Bypass Control

Minimum and Maximum Capacity Limit

A Minimum Capacity can be set to limit the unloading ability of the compressor thus forcing differential to stop to be reached cycling the chillers. Minimum capacity limit will be displayed when in this limit mode. This indicates when the chiller is running fully unloaded.

Similarly a maximum capacity can be set to limit normal chilled water temperature control, the maximum capacity relay is energized which is a signal used by generic BAS systems to start another chiller.

The minimum (default at 0 percent) and maximum (default at 100 percent) capacity are adjustable via the service tool.

Machine Protection and Adaptive Control

Evaporator Limit

Evaporator refrigerant temperature is continuously monitored to provide a limit function that prevents low refrigerant temperature trips which allows the chiller to continue to run at a reduced load instead of tripping off at the Low Evaporator Refrigerant Temperature Cutout Setpoint (LRTC).

Evaporator limit could occur with an initial pull down of a loop where the Condenser is colder than the Evaporator (Inverted Start), the Evaporator refrigerant temperature may drop below the Low Refrigerant Temperature Cutout (LRTC). This limit prevents the unit from shutting down on a diagnostic during this type of pulldown. Another example is a Chiller that is low on refrigerant charge will run with low Evaporator refrigerant temperatures. This limit allows the chiller to continue to run at a reduced load.

Evaporator Limit uses the Evaporator Refrigerant Temperature sensor in a PID algorithm (Similar to the Leaving Water Temperature control) that allows the chiller to run at the LRTC + 2 degree F.

When actively limiting machine control "Evaporator Temperature Limit" will be displayed as a sub-operating mode.

Leaving Water Temperature Cutout

Leaving water temperature cutout is a safety control that protects the chiller from damage caused by water freezing in the evaporator. The cutout setpoint is factory set however is adjustable with the Service tool.

The "Leaving Water Temperature Cutout Setpoint" is independently adjustable from the chilled water setpoint and factory set. Shutdown of the compressor due to violation of the Leaving Water Temperature Cutout results in an automatically resettable diagnostic (MAR). The DynaView™ Operating Mode indicates when the "Leaving Water Temperature Cutout Setpoint" conflicts with the chilled water temperature setpoint by a message on the display. The "Leaving Water Temperature Cutout Setpoint" and chilled water setpoint, both active and front panel, are separated by a minimum of 1.7°F. See Cutout Strategy, Figure 27. When either difference is violated, the UCP does not permit the above differences to be violated and the display exhibits a message to that effect and remains at the last valid setpoint. After violation of the "Leaving Water Temperature Cutout Setpoint" for 30°F seconds the chiller will shutdown and indicate a diagnostic.

Machine Protection and Adaptive Control

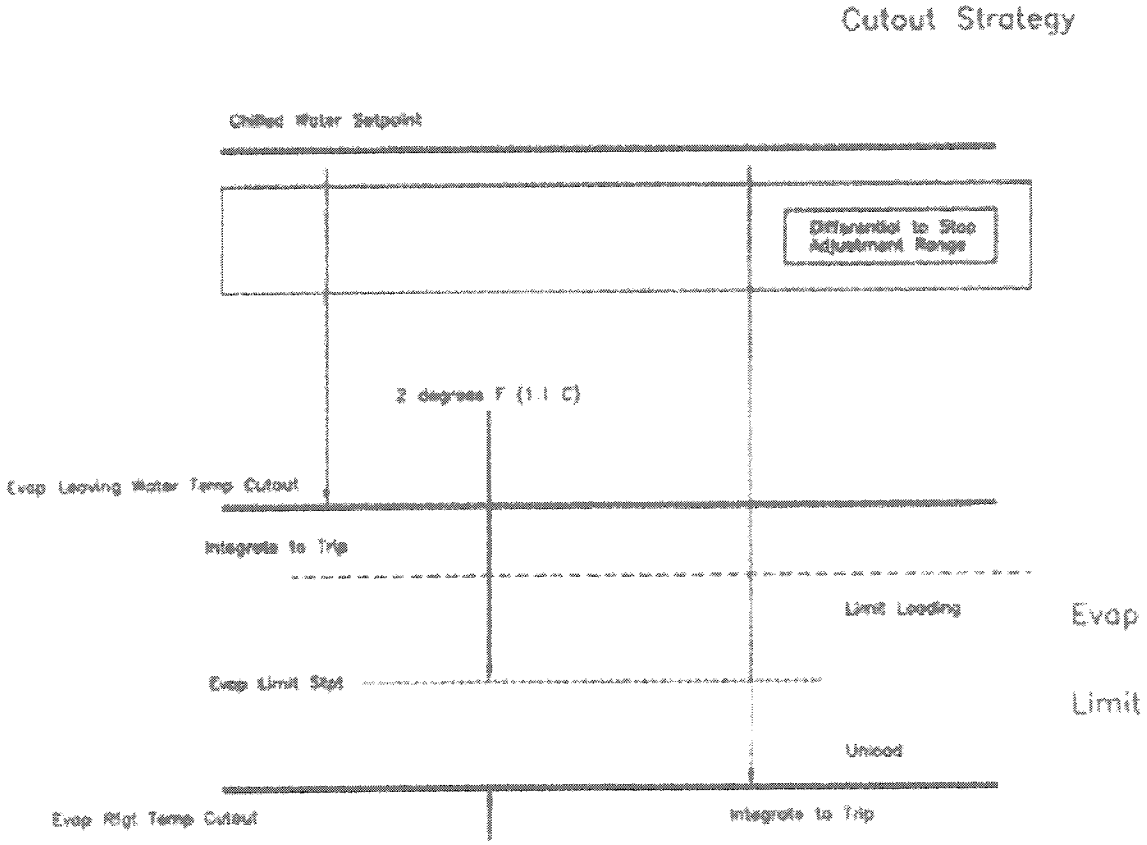
High Evaporator Leaving Water Temperature Cutout

(Main Processor Software Revision 6.0 and higher)
A High Evaporator Water Temperature Diagnostic was implemented that will turn off the Evaporator Water pump relay if the relay is being forced on due to a Loss of Evaporator Water Flow Lost diagnostic (MAR Diagnostic) and the Evaporator Leaving Water Temperature exceeds an adjustable High Evaporator Water Temperature Cutout for 15 continuous seconds. The High Evaporator Water Temperature diagnostic is an immediate shutdown and is nonlatching. The diagnostic will auto reset and the pump will return to normal control when the temperature falls 5°F below the cutout setting. High Evaporator Water Temperature Cutout is a setpoint that is adjustable in TechView from 80°F and 150°F. The default is 105°F.

Low Refrigerant Temperature Cutout

The purpose of the low evaporator refrigerant temperature protection is to prevent water in the evaporator from freezing. When the Low Evaporator Refrigerant Temperature Cutout (LRTC) trip point is violated, a latching diagnostic indicating the condition is displayed. The Low Evaporator Refrigerant Temperature Diagnostic is active in both the Running and Stopped modes.

The Low Evaporator Refrigerant Cutout Setpoint is factory set to 36°F. This can be altered via the service tool. A Service Tool adjustable setpoint that should be based on the percentage of antifreeze used in the customer's water loop. The Service tool will display a warning message such as "Warning: Adequate Antifreeze required" for any Evaporator Refrigerant Temperature Cutout below 28°F and any Leaving Water Temperature Cutout below 35°F.



The percent of antifreeze required is a function of the leaving water temperature setpoint and the worse case (lowest permitted water flow) approach temperatures of the chiller's evaporator design.

Head Relief Relay
(See page 53 also)

Surge, condenser limit, and certain conditions on ice mode will energize the head relief relay. Note: There is a TechView programmable head relief relay filter times setpoint. The default is one minute.

Machine Protection and Adaptive Control

Figure 27. Cutout strategy

Limit Loading: The potential to limit loading increases as the saturated evaporator temperature approaches the evaporator limit setpoint.

Unload: The potential to unload increases as the saturated evaporator temperature falls further below the evaporator limit setpoint.

Figure 27 illustrates these functions as follows:
- chilled water setpoint
- evap leaving water temp cutout
- evap rfgt temp output

Machine Protection and Adaptive Control

Evaporator Variable Flow Compensation

This option includes transducers for the differential evaporator and condenser water pressures (psid). Flow switches or some other means to prove flow are still required and must be field connected.

The following data will be shown at the DynaView and TechView displays and at Tracer Summit.

- Evaporator and condenser differential water pressures (psid)
- Evaporator and condenser gpm
- Evaporator tons

How It Works

The Tracer chiller controller uses a patented, variable, water-flow compensation algorithm to maintain stable, precise capacity control. Variable flow compensation is a new optional control feature for CTV chillers.

It will automatically adjust capacity control to:

- Maintain control stability at low flow.
- Reject variable-flow disturbance.

If the water-pressure transducer fails and the flow switch continues to prove flow, water-flow compensation will be disabled and the design delta T will be used.

For applications designed to operate with variable-primary (VPF) water-flow, variable flow compensation allows the chiller to respond quickly to accelerating or decelerating water. By automatically adjusting the control gain, large changes in the water-flow rate can be tolerated.

For details, refer to CTV-PRC007-EN.

Condenser Limit

Condenser pressure is continuously monitored to provide a limit function that prevents High Pressure Cutout (HPC) trips. This protection is called Condenser Refrigerant Pressure Limit, or High Pressure Limit. A fully loaded compressor, operating at high Evaporator Leaving Water Temperature (ELWT) and high condenser temperatures causes high condenser pressures. The purpose of this limit is to avoid High Pressure Cutout (HPC) trips by allowing the Chiller to continue to run at a lower load instead of tripping off via HPC.

The Condenser Limit will be based from a pressure conversion from the Condenser Refrigerant Temperature sensor, unless there is a Condenser Refrigerant Pressure sensor installed (CDRP option). If the Condenser Refrigerant Pressure Sensor is installed, then the limit will be based from the Pressure sensor.

When limited by this action, "Condenser Pressure Limit" will be displayed as a sub-operating mode. The Condenser Limit Setpoint is factory set (93 percent of HPC), however can be altered via the service tool.

Machine Protection and Adaptive Control

Restart Inhibit.

This function provides short cycle protection for the motor, and indirectly also short cycling protection for the starter since the starter is designed to operate the motor under all the conditions of motor performance.

The operation of the restart inhibit function is dependent upon two setpoints. The Restart Inhibit Free Starts (1-5, 3 default), and the Restart Inhibit Start to Start Timer (10-30 min, 20 default). These settings are adjustable via the service tool.

Restart Inhibit Free Starts

This setting will allow a number of rapid restarts equal to its value. If the number of free starts is set to "1", this will allow only one start within the time period set by the Start to Start Time Setting. The next start will be allowed only after the start to start timer has expired. If the number of free starts is programmed to "3", the control will allow three starts in rapid succession, but thereafter, it would hold off on a compressor start until the Start to Start timer expired. i.e. with 3 free starts and 20 min. restart inhibit settings, it will take 60 minutes of run time to restore the total of 3 free starts.

Restart Inhibit Start to Start Time Setting

This setting defines the shortest chiller cycle period possible after the free starts have been used. If the number of free starts is programmed to "1", and the Start to Start Time Setting is programmed to 10 minutes, then the compressor will be allowed one start every 10 minutes. The start-to-start time is the time from when the motor was commanded to energize to when the next command to enter prestart is given.

Clear Restart Inhibit

A Clear Restart Inhibit "button" is provided within Settings; Manual Override on the DynaView display. This provides a way for an operator to allow a compressor start when there is a currently active Restart Inhibit that is prohibiting such a start. The "button" press will have no other function than to remove the restart inhibit if there is one active. It does not change the count of any internal restart inhibit timers or accumulators. command, but is inhibited, pending the expiration of the timer.

The restart inhibit function, setpoints and clear features exist for each compressor and operate independently of other compressors on that chiller.

During the time the start is inhibited due to the start-to-start timer, the DynaView shall display the mode 'Restart Inhibit' and the also display the time remaining in the restart inhibit.

A "Restart Inhibit Invoked" warning diagnostic will exist when the attempted restart of a compressor is inhibited.

If all three motor winding temperatures are less than the "Restart Inhibit Temperature" Setpoint (default 165°F/74°C) then restart is allowed.

Restart inhibit mode exist when at least one of the three motor winding temperatures is greater than or equal to the "Restart Inhibit Temperature" Setpoint but less than 265°F/129.4°C. Restart inhibit mode is entered until all three motor winding temperatures are less than the 'Restart Inhibit Temperature' Setpoint

Note: When one of the three motor winding temperatures is 265°F/ 129.4°C or greater, a High Motor Winding Temperature diagnostic shall be called.

Note: When the start is inhibited by the restart inhibit function, the time remaining will be displayed along with the restart inhibit mode.

Machine Protection and Adaptive Control

High Vacuum Lockout
The oil sump pressure is below the lockout setpoint. Starting of compressor is inhibited as a result.

Low Oil Temperature Start Inhibit
The oil temperature is at or below the low oil temperature start inhibit setpoint (143°F/61.7°C). The heater is energized to raise the oil temperature.

Low oil temperature is indicative of refrigerant dilution in the oil. Oil temperature is used to estimate this dilution since the oil temperature directly corresponds to amount of refrigeration dilution in the oil. It is required that oil contains minimal refrigerant in it. This is accomplished by boiling the refrigerant out of the oil by maintaining a high enough oil temperature.

If the oil temperature is at or below a given Low Oil Temperature Inhibit setting (default 95°F/35°C) the compressor cannot be started. This is an inhibit mode and will be reported to the operator interface. The oil heater is energized in an attempt to raise the oil temperature over this inhibit temperature setpoint. The compressor is inhibited from starting until the oil temperature is raised 5 or more degrees above this setpoint.

The Low Oil Temperature Start Inhibit is tested on every start unless a quick restart is being performed during post lube.

If the Enhanced Oil Temperature Protection setting is enabled, the Low Oil Temperature Start Inhibit value is the greater of 100°F/37.8°C or the Saturated Evaporator Refrigerant Temperature + 30°F/16.7°C.

If the Enhanced Oil Temperature Protection setting is not enabled, the Low Oil Temperature Start Inhibit value is settable with the Low Oil Temperature Start Inhibit Setpoint via the service tool.

Machine Protection and Adaptive Control

Oil Temperature Control
The oil heater is used to maintain the oil temperature within +/- 2.5°F (1.4°C) of the oil temperature control setpoint. The oil heater is commanded off when the oil pump is commanded on.

If the oil temperature is at or below the Low Oil Temperature Cutout setpoint, this diagnostic will be issued and stops the compressor.

This diagnostic is ignored for the first 10 minutes of compressor run. After that, if the oil temperature falls below this cutout temperature for more than 60 consecutive seconds this diagnostic is issued.

High Oil Temperature Cutout
Name: High Oil Temperature Cutout
Type of Diagnostic: Latching, results in Immediate Shutdown.
Default Setpoint value: 180°F (82.2°C)

Implemented to avoid overheating of the oil and the bearings.

If the oil temperature is at or above the High Oil Temperature Cutout setpoint this diagnostic will be issued - which will stop the compressor.

If Oil Temperature violates this temperature cutout for more than 120 seconds this diagnostic is issued.

Manual Oil Pump Control
The oil pump control accepts commands to turn on the oil pump. The manual oil pump choices will be "Auto" or "On". When the oil pump is commanded "On", it will revert to "Auto" in 15 minutes.

Machine Protection and Adaptive Control

Controls Chilled Water Reset (CWR)

Chilled water reset is designed for those applications where the design chilled water temperature is not required at partload. In these cases, the leaving chilled water temperature setpoint can be reset upward using the CWR features.

When the CWR function is based on return water temperature, the CWR feature is standard.

When the CWR function is based on outdoor air temperature, the CWR feature is an option requiring an outdoor temperature sensor module installed in the UCP panel, and sensor installed outdoors.

The type of CWR is selected in the Operator Interface settings Menu along with the Reset Ratio, Start Reset Setpoint, and the Maximum Reset Setpoint.

The following equations and parameters apply for CWR.

Return Water

CWS' = CWS + RATIO (START RESET - TWE - TWL) and CWS' > or = CWS and CWS' - CWS < or = *Maximum Reset.*

Outdoor Air Temperature

CWS = CWS + RATIO (START RESET - TOD) and CWS' > or = CWS and CWS - CWS < or = Maximum Reset.

Where

CWS' is the new chilled water setpoint.

CWS is the active chilled water setpoint before any reset has occurred.

RESET RATIO is a user adjustable gain.

START RESET is a user adjustable reference.

TOD is the Temperature Outdoor Sensor.

TWE is entering evaporator water temperature.

TWL is the Leaving Evaporator Temperature.

MAXIMUM RESET is a user adjustable limit providing the maximum amount of reset. For all types of reset, CWS - CWS < or = Maximum Reset.

Both Return and Outdoor Reset do not apply to Heating Mode where the UCP is controlling the Leaving Condensing Hot Water Temperature.

Constant Return Reset will reset the leaving water temperature setpoint so as to provide a constant entering water temperature. The Constant Return Reset equation is the same as the Return Reset equation except on selection of Constant Return Reset, the UCP shall automatically set RATIO, START RESET, and MAXIMUM RESET to the following:

The RATIO = 100 percent
The START RESET = Design Delta Temperature
The MAXIMUM RESET = Design Delta Temperature

The equation for Constant Return is as follows:

Machine Protection and Adaptive Control

Table 3. Values for start reset types

The values for "RESET TYPE" are:

Reset Type:	Disable	Outdoor Air Reset	Return Reset	Const Return Reset

The values for "RESET RATIO" for each of the reset types are:

Reset Type	Reset Ratio Range	Increment English Units	Increment SI Units	Factory Default Value
Return	10 to 120 percent	1 percent	1 percent	50 percent
Outdoor	-80 to 80 percent	1 percent	1 percent	10 percent

The values for "START RESET " for each of the reset types are:

Reset Type	Start Reset Range	Increment English Units	Increment SI Units	Factory Default Value
Return	4 to 30°F (2.2 to 16.7°C)	0.1°F	0.1°C	10°F (5.6°C)
Outdoor	50 to 130°F (10 to 54.44°C)	0.1°F	0.1°C	90°F (32.22°C)

The values for "MAXIMUM RESET" for each of the reset types are:

Reset	Maximum Reset Range	Increment English Units	Increment SI Units	Factory Default Value
Return	0 to 20°F (0.0 to 11.11°C)	0.1°F	0.1°C	5°F (2.78°C)
Outdoor	0 to 20°F (0.2 to 11.11°C)	0.1°F	0.1°C	5°F (2.78°C)

Constant Return

CWS' = CWS + 100 percent (Design Delta Temperature) - (TWE-TWL) and CWS' > or = CWS and CWS' -CWS < or = Maximum Reset

Notice that Constant Return is nothing more than a specific case of Return Reset offered for operator convenience.

When any type of CWR is enabled, the UCP will step the CWS toward the desired CWS (based on the above equations and setup parameters) at a rate of 1°F every 5 minutes until the Active CWS equals the desired CWS'. This applies when the chiller is running only.

Using the Equation for calculating CWR for Outdoor Air Temperature

Equation:
Degrees of Reset = Reset Ratio*(Start Reset - TOD)

The chiller will start at the Differential to Start value above a fully reset CWS or CWS for both Return and Outdoor Reset.

The graph on the next page, shows the reset function for Outdoor Air Temperature: **Note:** This graph assumes that Maximum Reset is set to 20 degrees.

Degrees of Reset:
Degrees of Reset = Active CWS - Front Panel CWS
or
Degrees of Reset = CWS' - CWS

To obtain Active CWS from Degrees of Reset: Active CWS = Degrees of Reset + Front Panel CWS

(* = multiply)

Machine Protection and Adaptive Control

Reset Ratio:
The Reset Ratio is displayed as a percentage. To use it in the above equation it must be converted to it's decimal form.

Reset Ratio percent /100 = Reset Ratio decimal

Example of converting Reset Ratio:

If the Reset Ratio displayed on the CLD is 50 percent then use (50/100)= .5 in the equation

TOD = Outdoor Air Temperature

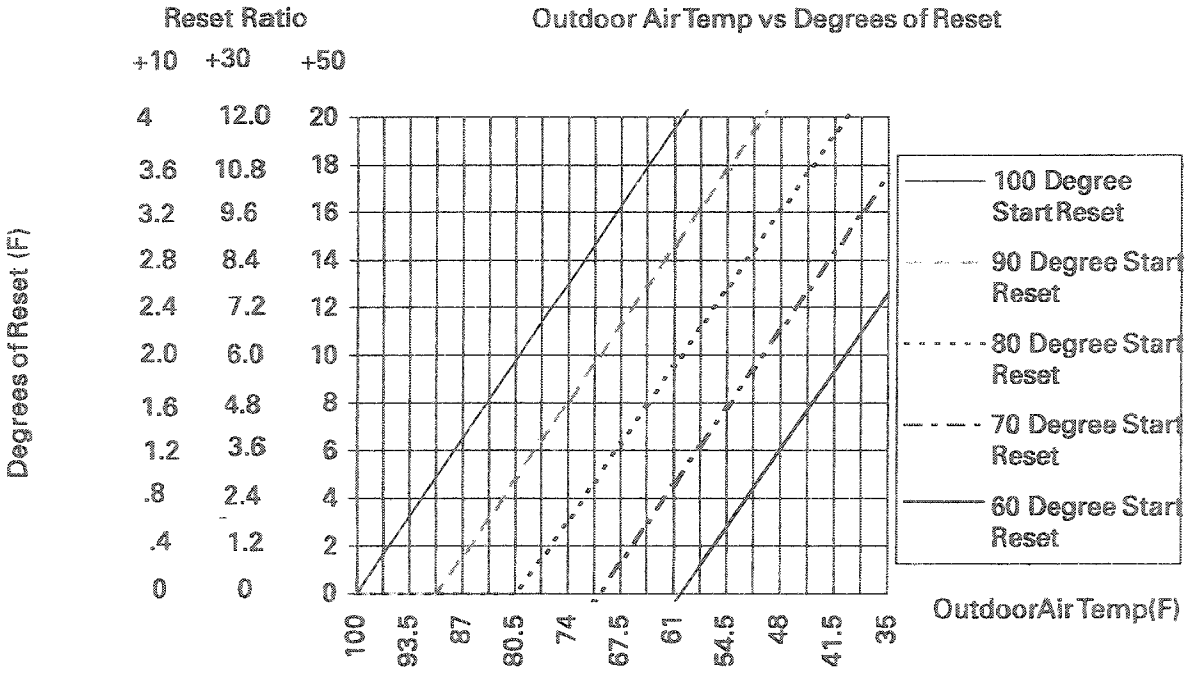
Start Reset = Outdoor Air Start Reset

Example of Calculating Reset for Outdoor Air Temperature:

If:
Reset Ratio = 35 percent
Start Reset = 80
TOD = 65
Maximum Reset = 10.5

How many Degrees of Reset will there be?

Degrees of Reset = Reset Ratio*(Start Reset - TOD)
Degrees of Reset = .35*(80-65)
Degrees of Reset = 5.25



If:
Reset Ratio = -70 percent
Start Reset = 90
TOD = 100
Maximum Reset = 17

How many Degrees of Reset will there be?

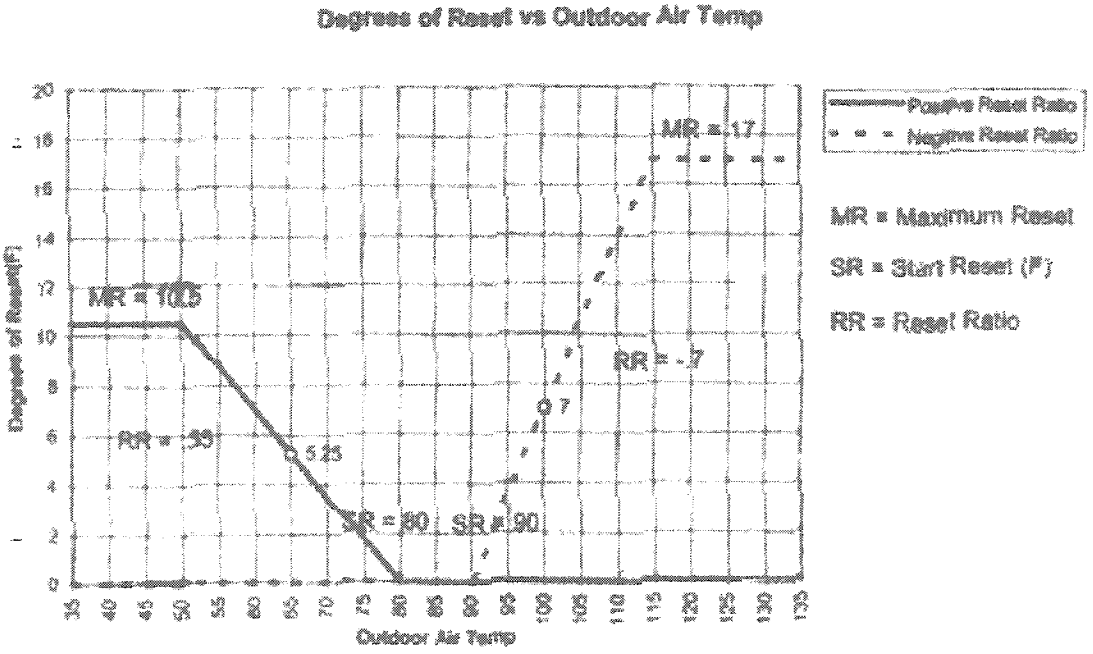
Degrees of Reset = Reset Ratio* (Start Reset - TOD)
Degrees of Reset = -7* (90-100)
Degrees of Reset = 7

(* = multiply)

Figure 28. Outdoor air temperature versus degrees of reset

Machine Protection and Adaptive Control

Figure 29. Reset function for return CWR



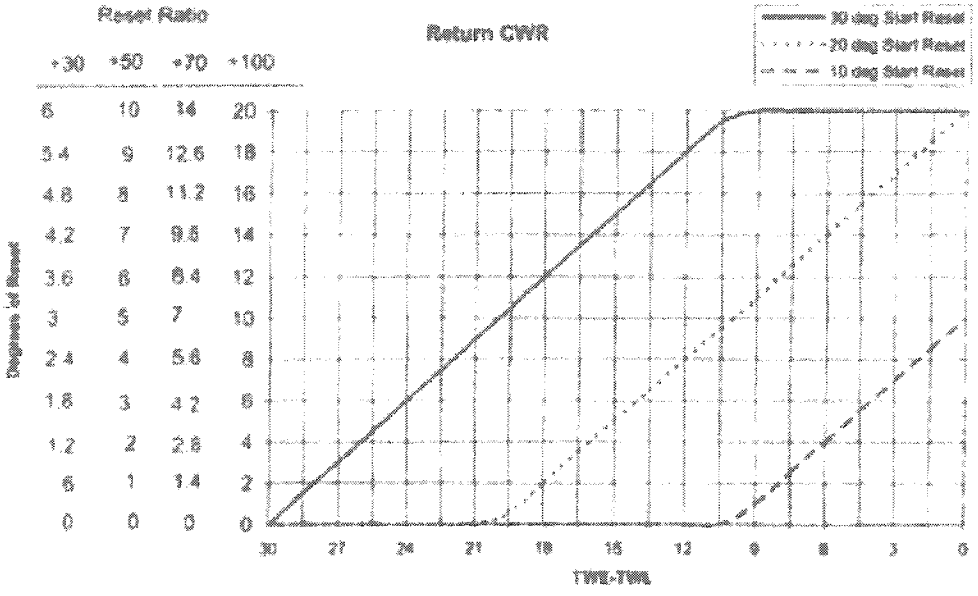


Figure 30. Reset function for return CWR

Note: This graph assumes Maximum Reset is set to 20 degrees.

Machine Protection and Adaptive Control

Example of Calculating Return Reset:

If:
Reset Ratio = 50%
Start Reset = 25
TWE = 65
TWL = 45
Maximum Reset = 8

How many Degrees of Reset will there be?

Degrees of Reset = Reset Ratio*(Start Reset - (TWE-TWL))
Degrees of Reset = .5*(25-(65-45))
Degrees of Reset = 2.5

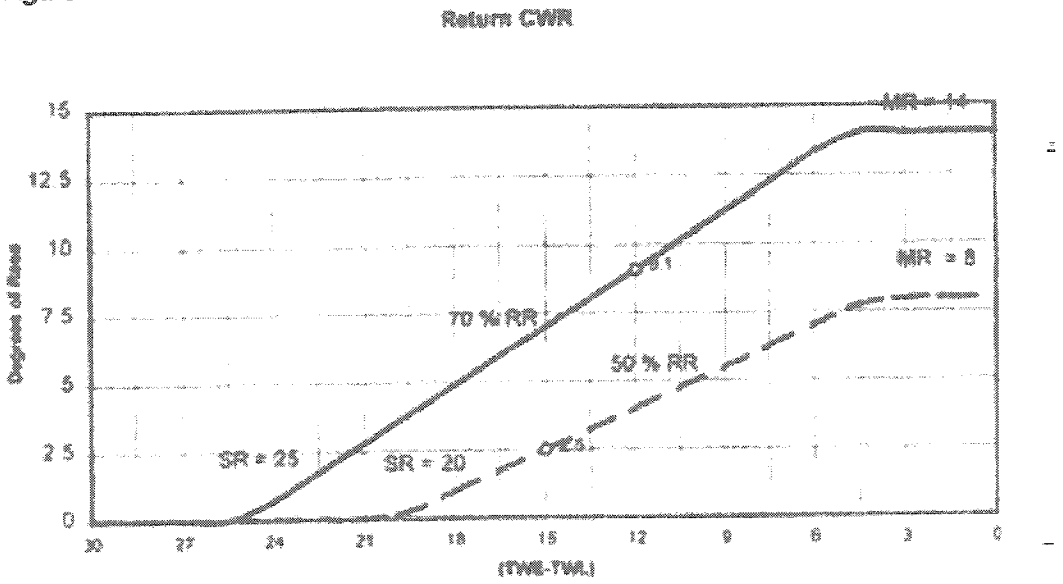
If:
Reset Ratio = 70%
Start Reset = 20
TWE = 60
TWL = 53
Maximum Reset = 14

How many Degrees of Reset will there be?

Degrees of Reset = Reset Ratio*(Start Reset - (TWE-TWL))
Degrees of Reset = .7*(20-(60-53))
Degrees of Reset = 9.1

Machine Protection and Adaptive Control

Figure 31. Return CWR



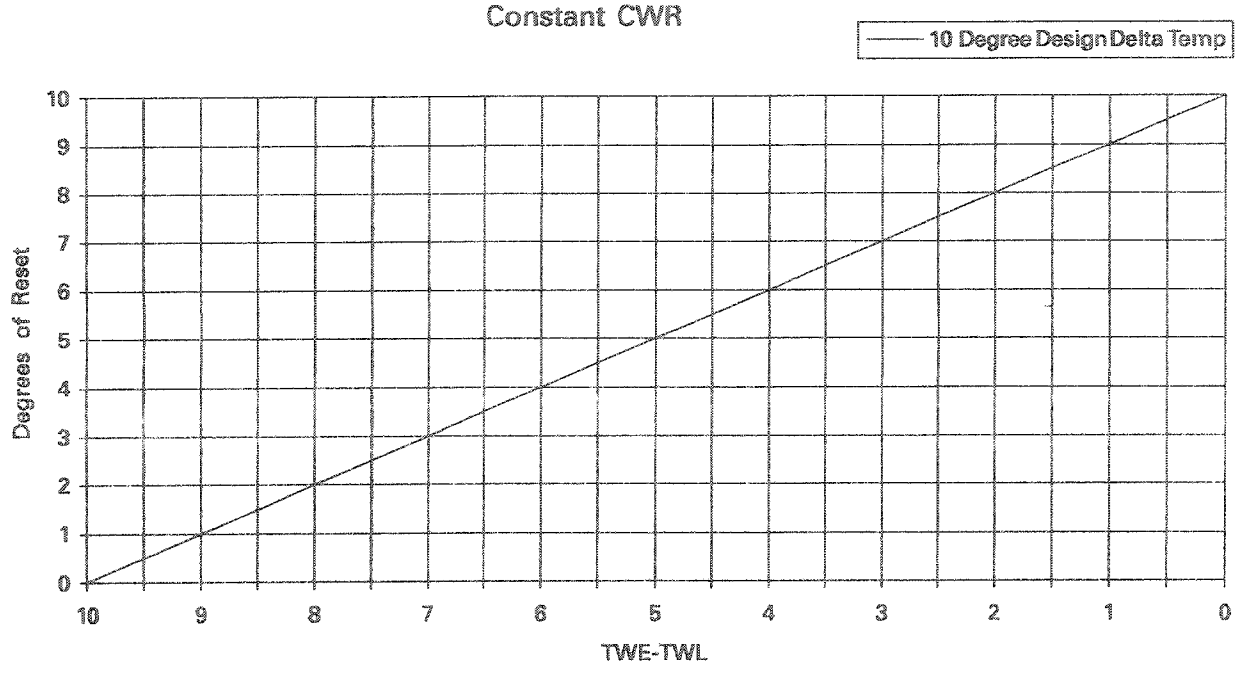


Figure 32. Constant CWR

Unit Startup

Unit Start-Up Procedures

Daily Unit Start-Up

1. Verify the chilled water pump and condenser water pump starter are in "ON" or "AUTO".
2. Verify the cooling tower is in "ON" or "AUTO".
3. Check the oil tank oil level; the level must be visible in or above the lower sight glass. Also, be sure to check the oil tank temperature; normal oil tank temperature before start-up is 140°F to 145°F (60 to 63°C).

Note: The oil heater is energized during the compressor off cycle. During unit operation, the oil tank heater is de-energized.

4. If the chiller is equipped with the free cooling option, ensure that the free cooling option is disabled in the Chiller Settings menu.
5. Check the chilled water setpoint and readjust it, if necessary, in the Chiller Settings menu.
6. If necessary, readjust the current limit setpoint in the Chiller Setpoints menu.
7. Press "AUTO".

The UCP also checks compressor motor winding temperature, and a start is initiated if the winding temperature is less than 265°F. The chilled water pump relay is energized and evaporator water flow is proven.

Next, the UCP checks the leaving evaporator water temperature and compares it to the chilled water setpoint. If the difference between these values is less than the start differential setpoint, cooling is not needed.

If the UCP determines that the difference between the evaporator leaving water temperature and chilled water setpoint exceeds the start differential setpoint, the unit enters the initiate Start Mode and the oil pump and Refrigerant pump and the condenser water pump are started. If condenser water flow is not proven (flow switch 5S3 does not close) within 4-minutes 15 seconds, the unit is locked out on a MMR Diagnostic.

Oil pressure must be verified within 3 minutes or a MMR diagnostic is generated.

When less than 5 seconds remain on the restart inhibit, the pre-start starter test is conducted on Y-Delta starters. If faults are detected, the unit's compressor will not start, and a MMR Diagnostic will be generated.

If the compressor motor starts and accelerates successfully, "Unit is Running" appears on the display. At this time the purge unit will start operating on "Automatic" and will continue to operate as long as chiller compressor is running.

Note: Whenever the UCP detects a MMR diagnostic condition during start-up, unit operation is locked out, and manual reset is required before the start-up sequence can begin again. If the fault condition has not cleared, the UCP will not permit restart.

Unit Startup

When the cooling requirement is satisfied, the UCP originates a "Shutting down" signal. The inlet guide vanes are driven closed for 50 seconds, and the unit enters a 3-minute post-lube period. The compressor motor and condenser water pump starter are de-energized immediately, but the oil pump continues to run during this 3-minute interval; the evaporator pump will continue to run.

Once the post-lube cycle is done, the unit returns to auto mode.

Seasonal Unit Start-Up

1. Close all drain valves, and re-install the drain plugs in the evaporator and condenser headers.
2. Service the auxiliary equipment according to the start-up and maintenance instructions provided by the respective equipment manufacturers.
3. Vent and fill the cooling tower, if used, as well as the condenser and piping. At this point, all air must be removed from the system (including each pass). Then close the vents in the condenser water boxes.
4. Open all of the valves in the evaporator chilled water circuit.
5. If the evaporator was previously drained, vent and fill the evaporator and chilled water circuit. When all air is removed from the system (including each pass), close the vent valves in the evaporator water boxes.
6. Lubricate the external vane control linkage as needed.
7. Check the adjustment and operation of each safety and operating control.
8. Close all disconnect switches.
9. Perform instructions listed in "Daily Unit Start-up" section.

⚠ WARNING

Live Electrical Components!

During installation, testing, servicing and troubleshooting of this product, it may be necessary to work with live electrical components. Have a qualified licensed electrician or other individual who has been properly trained in handling live electrical components perform these tasks. Failure to follow all electrical safety precautions when exposed to live electrical components could result in death or serious injury.

⚠ WARNING

Toxic Hazards!

- **Do not run evaporator water pump longer than 30 minutes after the chiller is shutdown.**
- **Ensure that the evaporator is isolated from the hot water loop before changeover to heating mode.**

Do not allow the chiller to increase above 110°F in temperature while unit is off. Failure to prevent high chiller temperature will cause the inside pressure to rise. The rupture disk is designed to relieve and discharge the refrigerant from the unit if the pressure in the evaporator exceeds 15 PSIG (103.4 Kpa). A significant release of refrigerant into a confined space due to a rupture disk failure could displace available oxygen to breathe and cause possible asphyxiation. Should a rupture disk fail, evacuate the area immediately and contact the appropriate rescue or response authority. Failure to take appropriate precautions or react properly to a potential hazard could result in death or serious injury.

Unit Shutdown

Unit Shutdown Procedures

Daily Unit Shutdown

Note: Refer to Start-Run Shutdown sequence in General Information Overview Sequence of Operation.

1. Press STOP.
2. After compressor and water pumps shutdown turn Pump Contactors to OFF or open pump disconnects.

Seasonal Unit Shutdown

CAUTION

Oil Pump Heater Operation!

CONTROL POWER DISCONNECT SWITCH MUST REMAIN CLOSED TO ALLOW OIL SUMP HEATER OPERATION. Failure to do this will allow refrigerant to condense in the oil pump.

3. Open all disconnect switches except the control power disconnect switch.
4. Drain the condenser piping and cooling tower, if used. Rinse with clean water.
5. Remove the drain and vent plugs from the condenser headers to drain the condenser. Air dry bundle of residual water.
6. Once the unit is secured for winter, the maintenance procedures described under "Annual Maintenance" in the Periodic Maintenance section of this manual should be performed by qualified Trane service technicians.

Note: During extended shutdown, be sure to operate the purge unit for a 2-hour period every two weeks. This will prevent the accumulation of air and noncompensable in the machine. To start the purge, change the purge mode to ON in the DynaView™ Settings Purge Menu. Remember to turn the purge mode to Adaptive after the 2-hour run time.

Trouble Analysis

If the ALARM indicator on the control panel is flashing, an MMR diagnostic has occurred. Refer to Diagnostic section for trouble shooting information. (page 35)

Periodic Maintenance

Overview

This section describes the basic chiller preventive maintenance procedures, and recommends the intervals at which these procedures should be performed. Use of a periodic maintenance program is important to ensure the best possible performance and efficiency from a CenTraVac® chiller.

Recommended purge maintenance procedures for the Purifier Purge unit are covered by PRGD-SVU01A-EN or the latest revision which can be obtained at the nearest Trane office.

Record Keeping Forms

An important aspect of the chiller maintenance program is the regular completion of records. Provided at the end of this manual are copies of the "Annual Inspection Check List and Report", "CenTraVac with UCP Commissioning Checklist and "Start-Up Test Log", a "Start-Up Test Log for Water Cooled CenTraVacs with UCP Control Panels" and "UCP "Settings Group" Menu Record". When filled out accurately by the machine operator, the completed logs can be reviewed to identify any developing trends in the chiller's operating conditions.

For example, if the machine operator notices a gradual increase in condensing pressure during a month's time, he can systematically check, then correct the possible cause(s) of this condition (fouled condenser tubes, noncondensable in the system, etcetera)

Daily Maintenance and Checks

[ ] Check the chiller's evaporator and condenser pressures, oil tank pressure, differential oil pressure and discharge oil pressure. Compare the readings with the values provided in the Normal Chiller Operating Characteristics table.

IMPORTANT: IT IS HIGHLY RECOMMENDED THAT THE OPERATING LOG BE COMPLETED ON A DAILY BASIS.

CAUTION

Moisture Contamination!

IF FREQUENT PURGING IS REQUIRED, MONITOR PURGE PUMPOUT RATE, IDENTIFY AND CORRECT SOURCE OF AIR OR WATER LEAK AS SOON AS POSSIBLE. Failure to do so can shorten chiller life expectancy, due to moisture contamination caused by leakage.

[ ] Check the oil level in the chiller oil sump using the two sight glasses provided in the oil sump head. When the unit is operating, the oil level should be visible in the lower sight glass.

Periodic Maintenance

⚠ WARNING

Hazardous Voltage w/ Capacitors!

Disconnect all electric power, including remote disconnects before servicing. Follow proper lockout/ tagout procedures to ensure the power cannot be inadvertently energized. For variable frequency drives or other energy storing components provided by Trane or others, refer to the appropriate manufacturer's literature for allowable waiting periods for discharge of capacitors. Verify with an appropriate voltmeter that all capacitors have discharged. Failure to disconnect power and discharge capacitors before servicing could result in death or serious injury.

Note: For additional information regarding the safe discharge of capacitors, see PROD-SVB06A-EN or PROD-SVB06A-FR

Weekly Maintenance

[ ] Complete all recommended daily maintenance procedures and checks. Complete logs on a daily basis.

Every 3 Months

[ ] Complete all recommended weekly maintenance procedures. Refer to the previous sections for details.

[ ] Clean all water strainers in the CenTraVac water piping system.

Every 6 Months

Normal Chiller Operating Characteristics

Operating Characteristic	Normal Reading
Approx. Evaporator Pressure	(6 to 9 PSIA) (-9 to -6 PSIG)
Approx. Condenser Pressure	(17 TO 27 PSIA) 2 to 12 PSIG (Standard Condensers)
Oil Sump Temperature:	
Unit Not Running	140°F to 145°F (60°C to 63°C)
Unit Running	80°F to 162°F (26.6°C to 72°C)
Differential Oil Pressure	18 to 22 psid

Notes:
1. Condenser pressure is dependent on condenser water temperature, and should equal the saturation pressure of HCFC-123 at a temperature above that of leaving condenser water at full load.
2. Normal pressure readings for ASME condensers exceed 12 PSIG.
3. Oil Tank Pressure 12" to 18" HG Discharge Oil Pressure 7 to 15 PSIG.

Periodic Maintenance

[ ] Complete all recommended quarterly maintenance procedures.

[ ] Lubricate the vane control linkage bearings, ball joints, and pivot points; as needed a few drops of light machine oil (SAE-20) is sufficient.

[ ] Lubricate vane operator tang o-rings as described in the maintenance section.

[ ] Lubricate the oil filter shutoff valve o-rings by removing the pipe plug and adding several drops of Trane OIL00022. Replace plug.

[ ] Drain the contents of the rupture disc and purge discharge ventline drip-leg, into an evacuated waste container minimally and more often if the purge is operated excessively.

Also, apply one or two drops of oil on the vane operator shaft and spread it into a very light film; this will protect the shaft from moisture and rust.

Off-Season Maintenance

During those periods of time when the chiller is not operated, be sure the control panel is energized. This is to keep the purge operational, the oil heater warm and will also keep air out of the machine.

Annual Maintenance

Shut down the chiller once each year to check the items listed ; a more detailed inspection checklist is provided on the "Model CVHE, CVHF and CVHG CenTraVac Annual Inspection Checklist and Report" illustrated in this manual.

[ ] Perform the annual maintenance procedures referred to in the Maintenance Section of the purge manual.

[ ] Use an ice water bath to verify that the accuracy of the evaporator refrigerant temperature sensor (4R10) is still within tolerance (+ or - 2.0° at 32°F (1° at 0°C)). If the evaporator refrigerant temperature displayed on the UCP's read-out is outside this 4-degree tolerance range, replace the sensor.

Note: If the sensor is exposed to temperature extremes outside its normal operating range (0°F to 90°F) (-18°C to 32°C), check its accuracy at six-month intervals.

Oil Maintenance

Compressor Oil Change on CVHE, CVHF, CVHG

Recommendations are to subscribe to an annual oil analysis program rather than automatically change the oil as part of scheduled maintenance. Change the oil only if indicated by the oil analysis. Use of an oil analysis program will reduce the chillers overall lifetime waste oil generation and minimize refrigerant emissions. The oil analysis should be performed by a qualified laboratory that is experienced in refrigerant and oil chemistry and in the servicing of Trane centrifugal chillers.

In conjunction with other diagnostics performed by a qualified service technician, oil analyses can provide valuable information on the performance of the chiller to help minimize operating and maintenance costs and maximize it's operating life. A drain fitting is installed in the oil filter top, after the oil filter, for obtaining oil samples.

Note: Use only Trane OIL00022. A full oil change is 9 gallons of OIL00022.

Oil Change Procedure

When oil analysis indicates the need to change compressor oil, use the following procedure for removing oil.

CAUTION

Heater Damage!

The oil sump heater must be deenergized before draining the sump. Failure to do so could possibly burn out the oil sump heater.

[ ] Draw the oil from the chiller through the oil charging valve on the chiller oil sump into an approved, evacuated tank; or,

[ ] Pump the oil from the chiller through the oil charging valve into an airtight resealable container, using a magnetically-driven auxiliary pump.

Forcing the oil from the oil sump by pressurizing the chiller (by raising chiller temperature or adding nitrogen) is not recommended.

Refrigerant dissolved in the oil can be removed and returned to the chiller by using an appropriate deep-vacuum recovery unit and heating and agitating the oil container. Follow all Federal, State and Local regulations with regard to disposal of waste oil.

Oil Maintenance

Replacing Oil Filter

Replace oil filter: (1) annually, (2) at each oil change, (3) or if erratic oil pressure is experienced during chiller operation.

Oil Filter Replacement

Use the following procedure to service the oil filter. Refer to Figure 34.

1. Run the oil pump for two to three minutes to insure that the oil filter is warmed up to the oil sump temperature.
2. Turn the oil pump motor off.
3. Pull the "D" handle on the rotary valve locking pin out of its detent and rotate the valve to the "DRAIN" position. An offset pointer is located on top of the valve with wrench flats to allow turning. The spring force on the locking pin should allow the pin to drop into a detent at this position.
4. Allow at least 15 minutes for the oil to drain from the filter back into the oil sump.
5. Pull the "D" handle to unlock the pin and rotate the valve to the "Change Filter" position. This isolates the filter from the unit. The locking pin should drop into a detent in this position.
6. Remove and replace the filter as quickly as possible. Tighten filter 2/3 to 3/4 turn per instructions written on the filter. Place the used filter in a reusable container. Follow all local, state and federal regulations to dispose of the filter. Pull the "D" handle to unlock the pin and rotate the valve to the "RUN" position. The locking pin should drop into a detent in this position. The chiller is now ready for operation.
7. Purge unit.
8. Check oil pressure 18-27 psi.

Maintenance

Other Maintenance Requirements

Compressors using new seal technology will not use O-rings. The O-ring has been replaced by Loctite 515 applied at a minimum film thickness of .010 applied across the width of the flange. The current jack bolt holes remain for disassembly.

CAUTION

Oil Supply System Problems!

Plugging of oil supply system could lead to bearing failure. Failure to use care could result in Loctite getting into the chiller which may cause problems with the Oil supply system and eductor system.

[ ] Inspect the condenser tubes for fouling; clean if necessary.

⚠ WARNING

Hazardous Voltage w/ Capacitors!

Disconnect all electric power, including remote disconnects before servicing. Follow proper lockout/ tagout procedures to ensure the power cannot be inadvertently energized. For variable frequency drives or other energy storing components provided by Trane or others, refer to the appropriate manufacturer's literature for allowable waiting periods for discharge of capacitors. Verify with an appropriate voltmeter that all capacitors have discharged. Failure to disconnect power and discharge capacitors before servicing could result in death or serious injury. Note: For additional information regarding the safe discharge of capacitors, see PROD-SVB06A-EN or PROD-SVB06A-FR

[ ] Measure the compressor motor winding resistance to ground; a qualified service technician should conduct this check to ensure that the findings are properly interpreted.

Contact a qualified service organization to leak-test the chiller; this procedure is especially important if the system requires frequent purging.

[ ] Use a nondestructive tube test to inspect the condenser and evaporator tubes at 3-year intervals.

Note: It may be desirable to perform tube tests on these components at more frequent intervals, depending upon chiller application. This is especially true of critical process equipment.

[ ] Depending on chiller duty, contact a qualified service organization to determine when to conduct a complete examination of the unit to discern the condition of the compressor and internal components.

Note: (a) Chronic air leaks, which can cause acidic conditions in the compressor oil and result in premature bearing wear; and, (b) Evaporator or condenser water tube leaks. Water mixed with the compressor oil can result in bearing pitting, corrosion, or excessive wear.

[ ] Submit a sample of the compressor oil to a Trane qualified laboratory for comprehensive analysis on an annual basis; this analysis determines system moisture content, acid level and wear metal content of the oil, and can be used as a diagnostic tool.

Lubrication

The only CVHE, CVHF and CVHG chiller component that requires periodic lubrication is the external vane linkage assembly and Rotary oil valve.

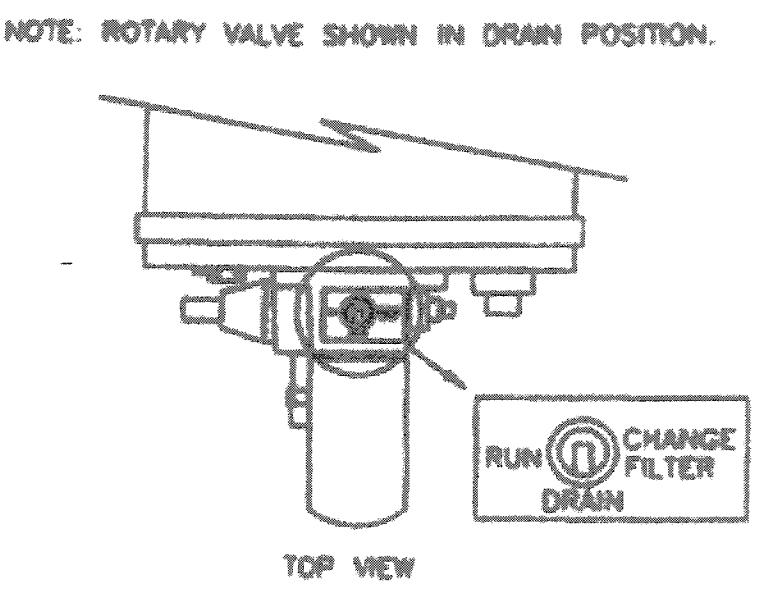
Lubricate the vane linkage shaft bearings and rod end bearings as needed with a few drops of light-weight machine oil.

The CenTraVac inlet guide vane tang operators should be serviced annually with R123 compatible grease. Use only Rheolube 734A, available from Trane as LUB00033 (16oz. standard grease gun cartridge) or LUB00063 (3oz. mini grease gun cartridge)

To service the 1st stage tang operator of all units except CVHF extended capacity chillers with 1470 or 1720 compressors.

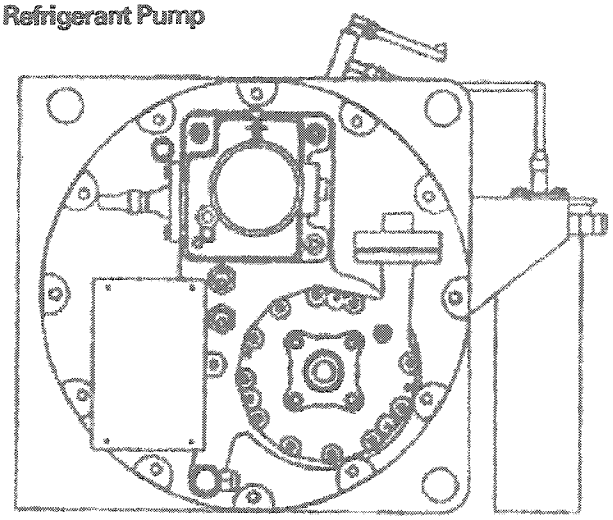
1. The chiller must be off.
2. Carefully remove any insulation that may have been placed over the two lubrication ports of the tang operator base. This insulation will need to be replaced after the service is complete.
3. Note the position of the tang operator arm, note the placement of spacing washers etc., then disconnect the linkage rod from the tang operator arm. Manually move the tang operator arm and note the amount of effort required to operate the assembly.
4. Loosen but DO NOT REMOVE the 1/16" NPT lubrication port plug that is highest on the assembly.
5. Loosen and remove the remaining lower 1/16" NPT plug.
6. Using a grease gun with an appropriate fitting, insert ONLY Rheolube grease into the open port until clean grease is seen to appear around the threads of the plug in the opposite port.
7. Tighten the plug that was loosened in step 4. Tighten the plug to hand tight plus 1/4 to 1/2 turn.
8. Remove the grease fitting, if used.

Maintenance



DO NOT LEAVE GREASE FITTINGS INSTALLED.
If grease fittings have been used for this procedure then they MUST BE REMOVED before returning the unit to service. Grease fittings are not vacuum-tight and will become a leak path.

9. Using a clean wooden dowel or other similar tool, remove excess grease from the remaining open lubrication port.
10. Clean and then lightly coat the threads of the plug with Rheolube grease and re-install it into the lubrication port. Tighten the plug to hand tight plus 1/4 to 1/2 turn.
11. Before reconnecting the vane linkage, grasp the tang operator arm and manually operate the vane assembly. If it is now difficult to move, then the tang operator may have become "hydraulically locked" because of excess grease in the assembly. This situation could cause damage to the o-rings of the assembly. If this occurs then remove one of the lubrication plugs, remove some of the grease, then re-install the plug.
12. Reconnect the linkage to the tang operator arm. Ensure the spacer washers between the linkage and the arm are properly placed and that the assembly does not bind. Re-install any insulation that was cut or removed. The unit may be restarted.



To service the 1st and 2nd stage tang operators on CVHF and CDHF extended capacity chillers with 1470 or 1720 compressors.
The 1st and 2nd stage rotary inlet guide vane tang operators of the extended capacity chillers also require periodic lubrication, at least annually, with R123 compatible Rheolube grease. These actuators have two 1/8" NPT plugs located 180 degrees apart, with one on the top and the other on the bottom of the operator base. Use the same procedure as described above, except that it will be necessary to temporarily disconnect the vane actuators from the tang operator arms in order to test for a "hydraulically locked" condition.

The oil valve block rotary valve uses dual O-Rings to seal to atmosphere. These should be manually lubricated by removing the pipe plug at the valve lubrication port and placing a few drops of Trane OIL00022 in the cavity. Be sure to reinstall the pipe plug when lubrication is completed.

Figure 33. Rotary valve in drain position

Front View with Refrigerant Pump

Maintenance

Refrigerant Charge

⚠ WARNING

Contains Refrigerant!

System contains oil and refrigerant and may be under positive pressure. Recover refrigerant to relieve pressure before opening the system. See unit nameplate for refrigerant type. Do not use non-approved refrigerants, refrigerant substitutes, or refrigerant additives.

Failure to follow proper procedures or the use of non-approved refrigerants, refrigerant substitutes, or refrigerant additives could result in death or serious injury or equipment damage.

The refrigerant charging procedure for Trane centrifugal chillers is:

1. If water is present in the tubes, break machine vacuum with refrigerant vapor, or circulate water, to avoid tube damage.
2. Always use refrigerant compatible hoses or copper-tubing with self-sealing connections or shut-off valves.
3. Transfer the refrigerant using one of the following (listed in order of preference):
   a. An approved Trane low-pressure refrigerant recovery and recycle unit.
   b. The available pressure differential.
   c. Gravity. (Use a return vent line to refrigerant drums to equalize pressure.)
5. Do not use dry nitrogen to push refrigerant into the chiller as was common practice in the past. This will contaminate the charge and require excessive purging, which will result in unnecessary release of refrigerant.
6. Weigh in the proper charge.
7. Use recovery and recyle unit or vacuum pump to evacuate hoses; discharge outdoors.
8. If refrigerant is supplied in new returnable cylinders, be sure and refer to General Service Bulletin CVHE-SB-48B for information on returning cylinders. This service bulletin is available at the nearest Trane office.

Depending on the chiller duty, contact a qualified service organization to determine when to conduct a complete examination of the unit to discern the condition of the compressor and internal components.

Note: If your chiller is covered by a Trane extended warranty, the terms of that warranty may require that the procedures listed in the Periodic Maintenance section of this manual be followed for your extended warranty to remain in force. The terms may also require that the chiller be inspected by a Trane authorized warranty agent every 4-years or 40,000 operating hours, whichever occurs first. This inspection will include, at a minimum, a review of the annual inspection checklists and the daily operating logs, as well as performance of a leak test and a general inspection of the chiller. The owner is then required to follow the recommendations made as a result of this inspection at the owners expense.

Maintenance

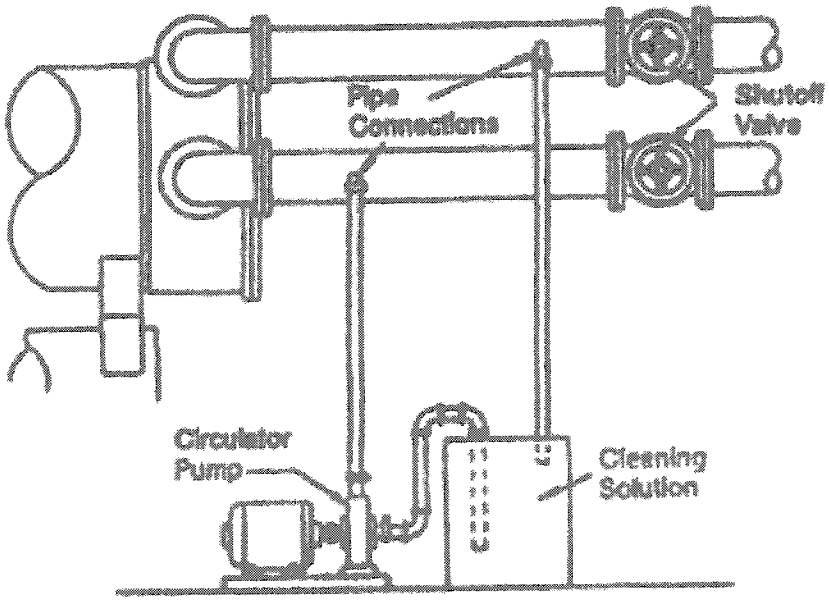
Recovery and Recycle Connections

To facilitate refrigerant removal and replacement, newer-design CVHE, CVHF and CVHG units are provided with a 3/4-inch vapor fitting with shutoff valve on the chiller suction and with a 3/4-inch liquid connection with shutoff valve at the bottom of the evaporator shell. (Refer to Refrigerant Handling Guidelines.)

Leak Testing

To leak-test a chiller containing full refrigerant charge, raise chiller pressure using a controlled hot water or electric-resistance system to a maximum of 8 psig. Do not use nitrogen, which will cause excessive refrigerant discharge by the purge system.

Cleaning the Condenser



CAUTION

Proper Water Treatment!

The use of untreated or improperly treated water in a CenTraVac may result in scaling, erosion, corrosion, algae or slime. It is recommended that the services of a qualified water treatment specialist be engaged to determine what water treatment, if any, is required. Trane assumes no responsibility for equipment failures which result from untreated or improperly treated water, or saline or brackish water.

See Figure 34 which shows a Typical Chemical Cleaning Setup.

Figure 34 - Typical Chemical Cleaning Setup

Maintenance

Condenser tube fouling is indicated when the approach temperature (the difference between the condensing refrigerant temperature and the leaving condenser water temperature) is higher than predicted.

If the annual condenser tube inspection indicates that the tubes are fouled, two cleaning methods, mechanical and chemical, can be used to rid the tubes of contaminants.

Use the mechanical cleaning method to remove sludge and loose material from smooth-bore tubes.

To clean other types of tubes including internally-enhanced types, consult a qualified service organization for recommendations.

1. Remove the retaining nuts and bolts from the water box covers at each end of the condenser. Use a hoist to lift the covers off the water box. (A threaded connection is provided on each water box cover to allow insertion of an eyebolt).
2. Work a round nylon or brass bristled brush (attached to a rod) in and out of each of the condenser water tubes to loosen the sludge.
3. Thoroughly flush the condenser water tubes with clean water.

Scale deposits may be best removed by chemical means. Be sure to consult a qualified chemical house in the area (one familiar with the local water supply's chemical mineral content) for a recommended cleaning solution suitable for the job. Remember, a standard condenser water circuit is composed solely of copper, cast iron and steel.

CAUTION

Unit Corrosion Damage!

Proper procedures must be followed when using corrosive chemicals to clean water side of unit. It is recommended that the services of a qualified chemical cleaning firm be used. Proper personal protective equipment as recommended by the chemical manufacturer should be used. Refer to the chemicals MSDS sheet for proper safety procedures. Failure to follow proper procedures could result in corrosion damage to the unit and tubes.

IMPORTANT: ALL OF THE MATERIALS USED IN THE EXTERNAL CIRCULATION SYSTEM, THE QUANTITY OF THE SOLUTION, THE DURATION OF THE CLEANING PERIOD, AND ANY REQUIRED SAFETY PRECAUTIONS SHOULD BE APPROVED BY THE COMPANY FURNISHING THE MATERIALS OR PERFORMING THE CLEANING.

REMEMBER, HOWEVER, THAT WHENEVER THE CHEMICAL TUBE CLEANING METHOD IS USED, IT MUST BE FOLLOWED UP WITH MECHANICAL TUBE CLEANING, FLUSHING AND INSPECTION.

Cleaning the Evaporator

Since the evaporator is typically part of a closed circuit, it does not accumulate appreciable amounts of scale or sludge. Normally, cleaning every 3 years is sufficient. However, on open CVHE, CVHF and CVHG systems, such as air washers, periodic inspection and cleaning is recommended.

Control Settings and Adjustments

Time delays and safety control cutout settings need to be checked annually. For control calibration and check-out, contact a Trane qualified service organization.

Maintenance

Purge System

Because some sections of the chiller's refrigeration system operate at less-than-atmospheric pressure, the possibility exists that air and moisture may leak into the system. If allowed to accumulate, these noncondensables become trapped in the condenser; this increases condensing pressure and compressor power requirements, and reduces the chiller's efficiency and cooling capacity.

The Trane EarthWise Purge is the only purge system available for the CVHE, CVHF and CVHG chiller. The purge is designed to remove noncondensable gases and water from the refrigeration system. EarthWise Purge unit operation, maintenance and trouble shooting is covered by a separate operation and maintenance manual, which may be obtained from the nearest Trane office.

Overview

This section describes extended storage requirements for UCP installed CVHE, CVHF and CVHG chillers to be removed from service for an undetermined length of time.

Unit Preparation

The following steps are necessary in order to properly prepare a unit for storage.

1. Remove all liquid refrigerant if the unit is charged.

⚠ WARNING

Contains Refrigerant!

System contains oil and refrigerant and may be under positive pressure. Recover refrigerant to relieve pressure before opening the system. See unit nameplate for refrigerant type. Do not use non-approved refrigerants, refrigerant substitutes, or refrigerant additives.

Failure to follow proper procedures or the use of non-approved refrigerants, refrigerant substitutes, or refrigerant additives could result in death or serious injury or equipment damage.

2. After the liquid refrigerant is removed, using a recovery or recycle unit or vacuum pump, pull a vacuum to remove remaining refrigerant vapor from the unit.
3. After all traces of refrigerant are out of the unit, a positive nitrogen charge should be put into the unit (6 to 8 psig). This positive pressure must be checked monthly to insure no noncondensables get into the unit. Use a pressure gage on the evaporator shell to verify that the 6 to 8 psig dry nitrogen holding charge is still in the chiller. If this charge has escaped, contact a qualified service organization and the Trane sales engineer that handled the order.
4. The refrigerant charge should be stored in proper refrigerant containers. Due to possible leakage, do not store in used drums.
5. Maintain control power to the control panel. This will maintain oil temperature in the oil sump and the capability of the control panel to present report information. The Chiller Reports should be viewed once a week for normal readings. Any abnormal observation must be reported to the Trane Sales Engineer that handled the order.

Maintenance

⚠ WARNING

Hazardous Voltage w/ Capacitors!

Disconnect all electric power, including remote disconnects before servicing. Follow proper lockout/ tagout procedures to ensure the power cannot be inadvertently energized. For variable frequency drives or other energy storing components provided by Trane or others, refer to the appropriate manufacturer's literature for allowable waiting periods for discharge of capacitors. Verify with an appropriate voltmeter that all capacitors have discharged. Failure to disconnect power and discharge capacitors before servicing could result in death or serious injury.

Note: For additional information regarding the safe discharge of capacitors, see PROD-SVB06A-EN or PROD-SVB06A-FR

6. Remove the factory installed jumper or the field installed wiring on terminals in the unit control panel. This will prevent unwanted chiller operation.
7. Set the purge operating mode to OFF on UCP chillers.
8. The oil can be left in the unit.
9. The water side should not cause a problem if shut down and drained. There may be slight scaling inside the tubes, but not enough to cause a problem. The customer should inspect and clean tubes before the unit is returned to service.

IMPORTANT: DO NOT USE UNTREATED OR IMPROPERLY TREATED WATER, OR EQUIPMENT DAMAGE MAY OCCUR.

IMPORTANT: SCALE DEPOSITS ARE BEST REMOVED BY CHEMICAL MEANS. BE SURE TO CONSULT ANY QUALIFIED CHEMICAL HOUSE IN THE AREA (ONE FAMILIAR WITH THE LOCAL WATER SUPPLY'S CHEMICAL MINERAL CONTENT) FOR A RECOMMENDED CLEANING SOLUTION SUITABLE FOR THE JOB.

10. Motor bearings: If the motor sits for a long time the bearings could take a set and cause bearing problems or replacement later. Once every six months the chiller oil pump must be started and the compressor motor bump started to rotate the shaft. Contact a qualified service organization to perform this task. If the compressor motor cannot be bump started, then the shaft must be rotated manually by a qualified service organization.
11. Obtain an oil analysis initially after six months of storage, and once each succeeding year. If no oil breakdown is evident do not change the oil. If breakdown is evident, the oil must be replaced.
12. If the unit is stored for more than five years, and the storage is expected to be indefinite, the unit should be examined for leaks every five years from the initial storage date.
13. When the unit is to be returned to service, the services of a qualified service organization should be obtained to conduct all activities associated with the startup of a new chiller.

CenTraVac®
Annual Inspection Check List and Report:

Compressor Motor

- ☐ Motor Continuity check
  Good ☐ Open ☐
- ☐ Check and tighten motor terminals
- ☐ Meg Motor
  Phase 1 ☐ Phase 2 ☐ Phase 3 ☐
- ☐ Check nameplate rating
  Amps ☐

Starter

- ☐ Check condition of starter contacts
  Good ☐ Fair ☐ Replace ☐
- ☐ Check, tighten if necessary all connections per manufactures specs

Oil Sump

- ☐ Change oil
  If oil analysis, refer to program procedure
- ☐ Gallons (9) required
- ☐ Refrigerant/Oil pump motor ground check
  Good ☐ Open ☐
- ☐ Check motor terminal
- ☐ Change oil filter

Condenser

- ☐ Visually inspect for scaling in tubes; not findings and make recommendations

Control Circuits

- ☐ Low refrigerant temperature sensor check
  ___°F set point ___°F trip point (ice water)
- ☐ Leaving Evaporator water temperature sensor check-out
  ___°F set point ___°F trip point (ice water)
- ☐ Condenser High Pressure Switch check-out
  ___psig set point
  ___psig trip point
- ☐ Check Net Oil Pressure
- ☐ Check adjustment and operation of inlet guide vane actuator stepper motor
  (Note: each machine is unique and must have the full open position number of steps input.)

Leak Test Chiller

- ☐ Refrigerant and oil analysis for acid content
- ☐ Sample refrigerant and oil for laboratory analysis (attach a copy of analysis to next monthly inspection report)

Purge Unit

- ☐ Review the purge operation maintenance manual and follow maintenance and/or inspection items identified.

CenTraVac®
Checksheet and Request for Serviceman

To: _____ Trane Service Company
S.O. No.: _____ Serial #s: _____
Job/Project Name: _____
Address: _____
The following items are being installed and will be completed by: _____
Check boxes if the task is complete or if the answer is "yes".

1. **CenTraVac**
   In place and piped. Do not insulate CenTraVac or adjacent piping. The contractor is responsible for any foreign material left in the unit. _____ ☐
2. **Piping**
   Chilled water piping connected to:
   - CenTraVac _____ ☐
   - Air handling units _____ ☐
   - Pumps _____ ☐

   Condenser and heat recovery condenser (as applicable) piping connected to:
   - CenTraVac _____ ☐
   - Pumps _____ ☐
   - Cooling tower _____ ☐
   - Heating loop (as applicable) _____ ☐

   Make-up water connected to cooling tower _____ ☐
   Water supply connected to filling system _____ ☐
   Systems filled _____ ☐
   Pumps run, air bled from system _____ ☐
   Strainers cleaned _____ ☐

3. **Flow Balancing Valves Installed**
   Leaving chilled water _____ ☐
   Leaving condenser water _____ ☐
   Heat recovery condenser leaving water _____ ☐

4. **Gauges, Thermometers and Air Vents**
   Installed on both sides of evaporator _____ ☐
   Installed on both sides of condenser and heat recover condenser (as applicable) _____ ☐

5. **Wiring**
   Compressor motor starter has been furnished by or approved by Trane La Crosse, WI _____ ☐
   Full Power available _____ ☐
   Interconnecting wiring, starter to panel (as req'd) ☐
   External interlocks (flow swtch, pumps aux, etc) ☐
   Chiller motor connection (remote starters)* _____ ☐
   Chilled water pump (connected and tested) _____ ☐
   Condenser water pump (connected and tested) ☐
   Cooling tower fan rotation checked _____ ☐
   Heat recovery condenser water pump (as applicable) _____ ☐
   Power available for Service tools 115 VAC _____ ☐
   All controls installed and connected _____ ☐
   All magnetic starters installed and connected _____ ☐

   *Note: Do not make final remote starter to compressor motor connections until requested to do so by the Trane Service representative.

6. **Testing**
   Dry nitrogen available for pressure testing _____ ☐
   Trace gas amounts of Refrigerant-22 or R-134a available for leak testing, if necessary _____ ☐

7. **Refrigerant On Job Site** _____ ☐

8. **Systems Can Be Operated Under Load Conditions** _____ ☐

9. **Electrical, Control Man and Contractor's Representative Are Available to Evacuate, Charge and Test the CenTraVac under Serviceman's Supervision** _____ ☐

10. **Equipment Room**
    Does the equipment room have a refrigerant monitor/sensor capable of monitoring and alarming within the allowable exposure level of the refirgerant? _____ ☐
    Does the installation have properly placed and operating audible and visual refrigerant alarms? _____ ☐

Continued on next page.....

10. Equipment Room (continued)

Does the equipment room have proper mechanical ventilation? _____ ■

If it is required by local code, is a self-contained breathing apparatus available? ■

11. Owner Awareness

Has the owner been fully instructed on the proper use of refrigerant HCFC-123? _____ ■

Does the owner have a copy of the MSDS for refrigerant HCFC-123? _____ ■

Was the owner given a copy of the Refrigerant Handling Guidelines? _____ ■

Note: Additional time required to properly complete the start-up and commissioning, due to any incompleteness of the of the installation, will be invoiced at prevailing rates.

This is to certify that the CenTraVac chiller(s) has/have been properly and completely installed, and that the applicable items listed above have been satisfactorily completed.

Checklist Completed By _____

Signed: _____ ***Date:*** _____

In accordance with your quotation and our purchase order number _____, we will therefore require the presence of Trane service on the site, for the purpose of start-up and commissioning, by: Date: _____

Note: Advance notification is required to allow scheduling of the start-up as close as possible to the requested date.

Additional Comments/Instructions _____

_____

_____

_____

_____

_____

_____

_____

A copy of this completed form must be submitted to the Trane Service Agency that will be responsible for the start-up of the chiller.

CenTraVac Commissioning Checklist

Job Name _____ Location _____
Model # _____ Serial # _____
Sales Order # _____ Start-up Date _____

Note: The Unit Installation, Operation and Maintenance Manuals including Warning and Cautions, Applicable Service Alerts and Bulletins, Submittals, and Design Specifications must be used in conjunction with this checklist.

I. PRECOMMISSIONING PROCEDURES

A. Obtain Installation Check Sheet

This must be prepared by installer for a particular unit, verifying the unit is ready for commissioning.

B. Obtain Design (order) Specification Data

This indicates the design criteria of the particular unit. A unit cannot be properly commissioned unless this data is known. It is the responsibility of the selling office to furnish this data.

C. Obtain Wiring Diagrams

The "as-wired" electrical diagram should be compatible with the recommended Trane submittals and diagrams. Are customer added external/remote control circuits compatible?

☐ Yes ☐ No

D. General Installation Observations

☐ 1. Is there any apparent shipping or rigging damage? ☐ Yes ☐ No

2. Record the unit pressure upon receipt:_____psig. If there is no pressure, a leak test will have to be done before the unit can be evacuated and charged.

☐ 3. Is the water piping correctly installed?

Flow Switches	☐ Yes	☐ No	Pressure Gauges	☐ Yes	☐ No
Isolations Valves	☐ Yes	☐ No	Flow Balancing Valves	☐ Yes	☐ No
Thermometer Wells	☐ Yes	☐ No	Vent Cocks and Drains	☐ Yes	☐ No

☐ 4. Have proper clearances around the unit been maintained per submittal and/or Installation?
Are there Manual guidelines available
☐ Yes ☐ No

☐ 5. Is power wiring of adequate ampacity and correct voltage?
☐ Yes ☐ No

☐ 6. Is the unit base acceptable, level, and is the unit on isolators (rubber as supplied by Trane or spring type)?
☐ Yes ☐ No

☐ 7. Have the low voltage circuits been properly isolated from the higher voltage control and power circuits?
☐ Yes ☐ No

E. Comments _____

II. COMMISSIONING PROCEDURES

A. Pre-start Operations

1. Holding Charge

- ☐ _____psig. Must be positive pressure or leak test must be done.

2. Before relieving the holding charge, calibrate the H.P.C. high-pressure control

This is a check of pressure to the H.P.C. as well as calibration of the control.

Disconnect and cap the flare. Calibrate H.P.C. and reconnect flare.

- ☐ Relieve the holding charge.
- ☐ Check and if necessary, tighten all connections per proper specs.

3. Megohm the Motor (500 volt Meggar)

- ☐ Compressor motor Megohms - refer to temp/resistance chart for acceptable values. Remove surge suppressors before Megging. Never Meg test with the unit in a vacuum.

T1 to Earth____	T4 to Earth____	T1 to T2	T1 to T4____
T2 to Earth____	T5 to Earth____	T1 to T3	T2 to T5____
T3 to Earth____	T6 to Earth____	T2 to T3	T3 to T6____

4. Evacuation

Connect the vacuum pump to start evacuation. Use a 2-stage pump with at least 5 CFM capacity.

Connect to the evaporator-charging valve with a hose no smaller than 3/4 inch ID.

a. For the IT Cutler-Hammer Solid State Starter it is necessary to shut off all power to the unit prior to evacuating the chiller. The IT starter has terminals 4, 5, & 6 hot when the unit is off. Failure to shut off power to the chiller, with the vacuum pump hook up, will cause a motor failure.

5. Condenser

- ☐ Isolation and flow valves installed
- ☐ Calibrated thermometers and pressure gauges installed in/out condenser on machine side of any valve or elbow.
- ☐ If condenser pump controlled by UCP, is field wiring correct and complete?
- ☐ Condenser pump(s) run, system and strainers properly cleaned and/or flushed.
- ☐ Condenser water strainer in close proximity to entering connection of condenser.
- ☐ Previsions installed to properly maintain water treatment additives.
- ☐ Initial water treatment added to system
- ☐ Flow or differential pressure switch installed and where possible, wired in series with auxiliary of pump motor starter. Verify correct operation of flow proving circuit.
- ☐ Condenser water flow balance.

PSID design_____	PSID actual_____
GPM design_____	GPM actual_____

6. Evaporator

- ☐ _____psig. Must be positive pressure or leak test must be done.
- ☐ Calibrated thermometers and pressure gauges installed in/out of evaporator on machine side of any valve or elbow.
- ☐ If evaporator pump controlled by UCP, is field wiring correct and complete?

- [ ] Evaporator pump(s) run 24 hrs. System and strainers properly cleaned and/or flushed.
- [ ] Evaporator water strainer in close proximity to entering connection of evaproator.
- [ ] Provisions installed to properly maintain water treatment additives.
- [ ] Initial water treatment added to system.
- [ ] Flow or differential pressure switch installed and where possible, wired in series with auxiliary of pump motor starter. Verify correct operation of flow proving circuit.
- [ ] Evaporator water flow balanced.

PSID design_____ PSID actual_____

GPM design_____ GPM actual_____

7. Electrical and Controls

a. Motor Starter Panel

- [ ] All terminals tightened.
- [ ] Wiring free from abrasion, kinks, and sharp corners.
- [ ] Contactors and relays have freedom of movement.
- [ ] All contacts are free of corrosion or dirt. Panel is free of dust, debris etc.
- [ ] Check the ratio of the current transformers. Record the part numbers on the start-up log.
- [ ] Use only twisted shielded pair for the IPC circuit between the starter and the UCP on remote starters. Recommended wire is Belden 8760, 18 AWG. Polarity is critical.
- [ ] The low voltage IPC link (__30 volts) must be in separate conduit from the 115-volt wiring.
- [ ] IPC link routing within the starter panel must stay a minimum of 6 inches from higher voltages.
- [ ] Remote starter to UCP connections are complete and comply with Trane requirements. Verify oil pump interlock circuit to 1A7J2-4 and J2-2.
- [ ] Check the correctness of the power connections from the starter to the motor.
- [ ] Check the wiring to the starter for size, voltage and correct phase rotation (A-L1, B-L2, & C-L3)
- [ ] Check the equal phase representation in each power-wiring conduit.

b. Control Panel

- [ ] All terminals tightened.
- [ ] Wiring free from abrasion, kinks, and sharp corners.
- [ ] Low voltage wires are isolated from high voltage wires.
- [ ] Panel is free of dust, debris etc.
- [ ] "Power Up" the control panel. (Non-AFD Starters)
    1. Starter disconnect locked open.
    2. Fuse 2F4 must be removed from the starter.
    3. Connect auxiliary 115VAC-power cord to Terminals 1X1-5(L1) and 1X1-17(L2) in the control panel. MAKE SURE OF THE POLARITY. THE 'HOT' SIDE MUST BE CONNECTED TO TERMINAL 1X1-5(L1) AND THE 'NEUTRAL' SIDE DO 1X1-17(L2).
    4. Plug in cord to 115VAC-power source. Control panel is now energized.
- [ ] Record the configuration and setpoints of the CH530 control system, using Service Tool.
- [ ] Using the unit nameplate data and the order specification, double check and reset, if required, the settings of RLA & STMS, using Service Tool.

If Evaporator and condenser water pumps are controlled by the UCP, use the DynaView (or Service Tool) manual override menu to manually start and test the control of the pumps.

- ☐ Check the setting of the oil pressure-regulating valve.
  1. Use the DynaView manual override of the UCP to manually start the oil pump.
  2. Proceed to the Compressor Report menu and observe the Differential Oil Pressure
  3. Adjust the oil pressure-regulating valve to maintain 18 to 22 psid. The oil pressure-regulating valve may require adjustment as the unit is started.
  4. This procedure also checks to ensure correct sensing of oil pressure. The Oil Pressure Cutout setting is adjustable within via the CH530 Service Tool.
  5. Return Oil Pump control to 'Auto' from within the DynaView.
- ☐ Check vane operator and vanes (Service Tool).
  1. Use the Service Tool manual override menu to manually override the vane control.
  2. Enter targets from 0% to 100% and observe vane operation. At minimum and maximum travel the operator should not exert any force on the vane assembly, adjust as required.
  3. Vane movement is smooth to open/close.
  4. Vane movement is reported back to the UCP.
  5. Return Vane control to 'Auto'.
- ☐ Dry run the starter (Service Tool).
  1. Make sure the starter disconnect is safety locked open.
  2. Use the Service Tool menu of the UCP to initiate the Starter Dry Run.
  3. Observe correct operation of starter contactors.
  4. Observe correct operation of transition complete signal (if required).
  5. Disable Starter Dry Run when complete.
- ☐ Remove Power
- ☐ Disconnect and remove temporary power cord.

B. Preparation for Start-up.

1. Evacuation and charging

- ☐ Evacuation leak test. When vacuum has been drawn down to 500 microns to 1000 micons, secure the vacuum pump. Wait for 12 hours for a valid vacuum leak test. If the rise in vacuum is less than 500 microns per 12 hours start-up may proceed.
- ☐ Charge refrigerant. MAKE SURE THE CHILLED WATER IS FLOWING TRHOUGH THE EVAPORATOR. Charge the prescribed amount of refrigerant through the liquid charging valve at the liquid inlet to the evaporator. Check that all drums contain a full amount of refrigerant. Amount charged _____ lgs and kg.

2. Electrical

- ☐ Disconnect all temporary power cords, replace all fuses, connect motor leads, make final electrical inspection.
- ☐ Power up the motor starter. Check for control voltage at control panel terminals 1X1-1 and 1X1-17.
  _____ Volts
- ☐ Check current to the oil sump heater.
  _____ Amperes
- ☐ As the oil heats up, finish any operations not yet completed in preparation for starting the unit.

C. Chiller Start-up

1. Make all preliminary checks.

- Oil temp, oil level, chilled water flow, chilled water load available (cooling units on) etc.

2. Start the unit

- If the phase rotation of the electrical power has not been positively confirmed, the actual rotation of the motor must be checked. Observe the rotation of the motor shaft through the sight glass on the end of the motor at the moment of start-up. Rotation must be CLOCKWISE. If the phase sequence is incorrect, confirmed by observation of the Phase Reversal diagnostic on the UCP, then the incoming power leads to the stator must be adjusted by authorized personnel.
- As the unit starts and runs, observe closely all operating conditions.
- Adjust the oil pressure regulator if necessary to 18 to 22 psi net.
- In the DynaView Purge Settings menu of the UCP, place the Purge Operating Mode to 'on' to allow the removal of non-condensables. It may also be necessary to disable the Purge Pumpout Limit timer found in the Purge Settings menu.
- After the unit has the system down to design leaving chilled water temp and is under control, and the purge is no longer relieving non-condensables, begin taking the start-up test log. Log the unit a minimum of 3 times at 15-minute intervals.
- In the DynaView Purge Settings menu of the UCP, return the purge-operating mode to 'Adaptive'.
- Restart the chiller and carefully observed the starting and loading sequence.

3. Instructions to the Chiller Operator.

- Instructions for starting, operating, and shutting down.
- Instructions for logging the unit.
- Instrucitons for periodic maintenance.

D. After 2 weeks of operation (International Units Only)

1. Replace the oil filter with the spare oil filter included in the control panel at time of shipment.

General Information

Literature Change History

CVHE-W-8A - June 1996
Addition of CVHG models and general update.

CVHE-W-8 - May 1994
Original issue of manual covering CVHE and CVHF models.

Design Sequences

CVHE units, A2 - 2J
CVHF units, A0 - T0
CVHG units, A0 - K0

Unit Models		
CVHE 60 HZ		
230	250	280
320	360	400
450	500	560
630	710	800
CVHE 50 HZ		
190	210	240
270	300	330
370	420	470
530	590	660
CVHF 60 HZ		
555	640	650
770	910	1060
1280		
CVHG 50 HZ		
670	780	920
1067		

Unit Information

To determine the electrical characteristics of a specific chiller, always refer to the unit nameplate. The unit nameplate is mounted on the left-hand side of the unit control panel and lists the installation and maintenance manuals required for the chiller. Example: CVHE-IN-8 and CVHE-M-7. The nameplate also provides electrical data for the compressor motor, oil pump motor, oil tank heater and purge compressor motor.

Use the chiller model number or product description block on the unit to determine the following information.

1. Machine design sequence;

2. Starter location (i.e., unit mounted versus remote-mounted);

3. Unit type (i.e., standard unit, heat recovery, auxiliary condenser, or free-cooling).

4. Whether the unit has Hot Gas By Pass.

For specific electrical connection and schematic information, always refer to the wiring diagrams and schematics that shipped with the unit.

As you review this manual, keep in mind that all field-installed wiring must conform to NEC guidelines, as well as to any applicable state and local codes. Be sure to satisfy any special grounding requirements that may be necessary.

All field-installed wiring should be checked for proper terminations, and for possible shorts or grounds.

Notice that warnings and cautions appear at appropriate intervals throughout this manual.

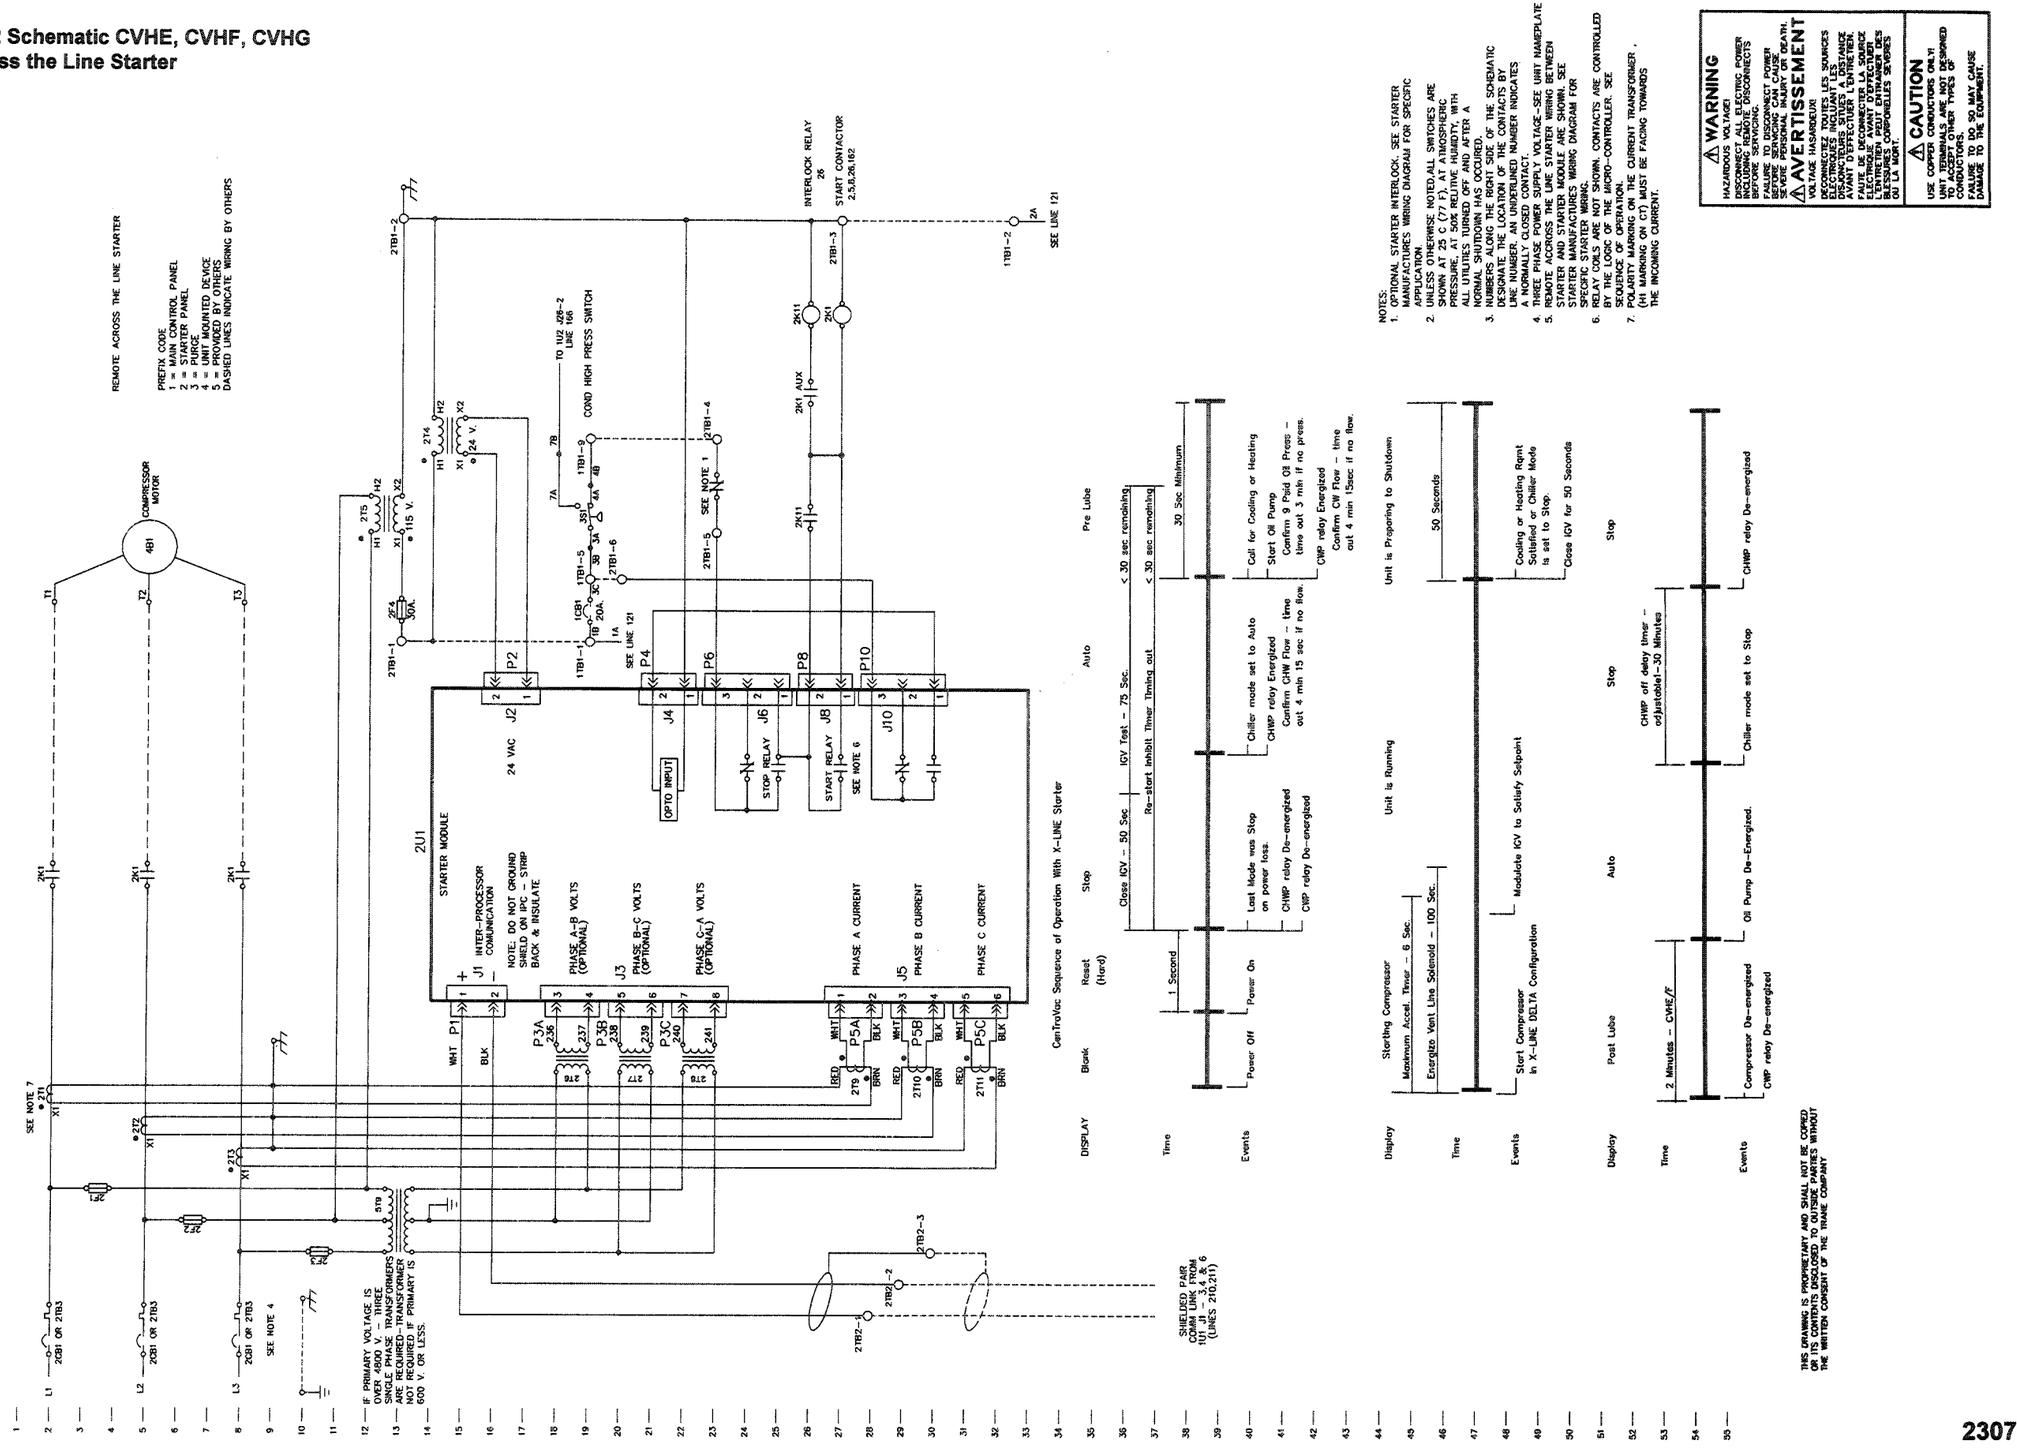
WARNINGS are provided to alert installing contractors to potential hazards that could result in personal injury or death, while CAUTIONS are designed to alert personnel to conditions that could result in equipment damage.

Caution!

⚠ The diagrams illustrated in this manual are typical for the above design sequence units. Refer to the "as-built" diagrams for specific information.

WARNING!

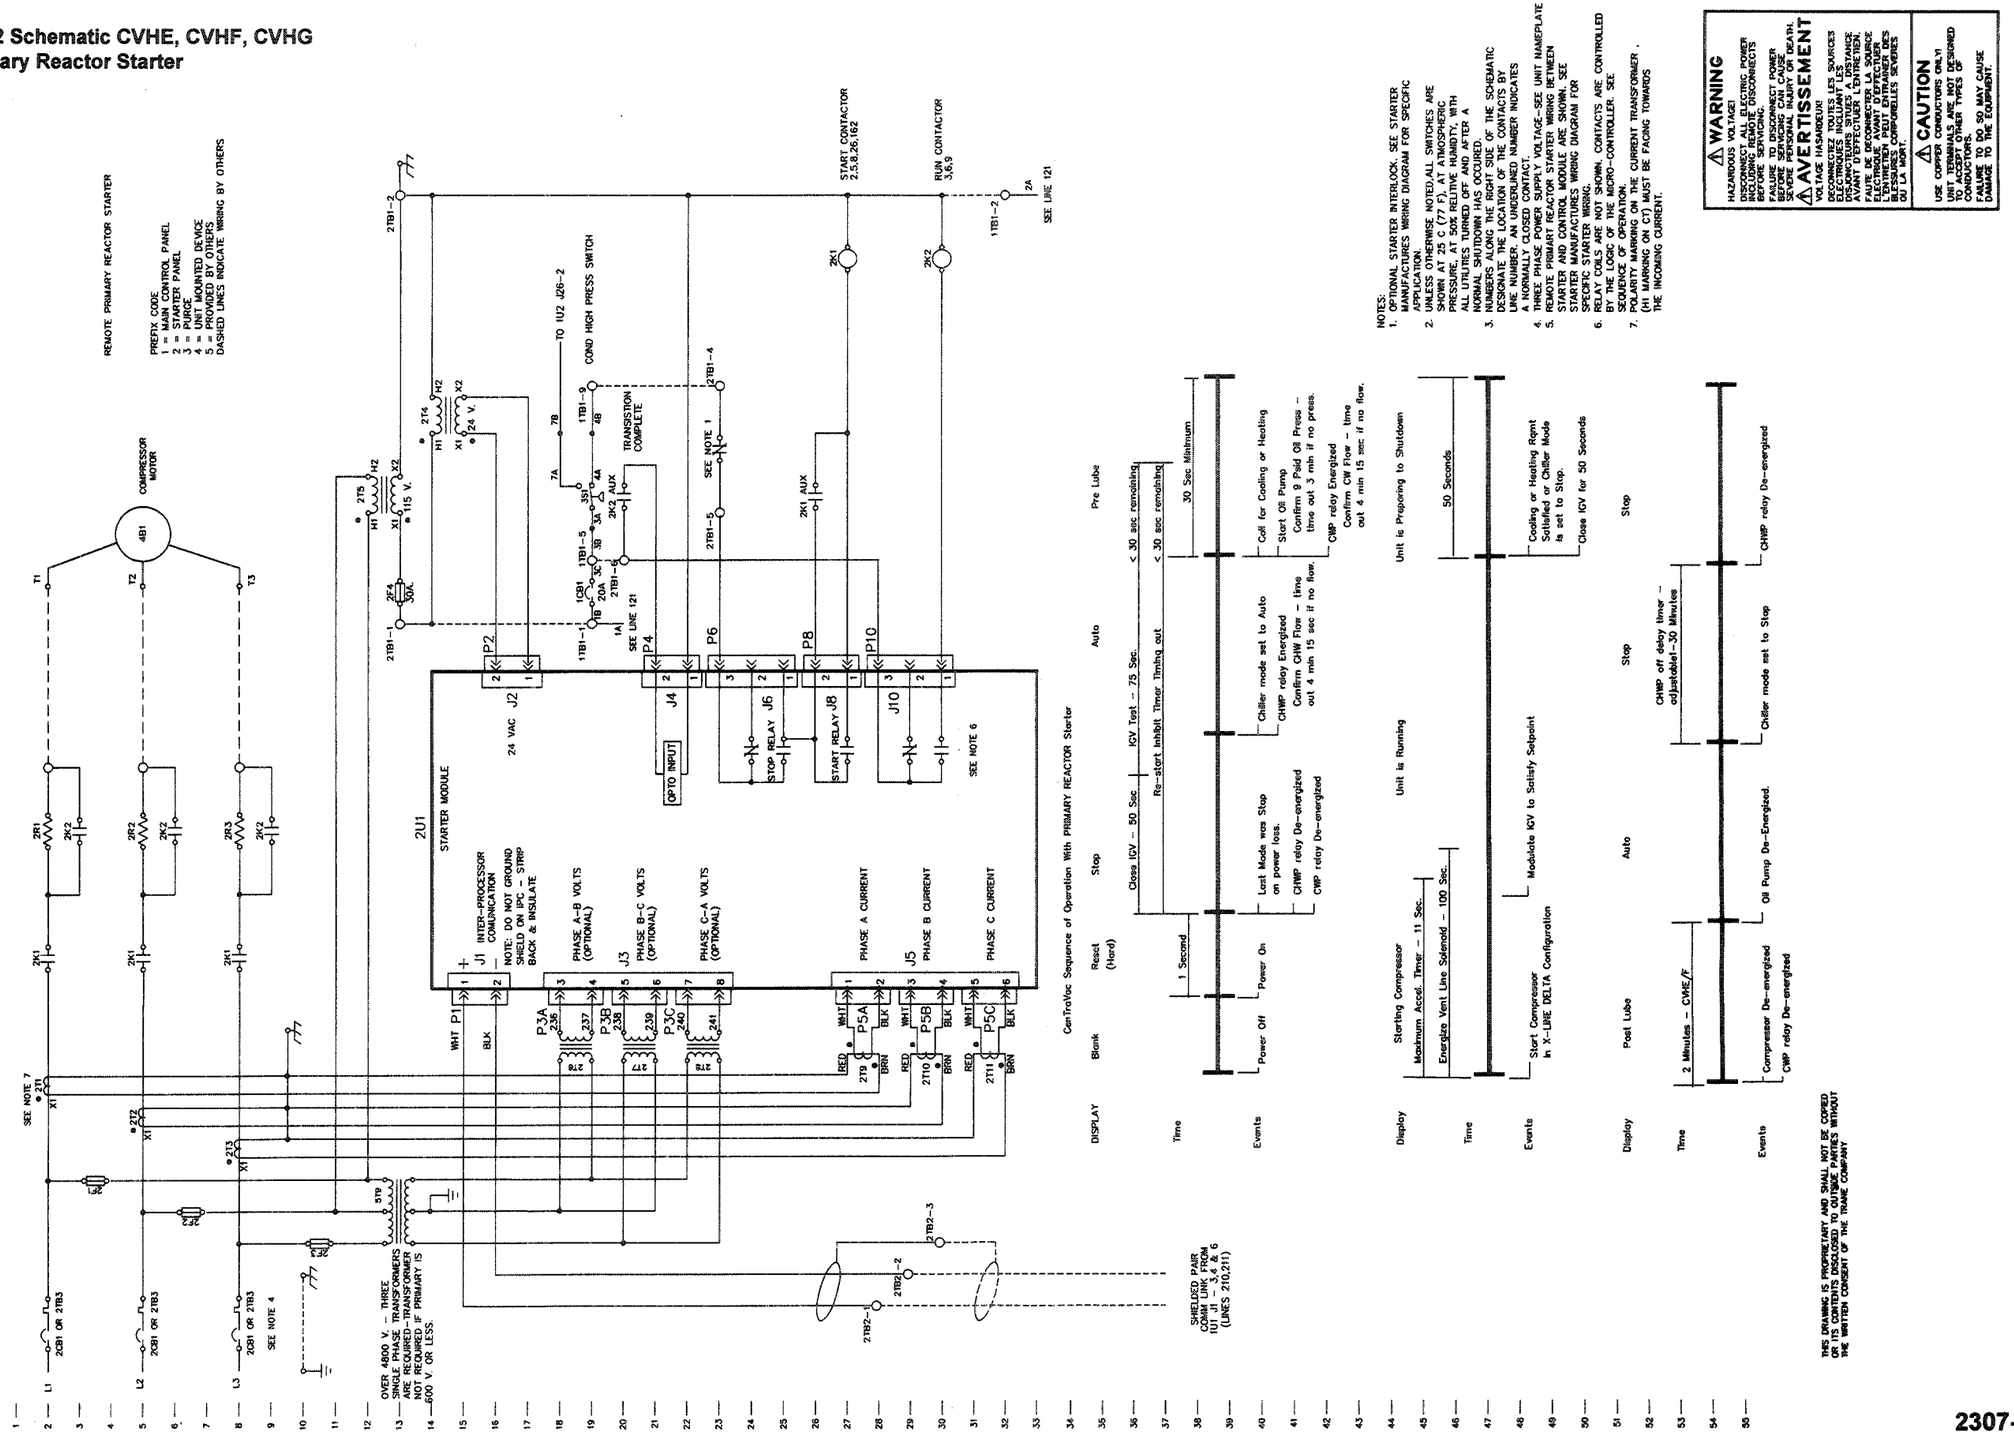
⚠ When servicing the machine, disconnect electrical power source to prevent injury or death due to electrical shock.



Adaptive Frequency Drive™

An overall field wiring layout of the Adaptive Frequency Drive is shown in this manual. The following information is offered when installing Adaptive Frequency Drive enclosure to provide electrical access. DO NOT CUT ADAPTIVE FREQUENCY DRIVE ENCLOSURE. Refer to the installation manual (AFDA-IN-1) which shipped with the Adaptive Frequency Drive.

WARNING!



⚠ **Do not cut Adaptive Frequency Drive enclosure. Debris falling inside frequency drive may cause failure of electronic components.**

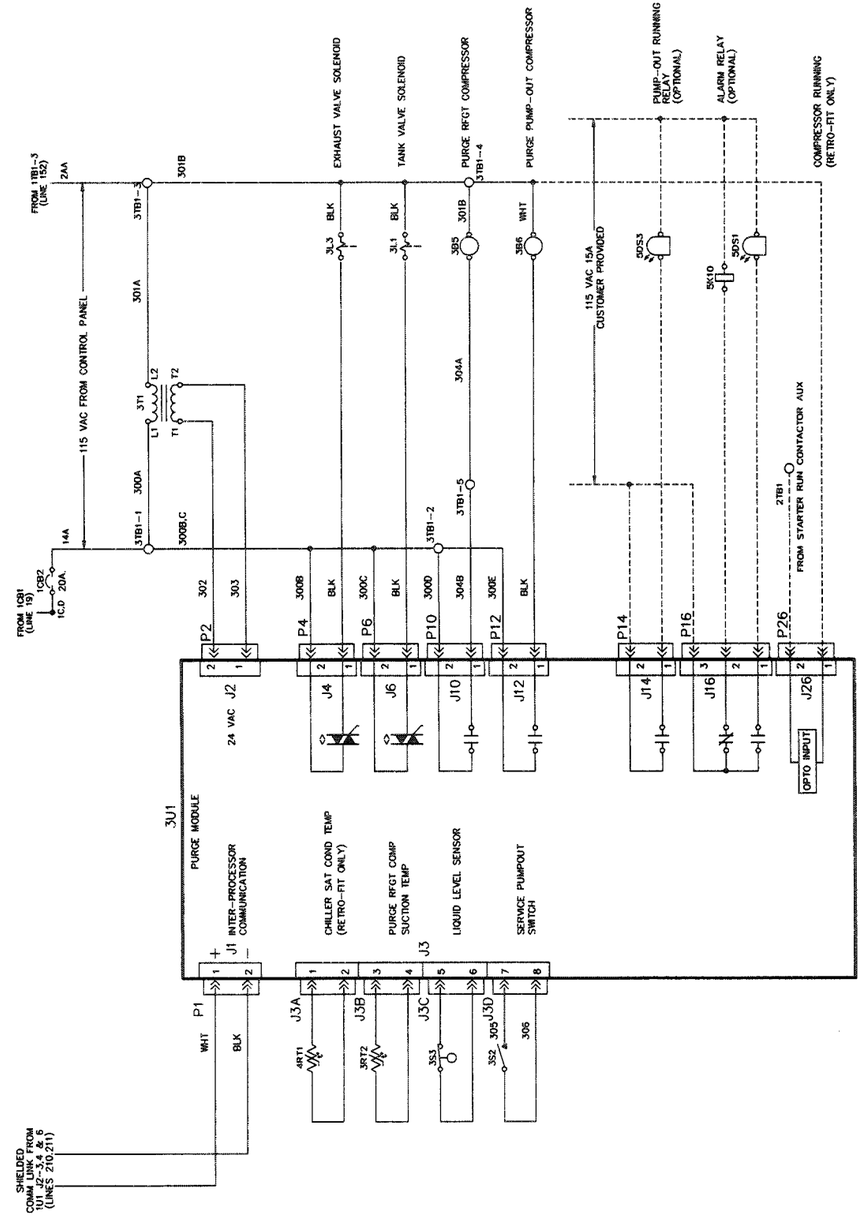
⚠ WARNING
HAZARDOUS VOLTAGE!
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
FAILURE TO DISCONNECT POWER BEFORE SERVICING COULD RESULT IN DEATH OR SERIOUS PERSONAL INJURY.



⚠ AVERTISSEMENT
VOLTAGE HASARDEUX!
DÉCONNECTEZ TOUTES LES SOURCES D'ALIMENTATION ÉLECTRIQUE Y COMPRIS LES DISJONCTEURS AVANT D'EFFECTUER L'ENTRETIEN.
AVANT DE PROCÉDER À L'ENTRETIEN, DÉCONNECTER TOUTES LES SOURCES D'ALIMENTATION ÉLECTRIQUE AFIN D'ÉVITER LES BLESSURES CORPORELLES GRAVES OU LA MORT.

⚠ CAUTION
USE COPPER CONDUCTORS ONLY!
UNIT TERMINALS ARE NOT DESIGNED TO ACCEPT OTHER TYPES OF CONDUCTORS.
FAILURE TO DO SO MAY CAUSE DAMAGE TO THE EQUIPMENT.

THIS DRAWING IS PROPRIETARY AND SHALL NOT BE COPIED OR ITS CONTENTS DISCLOSED TO OUTSIDE PARTIES WITHOUT THE WRITTEN CONSENT OF THE TRANE COMPANY

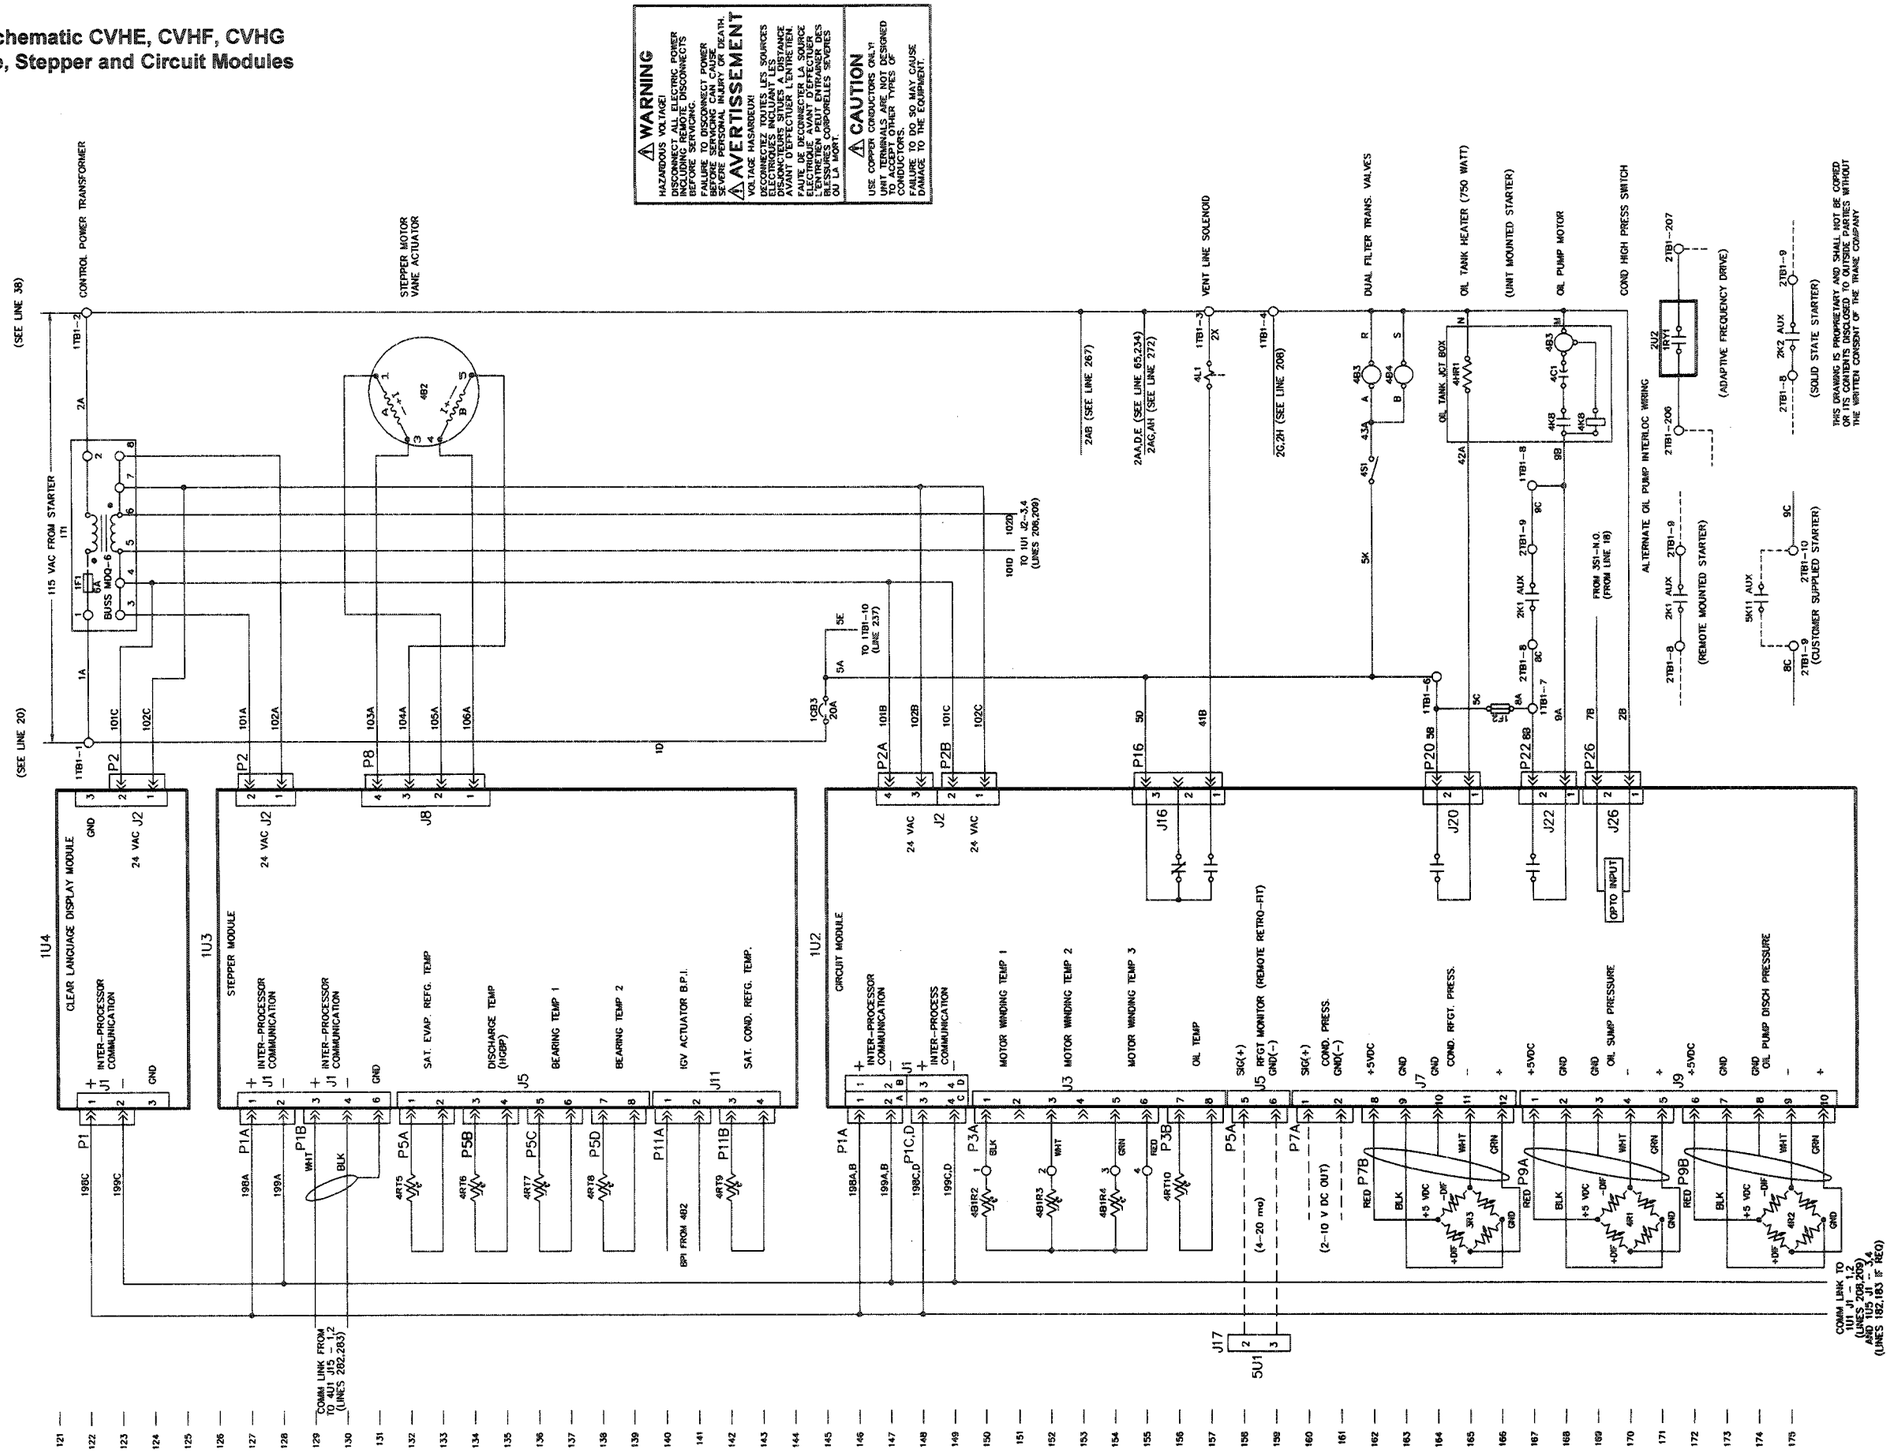
⚠ WARNING
HAZARDOUS VOLTAGE!
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
FAILURE TO DISCONNECT POWER BEFORE SERVICING COULD CAUSE SEVERE PERSONAL INJURY OR DEATH.



⚠ AVERTISSEMENT
VOLTAGE HASARDEUX!
DÉCONNECTEZ TOUTES LES SOURCES D'ALIMENTATION ÉLECTRIQUE, Y COMPRIS LES DISJONCTEURS DISTANTS, AVANT L'ENTRETIEN.
FAUTE DE DÉCONNECTER LA SOURCE ÉLECTRIQUE AVANT D'EFFECTUER L'ENTRETIEN PEUT ENTRAÎNER DES BLESSURES CORPORELLES SÉVÈRES OU LA MORT.

⚠ CAUTION
USE COPPER CONDUCTORS ONLY!
UNIT TERMINALS ARE DESIGNED FOR ACCEPTABLE TYPES OF CONDUCTORS.
FAILURE TO DO SO MAY CAUSE DAMAGE TO THE EQUIPMENT.

THIS DRAWING IS PROPRIETARY AND SHALL NOT BE COPIED OR LOANED OR DISCLOSED TO OTHERS FOR ANY PURPOSES WITHOUT THE WRITTEN CONSENT OF THE TRANE COMPANY

2307-5215 A

Figure 16
UCP2 Field Lay-Out Diagram
CVHE, CVHF, CVHG

PURPOSE: THIS DRAWING IS TO BE USED FOR ESTIMATING FIELD WIRING REQUIREMENTS.

NOTES:

1. DASHED LINES INDICATE FIELD WIRING BY OTHERS. CHECK SALES ORDER TO DETERMINE WHICH OPTIONS ARE SPECIFIED.
2. DO NOT ROUTE LOW VOLTAGE (30V MAX) WITH CONTROL VOLTAGE (115V) AND DO NOT POWER UNIT UNTIL CHECK-OUT AND START-UP PROCEDURES HAVE BEEN COMPLETED.
3. THE FOLLOWING OPTIONS ARE AVAILABLE, REFER TO MECHANICAL SPECIFICATION FOR DESCRIPTION:
   - <A> OPTIONS MODULE: REQUIRED W/FLAGGED FEATURES (REFER TO CONTROL SCHEMATICS)
   - <B> COMMUNICATIONS INTERFACE – COMM3 OR COMM4 (CONSULT SALES OFFICE FOR SELECTION)
   - <C> UNIT DISCONNECT, NON FUSED (STARTER OPTION)
   - <D> CHILLED WATER RESET-OUTDOOR AIR
4. EVAPORATOR AND CONDENSER FLOW SWITCHES ARE REQUIRED. THEY MUST BE INSTALLED AND WIRED TO THE TRANE PANEL BY THE INSTALLING CONTRACTOR. PURCHASE OF SWITCHES FROM TRANE IS OPTIONAL.

<5> AUXILIARY CONTROLS FOR A CUSTOMER SPECIFIED OR INSTALLED LATCHING TRIPOUT. THE CHILLER WILL RUN NORMALLY WHEN THE CONTACT IS CLOSED AND TRIP THE CHILLER OFF WITH A MANUALLY RESETTABLE DIAGNOSTIC WHEN THE CONTACT OPENS. MANUAL RESET IS ACCOMPLISHED AT THE DIAGNOSTIC KEY ON THE FRONT OF THE UNIT CONTROL PANEL (UCP2).

<6> AUXILIARY CONTROLS FOR A CUSTOMER SPECIFIED OR INSTALLED REMOTE AUTO/STOP FUNCTION. THE CHILLER WILL RUN NORMALLY WHEN THE CONTACT IS CLOSED AND STOP THE CHILLER WHEN THE CONTACT IS OPEN. RE-CLOSURE OF THE CONTACT WILL PERMIT THE CHILLER TO AUTOMATICALLY RETURN TO NORMAL OPERATION.

REQUIRED WIRING:

7. ALL CUSTOMER CONTROL CIRCUIT WIRING MUST HAVE A MINIMUM RATING OF 150 VOLTS.
8. ALL FIELD WIRING MUST BE IN ACCORDANCE WITH THE NATIONAL ELECTRICAL CODE (NEC), STATE AND LOCAL REQUIREMENTS. OUTSIDE THE UNITED STATES, OTHER COUNTRIES APPLICABLE NATIONAL AND/OR LOCAL REQUIREMENTS SHALL APPLY.

<9> THE UNIT CONTROL PANEL (UCP2) SUPPLIES A CONTACT OUTPUT TO CONTROL THIS CUSTOMER SUPPLIED DEVICE. MAXIMUM FUSE SIZE – 15 AMPS.

<10> COPPER WIRE ONLY – SIZED PER N.E.C. – BASED ON NAMEPLATE RATING.

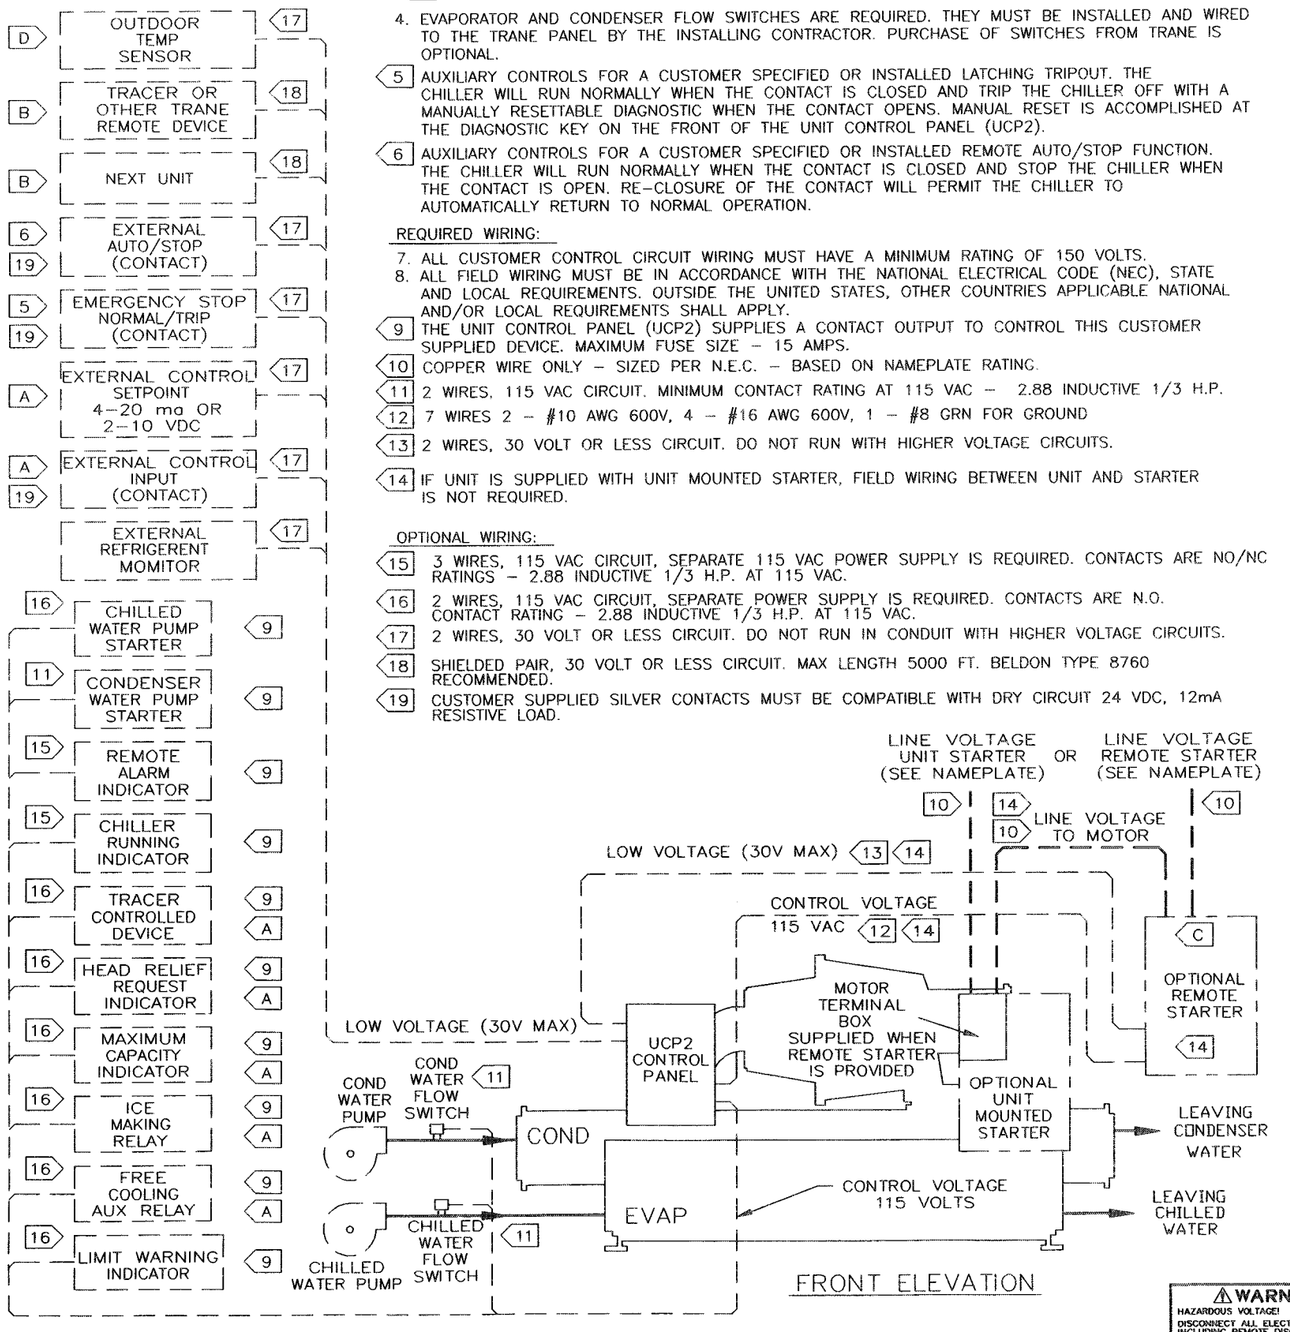
<11> 2 WIRES, 115 VAC CIRCUIT. MINIMUM CONTACT RATING AT 115 VAC – 2.88 INDUCTIVE 1/3 H.P.

<12> 7 WIRES 2 – #10 AWG 600V, 4 – #16 AWG 600V, 1 – #8 GRN FOR GROUND

<13> 2 WIRES, 30 VOLT OR LESS CIRCUIT. DO NOT RUN WITH HIGHER VOLTAGE CIRCUITS.

<14> IF UNIT IS SUPPLIED WITH UNIT MOUNTED STARTER, FIELD WIRING BETWEEN UNIT AND STARTER IS NOT REQUIRED.

OPTIONAL WIRING:



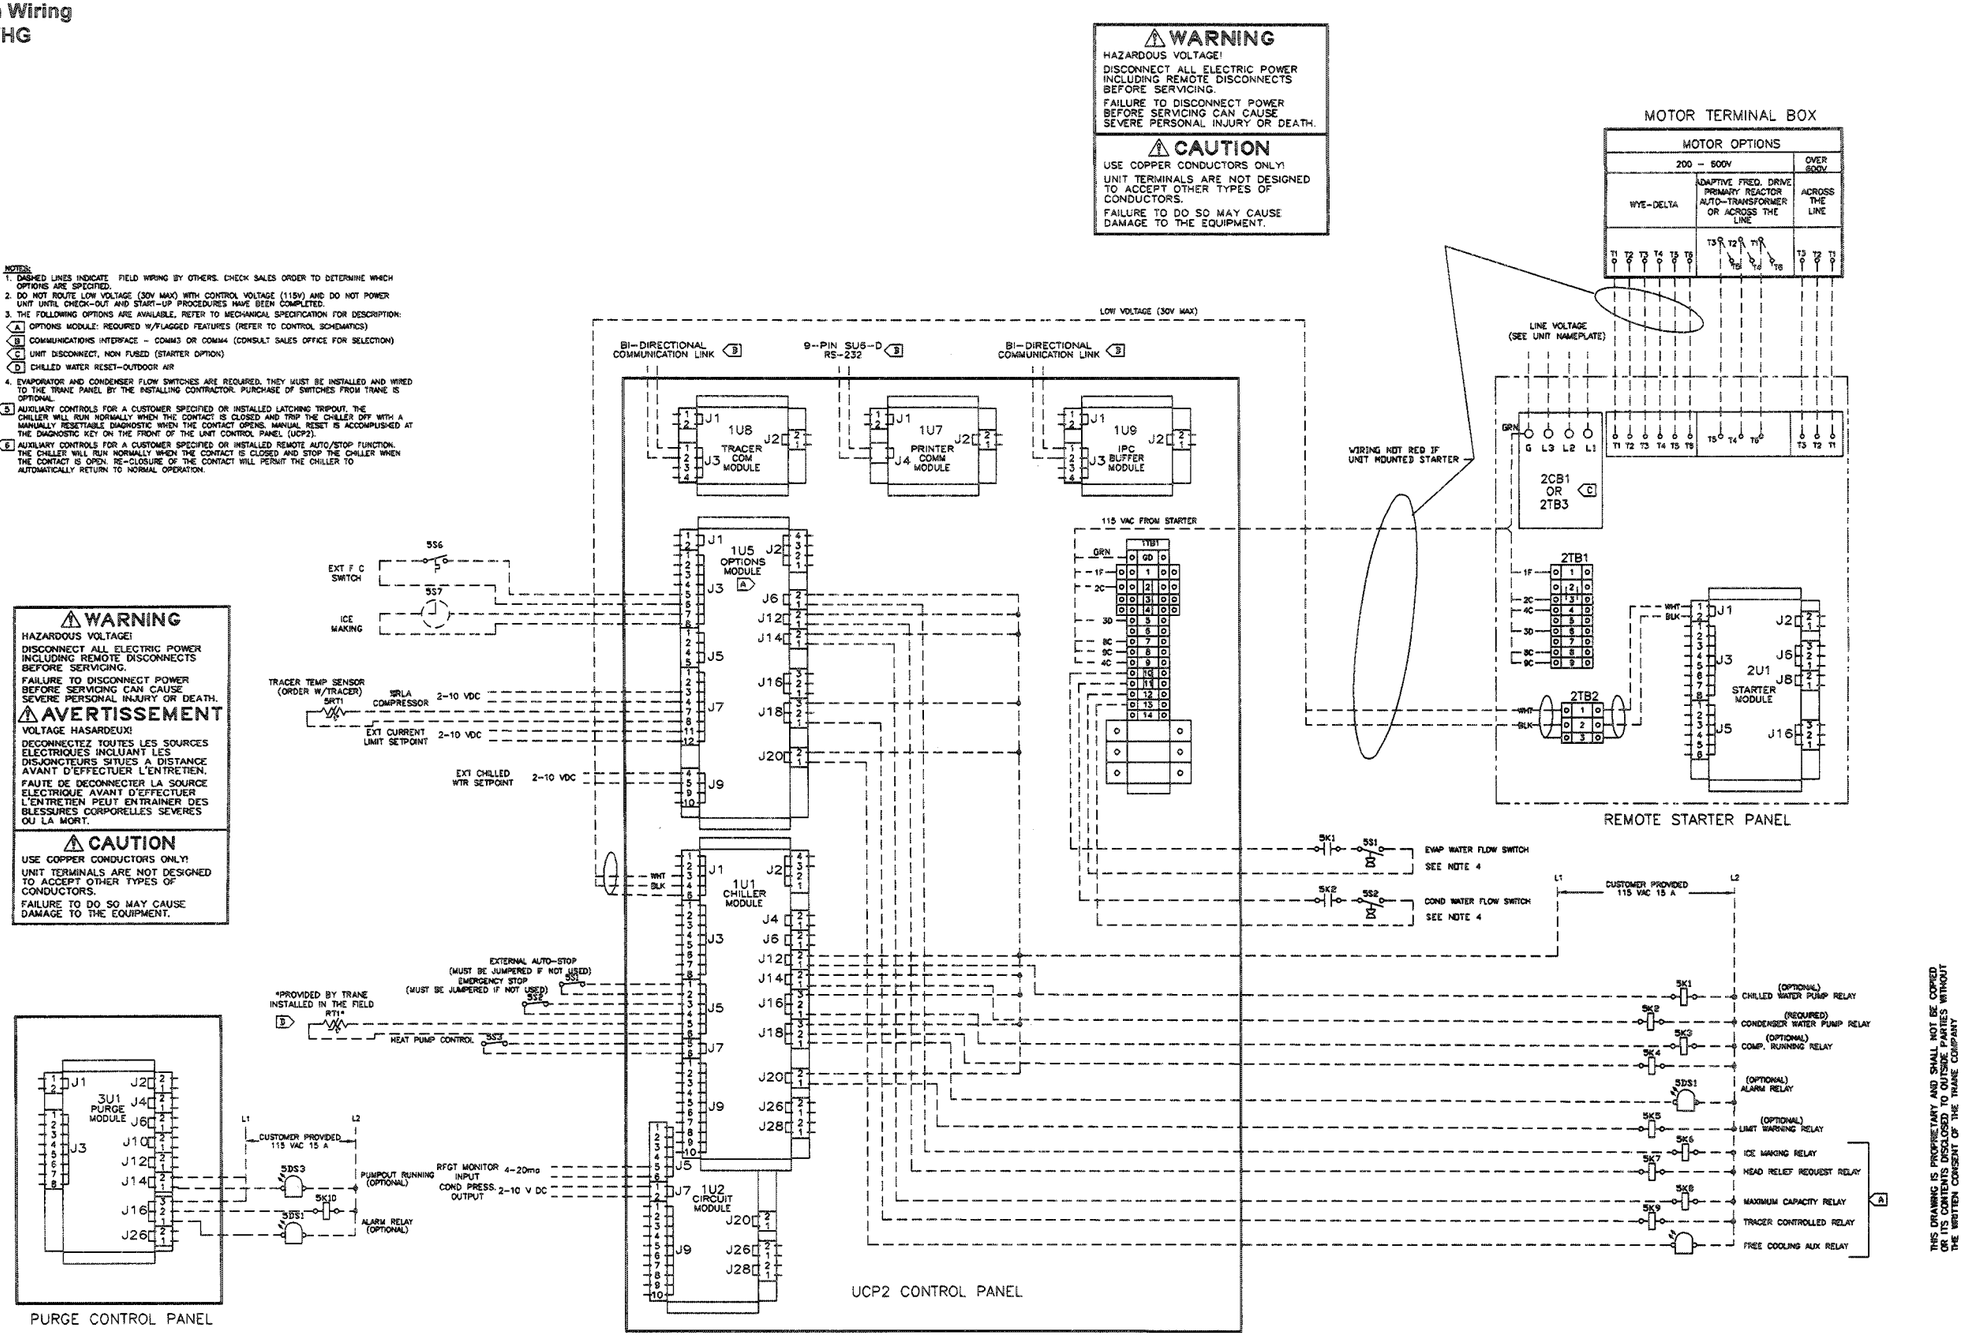
<15> 3 WIRES, 115 VAC CIRCUIT, SEPARATE 115 VAC POWER SUPPLY IS REQUIRED. CONTACTS ARE NO/NC RATINGS – 2.88 INDUCTIVE 1/3 H.P. AT 115 VAC.

<16> 2 WIRES, 115 VAC CIRCUIT, SEPARATE POWER SUPPLY IS REQUIRED. CONTACTS ARE N.O. CONTACT RATING – 2.88 INDUCTIVE 1/3 H.P. AT 115 VAC.

<17> 2 WIRES, 30 VOLT OR LESS CIRCUIT. DO NOT RUN IN CONDUIT WITH HIGHER VOLTAGE CIRCUITS.

<18> SHIELDED PAIR, 30 VOLT OR LESS CIRCUIT. MAX LENGTH 5000 FT. BELDON TYPE 8760 RECOMMENDED.

<19> CUSTOMER SUPPLIED SILVER CONTACTS MUST BE COMPATIBLE WITH DRY CIRCUIT 24 VDC, 12mA RESISTIVE LOAD.



THIS DRAWING IS PROPRIETARY AND SHALL NOT BE COPIED OR ITS CONTENTS DISCLOSED TO OUTSIDE PARTIES WITHOUT THE WRITTEN CONSENT OF THE TRANE COMPANY

⚠ WARNING
HAZARDOUS VOLTAGE!
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
FAILURE TO DISCONNECT POWER BEFORE SERVICING CAN CAUSE SEVERE PERSONAL INJURY OR DEATH.

⚠ AVERTISSEMENT
VOLTAGE HASARDEUX!
DECONNECTEZ TOUTES LES SOURCES ELECTRIQUES INCLUANT LES DISJONCTEURS SITUES A DISTANCE AVANT D'EFFECTUER L'ENTRETIEN.
FAUTE DE DECONNECTER LA SOURCE ELECTRIQUE AVANT D'EFFECTUER L'ENTRETIEN PEUT ENTRAINER DES BLESSURES CORPORELLES SEVERES OU LA MORT.

⚠ CAUTION
USE COPPER CONDUCTORS ONLY!
UNIT TERMINALS ARE NOT DESIGNED TO ACCEPT OTHER TYPES OF CONDUCTORS.
FAILURE TO DO SO MAY CAUSE DAMAGE TO THE EQUIPMENT.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

NOTICE

Warnings and Cautions appear at appropriate locations throughout this manual.

Read these carefully.

Warning: Indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

CAUTION: Indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury. It may also be used to alert against unsafe practices and where property-damage only accidents could occur.

Product Coding Definition

Introduction

The CDHF/CDHG is defined using the product definition and selection system. This system describes the product offerings in terms of a product coding block which is made up of feature categories and feature codes.

The operating components and options for any model CDHF or CDHG unit can be identified by referring to the alphanumeric product identification coding block located on the nameplate for the unit. The coding block precisely identifies all characteristics of a unit.

Typical Product Description Block

MODL CDHF	EVWA	CDCO FLNG	EVBS 2500
EVWC STD	CDBS 2500	PURG HERM	EVWC 150
EVCO FLNG	NTON 2500	SRT1 RPIR	HGBP W/O
DSEQ A0	CDWC 150	VOLT 460	

CDHF and CDHG Product Coding Explanation

MODL
Unit Model
CDHF = Duplex - 2 Stage Direct Drive
CDHG = Duplex - 3 Stage Direct Drive

DSEQ
Original Design Sequence - "JO"
Factory Assigned

HRTZ
Unit Hertz
50 = 50 Hertz
60 = 60 HertZ

NTON
Compressor Nominal Tonage
1250 = G Comp (2) - 670 Comp
1500 = F Comp (2) - 770 Comp
1750 = G Comp (2) - 780 Comp
2000 = F Comp (2) - 910 Comp
2100 = F Comp (2) - 1060 Comp
2150 = G Comp (2) - 1067 Comp
2500 = F Comp (2) - 1280 Comp

VOLT
Unit Voltage
3 Phase
380 = 380 Volt 60
380 = 380 Volt 50
400 = 400 Volt 50
415 = 415 Volt 50
440 = 440 Volt 60
460 = 460 Volt 60
480 = 480 Volt 60
575 = 575 Volt 60
600 = 600 Volt 60
2300 = 2300 Volt 60
2400 = 2400 Volt 60
3300 = 3300 Volt 60
3300 = 3300 Volt 50
4160 = 4160 Volt 60
6000 = 6000 Volt 50
6600 = 6600 Volt 50

CPM1

General Information

About this Manual

Literature Change History

CDHF-OM-1 = March, 1997

CDHF-OM-1A = May, 1998

CDHF-OM-1B = July, 2000

This manual contains information which describes the new refrigerant pump oil tank. It also includes operation and maintenance information of CDHF 60 Hz and CDHG 50 Hz. chillers equipped with microcomputer based controls systems. Throughout the manual reference is made to the CDHF model, but the information covered includes CDHG chillers as well.

By carefully reviewing the information in this manual and by following the instructions, the owner and operator can successfully operate and maintain a CDHF or CDHG chiller.

Important:
Diagnostic information pertaining to this chiller can be found in the Clear Language Display manual which shipped with the unit. If mechanical problems do occur, however, contact a qualified service organization to ensure proper diagnosis and repair of the unit.

Product Description Block

Trane 60 Hz. model CDHF units are defined by the product definition and selection system (PDS). Each unit is defined by the product description block which appears on the unit nameplate.

Commonly Used Acronyms

ASME = American Society of Mechanical Engineers
ASHRAE = American Society of Heating, Refrigerant and Air Conditioning Engineers

BA = Building Automation System
LBU = La Crosse Business Unit

CABS = Auxiliary Condenser Tube-Bundle Size
CDBS = Condenser Bundle Size

CDSZ = Condenser Shell Size
CWR = Chilled Water Reset

DCM = Duplex Control Module
DTFL = Delta-T at Full Load (i.e., the difference between entering and leaving chilled water temperatures at design load).

EVBS = Evaporator Bundle Size
EVSZ = Evaporator Shell Size

GPM = Gallons-per-Minute
HVAC = Heating, Ventilating, and Air Conditioning

IE = Internally Enhanced Tubes
IPC = Interprocessor Communication

PFCC = Power Factor Correction Capacitor
PSID = Pounds-per-Square-Inch (differential pressure)

PSIG = Pounds-per-Square-Inch (gauge pressure)

UCP2 = Chiller Control Panel for CenTraVacs

Warnings and Cautions

Notice that WARNINGS and CAUTIONS appear at appropriate intervals throughout this manual. WARNINGS are provided to alert operators of potential hazards that could result in personal injury or death, while CAUTIONS are designed to alert personnel to conditions that could result in equipment damage.

Your personal safety and the proper operation of this machine depend upon the strict observance of these precautions.

Unit Nameplate

The CDHF unit nameplate is located on the left side of the left hand unit control panel (UCP). A typical unit nameplate is illustrated in the installation manual, CDHF-IN-1A or latest revision. The following information is provided on the unit nameplate.

- Unit Model and Size Descriptor
- Unit Serial Number
- Unit Electrical Requirements
- Correct Operating Charge and Type of Refrigerant.
- Unit Test Pressures and Maximum Operating Pressures
- Unit Installation and Operation/ Maintenance manuals
- Product Description Block (Identifies all unit components and unit "Design Sequence" used to order literature and make other inquiries about the unit).

Metric Conversion

The following conversions apply for tables and charts in this manual,

In. x 2.54 = cm.
Ft. x 30.48 = cm.
Lb. x .453 = kg.

Mechanical Operation - CDHF

Overview

The following description applies to the duplex centrifugal chiller only. Refer to the appropriate operation manual for refrigeration cycle descriptions of other models.

Each CDHF unit is composed of basic components.

- The Evaporator
- 2 Stage Compressor (2 ea.)
- Water-Cooled Condenser
- Single-Stage Economizer (2 ea.)
- Related Interconnecting Piping

Important: The text of this manual describes a single refrigeration circuit. Please note that the Duplex, in reality, has TWO independent circuits.

Figure 1 illustrates the general component layout of a typical CDHF chiller.

The duplex unit has two CDHF compressors on independent evaporator and condenser circuits. Control is accomplished by a duplex control module (DCM) as explained in the "Electrical Sequence of Operation" section of this manual.

Cooling-Only Cycle

When the CDHF is functioning in the cooling mode, liquid refrigerant is distributed along the length of the evaporator and sprayed through small holes in a distributor (i.e., running the entire length of the shell) to uniformly coat each evaporator tube. Here, the liquid refrigerant absorbs enough heat from the system water circulating through the evaporator tubes to vaporize.

The gaseous refrigerant is then drawn through the eliminators (which remove droplets of liquid refrigerant from the gas), first-stage variable inlet guide vanes, and into the first-stage impeller.

Note: Inlet guide vanes are designed to modulate the flow of gaseous refrigerant to meet system capacity requirements; they also prerotate the gas allowing it to enter the impeller at an optimal angle that maximizes efficiency at all conditions.

Compressed gas from the first-stage impeller is discharged through the second-stage variable guide vanes and into the second-stage impeller. Here, the refrigerant gas is again compressed, and then discharged into the condenser.

Baffles within the condenser shell distribute the compressed refrigerant gas evenly across the condenser tube bundle. Cooling tower water, circulated through the condenser tubes, absorbs heat from the refrigerant, causing it to condense. The liquid refrigerant then flows out of the bottom of the condenser, passing through an orifice plate and into the economizer.

The economizer reduces the energy requirements of the refrigeration cycle by eliminating the need to pass all gaseous refrigerant through both stages of compression. See Figure 2. Notice that some of the liquid refrigerant flashes to a gas because of the pressure drop created by the orifice plate, thus further cooling the liquid refrigerant. This flash gas is then drawn directly from the economizer into the second-stage impeller of the compressor. All remaining liquid refrigerant flows out of the economizer, passes through another orifice plate and into the evaporator.

CDHF Units with Refrigerant Pump

Compressor Lubrication System for CDHF

A schematic diagram of the compressor refrigerant and oil lubrication system is illustrated in Figure 3 for the CDHF.

Oil is pumped from the oil tank through an oil pressure-regulating valve designed to maintain a net oil pressure of 18 to 22 psig. It is than filtered and sent to the oil cooler and on to the bearings.

From the bearings, the oil drains back to the manifold under the motor and then on to the oil tank.

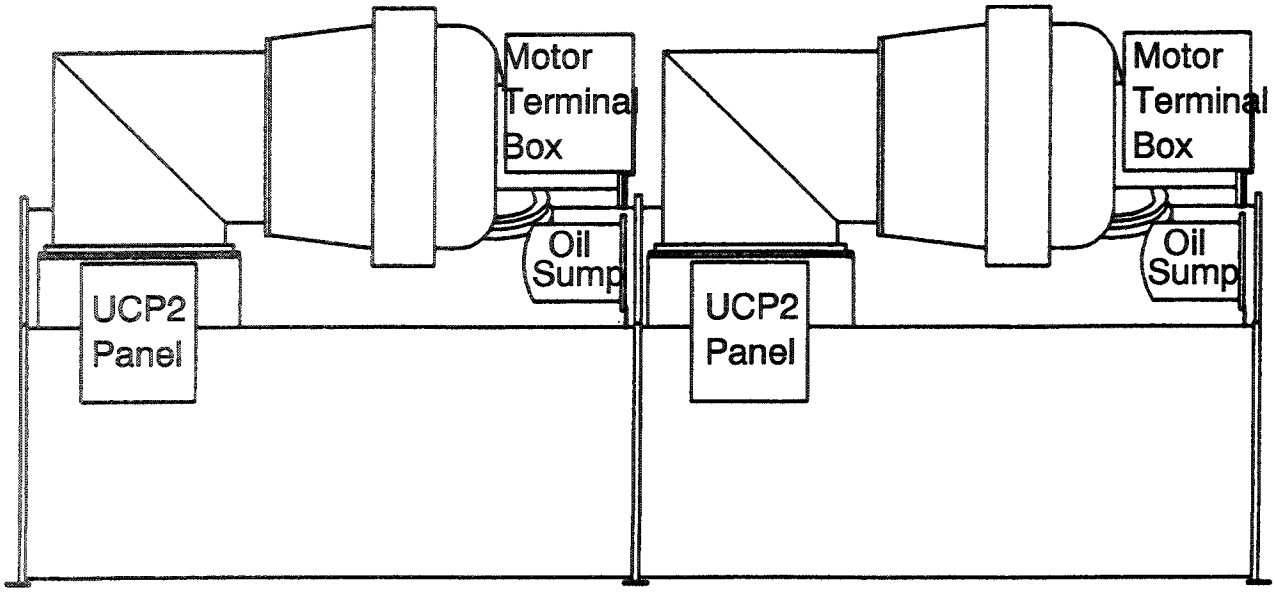
⚠ WARNING
SURFACE TEMPERATURES MAY EXCEED 150°F USE CAUTION WHILE WORKING ON CERTAIN AREAS OF THE UNIT, failure to do so may result in death or personal injury.

To ensure proper lubrication and prevent refrigerant from condensing in the oil tank, a 750-watt heater is immersed in the oil tank and is used to warm the oil while the unit is off. When the unit starts, the oil heater is de-energized. This heater energizes as needed to maintain 140°F to 145°F (60 to 63°C) when the chiller is not running. When the chiller is operating, the temperature of the oil tank is typically 115°F to 160°F (46 to 72°C). The oil return lines from the thrust and journal bearings, transport oil and some seal leakage refrigerant. The oil return lines are routed into a manifold under the motor. Gas flow exits the top of the manifold and is vented to the Evaporator.

A vent line solenoid is not needed with the refrigerant pump. Oil exits the bottom of the manifold and returns to the tank. Separation of the seal leakage gas in the manifold keeps this gas out of the tank.

A dual eductor system is used to reclaim oil from the suction cover and the evaporator, and deposit it back into the oil tank. These eductors use high-pressure condenser gas to draw the oil from the suction cover and evaporator back to the eductors and then discharged into the oil tank. The evaporator deductor line as a shut off valve mounted by the evaporator and ships with two turns open.

Liquid refrigerant is used to cool the oil supply to both the Thrust bearing and the Journal bearing on larger units (360 ton and larger). On refrigerant pump units the oil cooler is located inside the economizer and uses refrigerant passing from the condenser to evaporator to cool the oil. The oil leaves the oil cooler and flows to both the thrust and journal bearings.



Motor Cooling System

Compressor motors are cooled with liquid refrigerant, See Figure 3.

The refrigerant pump is located on the front of the oil tank motor (inside the oil tank). The refrigerant pump inlet is connected to the well at the bottom of the condenser. The connection is on the side where a weir assures a preferential supply of liquid. Refrigerant is delivered to the motor via the pump and delivered to the same connection as used on units without the refrigerant pump. Motor refrigerant drain lines are routed to the condenser.

Mechanical Operation - CDHF

Figure 1

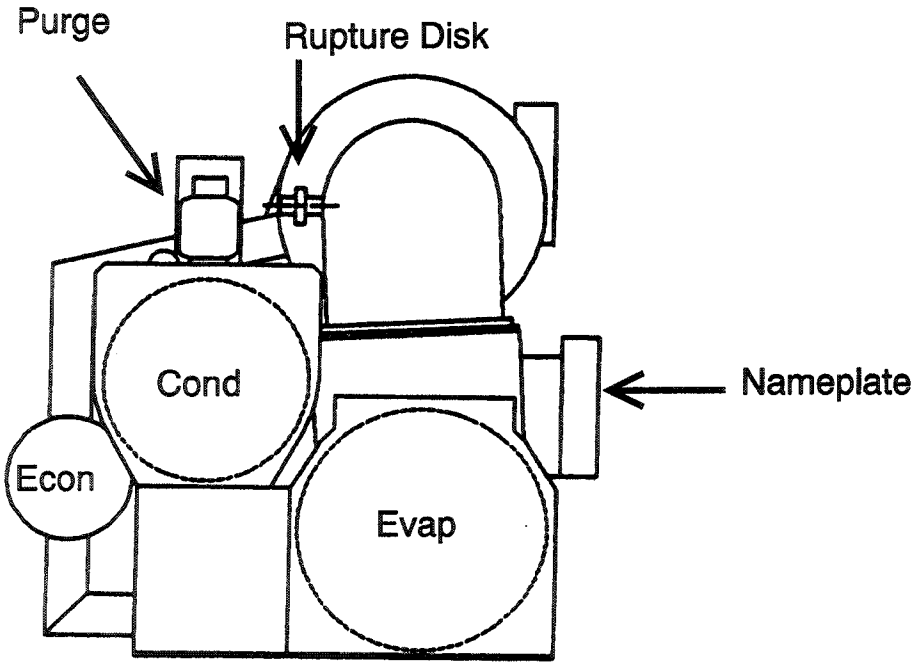
Layout of a Typical CDHF Chiller



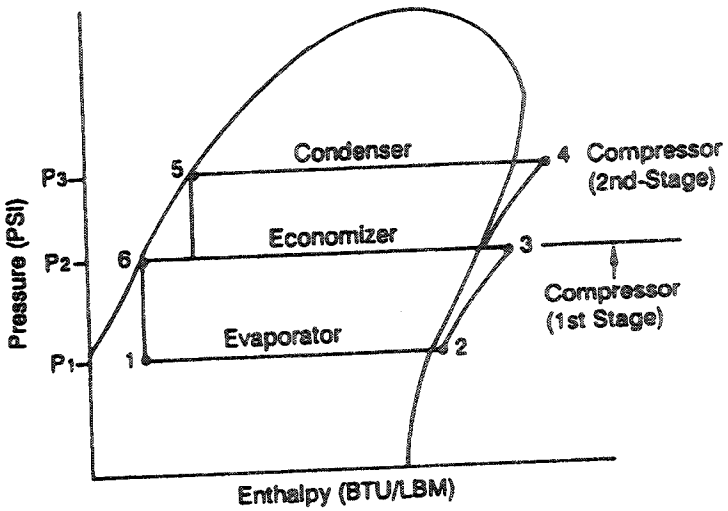


Figure 2
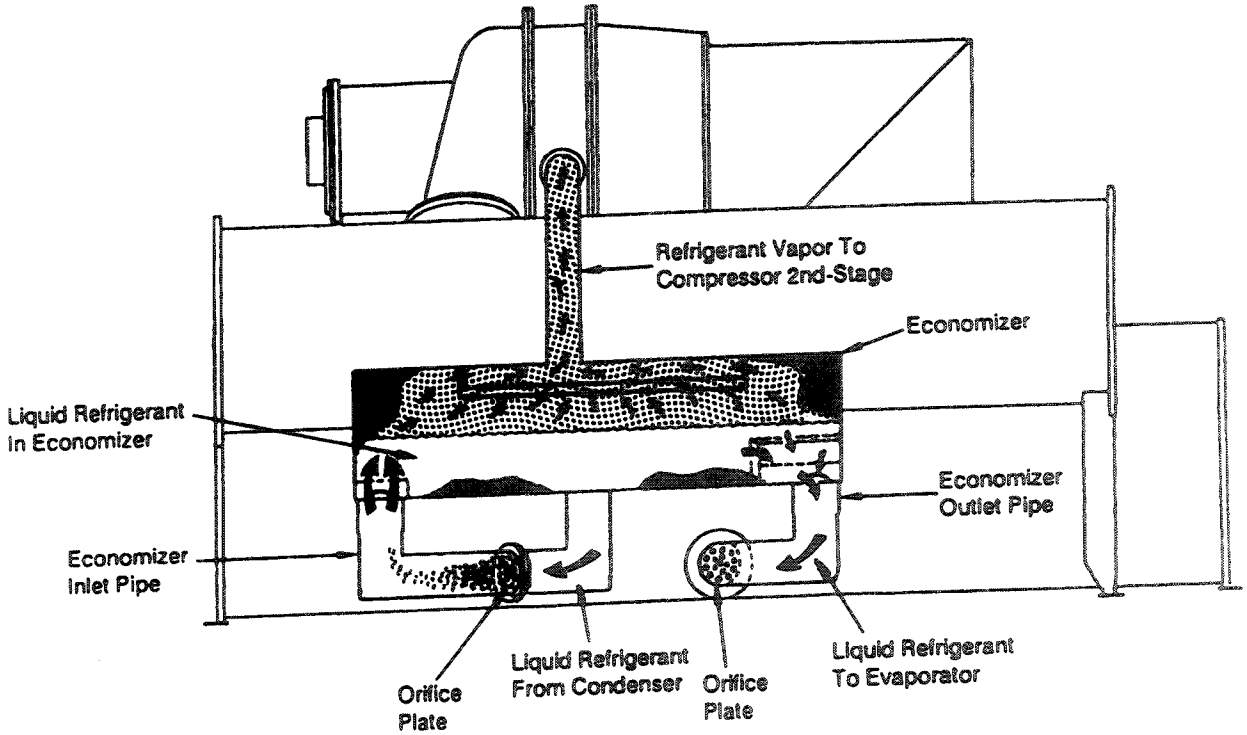
CDHF Pressure and Enthalpy Curve



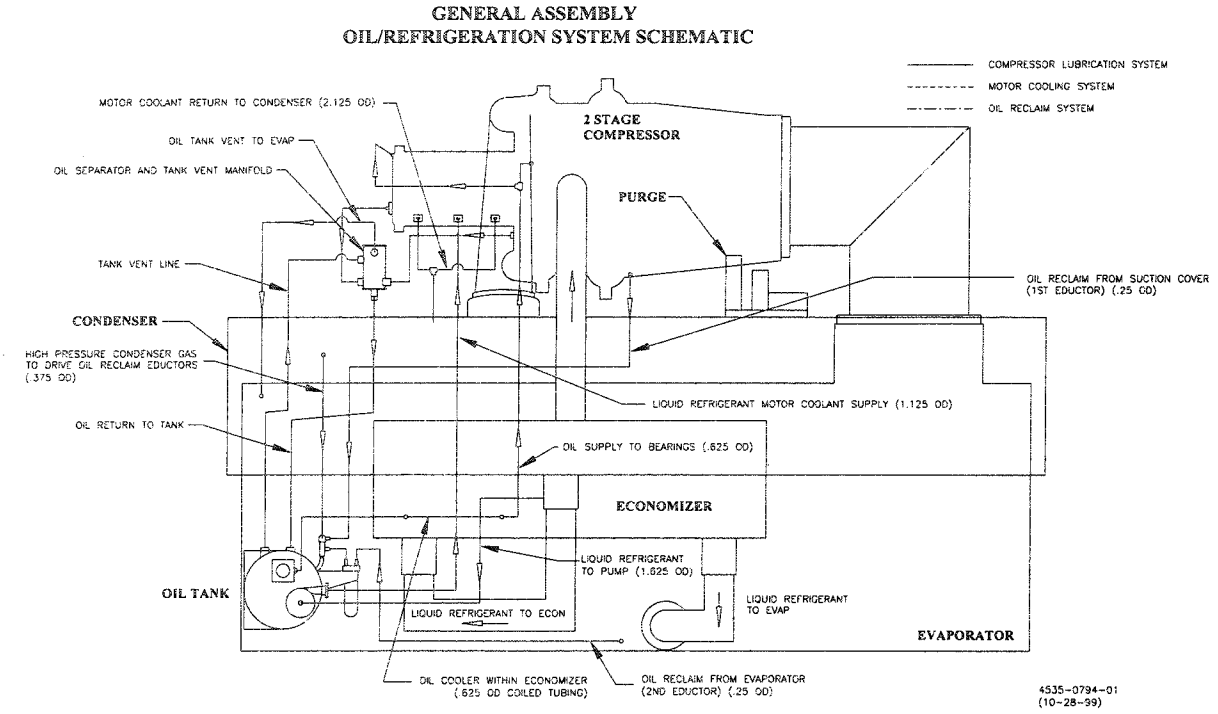


Figure 3
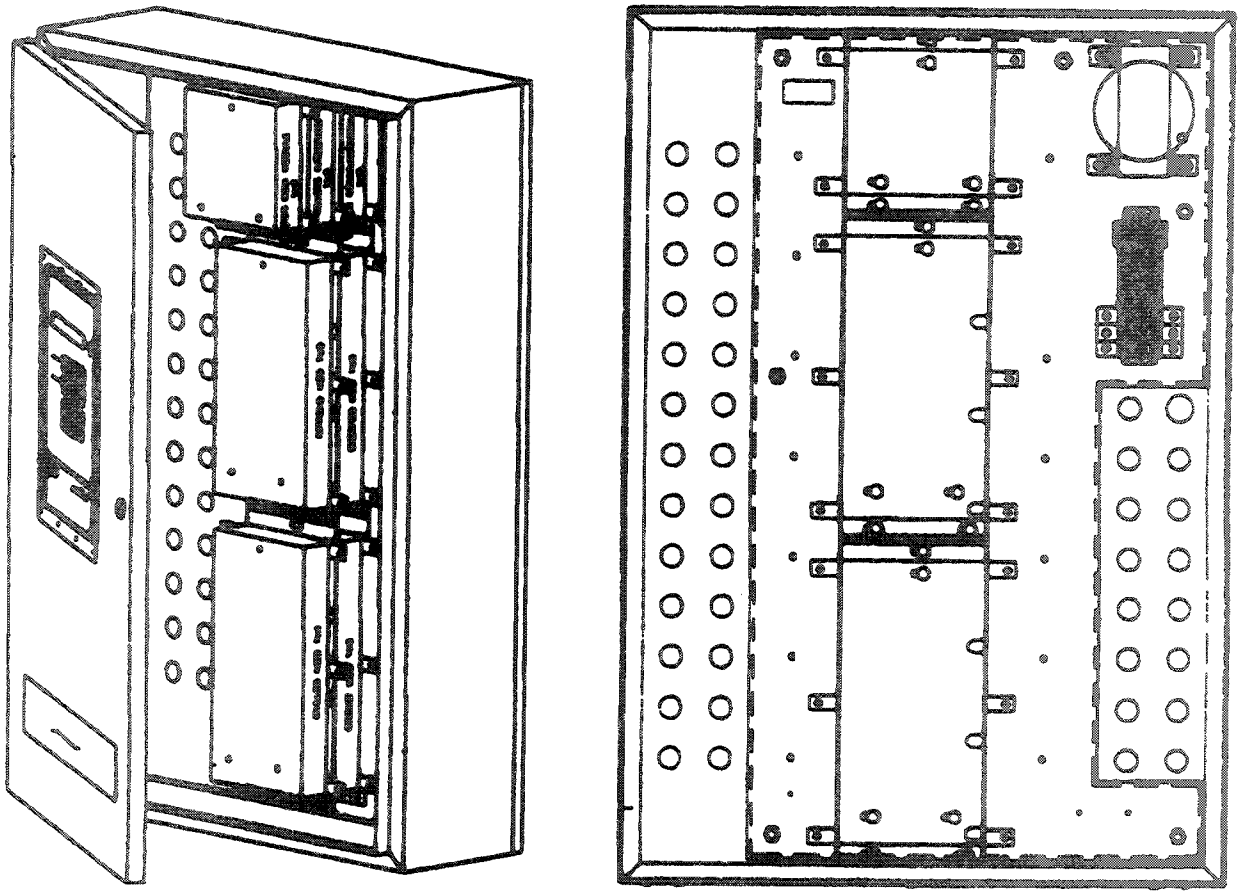
CDHF Compressor Lubrication System and Motor Cooling
(Please note only one of two compressors is shown for the Duplex)



Unit Control Panel

Safety and operating controls are housed in the UCP2 unit control panel on the unit, the starter panel and the purge control panel (Control Panel layout is illustrated in Figure 4)

The UCP2 control consists of a modular design partitioned by major function or group of functions. All modules communicate with each other through the IPC circuit.

Figure 4
Control Panel Layout

Electrical Sequence of Operation

Overview

This section will acquaint the operator with the control logic governing CDHF chillers equipped with UCP2 based control systems.

In the following discussion, reference is made to Chiller "A" and Chiller "B". Chiller "A" is ALWAYS the leaving chilled water side and Chiller "B" is the entering side for water.

Note: The typical wiring diagrams printed in the installation manual are representative of standard CDHF units and are provided only for general reference. They may not reflect the actual wiring of your unit. For specific electrical schematic and connection information, always refer to the wiring diagrams that shipped with the chiller.

With the supply power disconnect switch or circuit breaker (2CB1) closed, 120-volt control power is provided through control power transformer 2T5 and a 30-amp starter panel fuse (2F4) to terminal 1TB-1 in the UCP2 control panel. From this point, control voltage flows to:

Circuit Breaker 1CB1, supplying power to starter module (2U1) via terminal 2TB1-6 for starter contactors operation and the high condenser pressure switch 3S1.

Circuit Breaker 1CB2, supplying power to the purge module (3U1) and the 24 volt supply transformer 3T1 for the purge module (3U1).

Circuit Breaker 1CB3, supplying power to:

(a) Circuit Breaker 1CB3, 115- volt control power transformer 2T5 flows through branch circuit breaker 1CB3 and terminal 1TB1-6 to a 15 amp fuse (1F2) Fuse which protects the refrigerant and oil pump motor (4B3) from over amperage conditions. Current passing through fuse 1F2 reaches 3 normally open parallel sets of contacts: those of refrigerant and oil pump relay (1K5), 1U2-J22 relay and the start contactor 2K1-aux.

Note: While the 1U2-J22 relay automatically is closed by 1U2 as a part of the start sequence. It can also be closed manually by changing the oil pump status to "ON" in the service test mode.

Closure of the 1U2-J22 relay or 2K1 auxiliary contacts allows current to pass through the coil of the refrigerant pump starter relay (1K5), closing the contact of 1K5 to energize the Run winding of the refrigerant pump. When motor 4B3 first starts, current draw is high: this causes current sensing relay 4K8 to close its normally open contacts and pull in Capacitor 4C1 and the pump Start winding. Increasing motor speed and related decreasing current through the main winding and 4K8 relay coil reduces the magnetic force and the 4K8 armature drops out to open the 4K8 contacts and disconnect the Start winding and 4C1 Capacitor. Current now flows to the Run windings of the oil pump motor or refrigerant and oil pump motor.

(b) The Chiller Module (1U1) to operate the evaporator (4L2) and condenser (4L3) water pressure transducer solenoids and to the chilled water (5S1) and condenser water (5S2) flow switch circuits.

The Starter Module (2U1) receives 24 volt power from control power transformer 2T4 in the starter panel.

The Clear Language Display (1U4) Stepper (1U3), Circuit (1U2), Options (1U5), Chiller (1U1), and COMM (1U6), (1U7), (1U8) & (U10) modules obtain 24 volt power from control power transformer 1T1 in the control panel.

Chilled and Condenser Water Flow Interlock Circuits

Proof of chilled water flow for the evaporator is made by the closure of flow switch 5S1 and the closure of auxiliary contacts 5K1 on terminals 1TB1-10 and 1TB1-12.

Proof of condenser water flow for the condenser is made by the closure of flow switch 5S2 and the closure of auxiliary contacts 5K2 on terminals 1TB1-11 and 1TB1-13.

UCP2 and "Wye-Delta" Starter Control Circuits

Logic circuits within the various modules will determine the starting, running, and stopping operation of the chiller. If operation of the chiller is required and the chiller mode is set at "Auto", then the Chiller Module's logic decides to start the chiller based on the differential to start setpoint.

The Chilled Water Pump Relay (5K1) is energized by the Chiller Module (1U1-J12) and chilled water flow must be verified within 3 minutes by the Chiller Module (1U1-J26).

Based on the Restart Inhibit Timer and the differential to start setpoint, oil and refrigerant pump (4B3) will be energized by the Circuit Module (1U2-J22) and the condenser water pump relay (5K2) will be energized by the Chiller Module (1U2-J14) when the restart inhibit timer is at 30 seconds or less. The oil pressure must be at least 9 psid for 60 continuous seconds and condenser water flow verified within 3 minutes by the Chiller Module (1U1-J28) for the compressor start sequence to be initiated.

When less than 5 seconds remains before compressor start, a starter test is conducted to verify contactor states prior to starting the compressor. The test and start sequence shown below is conducted for "Wye-Delta" starters.

(a) Test for transition complete contact open (2K2 AUX at 2U1-J4) - 120 to 180 msec. An MMR diagnostic will be generated if the contact is closed.

(b) Delay time - 20 msec.

(c) If "Level 2 Contactor Integrity Test" is enabled, close start contactor (2K1) and check for no Current - 1 sec. If currents are detected, the MMR diagnostic "Starter Fault Type 1" is generated.

(d) Delay time - 200 msec.

(e) Close shorting contactor, (2K3) and check for no current - 1 sec. If currents are detected the MMR diagnostic "Starter Fault Type II" is generated.

(f) If no diagnostics are generated in the above tests, the Start Relay (2U1-J6) is closed for 2 seconds and the Stop relay (2U1-J8) is closed to energize the start contactor (2K1) in "A" chiller. The shorting contactor (2K3) has already been energized from (e) above. The compressor motor (4B1) starts in the "Wye" configuration, an auxiliary contact (2K1-AUX) locks in the start contactor (2K1) coil, and the acceleration timer begins to time out.

(g) After the compressor motor has accelerated and the maximum phase current has dropped below 85% of the chiller nameplate RLA for 1.5 seconds, the starter transition to the "Delta" configuration is initiated.

(h) The transition contactor (2K4) is closed through relay 2U1-J14, placing the transition resistors (2R1, 2R2 and 2R3) in parallel with the compressor motor windings.

(i) The shorting contactor (2K3) is opened through the opening of relay 2U1-J12 100 msec after the closure of the transition relay 2U1-J14.

(j) The run contactor (2K2) is closed through relay 2U1-J10 shorting out the transition resistors 260 msec after the opening of the shorting relay 2U1-J12. This places the compressor motor in the "Delta" configuration and the micro waits to look for this transition for 2.32 - 2.38 seconds through the closure of the transition complete contacts (2K2-AUX) at 2U1-J4.

(k) 140 msec after (2K2) is energized, the transition relay (2U1-J14) is opened de-energizing the transition contactor (2K4).

(l) The micro must now confirm closure of the transition complete contact (2K2-AUX) within 2.5 seconds after the run relay (2U1-J10) is closed. When this is verified the compressor motor starting sequence is complete. An MMR diagnostic will be generated if the transition complete contacts (2K2-AUX) do not close.

Now that the compressor motor in Chiller "A" (4B1) is running in the "Delta" configuration, the inlet guide vanes will modulate, based on Loading or Unloading sequence described below.

Duplex Chiller Loading Sequence

The duplex chiller control will be accomplished by the Duplex Control Module (DCM) that resides in downstream unit Chiller "A". Its main tasks are setpoint control (chilled water and current limit) and compressor staging. All other setpoints are controlled at each individual compressor UCP2 clear language display panel. Each unit can be reset or stopped separately through each clear language display. Options not available for duplex units are: tracer base loading, hot gas bypass, hot water control, free cooling and ice making.

To the Tracer or generic BAS, the duplex chiller acts as one chiller, by accepting only one set of control setpoints.

Chiller Loading Sequence:
Chiller "A" (the downstream chiller) starts first and loads to 100%. There is a dead band such that once Chiller "A" is above 80% for more than (5) minutes, Chiller "B" starts. While Chiller "B" loads up to 50% Chiller "A" unloads to 50%. At this point both compressors load as required jointly to 100%.

The duplex control module senses leaving chilled water of the downstream chiller (Chiller "A") and loads both simultaneously. The entering water temperature is sensed at the entering side of the upstream chiller (Chiller "B").

As the load decreases, the duplex chiller module UNLOADS both Chiller "A" and "B". Chiller "B" will drop off the line at a point below 35%. Chiller "A" takes up the load carried by Chiller "B" and then unloads based on system requirements.

Duplex Control Module (DCM) Setpoint Control management falls into (3) categories: Front Panel Equalization, Active Setpoint Transfer and Auto/Stop Management.

Front Panel Equalization:
Applies to only chilled water setpoint and current limit setpoint. When the DCM detects a change in one of these front panel setpoints on one of the panels it transfers the new value to the same setpoint on the other panel. This allows the user to modify any application front panel setpoint on either panel and have the change automatically sent to the other panel.

Active Setpoint Transfer:
Is nothing more than always sending the active current limit setpoint of panel "A" to panel "B" through the duplex control module. The duplex control module current limit setpoint should take precedence over all other current limit setpoints. If the DCM loses communications with panel "A", it will set the DCM current limit setpoint to panel "B" to invalid, causing panel "B" to choose its current limit setpoint from some other source: Front Panel, Tracer or external input.

Auto/Stop Management:
Allows Tracer or generic BAS system to stop the duplex as one machine. The chiller module puts information on the IPC that allows the DCM to know when to listen to Tracer Auto/Stop and other Tracer commands.

If the chilled water temperature drops below the chilled water setpoint by an amount set as the "differential to stop" setpoint, a normal chiller stop sequence is initiated as follows:

a. The inlet guide vanes are driven closed for 50 seconds.

b. After the 50 seconds has elapsed, the stop relay (2U1-J6) and the condenser water pump relays (1U1-J14) open to turn off the compressor motor (4B1) and the condenser water pump. The oil pump motor (4B3) will continue to run for 3 minutes post lube while the compressor coasts to a stop.

The chilled water pump will continue to run while the chiller module (1U1) monitors leaving chilled water temperature preparing for the next compressor motor start based on the "differential to start" setpoint.

If the STOP key is pressed on the Clear Language Display (CLD), the chiller will follow the same stop sequence as above except the chilled water pump relay (1U1-J12) will also open and stop the chilled water pump after the chilled water pump delay timer has timed out after compressor shut down.

If the STOP key is pressed twice in rapid succession (twice within 5 seconds), a "panic stop" is initiated which follows the same stop sequence as pressing the STOP key once except the inlet guide vanes are not sequence closed and the compressor motor is immediately turned off.

Duplex Unit UCP2 Displays and Diagnostic Description

The following is a list of new duplex unit displays that you will find in the UCP2 controls and a list of associated diagnostics.

Chiller Report Screen:

1. Chiller Operating Mode: DCM stop will be seen as a standard mode.

2. Active Chilled Water Setpoint/Chilled Water Setpoint source: Duplex control has been added as a setting source.

3. Active Current Limit Setpoint/Current Limit Setpoint source: Duplex control has been added as a setting source.

4. Chilled Water Setpoint source: Duplex control has been added as a setting source.

5. Current Limit Setpoint source: Duplex control has been added as a setting source.

Operator Settings:

6. Chilled Water Reset Type: This screen is suppressed when the chiller is under Duplex Control and is Compressor B.

Service Settings

7. Duplex Control Module (DCM) option: This has been added directly following the printer option screen. The options are installed or not installed. The DCM option will automatically be installed if communication with a DCM module occurs.

Diagnostic Descriptions

New diagnostic descriptions on the UCP2 that relate to the Duplex are shown in Table 1.

Table 1
Diagnostics that relate to the Duplex Unit

Diagnostic Description	Appl Unit Type	Diag Type	Cause	Can Be Remotely Reset	Help Message
DCM:Loss of communication with Chiller A	CTV	IFW	The DCM module lost communcations with the Chiller A Chiller Module for 15 contiguous seconds	Yes	Check IPC Wiring Connections
DCM: Loss of communication with Chiller B	CTV	IFW	The DCM module lost communcations with the Chiller B Chiller Module for 15 contiguous seconds	Yes	Check IPC Wiring Connections
DCM: Loss of communication with Starter A	CTV	IFW	The DCM module lost communcations with the Chiller A Starter Module for 15 contiguous seconds	Yes	Check IPC Wiring Connection
DCM: Loss of communication with Starter B	CTV	IFW	The DCM module lost communcations with the Chiller B Starter Module for 15 contiguous seconds	Yes	Check IPC Wiring Connection
DCM: Loss of communication with TCI A	CTV	IFW	The DCM module lost communcations with the Chiller A TCI Module for 15 contiguous seconds	Yes	Check IPC Wiring Connection

Vane Actuator Control

The 1U3 Stepper Module pulses a DC voltage to the windings of the 4B2 Stepper Module Vane Actuator to control inlet guide vane position.

While operation of this stepper motor is automatic, manual control is made possible by going to the Vane Control Status and Vane Position Commands screen in the Service Tests Menu and changing the "Target" value.

Note: If the chiller is operating in a limit mode (i.e. current limit, condenser limit, evaporator limit, etc.) the limit operation has priority over all manual modes of operation.

On each UCP power-up, the inlet guide vanes are driven fully closed to recalibrate the zero position (Steps) of the Stepper motor vane actuator. An inlet guide vane stroke test is conducted for BPI (Binary Position Indicator) position on all resets (hardware and software) if there has not been a Momentary Power Loss. This is also done if there is a call for a cooling or heating condition and it has been 24 hours or more since the last BPI test and there has not been a Momentary Power Loss for 5 minutes.

Note: The closed range of the BPI must straddle the factory programmed 90 degree Vane Position.

Unit Start-Up Procedures

Daily Unit Start-Up

1. Verify that both the chilled water pump and condenser water pump starter are in either "ON" or "AUTO" position.

2. Verify the cooling tower is in either "ON" or "AUTO" position.

3. Check the oil tank oil level; the level must be visible in or above the lower sight glass. Oil level may be easily gaged by the aluminum float balls in the sight glasses. Be sure to check the oil tank temperature; normal oil tank temperature before start-up is 140° F to 145°F (60° to 63° C).

Note: The oil heater is energized only when the unit if OFF.

4. Check the chilled water setpoint and readjust it, if necessary, in the Operator Settings menu.

5. If necessary, readjust the current limit setpoint in the Operators Setting Group.

6. Press "AUTO".

The UCP also checks compressor motor winding temperature, and a minimum 30 second delay is initiated if the winding temperature is less than 165° F. If it is greater than 165° F, however, a 15-minute delay period begins. The chilled water pump relay is energized and evaporator water flow is proven. Next, the UCP checks the leaving evaporator water temperature and compares it to the chilled water setpoint. If the difference between these values is less than the start differential setpoint, cooling is not needed.

If the UCP determines that the difference between the evaporator leaving water temperature and chilled water setpoint exceeds the start differential setpoint, the unit enters the Initiate Start Mode and the oil pump and the condenser water pump are started.

If condenser water flow is not proven (i.e., flow switch 5S3 does not close) within 4.25 minutes, the unit is locked out on a MAR diagnostic.

Oil pressure must be verified within Unit Start-Up Procedures.

When less than 5 seconds remain on the restart inhibit, the pre-start starter test is conducted on Y-Delta starters. If faults are detected, the Unit's compressor will not start, and a MMR Diagnostic will be generated.

After the pre-start Starter test, the UCP sends a start signal to the compressor motor. Within 2 seconds, 3 phases of current in the correct phase sequence must be detected. If there is no current, 1 or 2 phases missing, or reverse electrical sequence, diagnostics will occur.

Acceleration and proof of transition must occur within 2.5 seconds of transition initiation, or unit start-up is aborted. (If this occurs, the unit goes into the post-lube mode, and a MMR diagnostic is generated).

If the compressor motor starts and accelerates successfully, "Unit is Running" appears on the display. At this time the purge unit will start operating on "Automatic" and will continue to operate as long as chiller compressor is running.

Note: Whenever the UCP detects a MMR diagnostic condition during start-up, unit operation is locked out and manual reset is required before the start-up sequence can begin again. If the fault condition has not cleared, the UCP will not permit restart.

When the cooling requirement is satisfied, as determined by the differential to stop value, the UCP originates a "Shutdown" signal. The inlet guide vanes are driven closed for 50 seconds, and the unit enters a 3-minute post-lube period. The compressor motor and condenser water pump starter are de-energized immediately, but the oil pump continues to run during this 3-minute interval; the evaporator pump will continue to run for the time specified in the evap pumpoff delay. Once the post-lube cycle is complete, the unit returns to the auto mode.

Seasonal Unit Start-Up

Note: Refer to CVHE-W-8A or the most recent wiring manual for UCP Start-Run-Shutdown sequence and UCP timing functions.

1. Close all drain valves, and re-install the drain plugs in the evaporator and condenser headers.

3. Vent and fill the cooling tower, if used, as well as the condenser and piping. At this point, all air must be removed from the system (including each pass). Then closed the vent valves in the condenser water boxes.

4. Open all of the valves in the evaporator chilled water circuit.

5. If the evaporator was previously drained, vent and fill the evaporator and chilled water circuit. When all air is removed from the system (including each pass), close the vent valves in the evaporator water boxes.

6. Lubricate the external vane control linkage and the lubrication system spindle valve.

7. Check the adjustment and operation of each safety and operating control.

8. Equalize refrigerant charge between the two circuits.

9. Close all disconnect switches.

⚠ **WARNING**
ENSURE THE EQUIPMENT IS PROPERLY GROUNDED WHEN MEASUREMENTS, ADJUSTMENTS, OR OTHER SERVICE RELATED OPERATIONS ARE PERFORMED WITH POWER ON. Failure to do so could result in injury or death due to electrical shock or contact with moving parts.

10. Perform instructions listed in "Daily Unit Start-Up" section.

Unit Shutdown Procedures

Daily Unit Shutdown

1. Press STOP.

2. After compressor shutdown turn off the chilled water pump at the pump's push-button station. (Or stop chilled water flow by the means devised for this particular application.)

3. Open all disconnect switches except the control power disconnect switch.

Seasonal Unit Shutdown

1. Press STOP.

2. After compressor shutdown turn off the chilled water pump at the pump's push-button station. (Or stop chilled water flow by the means devised for this particular application.)

3. Open all disconnect switches except the control power disconnect switch.

⚠ WARNING
USE CARE AND ENSURE THE EQUIPMENT IS PROPERLY GROUNDED WHEN SERVICING SYSTEM WITH POWER ON. Failure to do so, could cause injury or death due to electrical shock or contact with moving parts.

⚠ CAUTION
CONTROL POWER DISCONNECT MUST REMAIN CLOSED DURING ENTIRE SHUTDOWN PERIOD, this will allow oil sump heater operation and prevent refrigeration from condensing in oil sump.

4. Drain the condenser piping and cooling tower, if used.

5. Remove the drain and vent plugs from the condenser headers to drain the condenser.

6. Once the unit is secured for shutdown, the maintenance procedures described under "Annual Maintenance" in the Periodic Maintenance section of this manual should be performed by qualified Trane service technicians.

Note: During extended shutdown, be sure to operate the purge unit for a two-hour period every two weeks. If the purge is not in the Adaptive mode. This will prevent the accumulation of air and non-condensable in the machine. to start the purge, change the purge mode to "ON" in the Operator Settings Menu. Remember to turn the page mode to AUTO after the two-hour run time.

⚠ CAUTION
DO NOT ALLOW THE CHILLER TEMPERATURE TO RISE ABOVE 110° F (43°c). CONTINUOUS RUNNING OF PUMPS WHILE THE MACHINE IS OFF MAY CAUSE THIS CONDITION TO OCCUR. Failure to watch the temperature will cause the rupture disk to relieve and discharge the refrigerant from the machine.

Trouble Analysis

If the red light on the control panel is flashing, an MMR diagnostic has occurred. For more diagnostic information, refer to the Diagnostic Section of the clear language display manual, CVHE-CLD-1A or latest revision. The diagnostic must be analyzed, corrections made by qualified personnel and the MMR diagnostic reset before the chiller can be returned to operation.

Periodic Maintenance

Overview

This section describes the basic chiller preventive maintenance procedures, and recommends the intervals at which these procedures should be performed. Use of a periodic maintenance program is important to ensure the best possible performance and efficiency from a chiller.

Recommended purge maintenance procedures for the Purifier Purge unit are covered in the latest Purge Operation and Maintenance manual.

An important aspect of the chiller maintenance program is the regular completion of records. Provided at the end of this manual are samples of the *"Annual Inspection Check List and Report"*, *"CenTraVac with UCP2 Commissioning Checklist & Start-Up Test Log"*, *"Start-Up Test Log for Water Cooled CenTraVacs with UCP2 Control Panels"* and *"UCP2 "Settings Group" Menu Record"*.

Table 2
Normal Chiller Operating Characteristics

Important: Always refer to the local Trane office for the latest revisions as there may be pertinent changes made since the printing of this manual.

When the logs are filled out accurately by the machine operator, the completed logs can be reviewed to identify any developing trends in the chiller's operating conditions. For example, if the machine operator notices a gradual increase in condensing pressure during a month's time, he can systematically check, then correct the possible cause(s) of this condition (e.g., fouled condenser tubes, non-condensable in the system, etc.)

Daily Maintenance and Checks

[ ] Check the chiller's evaporator and condenser pressures, oil tank pressure, differential oil pressure. Compare the readings with your previous records.

Below is Table 2 which shows normal chiller operating characteristics.

CAUTION
IF FREQUENT PURGING IS REQUIRED. MONITOR PURGE PUMPOUT RATE, IDENTIFY AND CORRECT SOURCE OF AIR OR WATER LEAK AS SOON AS POSSIBLE. Moisture contamination caused by leakage can shorten chiller life expectancy.

[ ] Check the oil level in the chiller oil sump using the 2 sight glasses provided in the oil sump head. When the unit is operating, the oil level should be visible in the lower sight glass. Oil level may be easily gaged by the aluminum float balls in the sight glasses.

Weekly Maintenance

[ ] Complete all daily maintenance procedures and checks.
Every 3 Months

WARNING
LOCK UNIT DISCONNECT SWITCH IN OPEN POSITION, failure to do so could cause injury or death due to electrical shock or contact with moving parts.

Operating Characteristics	Normal Reading
Evaporator Pressure	12" to 18" Hg (Vacuum)
Condenser Pressure (See Notes 1 and 2)	2 to 12 psig (Standard Condensers)
Oil Sump Temperature: Unit not Running	140° to 145° F (60° to 63°C)
Unit Running	115° to 150° F (45° to 66°C)
Differential Oil Pressure (Note 3)	18 to 22 psid

Notes:
1. Condenser pressure is dependent on condenser water temperature, and should equal the saturation pressure of HCFC-123 at a temperature 5-10°F (3 to 6°C) above that of leaving condenser water at full load.
2. Normal pressure readings for ASME condensers exceed 12 psig.
3. Oil Tank Pressure 12" to 18" Hg
   Discharge Oil Pressure 7 to 15 psig

Every 3 Months

⚠ WARNING
LOCK UNIT DISCONNECT SWITCH IN OPEN POSITION, failure to do so could cause injury or death due to electrical shock or contact with moving parts.

[ ] Complete all recommended weekly maintenance procedures. (Refer to the previous sections for details.)

[ ] Clean all water strainers in the CenTraVac water piping system.

Every 6 Months

⚠ WARNING
LOCK UNIT DISCONNECT SWITCH IN OPEN POSITION, failure to do so could cause injury or death due to electrical shock or contact with moving parts.

[ ] Complete all recommended quarterly maintenance procedures.

[ ] Lubricate the vane control linkage bearings, ball joints, pivot points and oil filter change valve; a few drops of OIL-22 is sufficient.

[ ] Drain the contents of the rupture disk and purge discharge vent-line drip-leg, into an evacuated waste container minimally, more often if the purge is operated excessively.

Also, apply one or two drops of oil on the vane operator shaft and spread it into a very light film; this will protect the shaft from moisture and rust.

Off-Season Maintenance

During those periods of time when the chiller is not operated, be sure the control panel is energized.

Annual Maintenance

Shut down the chiller once each year to check the items listed below; a more detailed inspection check list is provided on the "Model CDHF CenTraVac Annual Inspection Check list and Report" illustrated in this manual.

[ ] Perform the annual maintenance referred to in the Maintenance Section of the Purge manual.

[ ] Use an ice water bath to verify that the accuracy of the evaporator refrigerant temperature sensor (4RT5) is still within tolerance (i.e., ± 2.0° F at 32° F).

If the evaporator refrigerant temperature displayed on the UCP's read-out is outside this 4-degree tolerance range, replace the sensor.

Note: if the sensor is exposed to temperature extremes outside its normal operating range (0° F to 90° F) (-18° C to 32° C), check its accuracy at 6 month intervals.

Compressor Oil Change

Recommendations are to subscribe to an oil analysis program to determine the necessity to change oil, rather than change it automatically every year. This will reduce the chillers overall lifetime oil consumption and minimize refrigerant emissions. A drain fitting is installed in the oil filter housing for obtaining oil samples.

After the first six months of operation it is recommended to have the oil analyzed.

After one year of operation it is recommended to change the oil and filter and have the removed waste oil analyzed.

Beyond the first year, recommendations are to subscribe to an annual oil analysis program rather than change the oil automatically every year. This program will reduce the chiller's overall lifetime oil consumption and minimize refrigerant emissions. The oil analysis should be done by a qualified laboratory experienced in refrigerant/oil chemistry and the servicing of Trane Centrifugal chillers.

Oil Change Procedure

When oil analysis indicates the need to change compressor oil, use the following procedure for removing oil.

Note: Use only Trane Oil 0022. A full oil change is nine gallons of Oil 0022.

⚠ CAUTION
OPEN CONTROL PANEL DISCONNECT SWITCH BEFORE DRAINING THE SUMP. This will help prevent possible burnout of the oil sump heater.

[ ] Draw the oil from the chiller through the oil charging valve on the chiller oil sump into an approved, evacuated tank; or,

[ ] Pump the oil from the chiller through the oil charging valve into an air-tight resealable container, using a magnetically-driven auxiliary pump.

[ ] Forcing the oil from the oil pump by pressurizing the chiller (i.e. by raising chiller temperature or adding nitrogen) is NOT recommended.

Refrigerant dissolved in the oil can be removed and returned to the chiller by using an appropriate deep-vacuum recovery unit and heating/agitating the oil container. Follow all federal, state and local regulations with regard to disposal of waste oil.

Replacing Oil Filter

Replace oil filter. (1) Annually, (2) at each oil change, (3) or if erratic oil pressure is experienced during chiller operation.

Oil Filter Replacement Procedure

Use the following procedure to service the oil filter. Refer to Figure 5.

1. Run the oil pump for two to three minutes to insure that the oil filter is warmed up to the oil sump temperature.

2. Turn the oil pump motor off.

3. Pull the "D" handle on the rotary valve locking pin out of its detent and rotate the valve to the "DRAIN" position. An offset pointer is located on the top of the valve with wrench flats to allow turning. The spring force on the locking pin should allow the pin to drop into a detent at this position.

4. Allow at least 15 minutes for the oil to drain from the filter back into the oil sump.

5. Pull the "D" handle to unlock the pin and rotate the valve to the "CHANGE FILTER" position. This isolates the filter from the unit. The locking pin should drop into a detent in this position.

6. Remove and replace the filter as quickly as possible. Place the used filter in a resealable container. Follow all local, state and federal regulations to dispose of the filter.

Pull the "D" handle to unlock the pin and rotate the valve to the "RUN" position. The locking pin should drop into a detent in this position. The chiller is now ready for operation.

Other Maintenance Requirements

1. Inspect the condenser tubes for fouling; clean if necessary.

2. Measure the compressor motor winding resistance to ground; a qualified service technician should conduct this check to ensure that the findings are properly interpreted.

Contact a qualified service organization to leak-test the chiller; this procedure is especially important if the system requires frequent purging.

3. Use a nondestructive tube test to inspect the condenser and evaporator tubes at 3-year intervals.

Note: It may be desirable to perform tube tests on these components at more frequent intervals, depending upon chiller application. This is especially true
of critical process equipment.

4. Depending on chiller duty, contact a qualified service organization to determine when to conduct a complete examination of the unit to discern the condition of the compressor and internal components.

Note:
(a) Chronic air leaks can cause acidic conditions in the compressor oil and result in premature bearing wear.

(b) Evaporator or condenser water tube leaks. Water mixed with the compressor oil can result in bearing pitting, corrosion, or excessive wear.

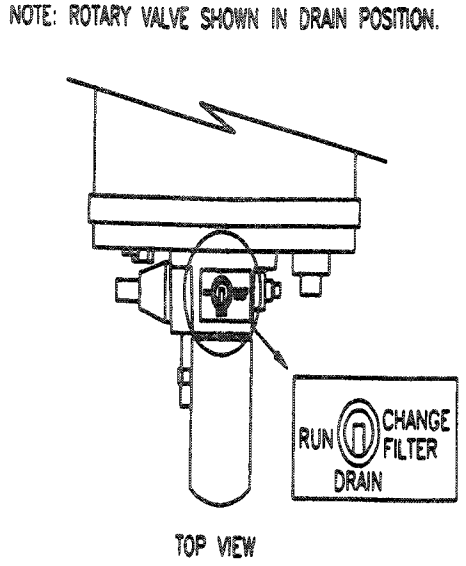
5. Submit a sample of the compressor oil to a Trane qualified laboratory for comprehensive analysis on an annual basis; this analysis determines system.

6. Submit a sample of the compressor oil to a Trane qualified laboratory for comprehensive analysis on an annual basis; this analysis determines system moisture content, acid level and wear content of the oil, and can be used as a diagnostic tool.

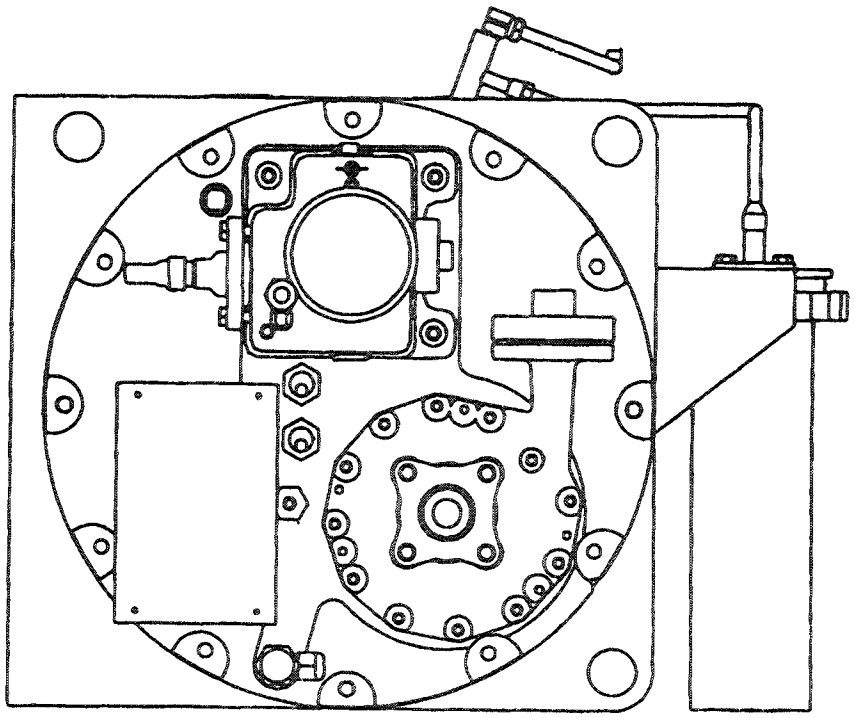
Lubrication

The only CDHF chiller components that require periodic lubrication are the external vane linkage assembly, oil filter change valve. 1st stage inlet guide vane tang assembly o ring and oil valve block o ring.

The Oil Valve Block Rotary Valve uses dual o rings to seal to atmosphere. These should be manually lubricated by removing the pipe plug at the valve lubrication port and placing a few drops of Trane OIL-0022 in the cavity. Be sure to reinstall the pipe plug when lubrication is completed.



Refrigerant Charge



⚠ WARNING
FOLLOW ALL SAFETY PROCEDURES DESCRIBED IN THE MSD SHEET FOR REFRIGERANT WHEN PROCEDURES OR SERVICE MIGHT EXPOSE PERSONNEL TO LIQUID OR VAPOROUS REFRIGERANT OR REFRIGERANT CONTAINERS. Failure to do so could result in injury or death.

The refrigerant charging procedure for Trane centrifugal chillers is:

1. If water is present in the tubes , break machine vacuum with refrigerant vapor, or circulate water to avoid tube damage.

Figure 5
Rotary Valve in Drain Position

Front View with Refrigerant Pump

2. Always use refrigerant compatible hoses or copper-tubing with self-sealing connections or shut-off valves.

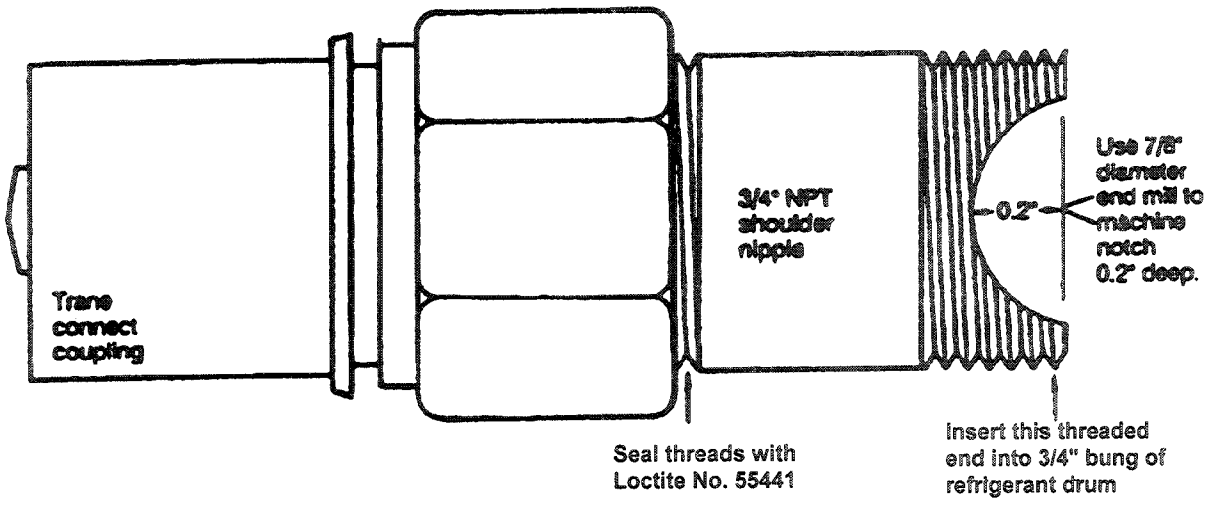
3. Transfer the refrigerant using one of the following (listed in order of preference):

(a) An EPA approved low-pressure refrigerant recovery/ recycle unit.

(b) The available pressure differential.

(c) Gravity. Use a return vent line to refrigerant containers to equalize pressure.

(d) A mechanical gear pump with compatible seals, or a magnetically-driven pump.



4. When charging from new drums, use fitting designed for use with 3/4 in center drum bung of 2-inch bung. Figure 6 shows drum bung fitting with Quick Connect Coupling.

5. Do not use dry nitrogen to push refrigerant into the chiller as was the common practice in the past. This will contaminate the charge and require excessive purging, which will result in unnecessary release of refrigerant.

6. Weigh in the proper charge.

7. Use recovery/recycle unit or vacuum pump to evacuate hoses; and fittings. Follow all Local, State and Federal regulations.

Figure 6
Drum Bung Fitting with Quick Connect Coupling

Recovery/Recycle Connections

To facilitate refrigerant removal and replacement, CDHF units are provided with a 3/4-inch vapor fitting with shutoff valve on the chiller suction and with a 3/4-inch liquid connection with shutoff valve at the bottom of the evaporator shell for each circuit.

Leak Testing

To leak-test a chiller containing full refrigerant charge, raise chiller pressure using a controlled hot water or electric-resistance system to a maximum of 8 psig. Do not use nitrogen, which will cause excessive refrigerant discharge by the purge system.

Cleaning the Condenser

⚠ **CAUTION**

DO NOT USE UNTREATED OR IMPROPERLY TREATED WATER, or equipment damage may occur.

Condenser tube fouling is indicated when "the approach" temperature (i.e., the difference between the saturated refrigerant temperature and the leaving condenser temperature) is higher than predicted.

If the annual condenser tube inspection indicates that the tubes are fouled, two cleaning methods (mechanical and chemical) can be used to rid the tubes of contaminants.

Use the mechanical cleaning method to remove sludge and loose material from tubes.

(To clean other types of fouling, including internally-enhanced types, consult a qualified service organization for recommendations.)

1. Remove the retaining nuts and bolts from the water box covers at each end of the condenser. Use a hoist to lift the covers off the water box (A threaded connection is provided on each water box cover to allow insertion of an eyebolt).

2. Work a round nylon or brass bristled brush (attached to a rod) in and out of each of the condenser water tubes to loosen the sludge.

3. Thoroughly flush the condenser water tubes with clean water.

Scale deposits are best removed by chemical means. Be sure to consult any qualified chemical house in the area (i.e., one familiar with the local water supply's chemical mineral content) for a recommended cleaning solution suitable for the job. (Remember, a standard condenser water circuit is composed solely of copper, cast iron, and steel).

A typical chemical cleaning setup is illustrated in Figure 7.

⚠ **CAUTION**

CONSULT A QUALIFIED CHEMICAL HOUSE IF USING CHEMICAL MEANS. MATERIALS USED IN THE EXTERNAL CIRCULATION SYSTEM, THE QUANTITY OF THE SOLUTION, THE DURATION OF THE CLEANING PERIOD, AND ANY REQUIRED SAFETY PRE-CAUTIONS SHOULD BE APPROVED BY THE COMPANY FURNISHING THE MATERIALS OR PERFORMING THE CLEAN-ING. Improper chemical cleaning can damage tube walls.

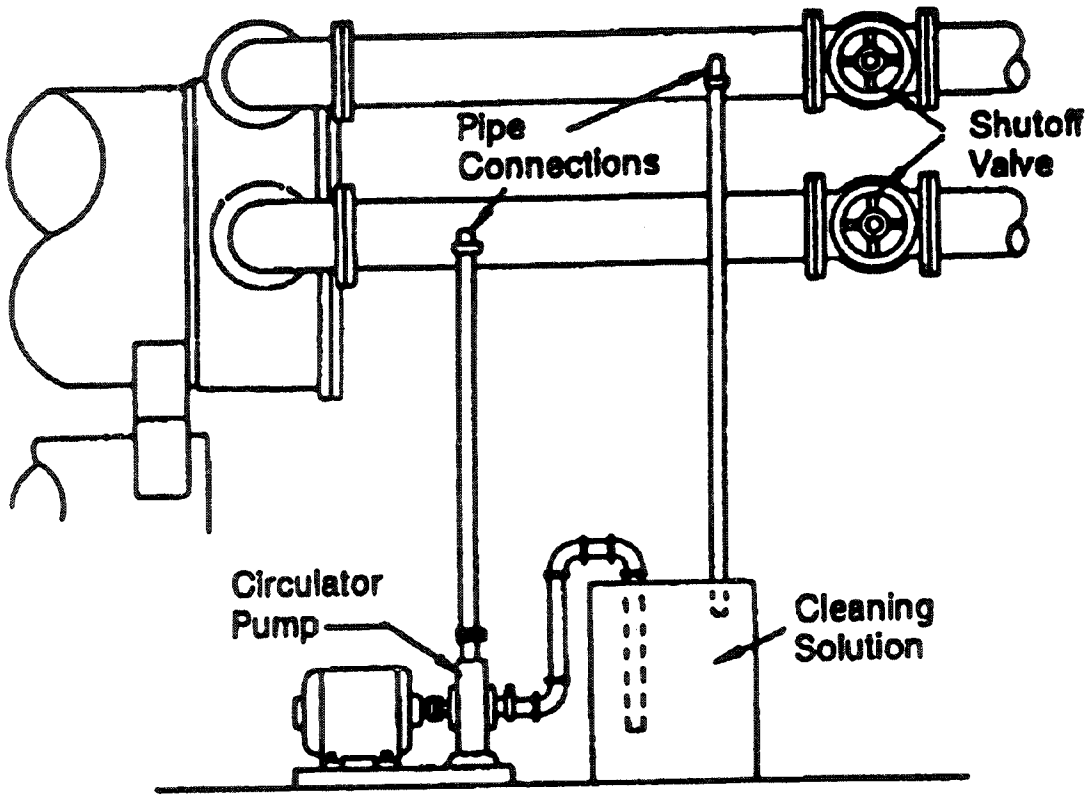
Remember, however, that whenever the chemical tube cleaning method is used, it must be followed up with mechanical tube cleaning, flushing and inspection.

Cleaning the Evaporator

Since the evaporator is typically part of a closed circuit, it does not accumulate appreciable amounts of scale or sludge. Normally, cleaning every 3 years is sufficient. However, on open CDHF systems, such as air washers, periodic inspection and cleaning is recommended.

Control Settings and Adjustments

A list of CDHF time delays and safety control cutout settings is provided in Table 3 called out in this manual.



For control calibration and check-out, contact a Trane qualified service organization.

Purge System

Because some sections of the chiller's refrigeration system operate at less-than-atmospheric pressure, the possibility exists that air and moisture may leak into the system. If allowed to accumulate, these non-condensables become trapped in the condenser and reduces the chiller's efficiency and cooling capacity.

The Trane Purifier Purge is the only purge system available for the CDHF chiller. The purge is designed to remove non-condensable gases and water from the refrigeration system. Purifier Purge unit operation, maintenance and trouble shooting is covered by a separate service literature manual and may be obtained through the nearest Trane office .

Figure 7
Chemical Cleaning Setup

Time Delays and Safety Controls

Table 3: **Unit Time Delays and Safety Control Cutout Settings for UCP2**

Operating Controls: **Timers**	**Timing Interval**
Evap Pump Off Delay Time	Adjustable 0-30 minutes
IGV BPI Test	75 seconds

CENTRAVAC WITH UCP2 COMMISSIONING CHECKLIST & START-UP TEST LOG

Job Name_____ **Location**_____

Model #_____ **Serial #**_____

Sales Order #_____ **Start-up Date**_____

NOTE: The Unit Installation, Operation and Maintenance Manuals, Submittals, and Design Specifications must be used in conjunction with this checklist.

I. PRECOMMISSIONING PROCEDURES

☐ **A. Obtain Installation Check Sheet**

This must be prepared by the installer for the particular unit, verifying the unit is ready for commissioning.

☐ **B. Obtain Design (order) Specification Data**

This indicates the design criteria of the particular unit. A unit cannot be properly commissioned unless this data is known. It is the responsibility of the selling office to furnish this data.

☐ **C. Obtain Wiring Diagrams**

The "as-wired" electrical diagram should be compatable with the recommended Trane submittals and diagrams. Are customer added external/remote control circuits compatable? ☐ Yes ☐ No

☐ **D. General Installation Observations**

☐ 1. Is there any apparent shipping or rigging damage? ☐ Yes ☐ No

☐ 2. Record the pressure on the shipping gauge_____PSIG. If there is no pressure on the gauge, a leak test will have to be done before the unit can be evacuated and charged.

☐ 3. Is the water piping correctly installed? ☐ Yes ☐ No

Flow Switches ☐ Yes ☐ No Pressure Gauges ☐ Yes ☐ No

Isolation Valves ☐ Yes ☐ No Flow Balancing Valves ☐ Yes ☐ No

Thermometer Wells ☐ Yes ☐ No Vent Cocks and Drains ☐ Yes ☐ No

☐ 4. Have proper clearances around the unit been maintained per submittal and/or installation Manual guidelines? ☐ Yes ☐ No

☐ 5. Is power wiring of adequate ampacity and correct voltage? ☐ Yes ☐ No

Are fuses or circuit breakers of the correct value or type? ☐ Yes ☐ No

☐ 6. Is the unit base acceptable, level, and is the unit on isolators (rubber as supplied by Trane or spring type)? ☐ Yes ☐ No

☐ 7. Have the micro (less than 30 volts) circuits been properly isolated from the higher voltage control and power circuits? ☐ Yes ☐ No

☐ **E. Comments**_____

Note: This form is suggested for your use.

II. COMMISSIONING PROCEDURES

A. Pre-start operations

1. Holding Charge
   - ☐ _____PSIG. Must be positive pressure or leak test must be done.
   - ☐ Relieve the holding charge.

2. Calibration of High Pressure Cutout
   - ☐Calibrate the HPC to cut out when 15 PSIG is exceeded. The cut in value is approximatly 10 PSIG. CUT OUT_____PSIG, CUT IN_____PSIG.

3. Meggar the Motor (500 volt Meggar)
   - ☐Compressor motor Megohms- refer to temp/resistance chart for acceptable values. Remove surge suppressors before Megging. Never Meg test with the unit in a vacuum.

T1 to Earth____	T4 to Earth____	T1 to T2____	T1 to T4____
T2 to Earth____	T5 to Earth____	T1 to T3____	T2 to T5____
T3 to Earth____	T6 to Earth____	T2 to T3____	T3 to T6____

4. Evacuation
   - ☐Connect the vacuum pump to start evacuation. Use a 2-stage pump with at least 5 CFM capacity. Connect to the evaporator charging valve with a hose no smaller than 3/4 inch ID.

5. Condenser
   - ☐Isolation and flow balancing valves installed.
   - ☐ Calibrated thermometers and pressure gauges installed in/out of condenser on machine side of any valve or elbow.
   - ☐ If condenser pump controlled by UCP2, is field wiring correct and complete?
   - ☐ Condenser pump(s) run, system and strainers properly cleaned and/or flushed.
   - ☐ Condenser water strainer in close proximity to entering connection of condenser.
   - ☐ Provisions installed to properly maintain water treatment additives.
   - ☐ Initial water treatment added to system.
   - ☐ Flow or differential pressure switch installed and wired in series with auxiliary of pump motor starter. Operation of circuit verified.
   - ☐ Condenser water flow balanced. Ft H2O PD design_____, Ft H2O actual_____ GPM design_____ GPM actual_____

6. Evaporator

☐ _____PSIG. Must be positive pressure or leak test must be done.

☐ Calibrated thermometers and pressure gauges installed in/out of evaporator on machine side of any valve or elbow.

☐ If evaporator pump controlled by UCP2, is field wiring correct and complete?

☐ Evaporator pump(s) run 24 hrs. System and strainers properly cleaned and/or flushed.

☐ Evaporator water strainer in close proximity to entering connection of evaporator.

☐ Provisions installed to properly maintain water treatment additives.

☐ Initial water treatment added to system.

☐ Flow or differential pressure switch installed and wired in series with auxiliary of pump motor starter. Operation of circuit verified.

☐ Evaporator water flow balanced. Ft H2O PD design_____, Ft H2O PD actual_____
GPM design_____ GPM actual_____

7. Electrical and Controls

a. Motor starter panel

☐ All terminals tightened.

☐ Wiring free from abrasion, kinks, and sharp corners.

☐ Contactors and relays have freedom of movement.

☐ All contacts are free of corrosion or dirt. Panel is free of dust, debris etc.

☐ Check the ratio of the current transformers. Record the part #s on the start-up log.

☐ Use only twisted shielded pair for the IPC circuit between the starter and the UCP2 on remote starters. Recommended wire is Beldon 8760, 18 AWG. Polarity is critical.

☐ The low voltage IPC link (< 30 volts) must be in a separate conduit from the 115 volt wiring.

☐ IPC link routing within the starter panel must stay a minimum of 6 inches from higher voltages.

☐ Remote starter to UCP2 connections are complete and comply with Trane requirements.

☐ Check the correctness of the power connections from the starter to the motor.

☐ Check the wiring to the starter for size, voltage, and correct phase rotation (A-L1, B-L2, C-L3).

☐ Check for equal phase representation in each power wiring conduit.

b. Control panel

☐ All terminals tightened.

☐ Wires free from abrasion, kinks, sharp corners.

☐ Low voltage wires are isolated from high voltage wires.

☐ Panel is free of debris, dust, etc.

☐ "Power up" the control panel.

1. Starter disconnect locked open.
2. Fuse 2F4 must be removed from the starter.
3. Connect auxiliary 115VAC power cord to Terminals 1TB1-1 and 1TB1-2 in the control panel. **MAKE SURE OF THE POLARITY. THE 'HOT' SIDE MUST BE CONNECTED TO TERMINAL 1TB1-1 AND THE 'NEUTRAL' SIDE TO 1TB1-2.**
4. Plug in cord to 115VAC power source. Control panel is now energized.

☐ Record the settings found in the Operator Settings,Service Settings Field Start-up Group, and Machine Configuration Menus in the UCP2.

☐ Using the CVHE Operation and Maintenance manual and the order specification, double check and reset, if required, the settings of Current Overload Setting #1 and Current Overload Setting #2 found in the Machine Configuration menu of the UCP2.

NOTE: DO NOT FORGET TO ADJUST THE RLA RATING TO MATCH THE ACTUAL JOBSITE VOLTAGE IF IT DIFFERS FROM THE DESIGN VOLTAGE.

☐ If Evaporator and/or condenser water pumps are controlled by the UCP2, use the Service Test menu of the UCP2 to manually start and test the control of the pumps.

☐ Check the setting of the oil pressure regulating valve.

1. Use the Service Tests menu of the UCP2 to manually start the oil pump.
2. Proceed to the Compressor Report menu of the UCP2 and observe the Differential Oil Pressure.
3. Adjust the oil pressure regulating valve to maintain 12 to 18 psid. The oil pressure regulating valve may require adjustment as the unit is started.
4. This procedure also checks to ensure correct sensing of oil pressure. The Oil Pressure Cutout setting is a non-adjustable 9 psid within the logic of the UCP2.
5. Return Oil Pump control to 'auto'.

☐ Check vane operator and vanes.

1. Use the Service Tests menu of the UCP2 to manually overide the vane control.
2. Enter targets from 0% to 100% and observe vane operation. At minimum and maximum travel the operator should not exert any force on the vane assembly, adjust as required.
3. Vane movement is smooth to open/close.
4. Vane movement is reported back to the UCP2.
5. Return Vane control to 'auto'.

☐ Dry run the starter

1. Make sure the starter disconnect is safety locked open.
2. Use the Service Tests menu of the UCP2 to initiate the Starter Dry Run.
3. Observe correct operation of starter contactors.
4. Observe correct operation of transition complete signal (if required).
5. Disable Starter Dry Run when complete.

☐ Disconnect and remove the temporary power cord.

B. Preparation for Start-up.

1. Evacuation and charging

☐ Evacuation leak test. When vacuum has been drawn down to 1-2 MM Hg, secure the vacuum pump.Wait for 12 hours for a valid vacuum leak test. If the rise in vacuum is less than 2.5 per 12 hours, start-up may proceed.

☐ Charge refrigerant. **MAKE SURE THE CHILLED WATER IS FLOWING THROUGH THE EVAPORATOR.** Charge the prescribed amount of refrigerant through the liquid charging valve at the liquid inlet to the evaporator. Check that all drums contain a full amount of refrigerant. Amount charged _____lbs/kg.

2. Electrical

☐ Disconnect all temporary power cords, replace all fuses, connect motor leads, make final electrical inspection.

☐ Power up the motor starter. Check for control voltage at control panel terminals 1TB1-1 and 1TB1-2. _____volts

☐ Check current to the oil sump heater. ____amperes

☐ As the oil heats up, finish any operations not yet completed in preparation for starting the unit.

C. Chiller Start-up

1. Make all preliminary checks.

☐ Oil temp, oil level, chilled water flow, chilled water load available (cooling units on) etc.

2. Start the unit.

☐ If the phase rotation of the electrical power has not been positivly confirmed, the actual rotation of the motor must be checked. Observe the rotation of the motor shaft through the sight glass on the end of the motor at the moment of start-up. Rotation must be CLOCKWISE. If the phase sequence is incorrect, confirmed by observation of the Phase Reversal diagnostic on the UCP2, then L1 and L3 power leads to the starter must be reversed.

☐ As the unit starts and runs, observe closely all operating conditions.

☐ Adjust the oil pressure regulator if necessary to 12 to 18 psi net.

☐ In the Operator Settings menu of the UCP2, place the Purge Operating Mode to 'on' to allow the removal of non-condensables. It may also be necessary to increase the length of the Purge Service Override timer found in the Field Startup Group menu.

☐ After the unit has the system down to design leaving chilled water temp and is under control, and the purge is no longer relieving non-condensables, begin taking the startup test log. Log the unit a minimum of 3 times at 15 minute intervals.

☐ In the Operator Settings menu of the UCP2, return the purge operating mode to 'Adaptive'.

☐ When the logging is complete, shut the chiller down. Allow the unit to sit idle for 5-10 minutes. Attach a piece of clear plastic hose between the 1/2 inch valve at the bottom of the evaporator and the 1/4 inch valve near the top of the evaporator. Open the valves and record or mark permanently the refrigerant level in the hose.
RECORD THIS LEVEL - IT IS VERY IMPORTANT! At some later time, the refrigerant charge can be easily checked and verified.

☐ Restart the chiller and carefully observe the starting and loading sequence.

3. Instructions to the Chiller Operator.
   ☐ Instructions for starting, operating, and shutting down.

   ☐ Instructions for logging the unit.

   ☐ Instructions for periodic maintenance.

D. After 2 weeks of operation.

1. Remove the water box covers on both the evaporator and condenser. Mechanically brush clean all the tubes. This is to assure there is no debris blocking any of the tubes. A piece of debris partially blocking a tube may cause that tube to fail prematurely.

2. Replace the oil filter with the spare oil filter included in the control panel at time of shipment.

CenTraVac®
Checksheet And Request For Serviceman

To: _____ Trane Service Company

S.O. No.:_____ Serial No.: _____

Job/Project Name:_____

The Following Items Are Being Installed And Will Be Complete By _____

1. CenTraVac:
In place and piped. Do not insulate CenTraVac or adjacent piping. The contractor is responsible for any foreign material left in the unit. ..... ☐

2. Piping:
Chilled water piping connected to:
- CenTraVac ..... ☐
- Air handling units ..... ☐
- Pumps ..... ☐

Condenser and heat recovery condenser (as applicable) piping connected to:
- CenTraVac ..... ☐
- Pumps ..... ☐
- Cooling tower ..... ☐
- Heating loop ..... ☐

Make-up water connected to cooling tower ..... ☐
Water supply connected to filling system ..... ☐
Systems filled ..... ☐
Pumps run, air bled from system ..... ☐
Strainers cleaned ..... ☐

3. Flow Balancing Valves Installed:
Leaving chilled water ..... ☐
Leaving condenser water ..... ☐
Heat recovery condenser leaving water ..... ☐

4. Wiring:
Compressor motor starter has been furnished by or approved by The Trane Company, La Crosse, WI . ☐
Power available ..... ☐
Interconnecting wiring, starter to control panel ... ☐
External interlock (flow switches, water pump aux., etc.) ..... ☐

Motors connected on:
- CenTraVac* ..... ☐
- Chilled water pump ..... ☐

Cooling tower fan rotation checked ..... ☐
Condenser water pump ..... ☐
Heat recovery condenser water pump (as applicable) ..... ☐
Power available for vacuum pump ..... ☐
(115V AC) ..... ☐
All controls installed and connected ..... ☐
All magnetic starters installed and connected ..... ☐

*NOTE: Do not make final connections to compressor motor until requested by Trane Service Representative.

5. Testing:
Dry nitrogen available for pressure testing ..... ☐
Refrigerant-22 available for leak testing if necessary (25 lbs.) ..... ☐

6. Refrigerant On Job Site ..... ☐

7. Gauges, Thermometers And Air Vents
Installed on both sides of evaporator ..... ☐
Installed on both sides of condenser and heat recovery condenser (as applicable) ..... ☐

8. System Can Be Operated Under Load Conditions ..... ☐

9. Electrician, Control Man And Contractor's Representative Are Available To Evacuate, Charge And Test The CenTraVac Under Serviceman's Supervision ..... ☐

In Accordance With Your Quotation And Our Purchase Order Number _____

We Will Therefore Require Your Serviceman On The Job By**_____

This is to certify that the CenTraVac(s) has been properly and completely installed and the applicable items listed above have been completed.

**Advance notification is required to allow scheduling of the start-up as close to the requested date as possible.

Supersedes 1-27.08-6—(895)

Compliance To ASHRAE Standard 15

Yes No 1. Does the equipment room have a refrigerant monitor/sensor capable of monitoring and alarming within the acceptable exposure level (AEL) of the refrigerant?

Yes No 2. Does the equipment room have an audible or visual alarm (other than the light on the monitor) which is controlled by the monitor?

Yes No 3. Does the equipment room have mechanical ventilation?†

Yes No 4. Is a self contained breathing apparatus available in close proximity of the equipment room?

Yes No 5. Are the purge discharge and the rupture disk piped to the outdoors?

†The mechanical ventilation consists of two flow requirements i.e., a two-speed fan where the high speed is sized by the formula Cfm = 100 × the square root of the pounds of refrigerant of the largest chiller, and low speed is 0.5 Cfm per square foot of the equipment room space. (This requirement is for chillers located within the building which is the most common.)

Owner Awareness Of Safe Refrigerant Handling Procedures

Yes No 1. Has the owner been fully instructed on the proper use of refrigerant 123?

Yes No 2. Was the owner given a copy of the MSDS sheet for HCFC-123?

Yes No 3. Was the owner given a copy of Trane publication "CFC-GUIDE-2, Refrigerant Handling Guidelines"?

Additional time required to complete the start-up and adjustment due to incompleteness of the installation will be invoiced at prevailing rates.

Model Number

Unit Model Number

For service and replacement purposes, the Trane Model AFDA Adaptive Frequency Drive (AFD) and the AFDA controller are assigned a multiple-character alphanumeric model numbers that precisely identifies each unit. The model number key is shown here. Use of the model number will enable the owner/operator, installing contractor, and service technician to define the characteristics of any AFDA unit. Be sure to refer to the model number when ordering replacement parts or requesting service.

General Information

About This Manual

The instructions outlined in this booklet describe the procedures for retrofitting a Trane Version A Adaptive Frequency Drive. The controls are designed to be added to an existing Trane chiller without replacing the present control system. The operation and maintenance of the controls are explained later in this manual. This manual is intended for use by experienced service personnel.

Specific information for the Accutrol 700 Drive is found in the manufacturer's Instruction Manual included in the ship/with literature packaged in the AFD:

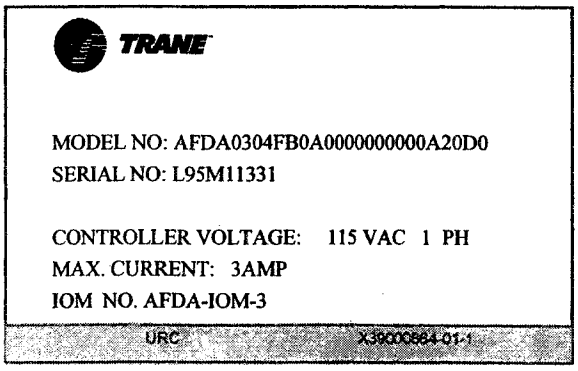
- Instruction Manual entitled "Installation, Start-up and Maintenance Manual CCPWM Adjustable Frequency AC Controller 100-600 HP Accutrol 700"

Literature Change History

AFDA-IOM-3 (January 1996)

Original issue of the manual containing design sequence "B0" and Controls design sequence "D".

Warnings and Cautions



Note that warnings and cautions appear in appropriate sections throughout this manual.

⚠ WARNINGS!
are provided to alert installing contractors and other personnel to potential hazards that could result in serious personal injury or death.

⚠ Cautions:
are provided to alert personnel to conditions which could result in moderate or minor personal injury or damage to equipment or property.

Your personal safety and the proper operation of this machine depend upon precautions. The Trane Company assumes no liability for installation or service procedures performed by unqualified personnel.

Figure 1
Typical Unit Nameplate Data

General Information

Adaptive Frequency Drive (AFD) Conversion Package Explanation

The Adaptive Frequency Drive Package comes in two configurations:

- Bypass option - Enables the drive to be wired through an existing Wye-Delta starter. This feature is useful for two reasons. The included transfer switch allows the chiller to operate with the existing electro-mechanical starter - (1) while servicing the AFD or (2) during prolonged periods of operating near the chiller's full capacity when AFD is not needed.
- Non Bypass option - The chiller is wired directly through the AFD.

The Version A controller is intended for operation with one of the following control systems:

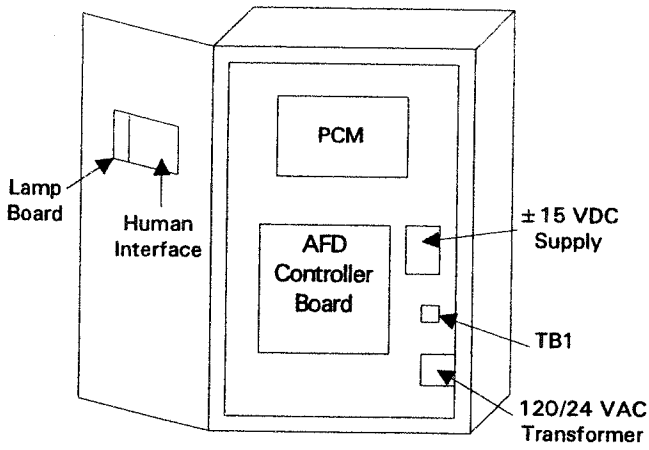
- UCP1
- Control Package Replacement (CPR) Kit
- Trane "Classic" black panel - With this system, the panel must have a Capacity Control Module (CCM) designated MOD0012, MOD0061 or MOD0182. "Classic Black" panels utilizing the "AGM" module will need to be retrofitted with a CCM module specified above.

Note: When retrofitting an AGM with a CCM, the leaving and/or return chilled water sensor needs to be replaced.

The Version A controller is not intended for use on pneumatic systems.

Adaptive Frequency Drive Nameplate

The Accutrol 700 has a nameplate similar to standard Trane starters. Refer to the model number printed on the Version A control panel nameplate when ordering replacement parts or requesting service for either the controller or the drive. Refer to Figure 1 for an example of a typical unit nameplate on the AFDA control panel.



Conversion Package Inspection

Before installing the AFD, compare the data on the controller and drive nameplates with the corresponding ordering and shipping information to verify that the proper AFD conversion package was shipped.

If a thorough inspection of the conversion package reveals damage or material shortages, file the claims with the carrier immediately and specify the extent and type of damage found. The Trane Company assumes no responsibility for transportation or jobsite damage. If damaged equipment is installed, Trane will not accept any claims involving that equipment.

General Information

Figure 1a - AFD Version A Controller Component Layout

Conversion Package Contents

Each conversion kit includes the following items:

- Version A control panel with components as shown in Figure 1a
- Accutrol 700 Drive with I/O Board
- Two (2) Pressure Transducers with cables for monitoring the evaporator and condenser pressure
- Inlet Guide Vane (IGV) Position Sensor with signal conditioning and mounting hardware
- Transfer Switch (optional) with interlocks
- Literature including AFDA-IOM-3 and Accutrol instruction manual

Field Provided Items

- Control Power Circuit Breaker
- Power Wiring
- #16 AWG Wire for 120 VAC Control Circuits
- Beldon Type 8760 Wire for <30 Volt Circuits
- Junction Box (for Bypass installations only)
- Current transducer TDR0269 and resistor RES0913 for Classic Black controls without bypass
- Pilot relay (for Classic Black Bypass and Non-Bypass installations)

General Information

The existing control system dictates how many current transformer(s) are required. Existing CT's can be used. Reference Table 1 to determine the CT arrangement necessary for your particular control system. The large donut type (line) CT must be sized according to chiller RLA, to step line current to a 5 amp signal. The small secondary current transformer(s) (if applicable) steps the 5 amp signal to an mA signal. The small current transformer part number is TRR0452. For Classic Black without bypass system, the TDR0269 current transducer and the RES0913 resistor will need to be ordered. (Refer to Figure 23 for wiring.)

- Wye-Delta Starter (optional)
- Junction Box (optional)
- Motor Terminal Junction Box (Non-bypass, unit mounted starter)

Note: Refer to Figures 4 and 5 for location of the components.

Table 1 - Current Transformers

Control System	Line CT(s) Required	Secondary CT(s) Required	CT5 Current Transducer Required
UCP1 with Bypass	3	3	No
UCP1 without Bypass	1	1	No
"Classic" black panel with Bypass	3	None	No
"Classic" black panel without Bypass	1	None	Yes
CPR with Bypass	1	None	*Yes
CPR without Bypass	1	None	*Yes

*Current Transducer is already in place in the CPR panel.

Note: CT's will be located in the starter panel for bypass systems and in the drive panel for non-bypass systems.

Physical Dimensions

Table 2 summarizes approximate dimensions for the AFD.

Table 2 - Physical Dimensions

Description		Dimensions	Weight
Drive	180 RLA	20" w x 90" h x 21" d	~ 800 lbs.
	240 - 304 RLA	28" w x 90" h x 21" d	~ 1000 lbs.
	360 - 734 RLA	60" w x 90" h x 21" d	~ 2000 lbs.
Transfer Switches	< 348 RLA	23 7/8" w x 54 1/4" h x 12 1/2" d	140 lbs.
	349 - 522 RLA	24 7/8" w x 63 3/4" h x 14 1/8" d	170 lbs.
	523 - 696 RLA	24 7/8" w x 63 3/4" h x 14 1/8" d	175 lbs.
Controller	—	22 1/2" w x 28 1/2" h x 4 1/8" d	~ 70 lbs.

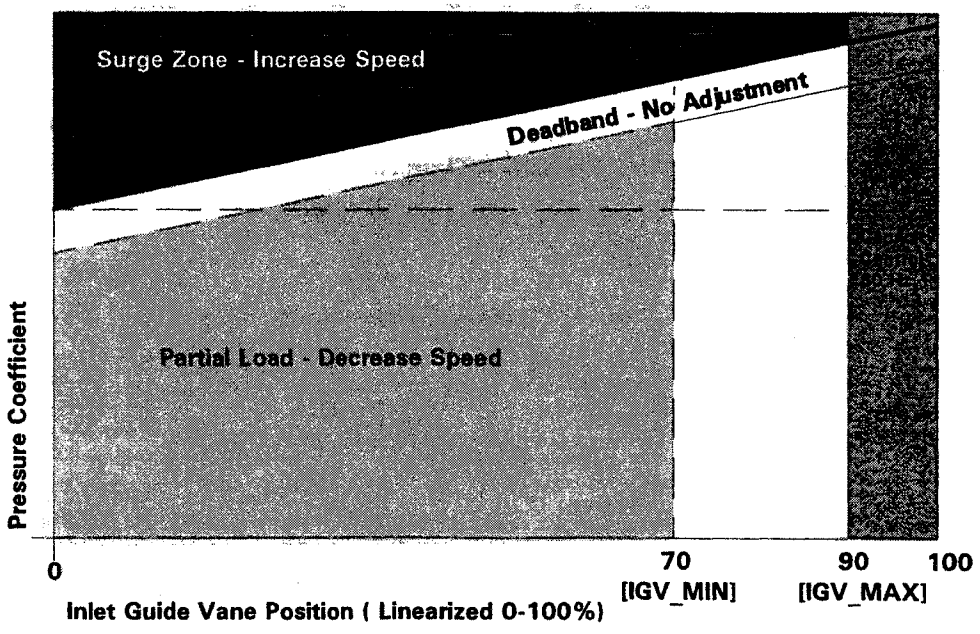
Introduction

The Trane Version A - Adaptive Frequency Drive package provides increased energy efficiency at partial load conditions by decreasing the speed (reducing frequency) of a centrifugal compressor motor. The Version A controls accomplish this by using the Inlet Guide Vane position to adjust the load on the chiller. Since the chiller operates most efficiently near surge conditions; the evaporator pressure and the condenser pressure and frequency are used to create a **pressure coefficient** that predicts where surge will occur. Manual or automatic adjustment of the Version A control to follow the "surge line" will fine tune this prediction to allow the system to control at a safe minimum speed in all operating conditions for a given chiller.

The Version A controls allow for five different operating scenarios (see Figure 2). They are :

Surge Zone - When surge is predicted, the frequency is increased in order to enter a more stable operating region. If surging continues at the maximum speed, the controls will shut down the chiller to protect the compressor.

<70% [IGV_MIN] Open Guide Vanes (Partial Load) - The controls will decrease speed until the surge boundary deadband is reached or at a minimum speed of 42 Hz. When the inverter decreases speed, the chiller controls will sense a need to increase capacity and open up the guide vanes thereby forcing control strategy into the next region.



70% [IGV_MIN] to 90% [IGV_MAX] Open Guide Vanes - In this range, frequency is not adjusted, allowing the guide vanes to accommodate changing load conditions.

>90% [IGV_MAX] Open Guide Vanes - The AFD will gradually ramp up to 60 Hz. (maximum speed) to allow the guide vanes to modulate for capacity control.

Deadband - In this region, the frequency is not adjusted.

See the Setup section for further explanation of the Programmable Control Module (PCM) parameters in brackets [ ].

Figure 2 - Speed Adjustment Criteria

Harmonics

Additional harmonic currents are added to the line by the Adaptive Frequency Drive, as with any non-sinusoidal electronic power converter such as a frequency inverter. This can affect other devices on the line if they are susceptible to the voltage distortion created. The two main factors in voltage distortion are total impedance of the system of components on a power line and current distortion injected back on the line by all devices.

Voltage distortions can, in rare circumstances, create failure of capacitor banks. Depending on the physical location of power lines, circuitry such as telephone equipment and other sensitive devices may also be effected.

IEEE 519 (Standard for Electrical Power Distortion) contains suggested maximum levels of harmonics for specific applications. If there is concern about equipment, a harmonic analysis may be beneficial before installing a drive. These results can suggest methods of protecting equipment from potentially harmful effects of distortion. Contact the local sales office for complete analysis information.

Removing the Old Starter

Note: This section applies only to non-bypass installations.

Preparation

Turn off the main power disconnect to the chiller.

⚠ WARNING!
To prevent injury or death due to electrical shock, disconnect electrical power source before making electrical connections.

Starter Removal Procedure

1. Disconnect and remove the Control Power Transformer (1T1).

2. Remove the line CT's and the Solid State Overload (if present).

3. Disconnect main power lines at L1, L2 and L3.

Note: Keep the items listed above if they are to be re-used on the new drive panel.

4. Disconnect T1 through T6. The motor leads must be connected at the inverter to join T1 to T6, T2 to T4 and T3 to T5 or a bus bar for the motor terminal junction box (field fabricated).

5. Move fuse blocks for F1, F2, F3 and F4 to the new AFD drive panel on older CTV's.

6. Remove starter from mounting pad or from the motor terminals. For a unit mounted starter, a field-supplied motor terminal junction box is required. Move the transformer 480 volt side fusing to the new AFD panel.

7. Reconnect all transformers and wiring.

Installation

Component Mounting Location

Accutrol 700 Drive - The drive should be located and mounted according to the procedures in the Instruction Manual included with the AFD literature package.

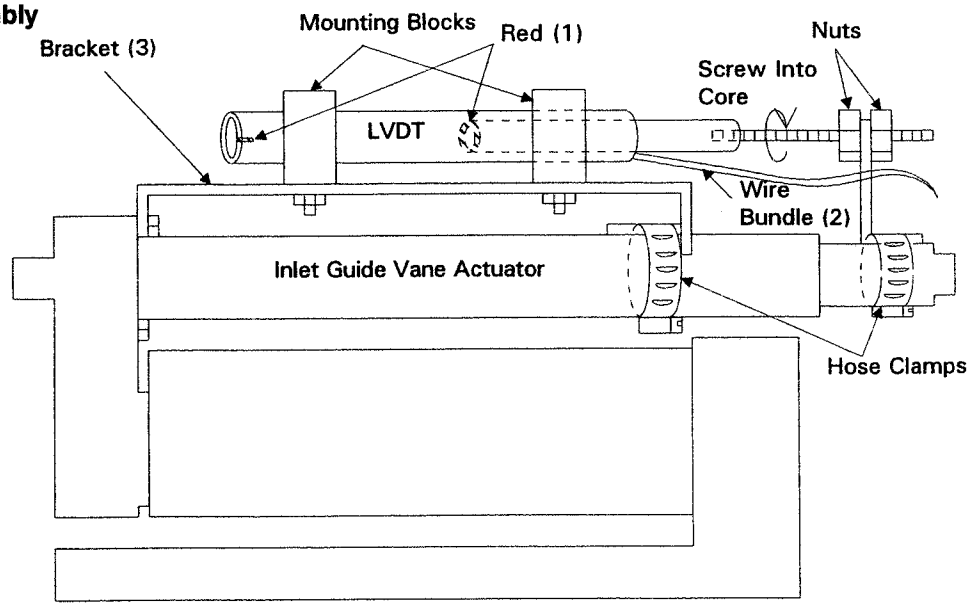
Version A AFD Controller - The controller is intended as an overlay to existing controls. Trane suggests mounting the controller on the wall adjacent to the drive and optional existing starter or building a stand so that the controller may be floor mounted.

⚠ Caution:
Do not unit mount the controls on the chiller. Doing so may cause damage due to vibration.

Transfer Switch (optional) - The switch should be wall mounted in an area that is accessible for wiring from the starter and the AFD Drive. Ideally, this is between the starter and the drive.

Junction Box (Bypass installations only) - Wall mount in a convenient location. See Figure 5 for wiring details.

Inlet Guide Vane Position Sensor - Use the provided bracket to mount on the Inlet Guide Vane Actuator. Assemble as shown in Figure 3.



Signal Conditioning Module - Mount the enclosure on the inlet guide vane position sensor bracket. See Figure 6 for wiring details.

Condenser Pressure Transducer - Install **vertically** in the vapor space with the wires pointing upward. Tee out of existing lines to maintain the refrigerant charge. See Figure 6 for wiring details.

Evaporator Pressure Transducer - Same as for the Condenser. See Figure 6 for wiring details.

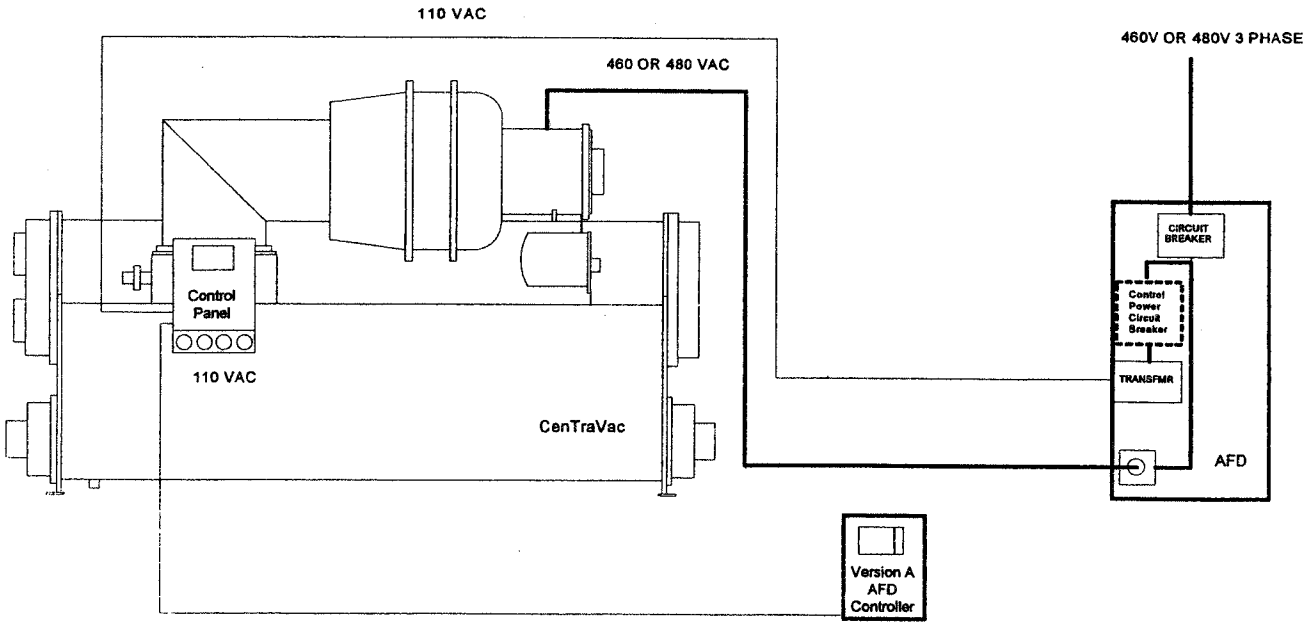
Relay Board (Optional bypass) - Mount in starter using standoffs provided. See Figure 15b for wiring details.

Figure 3 - Inlet Guide Vane Position Sensor Assembly

Notes:

1. Red on end of core and body must be oriented as shown to ensure proper operation.
2. Note location of leads. Make sure wire bundle is free to move as actuator strokes in and out.
3. Bracket can be side mounted if space is not available on top of the actuator.

Wiring - Power



⚠ WARNING!
To prevent injury or death due to electrical shock, disconnect electrical power source before making electrical connections.

⚠ Caution:
Do not cut AFD enclosure to provide electrical access; components and wiring could be damaged causing electrical failure. Removable panels have been provided for this purpose. Refer to installation information shipped with the AFD.

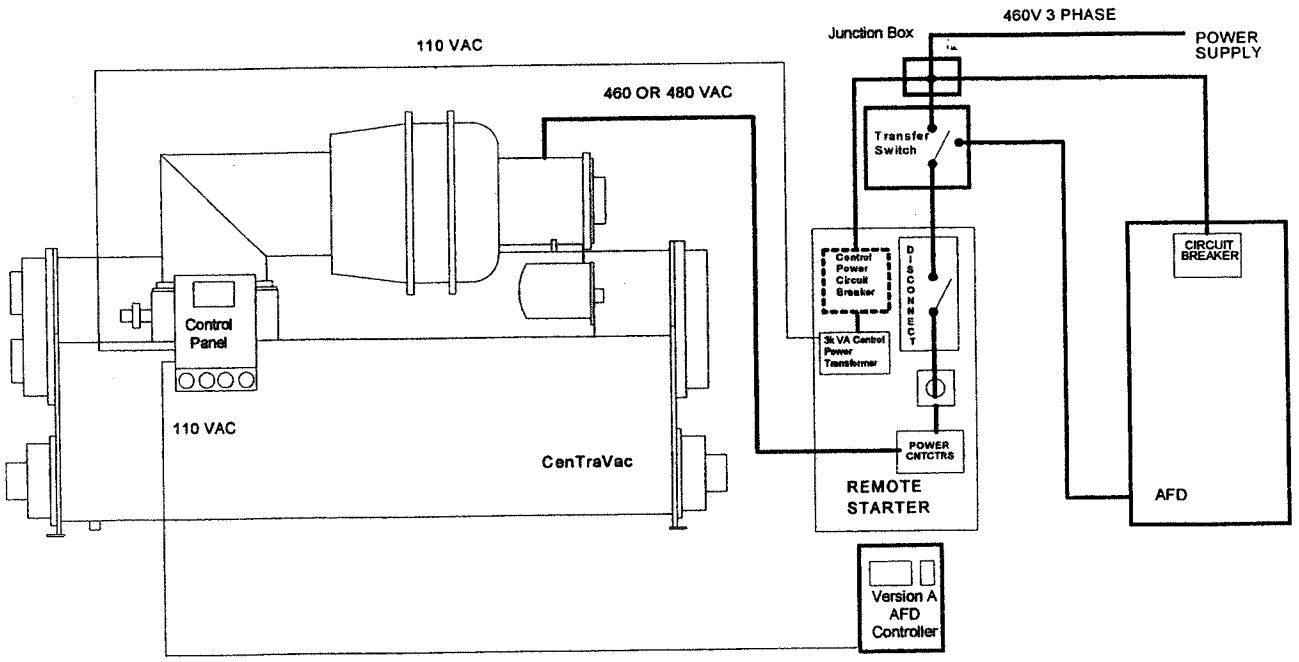
Non-Bypass

All power wiring must be done with the power off from the main disconnect. The lines from the drive to the compressor motor should not exceed 100 feet. Use the existing power wires from the line voltage to the motor. Figure 4 shows the power wiring for this configuration. Add an additional control power disconnect to the system. Remove the 3k VA control power transformer from the old starter and mount in the adaptive frequency drive.

Figure 4 - Power Wiring Start-up Non-Bypass

Note: The 3kVA control power transformer and one of the line CT's are moved from the starter to the AFD. The control circuit breaker is added for the AFD.

Wiring - Power



⚠ WARNING!
To prevent injury or death due to electrical shock, disconnect electrical power source before making electrical connections.

⚠ Caution:
Do not cut AFD enclosure to provide electrical access; components and wiring could be damaged causing electrical failure. Removable panels have been provided for this purpose. Refer to installation information shipped with the AFD.

Bypass

All power wiring must be done with the power off from the main disconnect. The lines from the drive to the compressor motor should not exceed 100 feet. The transfer switch must be installed as shown below. Connect the power wiring as shown in Figure 5.

Figure 5 - Power Wiring
Start-up Bypass

Wiring - Control

Control wiring to the AFD Controller Board is denoted by plug numbers (J*). The numbers are silk screened on the board behind the plugs. A ▲ indicates where pin 1 on the connector is located. "J" terminal block numbers are located on the relay board and AIP, AOP, BIP and BOP are located on the Programmable Control Module (PCM).

Factory Wiring

Table 3 summarizes all factory wiring.

Table 3 - Factory Wiring

From	To	Wire Number
J1-1	120 VAC Terminal Block Hot (TB1)	201A
J1-2	120 VAC Terminal Block Neutral (TB1)	201B
J2-1	120 VAC:15VDC Power Supply	202A

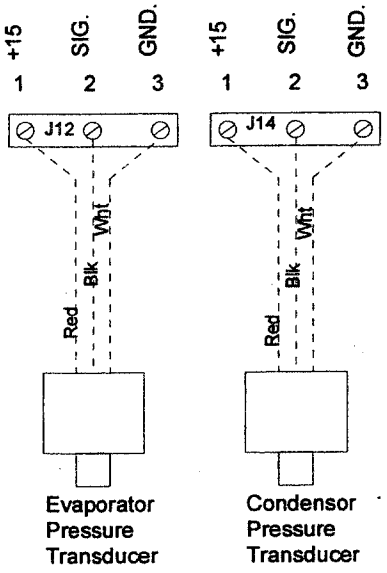
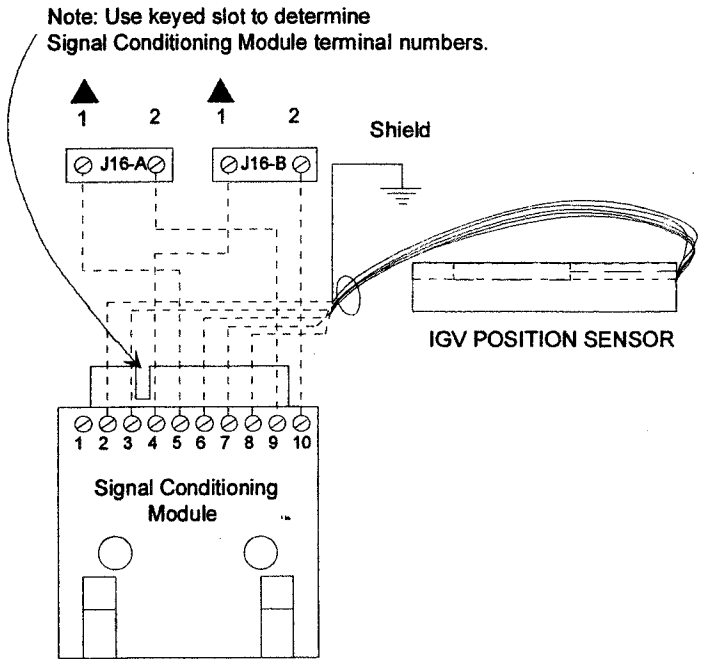
Sensor Wiring



A. Evaporator Pressure Transducer - Connect as shown in Figure 6.



B. Condenser Pressure Transducer - Connect as shown in Figure 6.

C. Inlet Guide Vane Position Sensor (IGV Position Sensor) - Refer to Figure 3 for assembly. Do not extend the leads provided. The factory supplied cable length of the IGV Position Sensor leads is six (6) inches.

D. Signal Conditioning Module - Mount the module inside the box provided as follows. Remove the four screws securing the box cover to the base. Center the module in the box; then attach with the two screws provided. The potentiometers and the terminal block on the board must be accessible. Remove the wiring knockout on the cover and reinstall the cover with the four screws. Mount on the inlet guide vane position sensor bracket. See chart and Figure 6a below.

7	Classic Black Only	21
9		F2
7	CPR Only	12
9		LL1

D. The Control Power Transformer (1T1) must be installed in the inverter. The CPT (1T1) should be powered directly from the line side of the inverter power section.

- For UCP1 installations - one donut CT and one auxiliary CT must be installed in the inverter. (See wiring to J34A).
- For Classic Black/CPR installations - one donut CT is required and is wired to the CT5 current transducer.

D. The bypass board (see Bypass wiring Figures 22, 24 and 26) is added to allow switching between interlocks.

Figure 8 - AFD Remote Wiring Bypass

Wiring - Control Panel

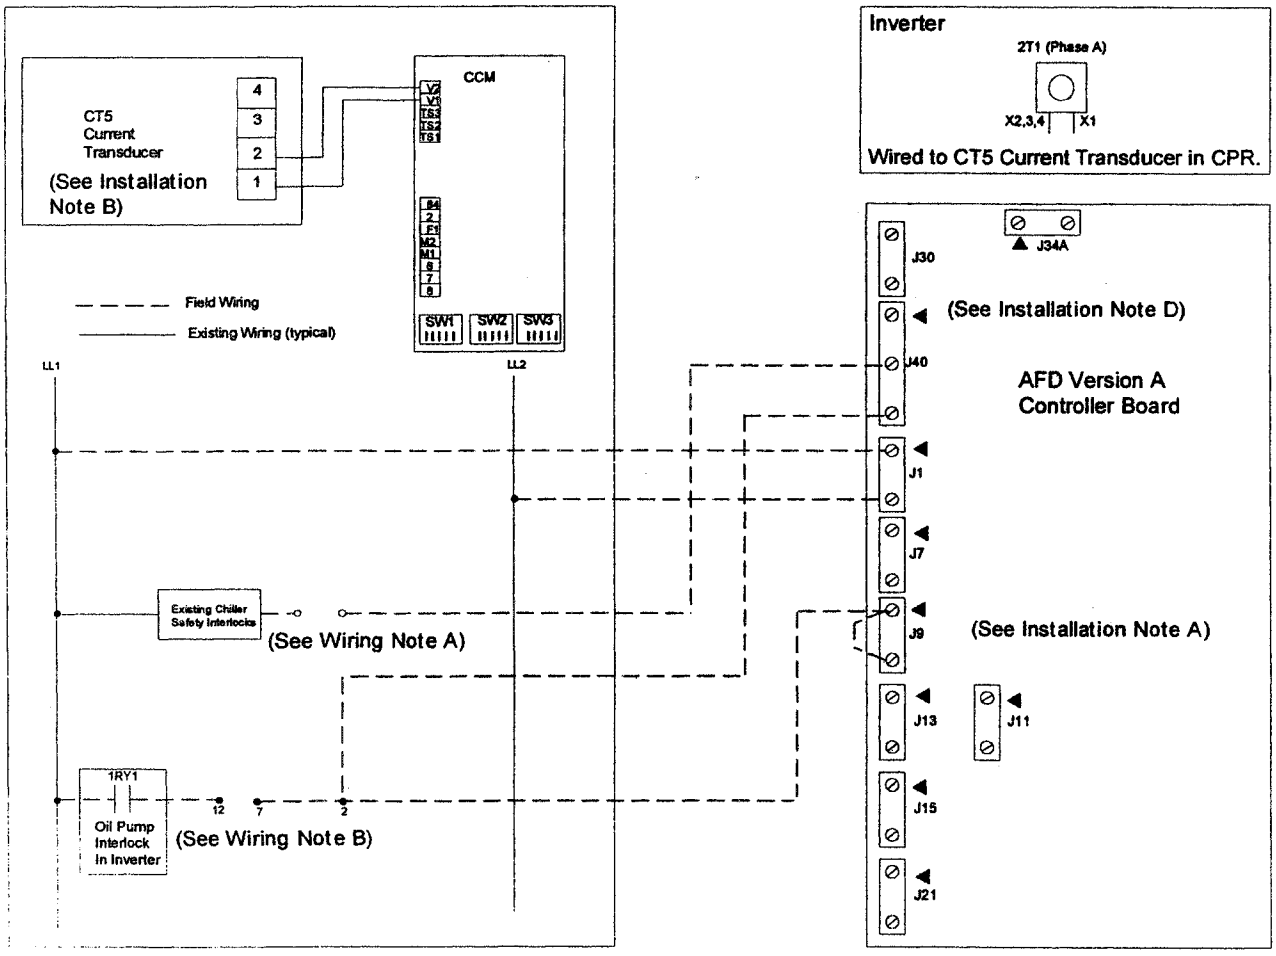
Capacity Control Module (CCM)

Two basic systems exist using the CCM; one is a Control Package Replacement (CPR) retrofit of a pneumatic control system and the other is the original Classic Black control panel. (For UCP1 wiring see page 26.)

Wire CPR Non-bypass as shown in Figure 9. Wire Classic Black panel Non-bypass as shown in Figure 12.

Wire CPR Bypass as shown in Figure 10. Wire Classic Black panel Bypass as shown in Figure 13.

Installation Notes



A. Start/Run Control - The start and run signals must be jumpered together. The signal is taken from the start string after the chiller safeties. (Figure 9, "J9")

B. Current Monitoring Circuit -

In Non-Bypass Systems:

- For Classic Black systems, the A1 solid state overload is no longer used. A current transducer like the one used in the CPR kit is required. This will produce the negative DC load proportional signal that is connected to the V1-V2 terminals on the CCM (Figure 12). The current transducer should to be mounted in the inverter. Refer to Page 7 for part numbers of the items required.
- For CPR systems, the current transducer will still be used to produce the load proportional signal (Figure 9).

Figure 9 - CPR Wiring Non- Bypass

Wiring Notes:

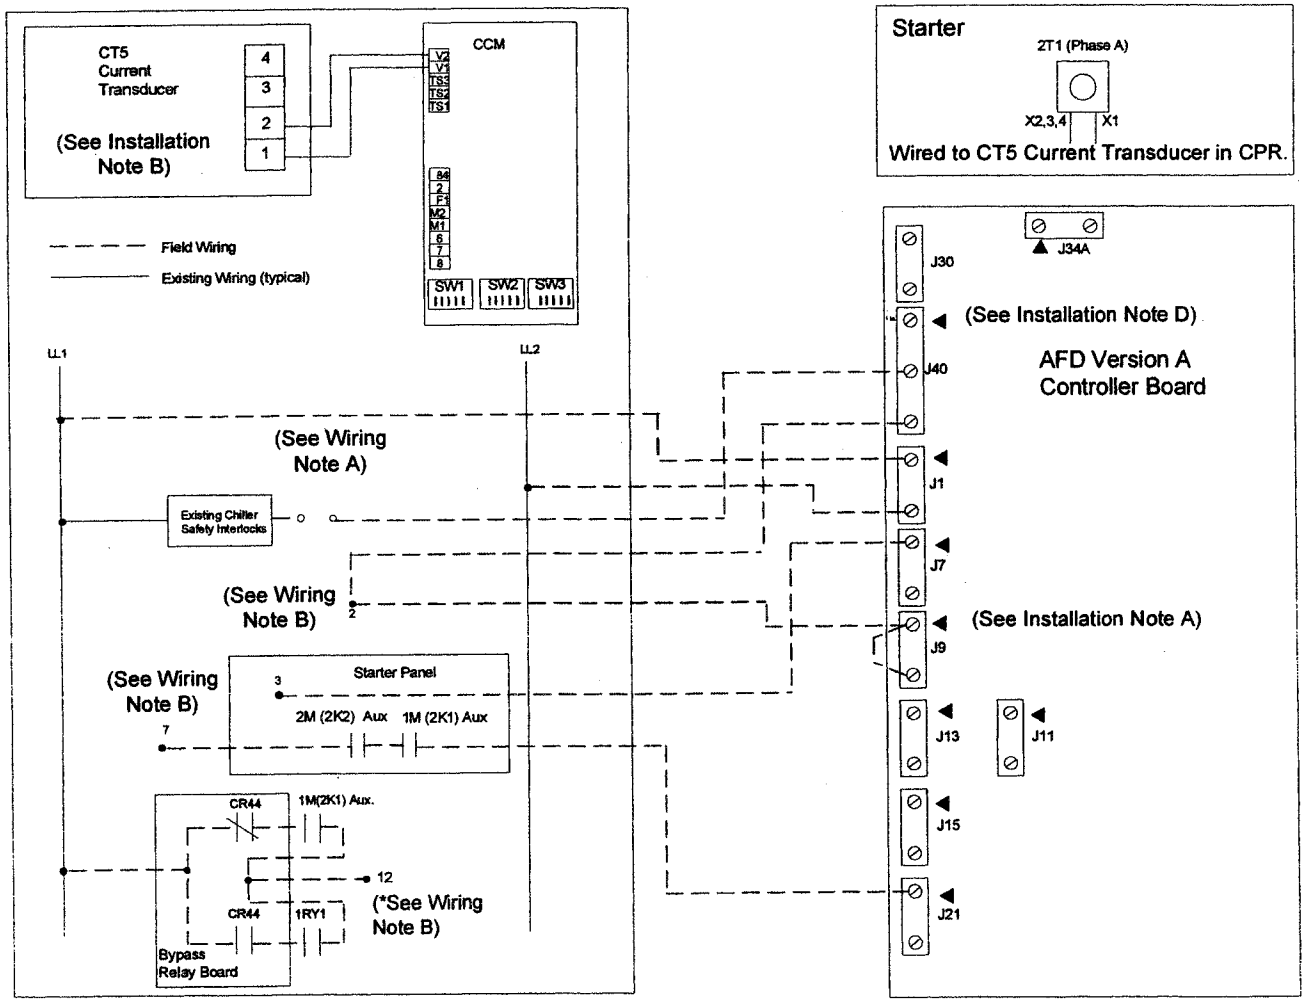
A. External Inhibit should be inserted into the start string in series with terminal TB1-8 or TB1-9 in the CPR panel.

B. Terminals are in existing pneumatic control panel.

Wiring - Control Panel

In Bypass systems:

- For Classic Black systems (see Figure 13) the A1 overload is kept to generate the V1-V2 load proportional signal for the CCM and to provide motor protection during operation of the electro-mechanical starter.
- For CPR systems (see Figure 10) the CT5 current transducer is kept to provide the load proportional signal for the CCM.



C. Transition (Starter Mode) - For Classic Black systems with bypass, the transition is controlled by the A1 overload. For CPR systems with bypass, transition is still controlled by the existing timed relay in the starter panel.

D. AFD Fault - The N.O. contacts of J40 must be inserted into the start string.

E. Dip Switches - On the CCM SW1 must be set for the RLA of the chiller. See following section and Table 4 for detailed information on proper settings. For Classic Black with bypass systems, the A1 overload has been calibrated to accommodate the CT ratio. The CCM should be calibrated so that 0-100% RLA = 0 to -8.25 Vdc.

Note: The calibration instructions in the Calibration Procedure are not used for this configuration.

Figure 10 - CPR Wiring Bypass

Wiring Notes:

A. External Inhibit should be inserted into the start string in series with terminal TB1-8 or TB1-9 in the CPR panel.

B. Terminals are in existing pneumatic control panel.

Wiring - Control Panel

100% RLA Calibration Procedure

Note: This procedure is used to calibrate the Capacity Control Module (CCM) for 100% RLA in systems utilizing a CT5 current transducer to produce the load proportional signal.

⚠ WARNING!
To prevent personal injury or death due to electrocution, which can result from using improper measurement techniques, the measurements required for this procedure should be made only by experienced technicians familiar with servicing chiller starters.

Procedure

1. Calculate the actual rated load amps on the worksheet below: First, enter the nameplate RLA and nameplate voltage. Then enter the highest voltage of the three power legs. If no leg is higher than the design voltage, enter the nameplate voltage in the "measured volts" space.

Example: A 350-amp, 480-volt nameplate motor is derated to a actual RLA of 329 amps when the measured voltage is 490 volts.

2. Calculate current transformer secondary amps on the worksheet below by dividing the desired RLA by the variable ratio current transformer ratio.

Example: 360 actual rated load amps divided by 400/5 variable ratio current transformer ratio equals 4.5 secondary amps.

3. Use Table 4 to select the proper setting for DIP switches SW1-1 thru 6 and set the switches to the proper settings. Then, operate chiller; check and record the amps for each leg.

Note: In this example, the correct setting for switches SW1-1 thru 6 at 4.5 secondary amps is:

ON|ON|OFF|OFF|ON|ON

4. When there is a significant current unbalance and the VRCT is not on the high leg, you can correct the secondary amps for phase imbalance by multiplying the amps for the current transformer leg divided by the amps of the highest power leg on the chiller.

Example: 4.5 secondary amps multiplied by 250 observed amps of the current transformer leg divided by 260 observed amps for the highest leg equals 4.33 corrected secondary amps.

5. Once you have determined the corrected secondary current value, use Table 4 to reselect the proper setting for current limiting DIP switches SW1-1 thru 6 and set the switches to the appropriate setting.

6. Confirm that the system current limits are at the proper values by operating the chiller at full rated current with the % current pot set at 100%. The current limit (amber) light should come on when full load current is observed at the starter. At this time, the DC voltage signal at terminals V1-V2 should be equal to the value shown next to the corresponding secondary amps value found in Table 4. If limiting does not occur at the level desired, minor adjustments can be made by selecting appropriate switch settings on SW1 (1 thru 6).

Figure 11 - 100% RLA Calibration Worksheet

1. Calculate actual rated load amps (RLA):

[_____] (Nameplate RLA) X [_____] (Nameplate Volts) = [_____] (Actual RLA)
[_____] (Measured Volts)

2. Calculate current transformer secondary amps by dividing the Actual RLA by the Transformer Ratio:

[_____] (Actual RLA) = [_____] (Secondary Amps)
[_____] (Transformer Ratio)

3. Correct the Secondary Amps (if necessary):

[_____] (Secondary Amps) X [_____] (Nameplate Volts) = [_____] (Actual RLA)
[_____] (Measured Volts)

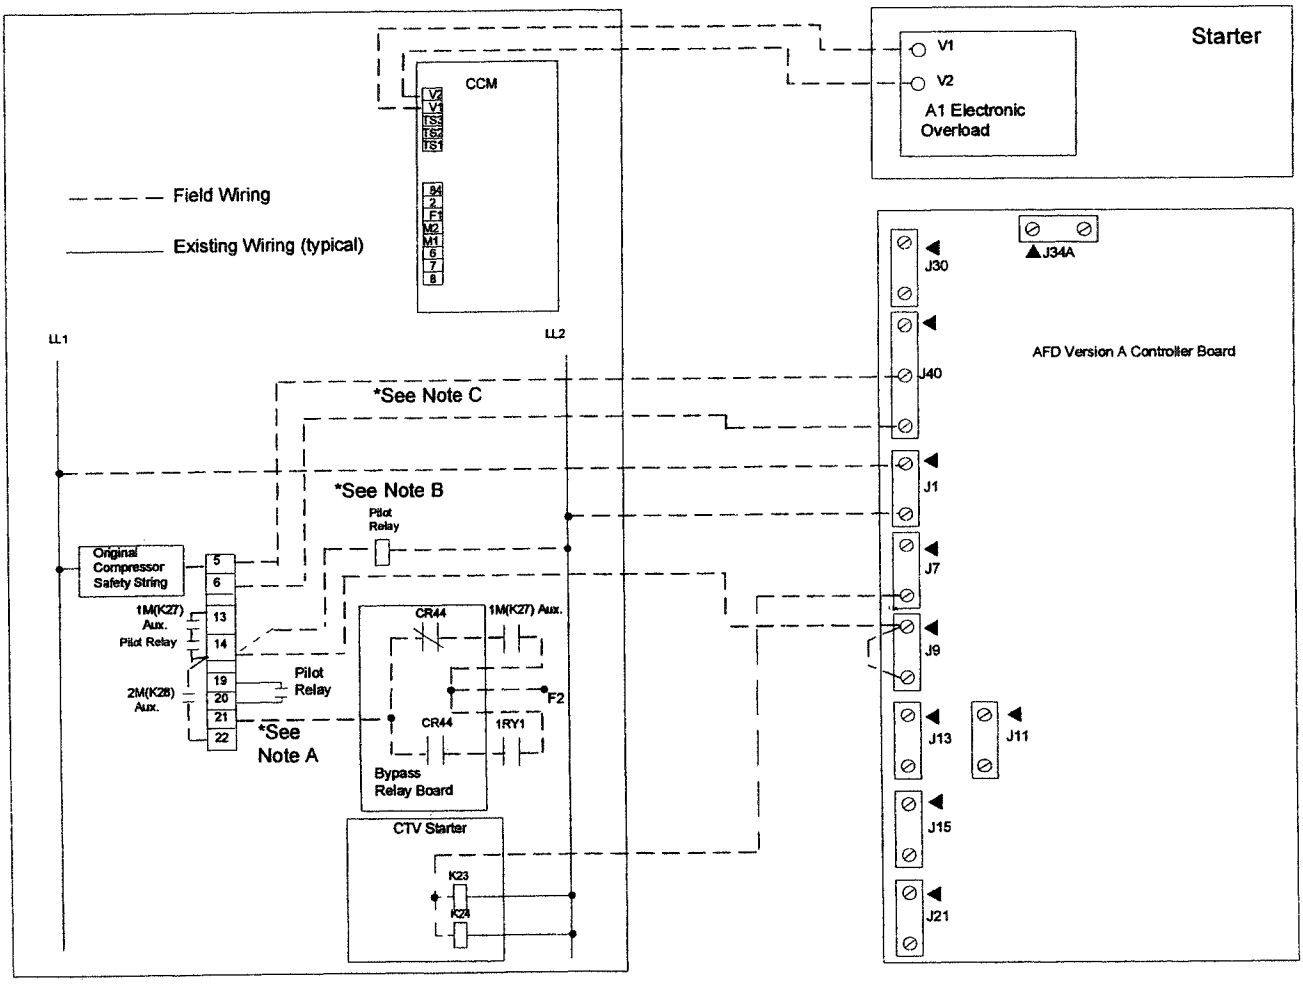
Note: DC voltage to V1-V2 (FV1) @ 100% RLA.

Wiring - Control Panel

Figure 12 - "Classic" Black Panel Wiring - Non-bypass



Notes:

A. Remove wire connected to terminal 22 from contactor auxiliary switch in starter and jumper terminal 22 to terminal 14.

B. Wire 120V coil of field provided pilot relay as show. The relay will be required to have two sets of NO contacts to be wired as shown.

C. Terminals 5 and 6 are recommended terminals for insertion of the external inhibit contacts from the drive controller. If these terminals have been used then wire external inhibit in series with safety string elsewhere upstream of condenser water pump.

Figure 13 - "Classic" Black Panel Wiring - Bypass

Notes:

A. Remove wire connected to terminal 22 from contactor auxiliary switch in starter. Wire 2M (K28) auxiliary contact between terminals 14 and 22.

B. Wire 120V coil of field provided pilot relay as show. The relay will be required to have two sets of N.O. contacts to be wired as shown.

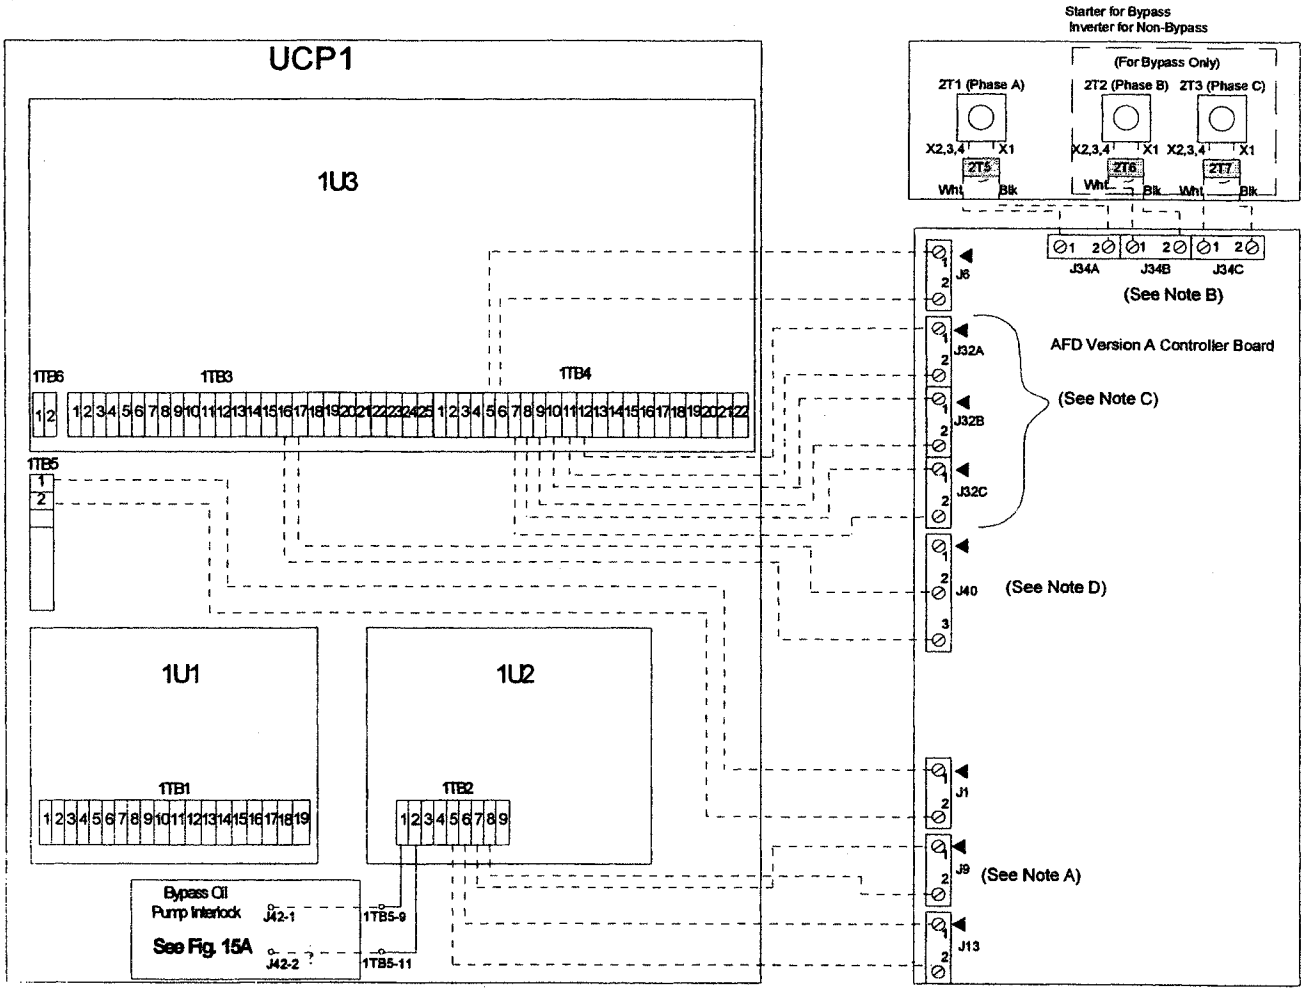
C. Terminals 5 and 6 are recommended terminals for insertion of the external inhibit contacts from the drive controller. If these terminals have been used then wire external inhibit in series with safety string elsewhere upstream of condenser water pump.

Chiller Controls Wiring

UCP1

Wire as shown in Figure 14.

Installation Notes



A. Start/Run Control - The UCP1 start and run signals are routed through the AFD Version A controller.

B. Current Monitoring Circuit - UCP1 systems use a 3-phase current monitoring input to provide motor protection. In Non-bypass systems, the inverter provides the motor protection so only one phase needs to be monitored for load. The AFD controller supplies the properly phased inputs for Phase B and C. **Note:** Phase A is referenced as the measure leg and this assumes a balanced system. If not balanced, the high current phase should be the leg monitored.

C. Transition - Since an inverter does not transition, the AFD controller simulates a Wye-Delta startup and provides the necessary feedback to the UCP1.

D. AFD External Inhibit - On earlier versions of UCP1, the Proof of Evaporator Flow circuit is used by the AFD controller to inhibit system operation when the controller senses a problem. This applies to CVHE units Design Sequence 1B and earlier and also applies to CVHB units Design sequence 1C and earlier. For these units wire terminals 1TB3-20 and 1TB3-21 in series with the evaporator flow proof string. On later UCP1's, the External Inhibit should be used. Refer to Figure 14 for this wiring scheme.

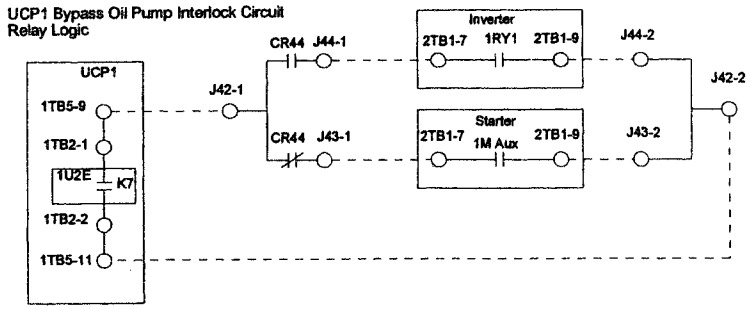
Figure 14 - UCP1 Wiring

Wiring - Starter (Bypass only)

Starter Rework (Bypass Only)

The Bypass Relay Board must be mounted in the existing starter and connected as shown Figures 15a and 15b below. The board contains circuitry for the oil pump interlock and contactor control.
Note: This replaces the existing oil pump interlock.

Figure 15a - Starter Rework



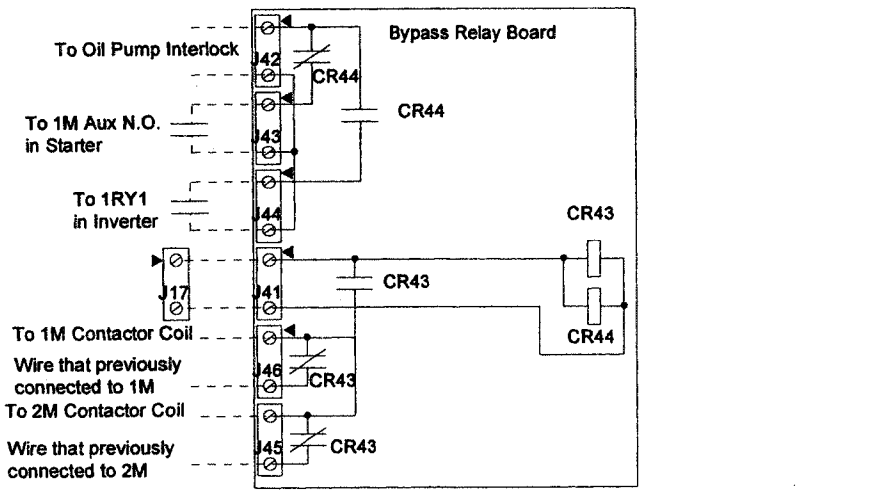


Figure 15b - Starter Rework

Note: Customer wiring to terminals **J41, J45, J46** is polarity sensitive. Wire exactly as shown for proper operation.

Startup

Adaptive Frequency Drive (AFD) Mode

1. For Bypass Systems ONLY, configure incoming power leads for bypass systems by placing the transfer switch in the AFD position which -

- energizes 1M and 2M contactors.
- energizes CR2 relay on controller board through interlocks (S1 and S2) on the transfer switch.

For Non-bypass systems, CR2 is jumpered to be on continuously.

Note: The interlock switches S1 and S2 are activated by engaging the transfer switch lever in either the AFD or bypass mode. These switches are late make/early break and must open up prior to the transfer switch main poles opening. Test by moving transfer switch lever slowly out of AFD and by-pass mode and listen for the click of the interlock switch opening. This should occur prior to the main poles opening. If the timing is not correct, consult factory for switch adjustment before to start up.

Note: The start string is wired through a set of N.O. contacts of the CR8 relay in the AFD controller panel at J40. The CR8 relay will be energized allowing the start string to pass as long as no faults are detected in the AFD mode.

CPR/Classic Black Systems:

Refer to Figures 9 and 25 for CPR systems or to Figures 12 and 23 for Classic Black systems.

2. When the chiller detects a load, the start/run signal from the chiller controls -

- (CPR systems only) Control power is sent to terminal 7 in the existing pneumatic panel from - a jumper from terminal 2 for non-bypass systems or through the 1M and 2M aux. contacts for bypass systems.
- Energizes CR3, the inverter run relay.
- Energizes CR4 which supplies a dry contact to the PCM indicating that the chiller has been requested to run.
- (Classic Black Only) The AFD energizes a field supplied pilot relay which locks in the start signal and it provides the run signal to the CCM.
- The AFD closes the oil pump interlock relay 1RY1.
- The AFD ramps to [HZ_START]
- The AFD controller modulates frequency according to the Speed Adjustment Criteria detailed in the Introduction section.

UCP1 Systems:

Refer to Figures 14 and 21.

2. When the chiller detects a load, the start signal from the chiller controls -

- Energizes CR3, the inverter run relay.
- Drives the CT filter to output a 7.0 VAC signal on the CT outputs (J32) to the UCP1 inputs.
- Oil pump interlock is provided by UCP1 contacts for non-bypass installations. For bypass installations oil pump interlock is provided by 1M aux. contact for bypass mode or from 1RY1 in inverter for AFD mode.

3. The run signal from the chiller controls -

- Locks in CR3 (for Bypass, through the 1M and 2M auxiliary's).
- Energizes CR4 which supplies a dry contact to the PCM indicating that the chiller has been requested to run.
- The AFD ramps to [HZ_START]

- The AFD closes the contacts on the At Speed relay in the drive.
- Energizes CR7 which latches through its dry contacts.
- Configures the CT outputs to a 60 Hz. line proportional signal.
- The UCP1 senses the drop in current and closes the initiate transition circuit.

4. The initiate transition signal from the UCP1 -

- Energizes CR5.
- Activates CR6 through a set of CR5 NO contacts and latches CR6 through one set of CR6 NO contacts.
- Signals transition complete back to the UCP1 through the other set of CR6 NO contacts.
- The AFD controller modulates frequency according to the Speed Adjustment Criteria detailed in the Introduction section.

Starter Bypass Mode (Optional)

Note: The start string is passed through the J40 (External Inhibit) contacts of the AFD controller so the controller must be powered and running to provide the start string for bypass mode also.

1. Bypass switch set to starter mode.

- CR2 is not activated, suppressing AFD diagnostics.
- CR1 is energized.

CPR Systems:

Refer to Figures 10 and 26.

- The start/run relay (2K5) in the starter is energized, which initiates a standard Wye-Delta startup.
- The oil pump interlock is provided through the 1M Aux. and the bypass board contacts.

Classic Black Systems:

Refer to Figures 13 and 24.

- The start/run signal energizes a field supplied pilot relay which locks in the start signal and it provides the run signal to the CCM.
- The start/run relays (K23 and K24) in the starter are energized, which initiates a standard Wye-Delta startup.
- The oil pump interlock is provided through the 1M Aux. and the bypass relay board contacts.

UCP1 Systems:

Refer to Figures 14 and 22.

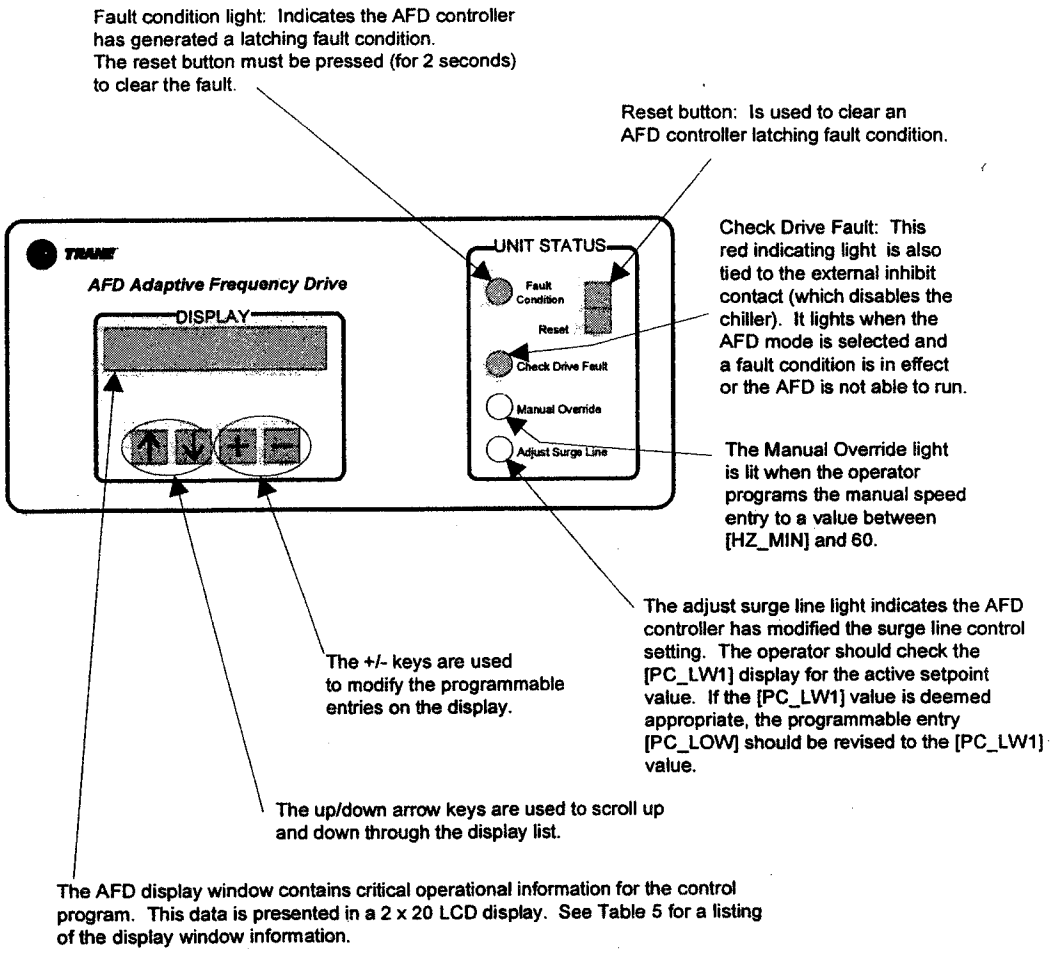
- The start/run relay 2K5 in the starter is energized, which initiates a standard Wye-Delta startup.
- A high in-rush current followed by a drop in current signals the controls to initiate transition. This energizes CR5 which activates the transition relay (K5).
- When the 1M and 2M auxiliary's N.O. contacts close, CR6 is energized and latched, signaling transition complete.

Shutdown

Adaptive Frequency Drive (AFD) Mode

Shutdown can be initiated in one of three places:

- the AFD
- the chiller controls
- the AFD controller



If the protection circuits in the AFD initiate a shutdown, the chiller controls will sense a Momentary Power Loss and the inverter fault will cause the AFD controller to lock out the unit controls until the inverter fault is reset. For a non-latching fault, the reset is accomplished when the chiller controls remove the run contact.

When the chiller controls stop the unit, the run signal is removed from the AFD, shutting it down also.

The AFD controller shuts down the chiller controls through the external inhibit, resulting in unit shutdown.

Check the AFD historical diagnostics in the inverter to find the cause of failure.

Figure 16 -
AFD Control Display

1. Programmable Control Module (PCM) Programmable Variables:

The AFD controller displays information on a 2 x 20 liquid crystal display (LCD) as shown in Figure 16. The operator can scroll through the entries by using the arrow keys underneath the display window. The programmable windows shown in Table 5 contain information that can be modified by the user. The "+" and "-" keys are used to make changes and lock in the data.

Table 5 -
AFD Controller Display

AFD DISPLAY	Description/Ranges
01-JAN-95 16:30	**Programmable:** Calendar and Clock for AFD controller (display use only). Use '-' key to select item. The '+' key will change the entry.
AFD_A101: COMM DOWN LOCAL o-	Status Display - indicating the rev level of the AFD software 'AFD_A101', the Tracer communication status 'COMM DOWN', 'LOCAL' control.
AFD FAULT CODE FAULTCOD: .0	AFD Fault code status - '.0' = OK, '1.0' = Drive not ready, '10.0' =Latching fault - drive is running, but no compressor run signal, '11.0' = Latching fault - unit in a prolonged surge condition, '12.0' = Latching fault - drive not running, but compressor run signal is present.
HERTZ - AFD TO CTV AFD_HZ : 45.2	Active control speed to the AFD. Range 42 to 60. Usually derived from the AFD controller but may be overridden by the manual hertz entry.
IGV POSITION IGV_POS : 65.3 PCT	Inlet Guide Vane Position. Range 0 to 100%. This display reflects the position of the guide vanes as determined by the IGV position sensor.
EVAP PRESSURE PSIA EVAPPRES: 7.3	Chiller Evaporator Refrigerant Pressure (PSI absolute). May vary from 0 to 30 PSIA. This data is determined from the evaporator transducer.
COND PRESSURE PSIA CONDPRES: 17.1	Chiller Condenser Refrigerant Pressure (PSI absolute). May vary from 0 to 30 PSIA. This data is determined from the condenser transducer.
ADJUST SURGE LINE AUTO_ADJ: YES	**Programmable:** This parameter is used to determine if the active surge control line may be modified by the program. (Suggested entry is 'YES'.)
IGV MIN DBND SETUP IGV_MIN : 60.0	**Programmable:** This entry sets up the lower bound of the dead band region for guide vanes. (Range 40 to 90. Default is '60.0'.)
IGV MAX DBND SETUP IGV_MAX : 90.0	**Programmable:** This entry sets up the upper bound of the dead band region for guide vanes. (Range 60 to 95. Default is '90.0'.)
HERTZ - START VAL HZ_START: 50.0	**Programmable:** This entry determines the start up speed for the chiller unless overridden by manual hertz. (Range 45 to 60. Default is '50.0'.)
MANUAL HRTZ ADJUST HZ_MANUL: .0	**Programmable:** This entry instructs the AFD to run at a given speed. (Range 0 to 60. Will take active control when value is between [HZ_MIN] and 60.)
MINIMUM HERTZ VAL HZ_MIN : 42.0	**Programmable:** This entry selects the lowest available speed for the chiller. (Range 42 to 55. Default is '42.0'.)
PRESSCOEF- LOW VAL PC_LOW : 92.0	**Programmable:** This entry selects the low value for the surge line as indicated in the overview section. (Range 20 to 140. Value changes for each chiller.)
PRESSCOEF- SLOPE PC_SLOPE: 13.0	**Programmable:** This entry determines the slope of the surge line as indicated in the overview section. (Range 0 to 30. Value may change per chiller. Try '15'.)
PRESSCOEF- DEADBAND PC_DBND : 3.0	**Programmable:** This entry selects the dead band region under the surge line. (Range 3 to 10. If cond water temp is stable, '3' is OK, otherwise increase number.)
PRESS COEFFICIENT PRESCOEF: 85.6	This is the calculated pressure coefficient for the chiller. The value of the pressure coefficient is compared to the surge line to determine proper speed.
LINEARIZED IGV POS IGV_LINR: 94.4	The linearized guide vane value is used with the surge line to determine the chillers proximity to surge.
SURGE COUNTER SRG_CNT : .0	This is an incremental surge counter used to determine if corrective action should be taken. Speed increases only occur if repeated surge events occur.
TOTAL SURGE COUNT TTL_SRGS: 22.0	This is a total surge counter that may be used by the operator to determine how much surging is taking place. (Range 0 to 3000. Recycles to 0 after 3000.)
LOW SIDE SURGE LIM PC_LW1 : 92.0	Active control point for the low value of the surge line. If AUTO_ADJ is 'YES', it may differ from [PC_LOW]. If different, the 'ADAPTED' light will be ON.

2. IGV Position Sensor:

After installing the IGV Position Sensor bracket and wiring between the IGV Position Sensor and Signal Conditioning Module as shown in Figure 3, the following setup procedure will allow the AFD controller to monitor Inlet Guide Vane Position.

Set jumpers S1, S2, S3 and S4 as shown in Figure 17.

Power up the Signal Conditioning Module by closing the Control Power Disconnect and allow the Signal Conditioning Module to warm up for 15 minutes before proceeding.

Connect a DC Voltmeter to Pins 9 (- or black lead) and 10.

Close the actuator.

Position the red end of the core flush with the red marked (opposite the wires) end of the IGV Position Sensor.

Tighten the nuts to fix the core extension rod to the actuator arm.

Adjust the Zero pot. until the output (pins 9 and 10) is 1 VDC.

Stroke the actuator out to the full open position and check that the core moves freely within the sensor.

Check the output voltage and adjust the Gain pot. to halfway between 9 VDC and the observed output voltage.

Close the actuator and adjust the Zero pot. to 1 VDC.

Alternate between fully open and fully closed positions until the 1 to 9 VDC range is achieved.

Check the AFD Controller screen to verify that [IGV_POS] reads 0 to 100% ± 2% at the endpoints.

3. Parameter Adjustment:

Parameters allow the customer to configure the Accutrol 700 to the job specific application. Many parameters can be adjusted while the drive is operating. Parameters are adjusted by pressing the ENTER key when in the PROGRAM function and the Parameter menu item is selected. This function is exited by pressing the MONITOR key to return to the monitor function or the PROGRAM key to return to the PROGRAM function main menu. Over 70 parameters, depending upon the selected options, can be accessed and modified. Table 6 contains a list of the available parameters.

Parameters which do not require adjustment have been password level 3 protected. The password for level 1 is "010101" and is required to access field adjustable parameters.

The individual parameters are accessed by scrolling up and down the wrap-around list with the up ⇑ and down ⇓ keys. Two types of parameters can be modified, numeric types and menu types.

Refer to the drive's Installation, Operation and Maintenance manual for a detailed explanation of these parameters. *See unit nameplate for compressor motor RLA. This is calibrated as a percentage for the drive nameplate rating and must be calculated for 105% of the compressor motor.

4. **Surge Line Setup Procedure:**

The AFD controller requires a chiller surge prediction to properly adjust chiller speed (see Figure 18a). This prediction curve is entered as a surge line defined by two input parameters [PC_LOW] and [PC_SLOPE]. These parameters are determined at startup by a qualified Service Engineer according to the following procedure.

A. To locate approximately three to four surge points on the accompanying graph (Figure 18):

- run the chilled water temperature near a typical operating point
- fix the AFD speed between 50 and 55 hertz by selecting a speed via the [MANUL_HZ] entry
- fix the IGV's to obtain a given point on the chart (suggest 15, 30, and 90%).
- raise the condensing temperature to cause a surge condition (choke off the condenser water flow or raise the tower temperature).
- Observe the [IGV_LINR] and [PRESCOEF] values from the AFD display window. Make note of the [PRESCOEF] just prior to the chiller surging. For a given IGV position, the [IGV_LINR] value will remain constant.
- The data points of [IGV_LINR] vs. [PRESCOEF] are plotted on a chart as shown on the Figure 19.

B. Determine a predicted Surge Line

- A surge line is drawn below the surge points as detailed on the chart. From the surge line, record the [PRESCOEF] value at an [IGV_LINR] value of 0 and 100. For the example detailed on Figure 18 these points would be:

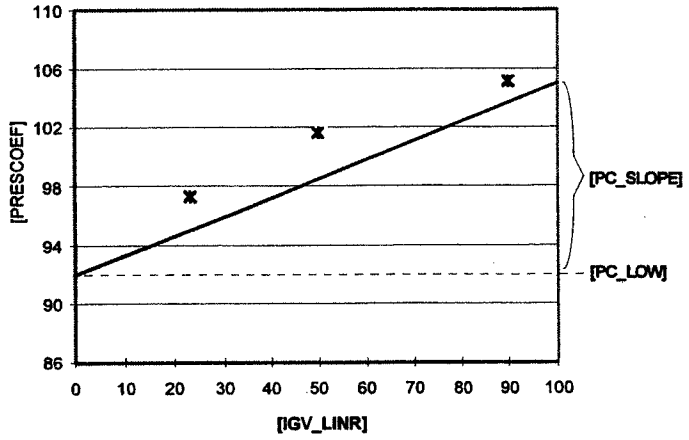
[IGV_LINR]	[PRESCOEF]
0	92
100	105

Trane recommends setting the surge line 5-10% below the measured points to insure the chiller won't surge.

C. Program the Predictive Surge Line into the AFD controller

- [PC_LOW] = 92
- [PC_SLOPE] = 13 (105-92 = 13).

Figure 18 - PC Slope



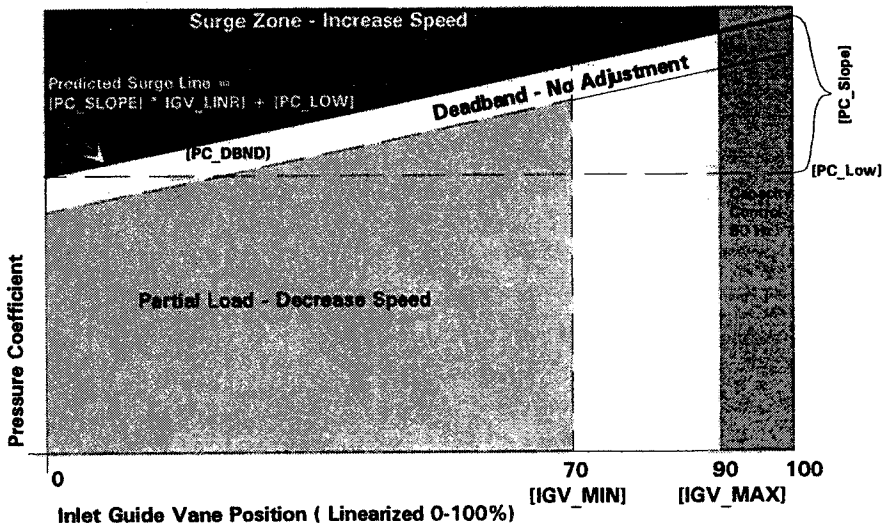


Figure 18 a - Speed Adjustment Criteria

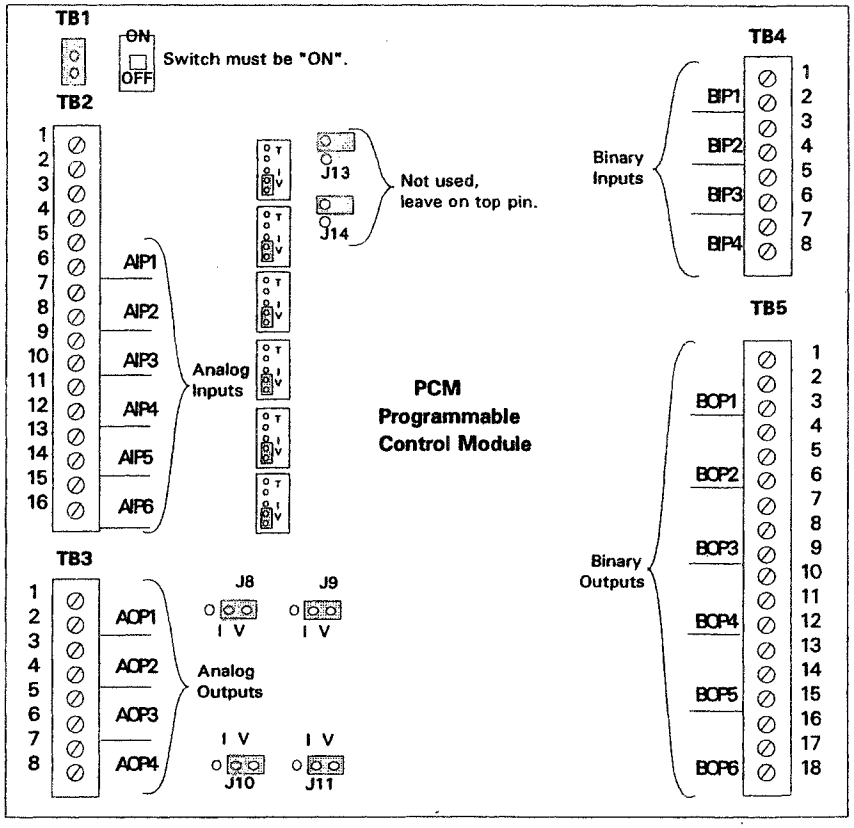
5. Circuit Board Jumper Configurations

Jumpers should be as shown on Figures 19 and 20 for the PCM and Controller Board.

Figure 19 - Programmable Control Module (PCM)



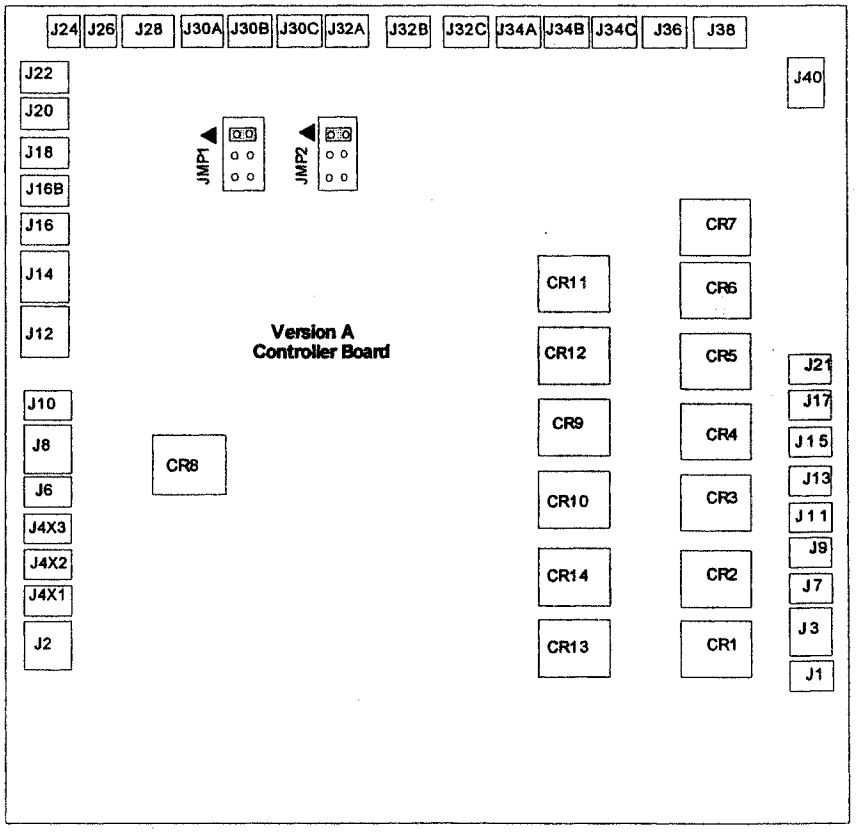


Figure 20 - AFD Version A Controller Board

Maintenance

Periodic Maintenance

A. IGV Position Sensor - Stroke Inlet Guide Vanes fully open and verify that the Human Interface reads 100 ± 2% for [IGV_POS] and 0 ± 2% with the vanes fully closed.

B. Filters in the Drive - Replace at least once a year. See Accutrol Instruction Manual for location.

C. Check Drive Historical Diagnostics - Found in the Fault History as described under the Inverter parameter section.

Since the Trane Company has a policy of continuous product improvement and product data improvement, it reserves the right to change design and specifications without notice. Only qualified technicians should perform the installation and servicing of the equipment referred to in this publication.

NOTICE

Warnings and Cautions appear at appropriate locations throughout this manual. Read these carefully.

WARNING: Indicates a potentially hazardous situation which, if not avoided, may result in serious personal injury or death.

CAUTION: Indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury. It may also be used to alert against unsafe practices and where property-damage only accidents could occur.

About this Manual

THIS MANUAL IS INTENDED FOR USE BY EXPERIENCED SERVICE PERSONNEL, QUALIFIED ELECTRICAL PERSONNEL, TRANE MANUFACTURING, AND ROCKWELL AUTOMATION GLOBAL TECHNICAL SERVICE PERSONNEL WHO ARE FAMILIAR WITH THE CUSTOM LIQUID-COOLING FEATURES DESCRIBED.

The instructions in this manual outline the procedures for operating the **UNIT-MOUNTED** Trane Adaptive Frequency™drive. Operation and maintenance of the controls are also explained in this manual.

Literature History

AFDB-OM-1C, November, 2000 = Added 1000 Hp, Replaced AFDB-OM-1B, Added Sizes 350, 414, 500, replaced AFDB-OM-1A, 5/99

Other Required Manuals

THE FOLLOWING PUBLICATIONS SHIP WITH THE TRANE ADAPTIVE FREQUENCY DRIVE FROM THE FACTORY:

- D2-3410 Liqui-Flo AC Drive Software Startup and Reference Manual
- D2-3411 Liqui-Flo AC Power Modules Hardware Reference, Installation, and Troubleshooting
- D2-3341 Remote Meter Interface (RMI) Board

Service Information

This equipment should be installed, adjusted and serviced by qualified electrical maintenance personnel who are familiar with the construction and operation of the equipment and the hazards involved, as defined in the National Electrical Code.

The Trane Company assumes no liability for installation or service procedures performed by unqualified personnel.

Parts Ordering Information

Refer to the model number printed on the Trane Adaptive Frequency Drive nameplate when ordering replacement parts or service for the drive. When ordering parts, contact the local Trane Parts Office in your area. For service, contact La Crosse Business Unit Technical Service, La Crosse, Wisconsin.

Primary Water Loop Water Charging

The primary water loop (the loop that runs through the inverter) must be charged with approximately 2 gallons of **distilled water**. In addition to the distilled water, you must add the 3-ounce bottle of **inhibitor solution** that has been shipped with the new unit from the factory. For replacement inhibitor solution, at a later date, contact the local Trane Parts Office.

Warnings and Cautions

NOTE THAT WARNINGS AND CAUTIONS APPEAR IN APPROPRIATE SECTIONS THROUGHOUT THIS MANUAL.

WARNINGS

Warnings are provided to alert installing contractors and other personnel to potential hazards that could result in serious personal injury or death.

CAUTIONS

Cautions are provided to alert personnel to conditions, which could result in moderate or minor personal injury, or damage to equipment or property. Your personal safety and the proper operation of this machine depend upon precautions.

⚠ WARNING

DO NOT CUT HOLES ADAPTIVE FREQUENCY™ DRIVE ENCLOSURE. DEBRIS FALLING INSIDE OF ADAPTIVE FREQUENCY DRIVE MAY CAUSE FAILURE OF ELECTRONIC COMPONENTS. Failure to follow this precaution could result in damaged equipment.

⚠ WARNING

HAZARDOUS VOLTAGE! ALLOW AT LEAST 10 MINUTES FOR DC UNITS TO DISCHARGE AFTER POWER IS DISCONNECTED BEFORE SERVICING. USE EXTREME CAUTION WHEN APPLYING POWER. EQUIPMENT TERMINALS AND OTHER INTERNAL PARTS OF THE CONTROLLER ARE AT LINE VOLTAGE WHEN AC POWER IS CONNECTED TO THE CONTROLLER. ALL UNGROUNDED CONDUCTORS OF THE AC POWER LINE MUST BE DISCONNECTED FROM THE CONTROLLER BEFORE IT IS SAFE TO TOUCH ANY INTERNAL PARTS OF THIS EQUIPMENT. AFTER POWER IS REMOVED, WAIT AT LEAST 10 MINUTES FOR THE DC LINK FILTER CAPACITORS TO DISCHARGE BELOW 50 VDC BEFORE TOUCHING ANY INTERNAL PARTS OF THE CONTROLLER. Failure to do so could result in death or bodily injury.

⚠ WARNING

ELECTRICAL INTERLOCKING CIRCUITS (MULTIPLE INTERCONNECTED ELECTRICAL CIRCUITS) MAY HAVE BEEN ADDED DURING INSTALLATION THAT COULD STILL BE ENERGIZED WHEN THE CONTROLLER INPUT MAIN BREAKER IS OPEN. SUITABLE WARNING TAGS OR DISCONNECTS SHOULD BE ADDED TO THESE CIRCUITS BEFORE ATTEMPTING TO ENERGIZE OR SERVICE THE CONTROLLER. Failure to follow these precautions can lead to death and bodily injury and/or equipment damage.

⚠ WARNING

DO NOT REMOVE OR INSERT CONTROL BOARDS OR FUSES WHILE INPUT POWER IS CONNECTED TO THE CONTROLLER. THIS CAUSES DAMAGE TO THE CONTROLLER, AS WELL AS BEING DANGEROUS TO PERSONNEL. Failure to follow this precaution could result in death or injury and equipment damage.

⚠ WARNING

BEFORE PROCEEDING WITH THE STARTUP PROCEDURE, DISCONNECT AND LOCKOUT ALL INCOMING POWER TO THE DRIVE CONTROLLER AND LOCKOUT ALL INCOMING POWER. Failure to follow this precaution could result in death or injury and equipment damage.

⚠ CAUTION

DO NOT USE A MEGGER TO PERFORM CONTINUITY CHECKS IN THE DRIVE EQUIPMENT.
Failure to follow the above precaution can cause damage to the controller circuitry.

⚠ WARNING
TERMINALS AND OTHER INTERNAL PARTS OF THE CONTROLLER ARE AT LINE VOLTAGE WHEN AC POWER IS CONNECTED TO THE CONTROLLER. ALL UNGROUNDED CONDUCTORS OF THE AC POWER LINE MUST BE DISCONNECTED FROM THE CONTROLLER BEFORE IT IS SAFE TO TOUCH INTERNAL PARTS OF THIS EQUIPMENT. EACH TIME POWER IS REMOVED, WAIT AT LEAST 10 MINUTES AND VERIFY THAT THE DC LINK FILTER CAPACITORS ARE DISCHARGED BEFORE TOUCHING ANY INTERNAL PARTS OF THE CONTROLLER. Failure to follow these precautions can result in death, injury and equipment damage.

⚠ WARNING
ELECTRICAL INTERLOCKING CIRCUITS MAY HAVE BEEN ADDED DURING INSTALLATION. THE CONTROLLER MAY STILL BE ENERGIZED WHEN THE CONTROLLER MAIN INPUT BREAKER IS OPEN. SUITABLE WARNING TAGS OR DISCONNECTS SHOULD BE ADDED TO THESE CIRCUITS AND ALL CIRCUITS SHOULD BE TESTED BEFORE ATTEMPTING TO ENERGIZE OR SERVICE THE CONTROLLER. IF THIS EQUIPMENT IS INTERLOCKED WITH OTHER EQUIPMENT, 115 VOLT AC MAY BE PRESENT IN THE CABINET EVEN THOUGH THE MAIN POWER IS DISCONNECTED. IF THIS IS THE CASE, THESE INTERLOCK SIGNALS SHOULD BE DEACTIVATED BEFORE ANY WORK IS PERFORMED ON THIS EQUIPMENT. Failure to do so could result in death, injury or equipment damage.

⚠ WARNING
FOLLOW SUBSEQUENT PRECAUTIONS IN THIS MANUAL. Failure to follow these precautions may cause death, serious personal injury, and/or property damage.

AFDB CHECKS

Safety Precautions

1. This equipment should be adjusted and serviced by qualified electrical maintenance personnel familiar with the construction and operation of the equipment and the hazards involved.
2. Be sure the input disconnect is in the correct position, either "on" or "off" depending on the work to be performed.
3. Check the status of the drive shutdown interlocks, if used. These interlocks can be limit switches, guards or safety switches installed around the driven machine or the system interface controller.

⚠ WARNING
THE INTERLOCKS ARE DEACTIVATED OR BYPASSED, EXTREME CAUTION MUST BE USED WHEN PERFORMING THE START-UP. Return all interlocks to operation when the start-up is completed.

4. Check to see that the AFDB is properly ground to earth. See "Grounding", in "Wire Routing" section.

5. Do not remove or insert control boards or fuses while input power is connected to the controller. This causes damage to the controller, as well as being dangerous to personnel.

⚠ WARNING
BEFORE WORKING ON THE CONTROLLER, CHECK TO BE SURE DC LINK CAPACITORS ARE DISCHARGED WITH A DC VOLTMETER ON THE 1000V SCALE. CHARGED CAPACITORS REQUIRE AT LEAST 10 MINUTES TO DISCHARGE TO LESS THAN 50V DC AFTER LINE POWER IS REMOVED. Failure to follow this precaution could result in severe burns or electrical shock.

⚠ WARNING
BEFORE PROCEEDING WITH THE START-UP PROCEDURE, DISCONNECT AND LOCKOUT ALL INCOMING POWER TO THE DRIVE CONTROLLER. Failure to heed this precaution could result in death due to severe electrical shock.

Motor Checks

1. Check the motor for proper horsepower and voltage ratings. Verify that the motor full load amps do not exceed the nameplate rating of the controller.

2. Check that the motor terminals are correctly connected to the controller's power terminals for the proper voltage and motor rotation.

3. Use an ohmmeter to check for any short circuits between the motor frame and the motor power leads. If a short circuit exists, it must be corrected before proceeding.

Controller Checks

1. Check that local, state and national electric codes have been observed for the installation and wiring of this equipment.

2. Check that all external power wiring has been properly routed through the cabinet.

3. Check all input power and output power connections for tightness.

4. Check the chassis ground and other connections for tightness.

5. Check all external control connections (this includes the operator station connections) for tightness.

6. Check to assure incoming power to the drive is phased A, B, C.

7. Check the primary water loop water pump for correct rotation.

Receiving and Storage

TRANE COMPANY STANDARD TERMS OF SALES ARE F.O.B. POINT OF ORIGIN; THEREFORE, IT IS IMPORTANT, THAT YOU THOROUGHLY INSPECT THIS EQUIPMENT BEFORE ACCEPTING SHIPMENT FROM THE TRANSPORTATION COMPANY.

If any of the items called for on the bill of lading or express receipt are damaged or the quantity is short, do not accept them until the freight or express agent makes an appropriate notation on your freight bill or express receipt. If any concealed loss or damage is discovered later, notify your freight or express agent within 15 days of receipt, request that he makes an inspection.

IT IS YOUR RESPONSIBILITY TO MAKE CLAIMS AGAINST THE TRANSPORTATION COMPANY FOR ANY SHORTAGE OR DAMAGE IN TRANSIT.

Claims for loss or damage in shipment must not be deducted from the Trane invoice, nor should payment of the invoice be withheld awaiting adjustment of such claims in as much as the transportation company guarantees safe delivery.

If considerable damage has been incurred and the situation is urgent, contact the nearest Trane Sales Office for assistance.

Lifting Instructions

Care should be used to prevent damage due to dropping or jolting when moving the controller. A fork lift truck or similar means of lifting and transporting may be used. Sling in a manner that will equalize the load at the pickup points. Use a spreader bar if the angle of the sling is less than 45 degrees relative to horizontal. Do not jolt while lifting.

AFDB Information

Environment Conditions and Location

IMPORTANT! LOCATION OF THE AFDB IS IMPORTANT IF PROPER PERFORMANCE AND NORMAL OPERATING LIFE IS TO BE EXPECTED. THEREFORE, UNLESS DESIGNED FOR SPECIAL ENVIRONMENTS, THE CONTROLLER SHOULD BE INSTALLED IN AN AREA WHERE THE FOLLOWING CONDITIONS EXIST:

1. Maximum ambient temperature of 40° C (104°F).
2. Ambient temperatures are not less than 0° C (32°F).
3. Line frequency is 60 Hz.
4. Line voltage is 480/460 volts; variations are within ±10%.
5. Altitude above sea level does not exceed 3,300 feet (1000 meters) without de-rating.
6. Ambient humidity is 0 to 95%, non-condensing.
7. Non-corrosive location.
8. NEMA 1 enclosure, clean location.
9. No outdoor applications are permitted to prevent freezing of the water-cooled inverter.

IMPORTANT: THIS IS A WATER-COOLED INVERTER THAT CONTAINS WATER IN THE INVERTER. THE UNIT MUST BE KEPT ABOVE 32° (DEGREES) IN STORAGE AND OPERATION.

(2) Introduction

The AFDB water-cooled Adaptive Frequency™ Drive is a pulse width modulated (PWM) inverter. The function of the inverter is to change a DC input voltage to a symmetrical AC output voltage of desired magnitude and frequency. It is designed for 460/480-volt application. This drive converts AC power to DC power and back to AC power. The incoming 460/480 volts are converted to a constant 650 VDC by a rectifier bridge (SCR's and diodes), and into a section of water-cooled capacitors that are used to store the DC voltage. The DC output feeds the IGBT (insulated gate by polar transistors section) which are transistors that switch at predetermined time to change the output frequencies from 38 to 60 hertz.

The DC voltage is fixed at 650 VDC. A variable output is accomplished by pulse-width-modulation (PWM) control within the inverter by IGBTs which are basically transistors that turn on and off in response to the gate driver (which in this case is the power module adapter board).

Two distinct operating modes make up the AFDB control within the UCP2. In the 1st mode, the capacity is modulated by controlling the inlet vanes. Once the vanes are wide open the capacity is controlled by modulating impeller speed from 38 to 60 hertz. The IGBTs control the speed in response to the UCP2 load demand sending a signal to the AFDB power module adapter board.

Circuit breakers, surge capacitors and ground faults are standard on all AFDB units.

Some of the basic principles of the drive are:

- Low in rush current
- The current never exceeds the full load amps
- The AFDB varies the motor speed in response to the load demand of the CenTraVac®

The CenTraVac Control Panel has full control of the unit operation, including the start/stop functions. If you encounter a fault condition or an alarm on the drive, a (3) letter code will be displayed on the drive display only.

AFDB-OM-1 covers the features and specifications that are unique to the Trane Adaptive Frequency drives being produced for the Trane Company. Only product information is covered here that supplements that presented in the standard Liqui-Flo instruction manuals that ship with the unit. AFDB-OM-1 must be used with the Liqui-Flo software and hardware instruction manuals listed below.

1.1 Intended Audience

This manual is intended for Trane Technical Service personnel who are familiar with the custom liquid-cooling features described.

1.2 Other Required Manuals

The manuals below ship with the Adaptive Frequency Drive from the factory.

- D2-3410 Liqui-Flo AC Drive Software Startup and Reference Manual
- D2-3411 Liqui-Flo AC Power Modules Hardware Reference, Installation, and Troubleshooting
- D2-3341 Remote Meter Interface (RMI) Board

(3) Product Coding

Service Model Number

An example of a typical model number is: **AFDB0035FA0A1ASA6CE**

Model Number Digit Identification – model number digits are selected and assigned in accordance with the following definitions using the model number example shown above.

AFDB = Adaptive Frequency Drive
AFD = (1st, 2nd, 3rd.digit) = Adaptive Frequency Drive
B = (4th digit) = Development Sequence
B = Liquid Cooled

0035 = (5th, 6th, 7th, and 8th digit) Adaptive Frequency Drive Size

Use Rated Load Amps (RLA) value

F = (9th digit) Unit Voltage

F = 460V-60Hz-3Ph
G = 480V-60Hz-3Ph

A0 = (10th and 11th digit) Design Sequence

A0 = First Design
B0 = Add 500 SRRL and inc 386 to use 500
C0 = Revised Contactor Connection
D0 = 350 hp AFD and replace 386 Max RLA with 414 Max RLA
E0 = Standardized Pump Heat Exchanger

A = (12th digit) ADF Mounting Location

A = Unit mounted
B = Remote mounted

I = (13th digit) Agency Listing

I = UL & C UL

A = (14th digit) Harmonic Attenuation

0 = None
A = Size "1" line reactor 386 Max RLA
B = Size "2" line reactor 643 Max RLA
C = S12 Isolation Transformer (3 phase Line/load reactor)
D = Size "3" line reactor 500 Max RLA
E = Size "1" line reactor 414 Max RLA
F = Size "4" line reactor 1157 Max RLA

S = (15th digit) Special Options

0 = None
S = Special

A = (16th digit) Pump & Heat Exchanger Size

A = Size "A" Pump & Heat Exchanger
B = Size "B" Pump & Heat Exchanger
C = Size "C" Pump & Heat Exchanger
D = Size "D" Pump & Heat Exchanger

6 = (17th digit) Condenser Size

3 = 032S Short Condenser Shell
4 = 032L Long Condenser Shell
5 = 050S Short Condenser Shell
6 = 050L Long Condenser Shell
7 = 080S Short Condenser Shell
8 = 080L Long Condenser Shell
C = 142L Long Condenser Shell
E = 210L Long Condenser Shell
F = 250L Long Condenser Shell

C = (18th digit) Condenser Water Box

A = 150 PSI Marine – 2 pass STD
C = 150 PSI Non-Marine – 2 pass STD
E = 300 PSI Marine – 2 pass STD
G = 300 PSI Non-Marine – 2 pass STD

E = (19th digit) Condenser Water Box Arrangement

A = In RH end – Out RH end
B = In LH end – Out LH end
C = In LH front – Out LH front
D = In LH rear – Out LH rear
E – In RH front – Out RH front
F = In RH rear – Out RH rear
G = In LH front – Out LH rear
H = In LH rear – Out LH front
J = In RH front – Out RH rear
K = In RH rear – Out RH front

(3) Product Coding

Feature Category and Code Definitions

The following provides the description of the Feature Category for each Unit Mounted Frequency Inverter.

AFDB
Liquid Cooled Drive

CNIF
Control Interface

UCP2
Micro Processor 2nd Generation

MODL
Starter Model

CTV
CenTraVac® Unit

LNRC
Input Line Reactor
S12 = Isolation Transformer (Harmonic Attenuation)

SRTY
Starter Type

UAFD
Unit Mounted AFD

SRRL
Frequency Drive Frame Size
Frame Size 1 = 643 Max RLA
Frame Size 2 = 1157 Max RLA

VOLT
Unit Voltage
460 = 460V 3 Phase
480 = 480V 3 Phase

HRTZ
Unit Hertz
60 = 60 Hertz

FSUP
Factory Start-up - AFD
LM = 50 Miles or less
HM = 51 Miles or more

HRIN
Harmonic Attenuation

LNRC = S12 Isolation Transformer (Harmonic Attenuation)
Line Reactor

NMRA
Nameplate RLA

DSEQ
Design Sequence
AO = First Design
BO = Add 500 SRRL, include 386
CO = Revised Contactor Connection
DO = 350 AFD & 414 SRRL
EO = Standardized Pump Heat Exchanger

SOSPT
Special

(4) Drive and Cabinet

THIS SECTION DESCRIBES HOW TO IDENTIFY THE TRANE CABINET AND THE ADAPTIVE FREQUENCY™ DRIVE USING THE TRANE MODEL NUMBER MATRIX.

Drive power ratings are listed as well as available Trane options. Cabinet component drawings are also provided. Note that in the manual references to the "cabinet" refer to both the 6-pulse (Standard) and 12-pulse optional (S12 - Isolation Transformer) (Harmonic Attenuation) rectifier cabinets, unless otherwise indicated. Below Table 1 shows an example of a Trane Cabinet Model Number as well as enclosure and drive power ratings.

Table 1 - Table Power and Enclosure Ratings

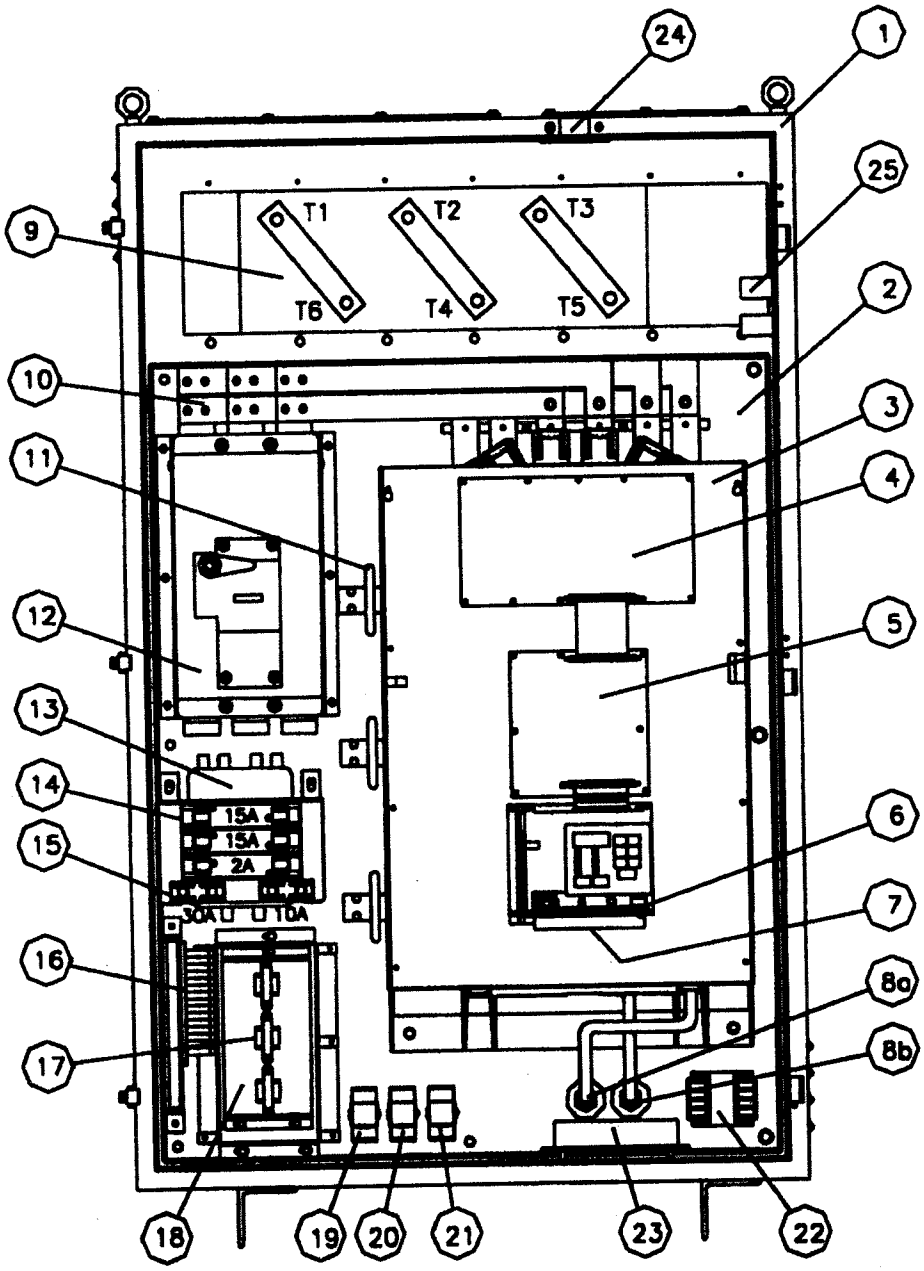
Trane Cabinet M/N	Frame Size	Cabinet Enclosure Rating	Input KVA	Input Amps	Output Amps at 2 kHz	Power Loss Watts (Full Load)
AFDB0643GA0A10	C	NEMA 1	555	667	643	9000

Enclosure Rating

The Trane cabinet has a NEMA 1 enclosure rating:

- NEMA 1: Vented. Intended for general-purpose indoor applications.

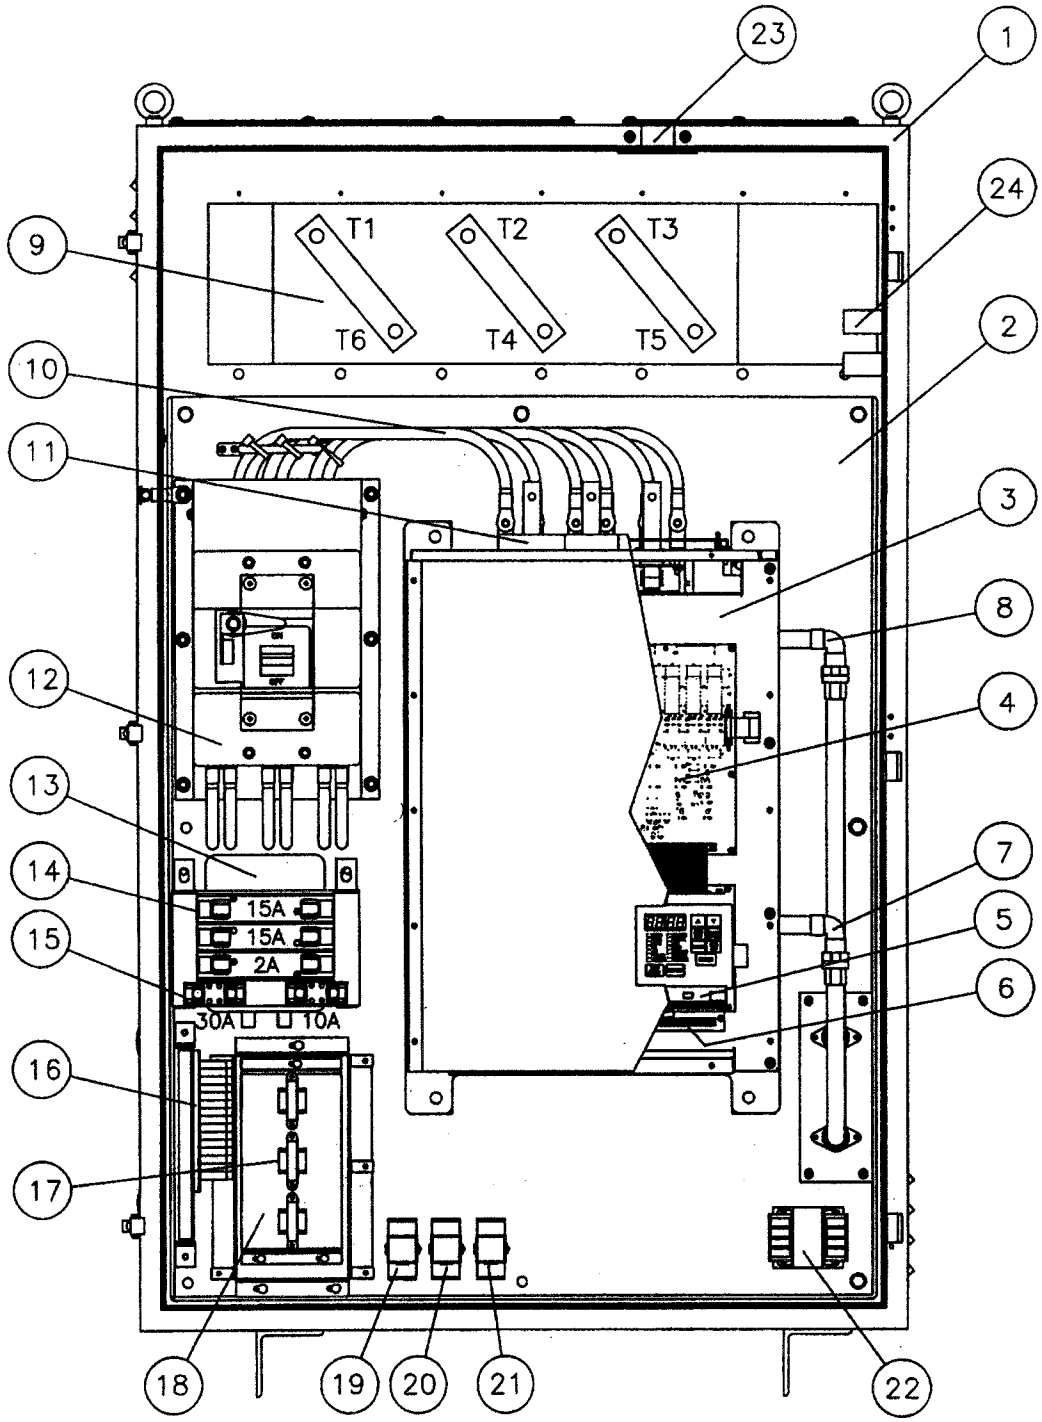
NEMA 1 enclosures are to be located in a clean, cool, and dry environment that is away form oil, coolant, or other airborne contaminants.



(4) Drive and Cabinet

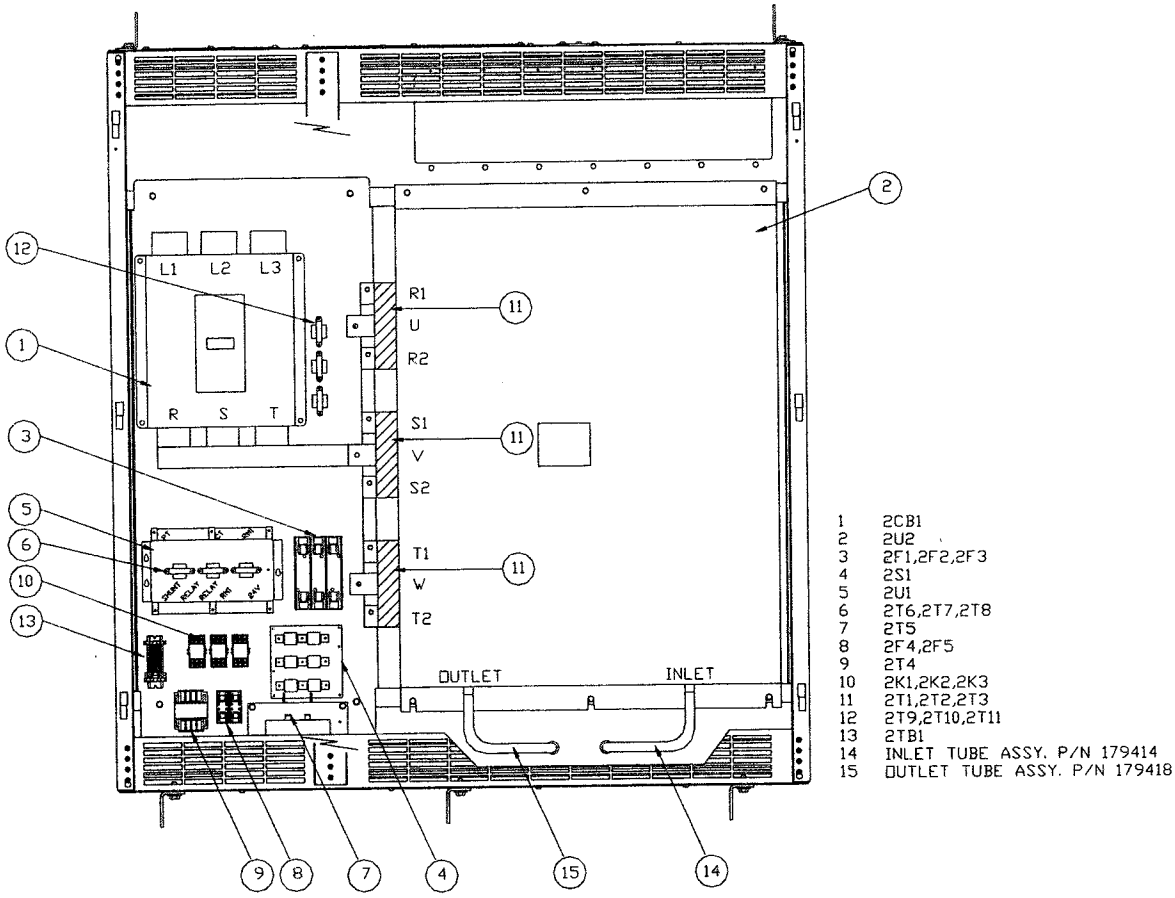
Identifying Trane Cabinet Components

The **6-pulse (Standard) rectifier** Trane cabinets have the following main components. The identification numbers provided correspond to the numbers used in Figure 1.



1. **Cabinet**
2. **Panel**
3. **C-Frame Adaptive Frequency™ Drive**
4. **Power Module Adapter Board** – Provides the interface between the drive's electronics and power structure.
5. **Liqui-Flo Bus Control Board** – Controls the drive's power supplies and SCRs
6. **Liqui-Flo Regulator Board** – Controls overall drive operation
7. **Super Remote Meter Interface (RMI) Board** – Provides additional analog I/O
8. **Coolant Lines** – (a) Outlet, (b) Inlet lines
9. **Motor Connection Studs (6) P/O CTV**
10. **AC Input Bus bars** (6-Pulse Standard Rectifier)
11. **Current Transformer (3)** – Used by the Trane UCP2 Control Panel to monitor output current
12. **1200 A Circuit Breaker**
13. **4 KVA Transformer** – Steps down the 480 VAC input voltage to 115 VAC
14. **(3) Type RK-5 Fuses** – Protect the primary of the 4 KVA transformer – (1 fuse: 2 Amp) (2 fuses: 15 Amp)
15. **(2) Type K5-Fuses** – Protect the coolant pump's reactor (1 fuse: 10 Amp) and the Starter module's 115 VAC line (1 fuse: 30 Amp)
16. **Terminal Block** – Provides termination points for cabinet I/O wiring
17. **Potential Transformer (3)** – used by the Trane UCP2 Control Panel to measure the 480 VAC input voltage
18. **Trane Starter Module** – Interfaces the Adaptive Frequency™ Drive to the Trane UCP2 Control Panel
19. **Relay 2K1** – Oil pump interposing relay
20. **Relay 2K2** – Run/Stop function interposing relay
21. **Relay 2K3** – Circulating coolant pump motor interposing relay
22. **50 VA Transformer 460VAC / 115VAC / 24VAC** – Supplies power to the Trane Starter Module
23. **Fan** – Provides cooling for the DC bus reactor
24. **Removable Plate** - Provides chain hoist access
25. **Surge Suppressor**

Figure 1 - Trane Cabinet Component Locations (Standard) 6-Pulse Rectifier 600/450 HP and 350 HP continued on next page.

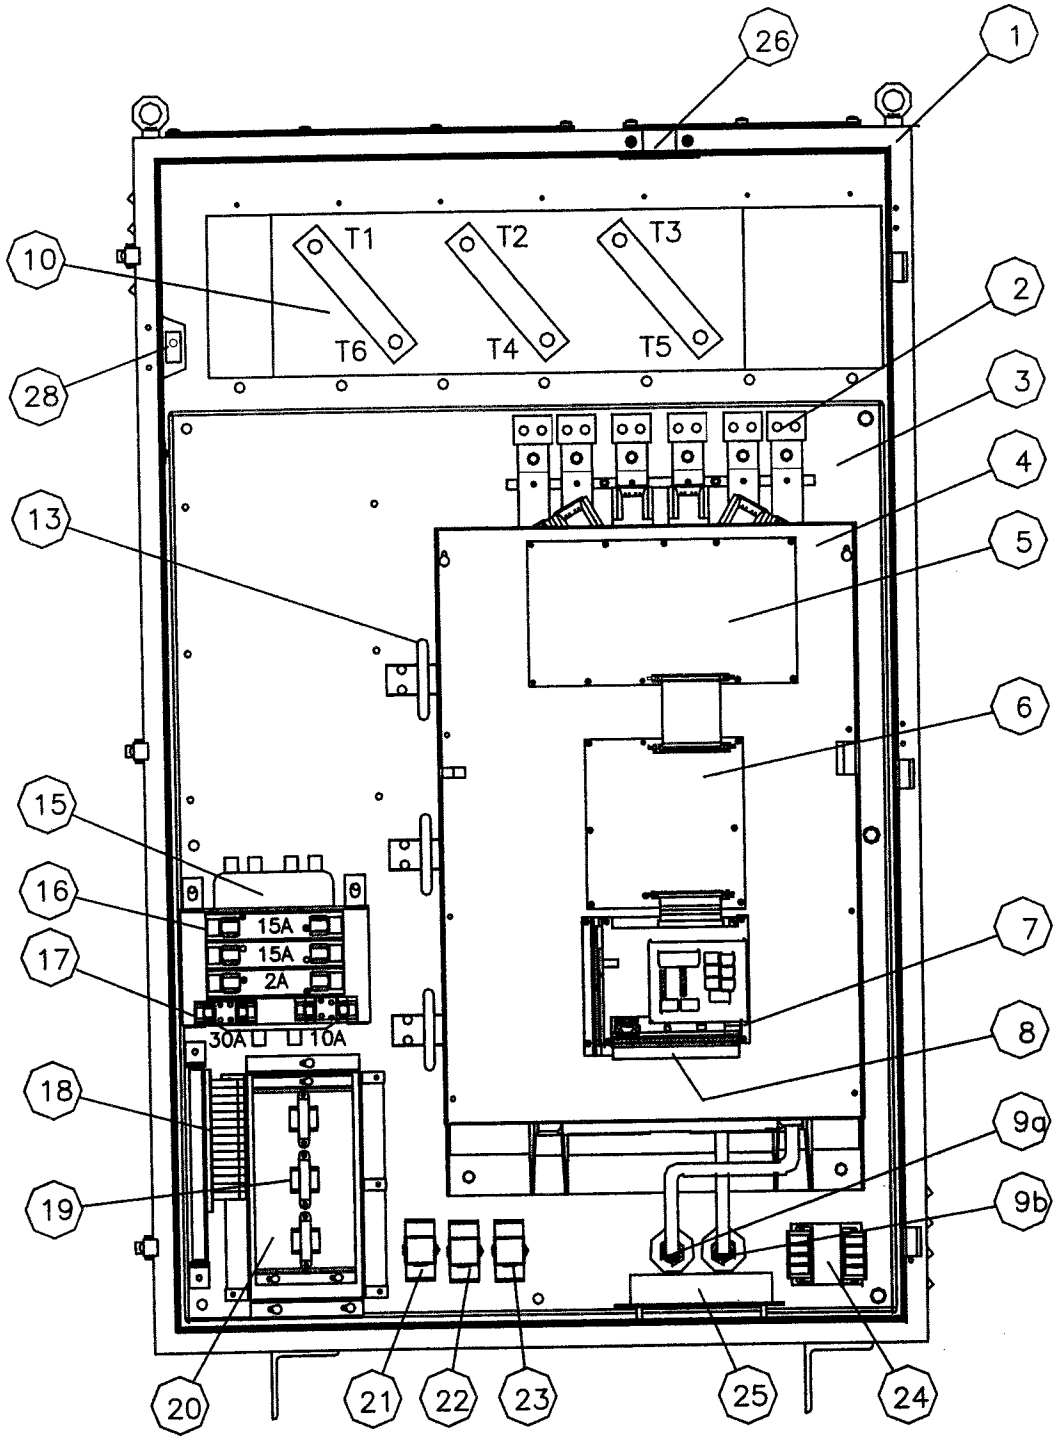


Front View

Continued - Figure 1 - Trane Cabinet Component Locations (Standard) 6-Pulse Rectifier 350 HP

Front View

Figure 2 - Trane Cabinet Component Locations (Standard) 6-Pulse Rectifier 1000 HP



(4) Drive and Cabinet

The **12-pulse rectifier** (Optional Isolation Transformer Harmonic Attenuation) Trane cabinets have the following main components. The identification numbers provided correspond to the numbers used in Figure 3.

NOTE: HAS TO USED WITH OPTIONAL S-12 ISOLATION TRANSFORMER

1. **Cabinet**
2. **AC Input to Drive** (from Secondary of Isolation Transformer)
3. **Panel**
4. **C-Frame Adaptive Frequency™ Drive**
5. **Power Module Adapter Board** – Provides the interface between the drive's electronics and power structure.
6. **Liqui-Flo Bus Control Board** – Controls the drive's power supplies and SCRs
7. **Liqui-Flo Regulator Board** – Controls overall drive operation
8. **Super Remote Meter Interface (RMI) Board** – Provides additional analog I/O
9. **Coolant Lines (2)** – 9a outlet and 9b inlet lines
10. **Motor Connection Studs (6) P/O CTV**
13. **Current Transformer (3)** – Used by the Trane UCP2 Control Panel to monitor output current
15. **4 KVA Transformer** – Steps down the 480 VAC input voltage to 115 VAC
16. **(3) Type RK-5 Fuses** – Protect the primary of the 4 KVA transformer – (1 fuse: 2 Amp) (2 fuses: 15 Amp)
17. **(2) Type K5 Fuses** – Protect the coolant pump's reactor (1 fuse: 10 Amp) and the Starter module's 115 VAC line (1 fuse: 30 Amp)
18. **Terminal Block** – Provides termination points for cabinet I/O wiring
19. **Potential Transformer (3)** – used by the Trane UCP2 Control Panel to measure the 480 VAC input voltage
20. **Trane Starter Module** – Interfaces the Liqui-Flo Drive to the Trane UCP2 Control Panel
21. **Relay 2K1** – Oil pump interposing relay
22. **Relay 2K2** – Run/Stop function interposing relay
23. **Relay 2K3** – Circulating coolant pump motor interposing relay
24. **50 VA Transformer 460VAC / 115VAC / 24VAC** – Supplies power to the Trane Starter Module
25. **Fan** – Provides cooling for the DC bus reactor
26. **Removable Plate** - Provides chain hoist access
28. **Door Interlock Switch** - Rating 10A – 125/250 VAC

Figure 3 - Trane Cabinet Component Locations (12-Pulse Rectifier Optional S12 Isolation Transformer) (Harmonic Attenuation Device)

Adaptive Frequency Drive TRANE Options

THERE ARE THREE AVAILABLE TRANE OPTIONS WHICH CAN SHIP EITHER FACTORY INSTALLED OR FIELD INSTALLED.

1. 3-PHASE LINE/LOAD REACTOR

1.1. Physical Characteristics (See Figure 4)

a. Ratings

1. 480 volts, 50/60 Hz, 3 PH
   350 HP/262 kw
   5% Impedance

2. 480 volts, 50/60 Hz, 3PH
   500 HP/375 kw
   5% Impedance

3. 480 volts, 50/60 Hz, 3PH
   600 Hp/450 kw
   5% Impedance

4. 480 volts, 50/60 Hz, 3PH
   1000 Hp/750 kw
   5% Impedance

b. Enclosure and Dimensions

All line reactors come in NEMA Type 1 general purpose enclosures. (See Figure 4).

1. W x H X D, 17 x 24 x 17 (inches) – 350 Hp
2. W X H X D, 17 x 24 x 17 (inches) – 500 Hp
3. W X H X D, 24 x 30 x 24 (inches) – 600 Hp
4. W X H X D, 36 x 43 x 26 (inches) -- 1000 Hp

c. Weight

1. 335 lbs. - 350 Hp
2. 335 lbs. - 500 Hp
3. 483 lbs. - 600 Hp
4. 780 lbs. - 1000Hp

1.2. Mounting

Following are recommendation guidelines for the mounting of the line reactor. Floor mount design, however, could be wall mounted by the field using proper guidelines. (Brackets, which are required, are not supplied and would have to be field fabricated.) Line Reactor not designed for hanging.

The Line Reactor should be placed at least 6" from any combustible surface. Wire size should be per the drive requirements. There are no knockouts in the cabinet: Entry/exit openings must be made in the field.

For additional information about the Line Reactor, see Figure 4.

1.3. Line Reactor Installing Guidelines

The line reactor should be placed at least 6" from any combustible material/surface, at least 2" from any wall/surface so the vents are not blocked and air flow is not hampered, and not on top of any significant heat source.

Wire size should be per the drive requirements.

Use metallic conduit/shielded cable in accordance with local codes.

IDEALLY, THE LINE REACTOR SHOULD BE INSTALLED AS CLOSE TO THE AFD AS POSSIBLE. IF METALLIC CONDUIT IS USED, RECOMMENDED MAXIMUM CABLE DISTANCE BETWEEN THE REACTOR AND INVERTER IS 8-10 FEET. IF METALLIC CONDUIT IS NOT USED, CABLE DISTANCE BEWEEN THE REACTOR AND INVERTER SHOULD NOT EXCEED 5-FEET. If cable does run near other circuitry wire, it is recommended to run cable perpendicular to other wire(s).

There are no knockouts in the cabinet. Entry/exit openings must be made in the field. RECOMMENDED ENTRY/EXIT OPENINGS ARE THROUGH THE TOP.

For additional information about the Line Reactor, see Figure 4.

1.4. Wiring

Size – Based on inverter requirements (Running Load Amps) Line side – based on nameplate amps and local code requirements (NEC). See Figure 5.

Wire termination devices on the primary and secondary of the transformer (for field installed) or primary/line side only (for factory mounted) must be field furnished and installed. Ring-type compression terminal devices are suggested.

Entry/Exit points are made in the field. Typical entry/exit points are through the top. Avoid getting any enclosure shavings on line reactor. A punch out is recommended to make hole. For Factory Unit Mounted version only entry point is needed.

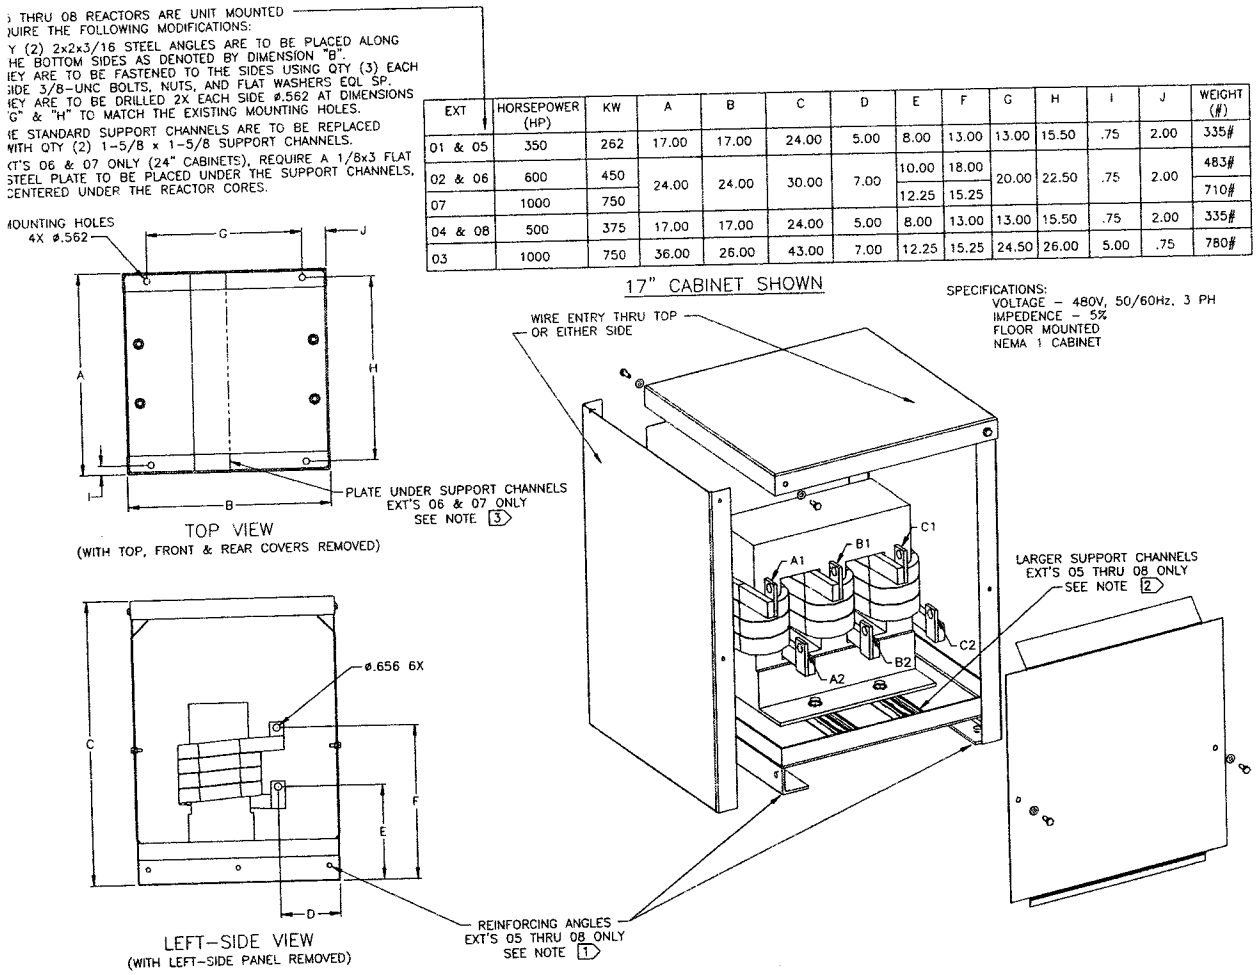
1.5. Grounding

The field will have to provide a grounding lug(s) and the proper size wire based on NEC.

1.6. Environment Conditions and Location

a. Maximum ambient temperature of 40° C (104°F).

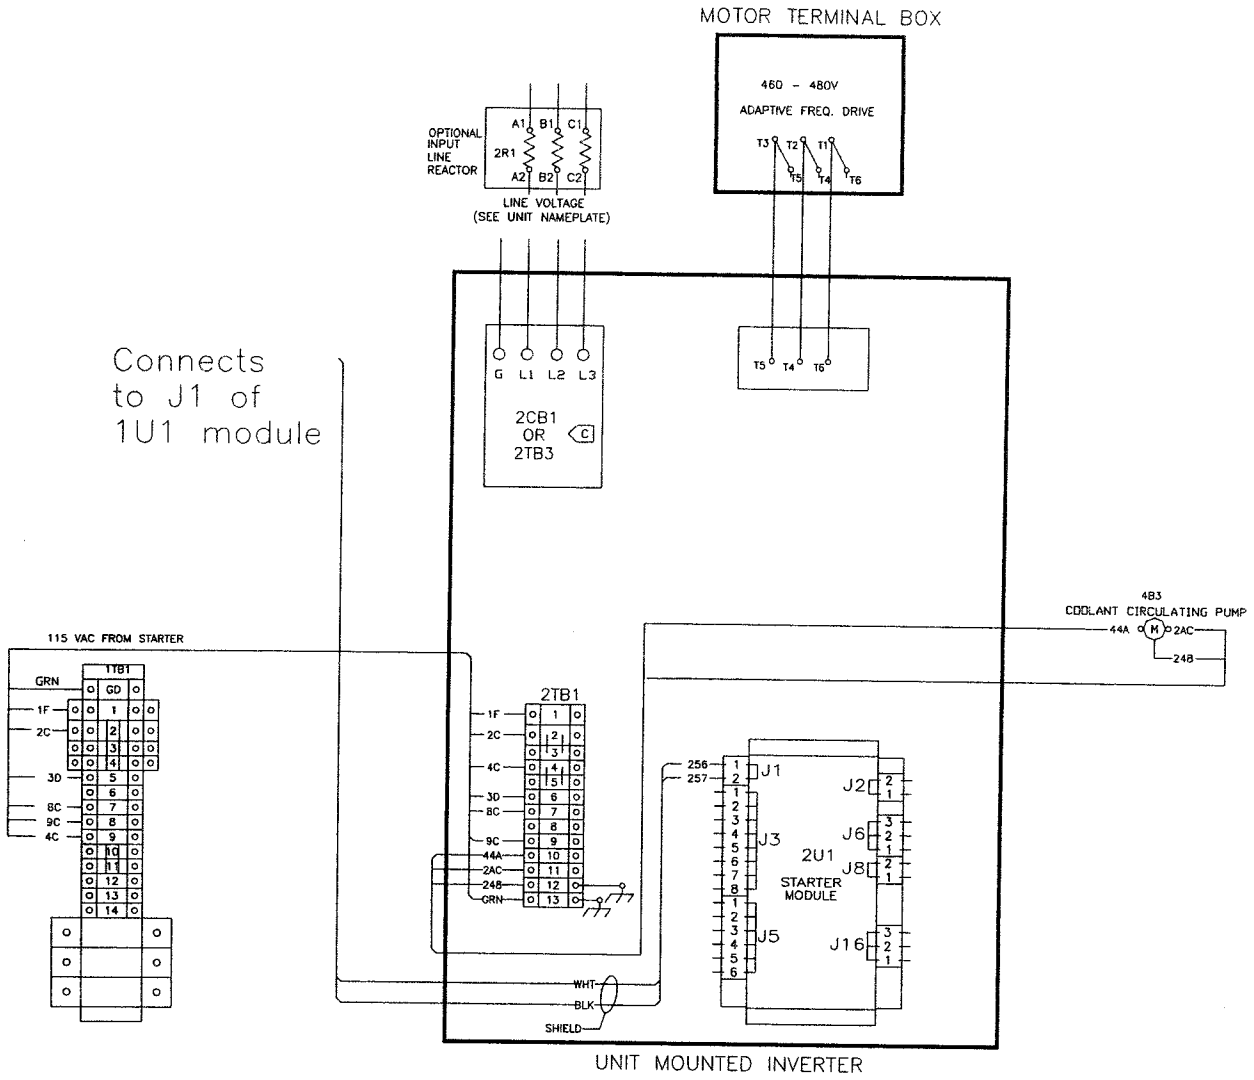
b. For every 300 feet above 3,300 feet, the rated output current shall be decreased by 1%.



2. S12 ISOLATION TRANSFORMER (HARMONIC ATTENUATION)

When this option is provided, the standard inverter circuit breaker will be relocated from the drive cabinet to this autotransformer cabinet. This is field installed and must be mounted within sight of the chiller motor.

3. FACTORY STARTUP



(Factory Startup by Rockwell is an option that can be purchase with the unit.) See Start-Up Checklist and Service Request form at the end of this manual.

gure 4 - Typical Line Reactor Showing General Purpose Enclosures

EXT	HORSEPOWER (HP)	KW	A	B	C	D	E	F	G	H	I	J	WEIGHT (#)
01 & 05	350	262	17.00	17.00	24.00	5.00	8.00	13.00	13.00	15.50	.75	2.00	335#

Figure 5 - Typical Line Wiring Showing Field Connection Point for Inverter

(5) Wire Routing

THIS SECTION PROVIDES CABINET DIMENSION INFORMATION. IT DESCRIBES THE CABINET AND SHOWS WHERE THE WIRE ENTRY AREAS AND LIQUID-COOLING CONNECTION POINTS ARE LOCATED.

About the Cabinet

Cabinet dimensions and weights are listed in Table 2. Overall cabinet dimensions are illustrated in Figures 6 through 6B. Cabinet mounting holes are shown in Figures 7 through 7B.

Table 2 – Cabinet Dimensions - 350 HP, 450/600 HP and 1000 HP

HP	A	B	C	D	E	F	Wt.
350	38.0 inch 965 mm	60.0 inch 1524 mm	15.3 inch 389 mm	63.3 inch 1608 mm	17.7 inch 450 mm	.53 inch 13.5 mm	800 lb 364 kg
450/ 600	38.0 inch 965 mm	60.0 inch 1524 mm	15.3 inch 389 mm	63.3 inch 1608 mm	17.7 inch 450 mm	.91 inch 22.3 mm	970 lb 449 kg
1000	64.0 inch 1626 mm	68.9 inch 1750 mm	16.3 inch 414 mm	72.2 inch 1834 mm	18.9 inch 480 mm	1.30 inch 31.9 mm	1700 lb 805

Be sure there is adequate clearance for air ventilation around the cabinet. Allow a minimum clearance for air ventilation around the cabinet. Allow a minimum clearance of 0.3 meters or 1 foot per side.

Attach the cabinet to the CenTraVac® chiller using the 7 mounting holes and 4 slots provided. In order to maintain a flat mounting surface and to ensure that screw tightness is maintained, use a washer and lock washer under the screw heads. Refer to Figures 6 through 6B and Table 2 for cabinet mounting dimensions. Use 3/8" (upper) and 1/2" (lower) mounting screws and washers to attach the cabinet to the chiller. See Table 3 and Figures 7 through 7B for mounting hole locations and dimensions.

Table 3 - Cabinet Mounting Hole Dimensions - 350 HP, 450/600 HP and 1000 HP

HP	G	H	J	K	L	M
350	49.9 inches 1255 mm	3.38 inches 85.9 mm	6.0 inches 152.4 mm	12.4 inches 315 mm	3.0 inches 76.2 mm	26.0 inches 660.4 mm
450/ 600	49.9 inches 1255 mm	3.38 inches 85.9 mm	6.0 inches 152.4 mm	12.4 inches 315 mm	3.0 inches 76.2 mm	26.0 inches 660.4 mm
1000	59.9 inches 1522 mm	5.34 inches 136 mm	4.25 inches 108 mm	11.25 inches 286 mm	4.5 inches 30 mm	26.0 inches 660.4 mm

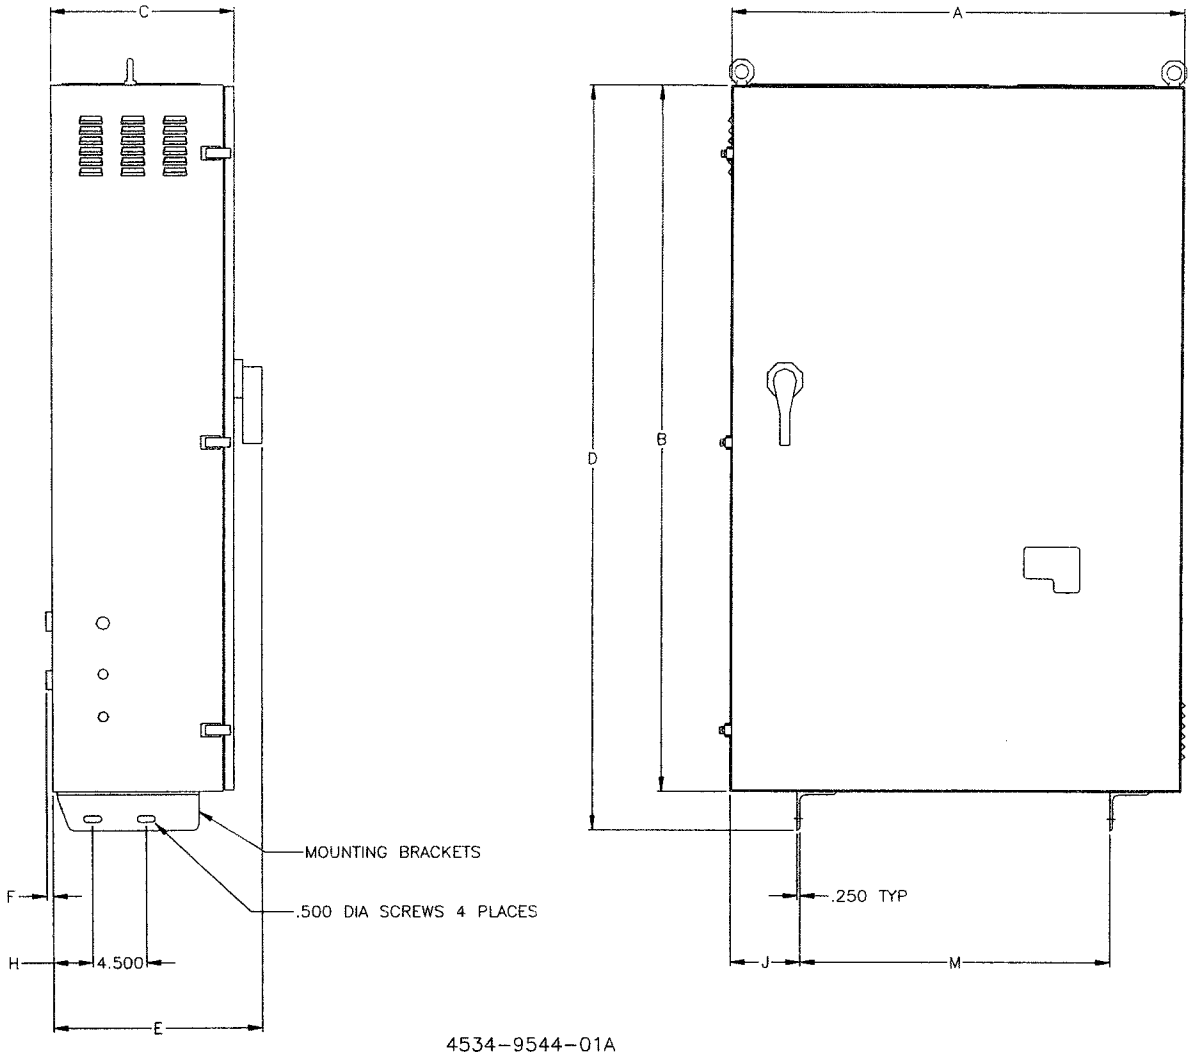

Figure 6A - Overall Cabinet Dimensions - 450/600 HP Shown See Table 2

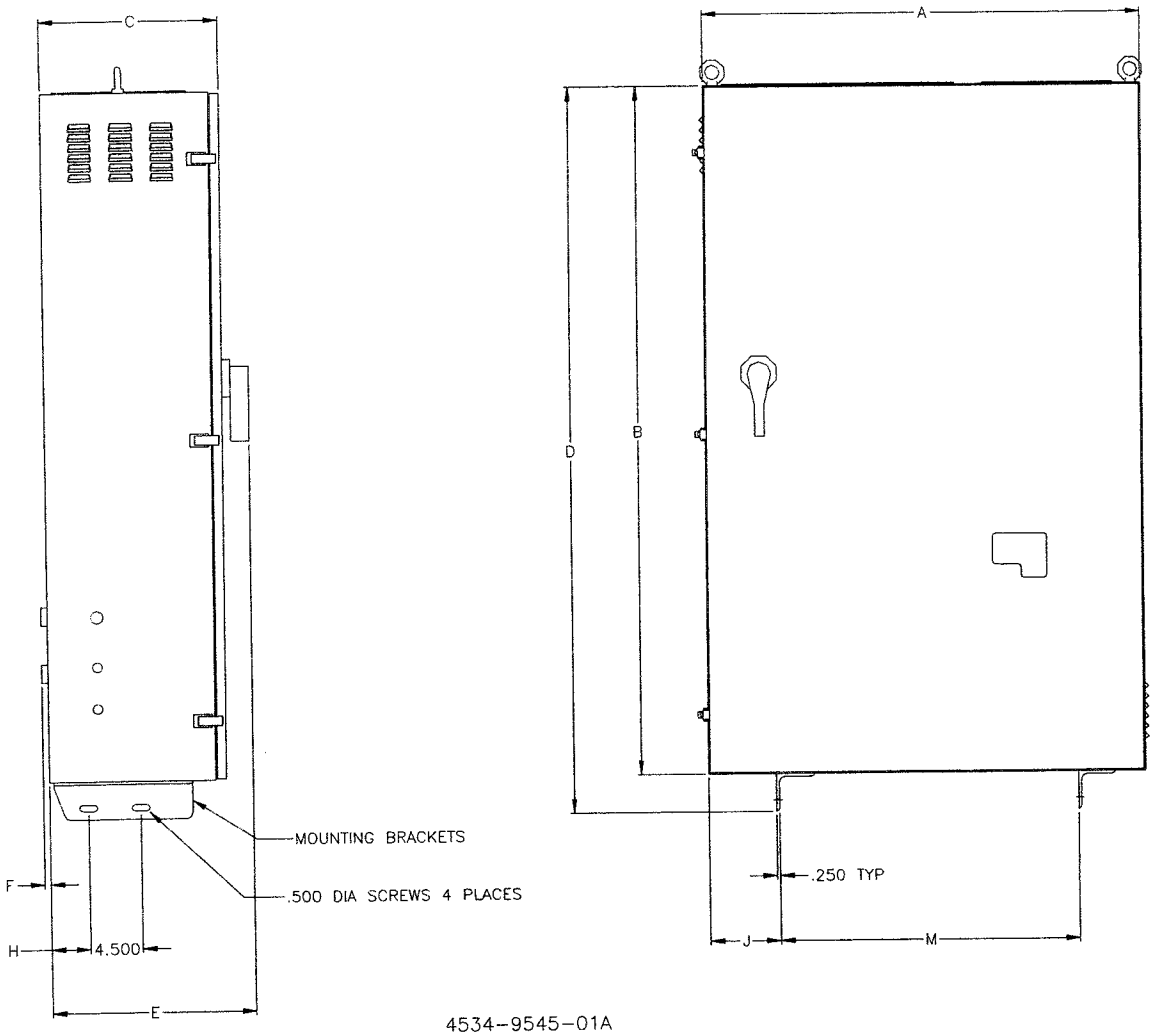

Figure 6B - Overall Cabinet Dimensions - 1000HP

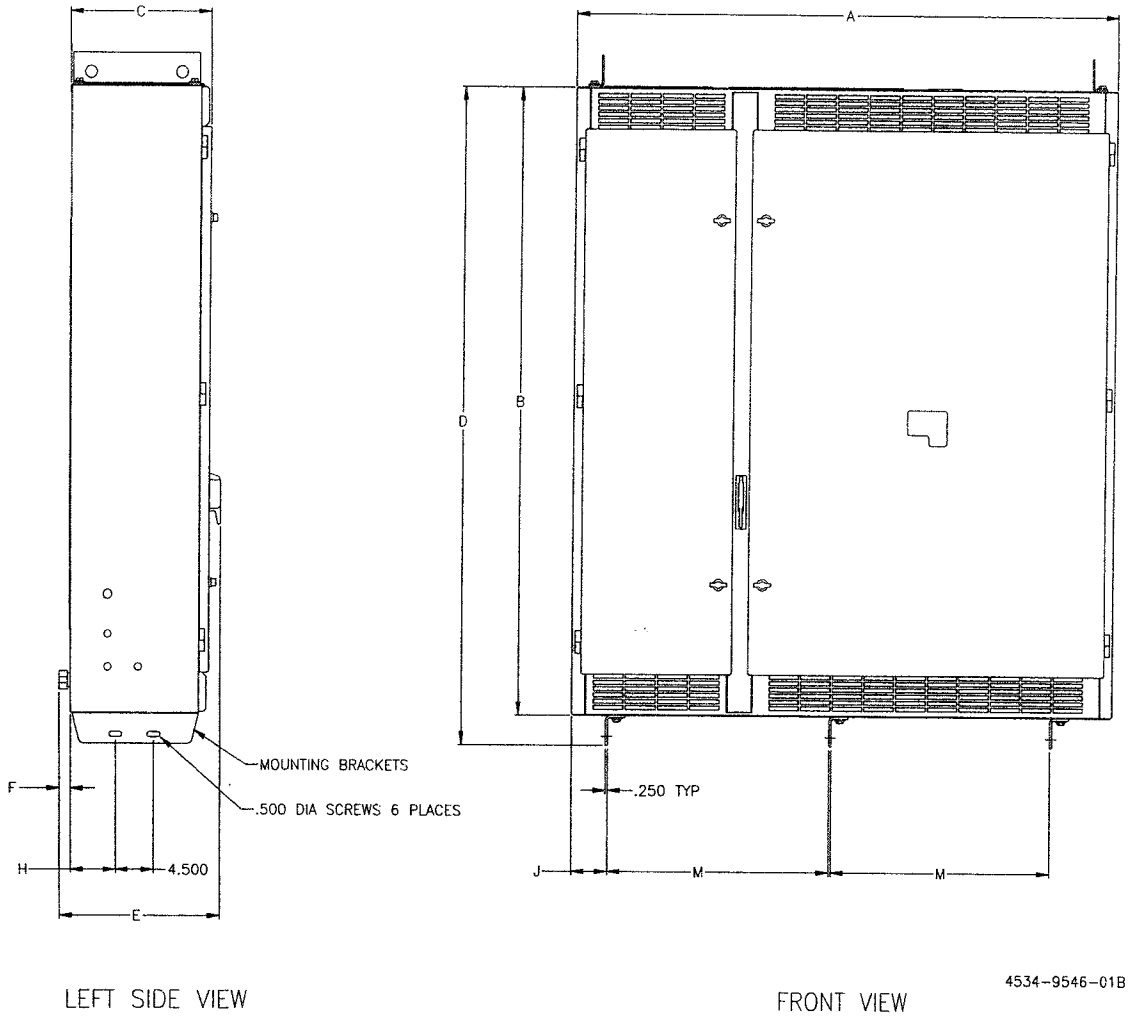

Figure 7 - 350 HP Cabinet Mounting Holes/Slots - (See Table 3)

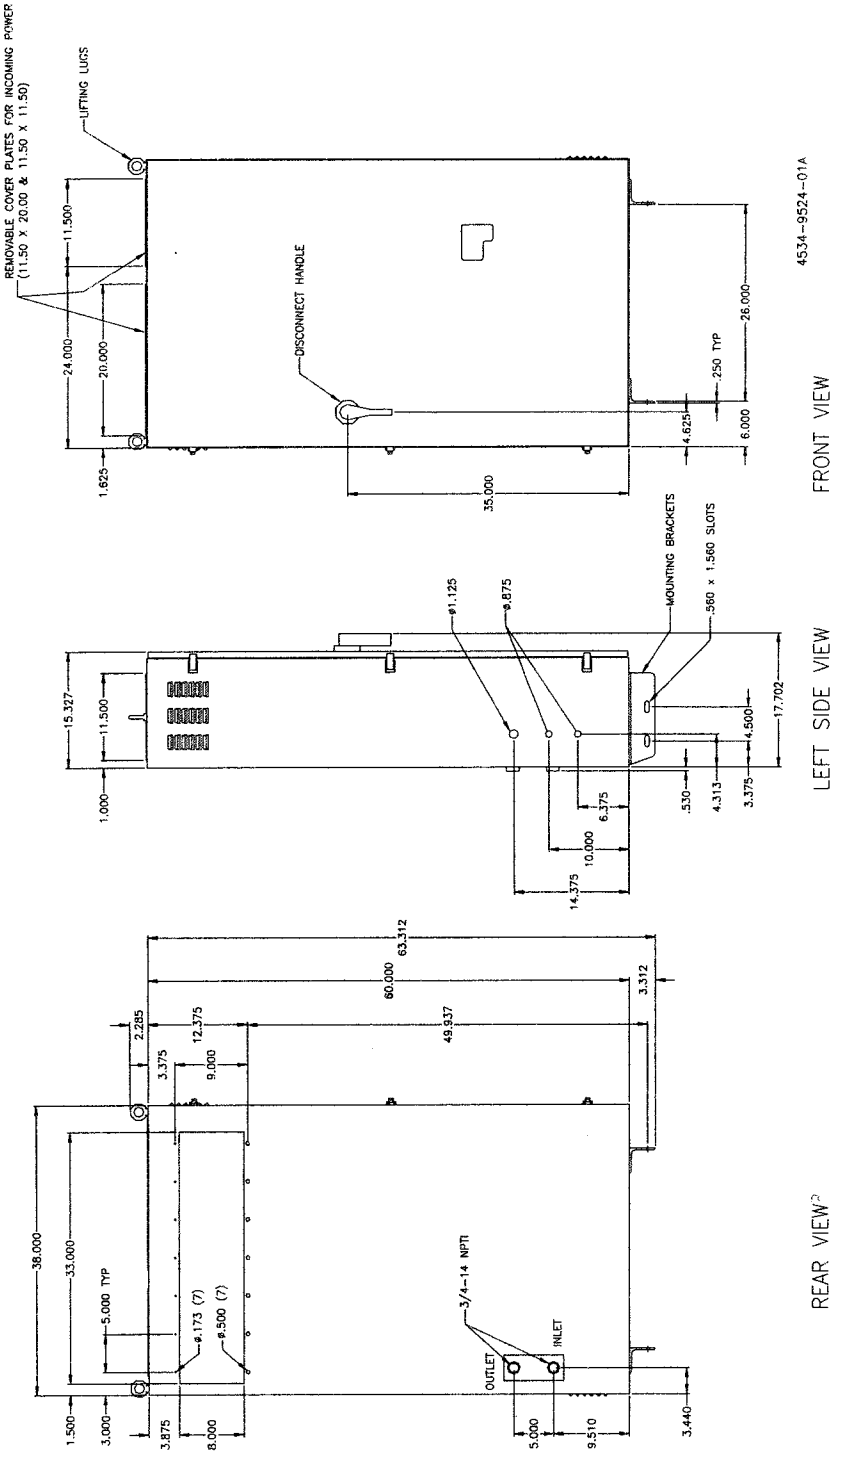

Figure 7A - 450/600 HP Cabinet Mounting Holes/Slots - (See Table 3)

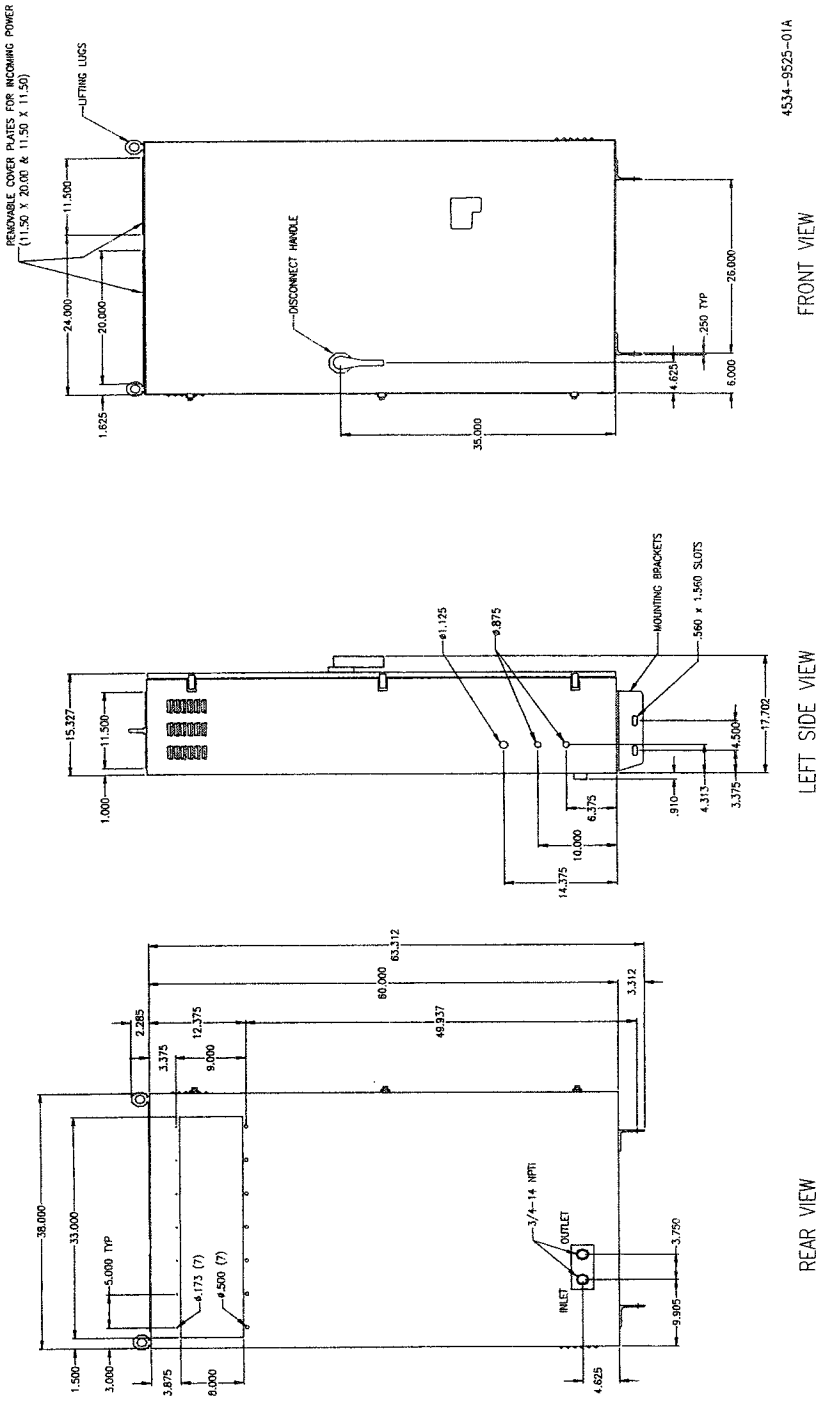

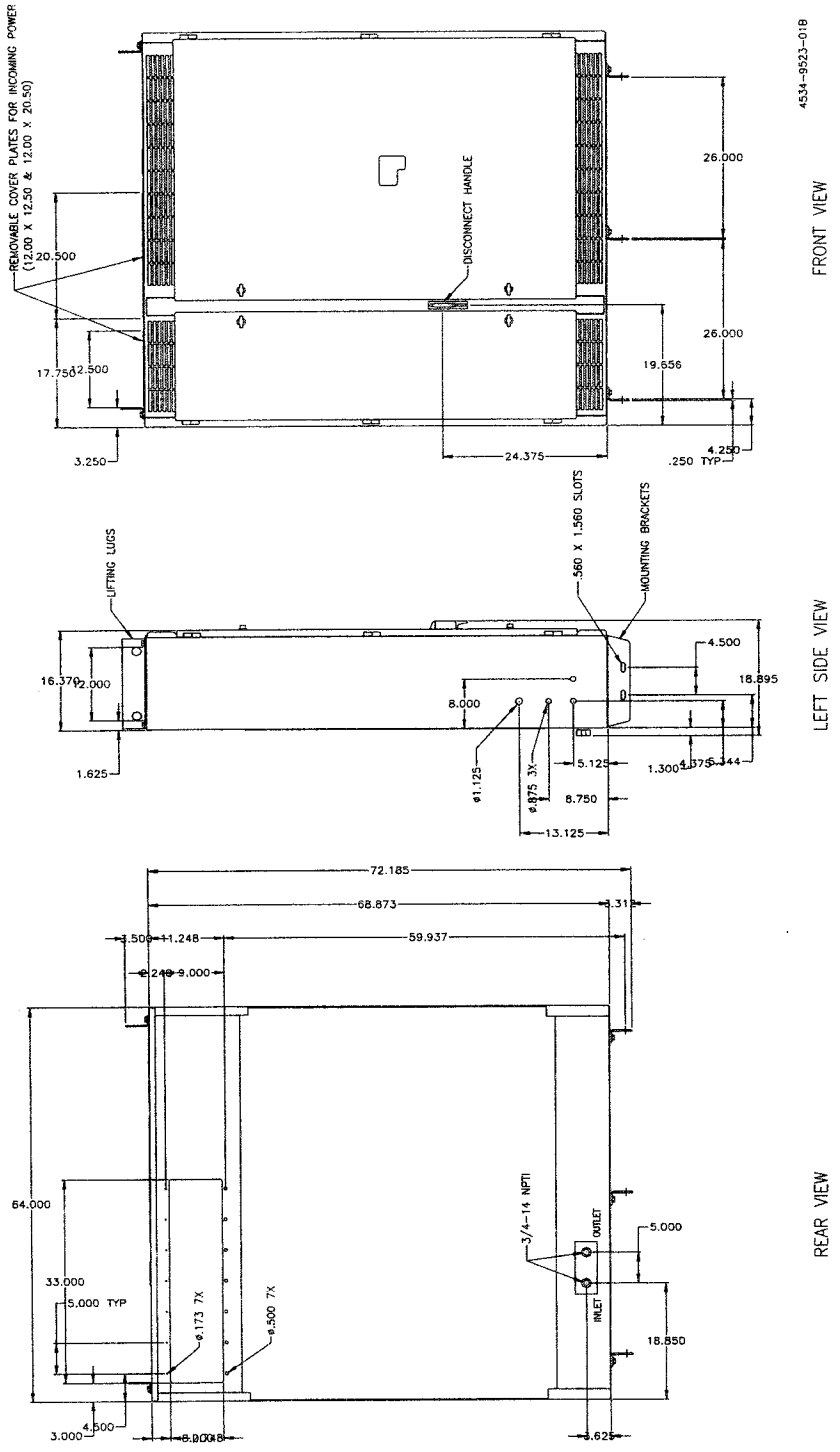

Figure 7B - 1000 HP Cabinet Mounting Holes/Slots - (See Table 3)

(5) Wire Routing

Wire Sizing

Care should be taken to see that all interconnection wiring and ground wiring is sized and installed in conformance with the National Electrical Code (NEC), the National Fire Protection Association (NFPA), or the Canadian Electrical Code (CEC) as applicable, and other appropriate local codes. Refer to controller and motor nameplates for electrical data.

Grounding

THE MOTOR CONTROLLER HAS A CHASSIS GROUND CONNECTED TO EARTH GROUND. IF YOUR CONTROLLER IS MOUNTED SUCH THAT THE ENCLOSURE IS NOT GROUNDED, A GROUND WIRE MUST BE CONNECTED TO THE ENCLOSURE FOR PERSONNEL SAFETY. THE MOTOR FRAME MUST ALSO BE GROUNDED TO THE DRIVE CONTROLLER.

Refer to submittals for power lug sizes and location along with control wiring specifics for the controller.

Torquing Electrical Power Connections

Utilizing a torque wrench can best control proper tightness of power connections. Since each individual will have a different sense of feel to what is tight, a torque wrench eliminates the human element and provides proper hardware tightening.

Proper torque for connections depends on both the bolting materials and the metals being connected. Both copper and aluminum will flow under prolonged pressure. Flow is greater for aluminum. For this reason, follow up tightening for connected aluminum conductor is even more important than for copper.

Electrical power terminations should be rechecked for tightness when the apparatus is first installed and periodically afterwards. The conductor could flow under prolonged pressure. Thermal cycling will be greater during the first few months in operation. POWER CONNECTIONS SHOULD BE RETORQUED AFTER THE FIRST THREE TO SIX MONTHS OF OPERATION AND ON AN ANNUAL BASIS THEREAFTER.

Most hardware used for making a bolted electrical joint will be low carbon steel. The hardware does not carry electrical current but holds the two conducting surfaces together under pressure. When properly torqued, the slight elongation of the bolt or screw acts to maintain pressure on the electrical joint. The thermal expansion of steel is less than that of the conducting metals which is usually copper or aluminum.

The pressure at the electrical joint will vary slightly during thermal cycling and reduces somewhat when there is cold flow in the conducting metals. Retorquing will reestablish the surface pressure, which is essential to keep a low resistance drop between the two conducting surfaces and thus avoid eventual failure.

(5) Wire Routing

Note: Connection from the AFDB output to the motor is made with flexibar. PROPER TORQUE IS "CRITICAL". See Table 4.

Table 4 - Torque Value for the AFDB Output to Motor Flexibar

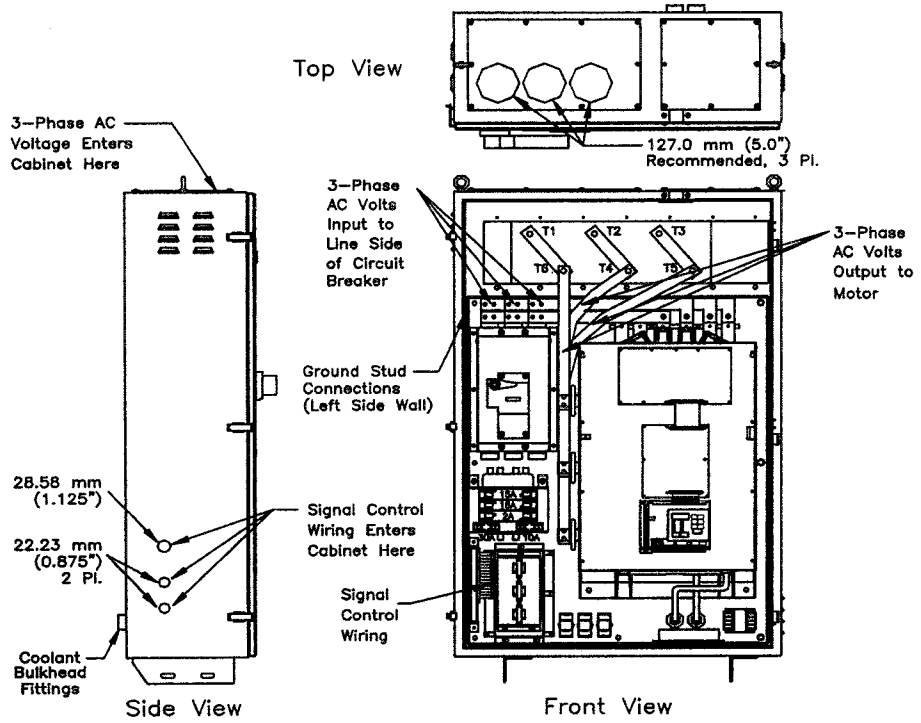
Bolt Size	Torque Value
3/8"	30 Foot-Pounds.

Cabinet Wire Routing

All wiring should be installed in conformance with the applicable local, national, and international codes (for example, NEC/CEC). Figures 7 and 8 the wire routing, grounding terminal and power terminal strips of a cabinet. Control wiring enters the cabinet through the three holes on the left side and terminates at the control panel's terminal block. Tighten the control wire connections, 7.1 to 8.9 in-lbs.

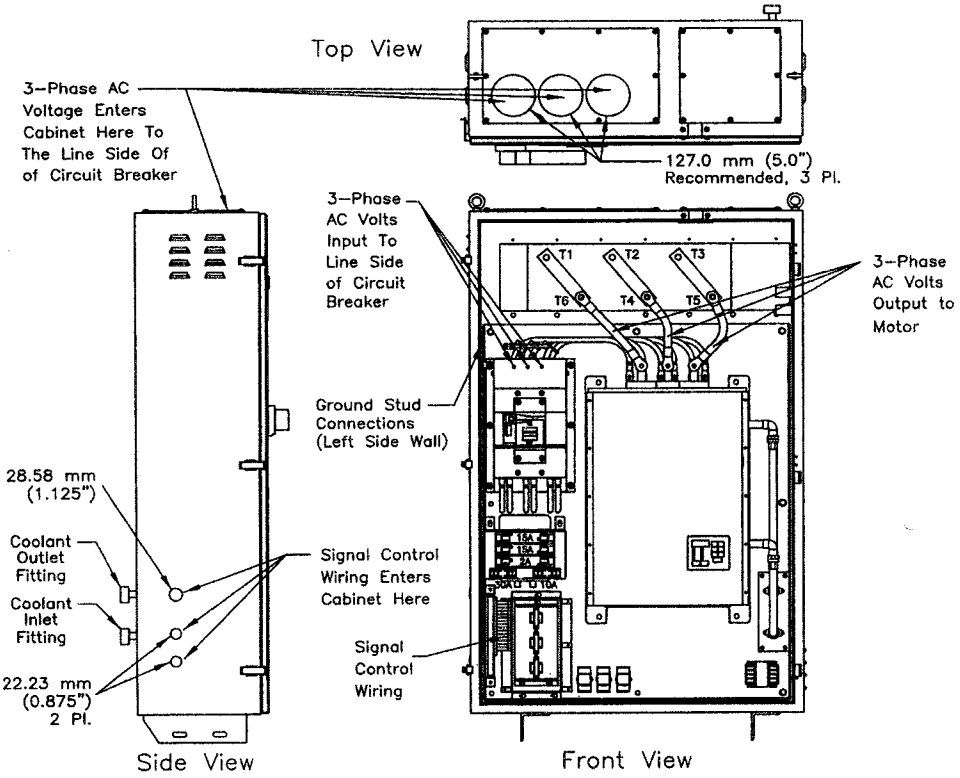
Grounding the Cabinet

CAUTION
THE USER IS RESPONSIBLE FOR CONFORMING TO ALL APPLICABLE, LOCAL, NATIONAL, AND INTERNATIONAL CODES. Failure to observe this precaution could result in damage to, or destruction of, the equipment.



USE THE FOLLOWING STEPS TO GROUND THE CABINET:

Step 1. Open the cabinet's door. The grounding stud is located on the left side of the cabinet.



Step 2. Run a suitable grounding conductor unbroken from the cabinet's ground stud to the motor's ground terminal **(completed at factory)** and then to earth ground **(completed by field).** See Figures 8, 8A and 9. The cabinet's ground stud connection point has two 5/16" socket-head screws. Tighten the ground connections to 23-ft lbs.

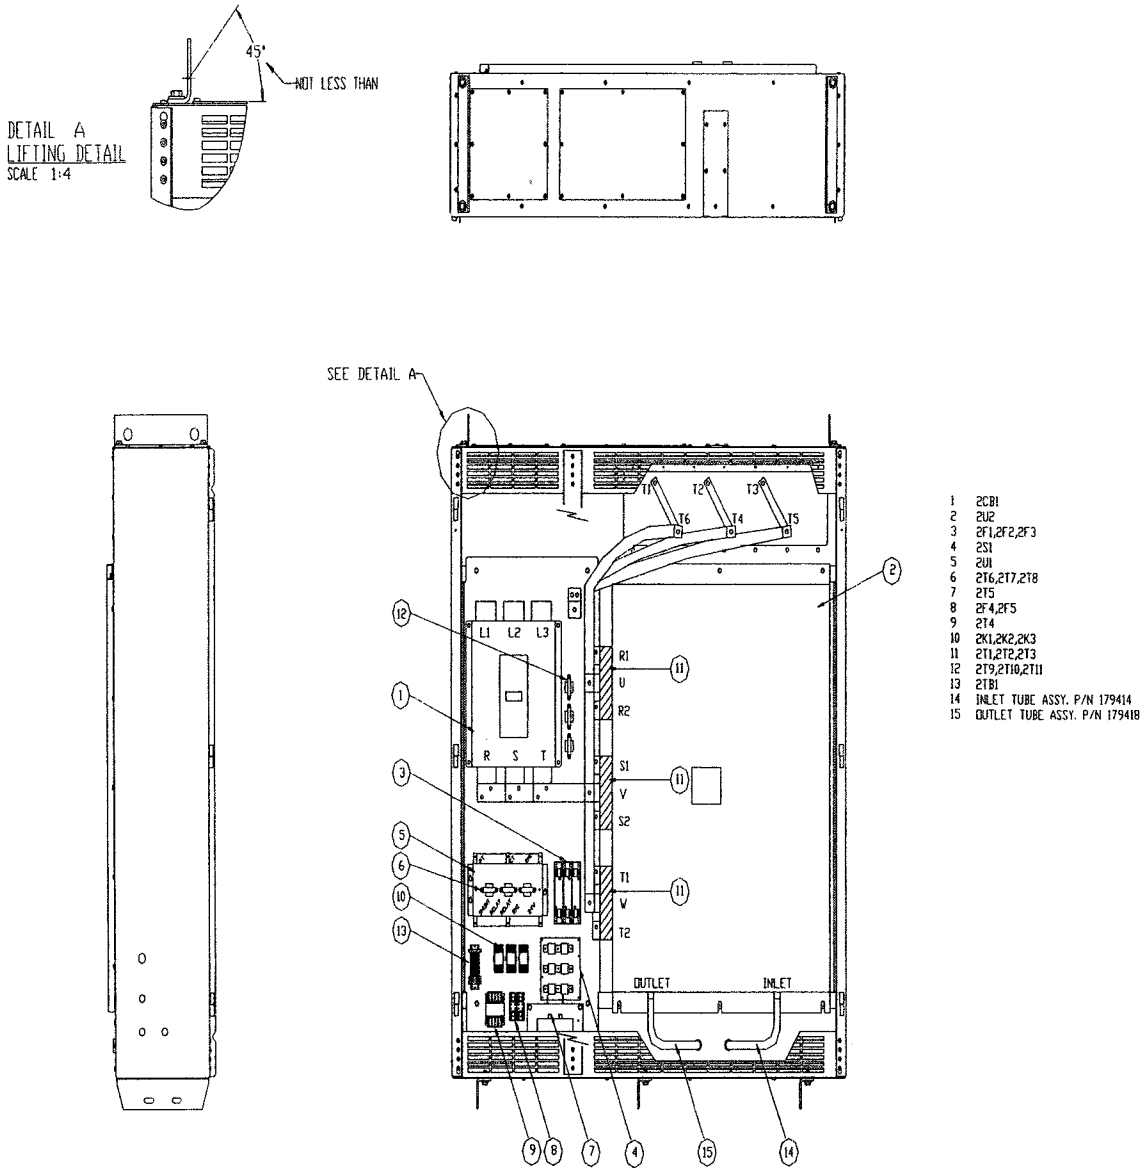
Step 3. Connect a suitable grounding conductor to the motor frame and the Delta-Wye Transformer (if used). Run each conductor unbroken to earth ground.

Figure 8 – 350 HP and 450/600 HP Cabinet Wire Routing Locations (6-Pulse Rectifier) Standard

450/600 HP

350HP

Figure 8A - 1000 HP Cabinet Wire Routing Locations (6-Pulse Rectifier) Standard



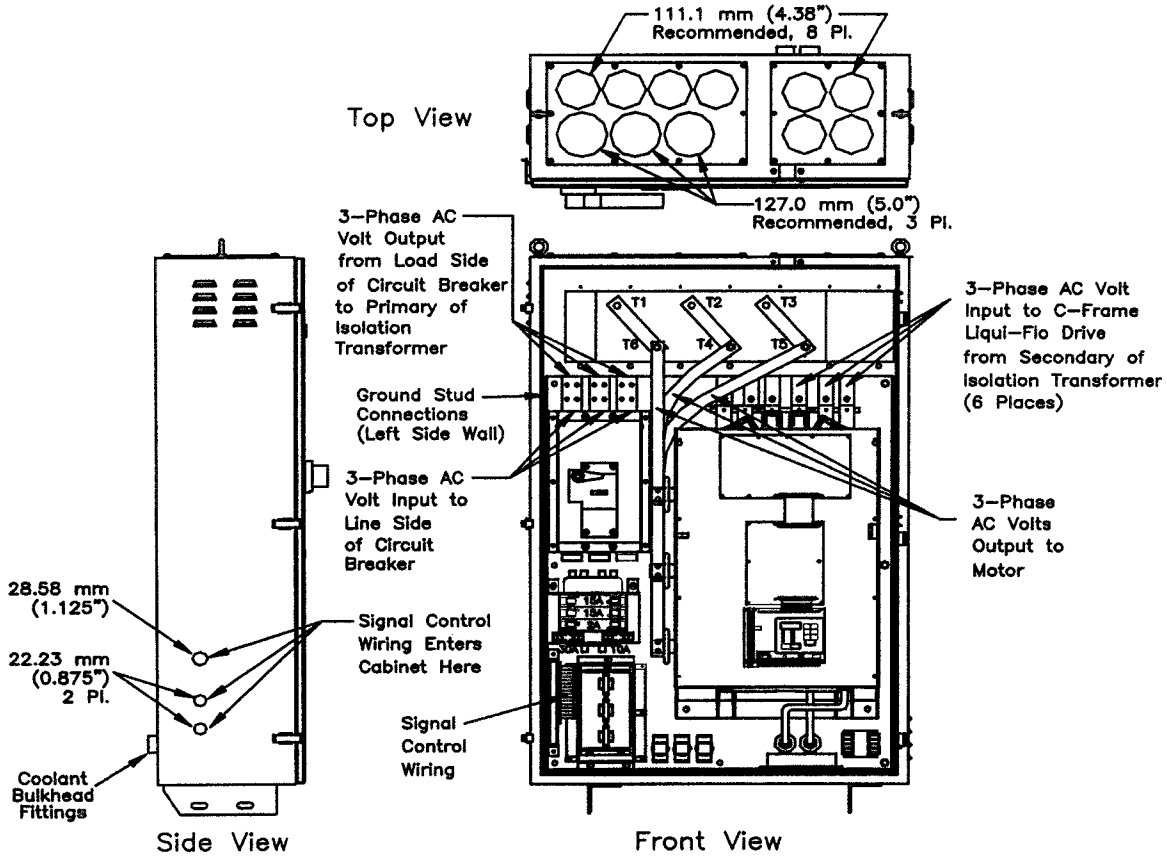


Figure 9 - Cabinet Wire Routing Locations (12-Pulse Rectifier) S12 Isolation Transformer (Harmonic Attenuation)

(5) Wire Routing

THIS SECTION DESCRIBES THE CONVERSION PROCESS FROM A 6-PULSE STANDARD TO A 12-PULSE (S12 ISOLATION Transformer)(HARMONIC ATTENUATION.)

Conversion From 6-Pulse (Standard) to 12-Pulse (S12 Isolation Transformer) (Harmonic Attenuation)

Note: The above conversion process not available on 1000 Drive.

110 inches-pounds
See Figure 10 showing Diagram of 6 Pulse – 12 Pulse Conversion.

1. Remove Bussbar from Drive:

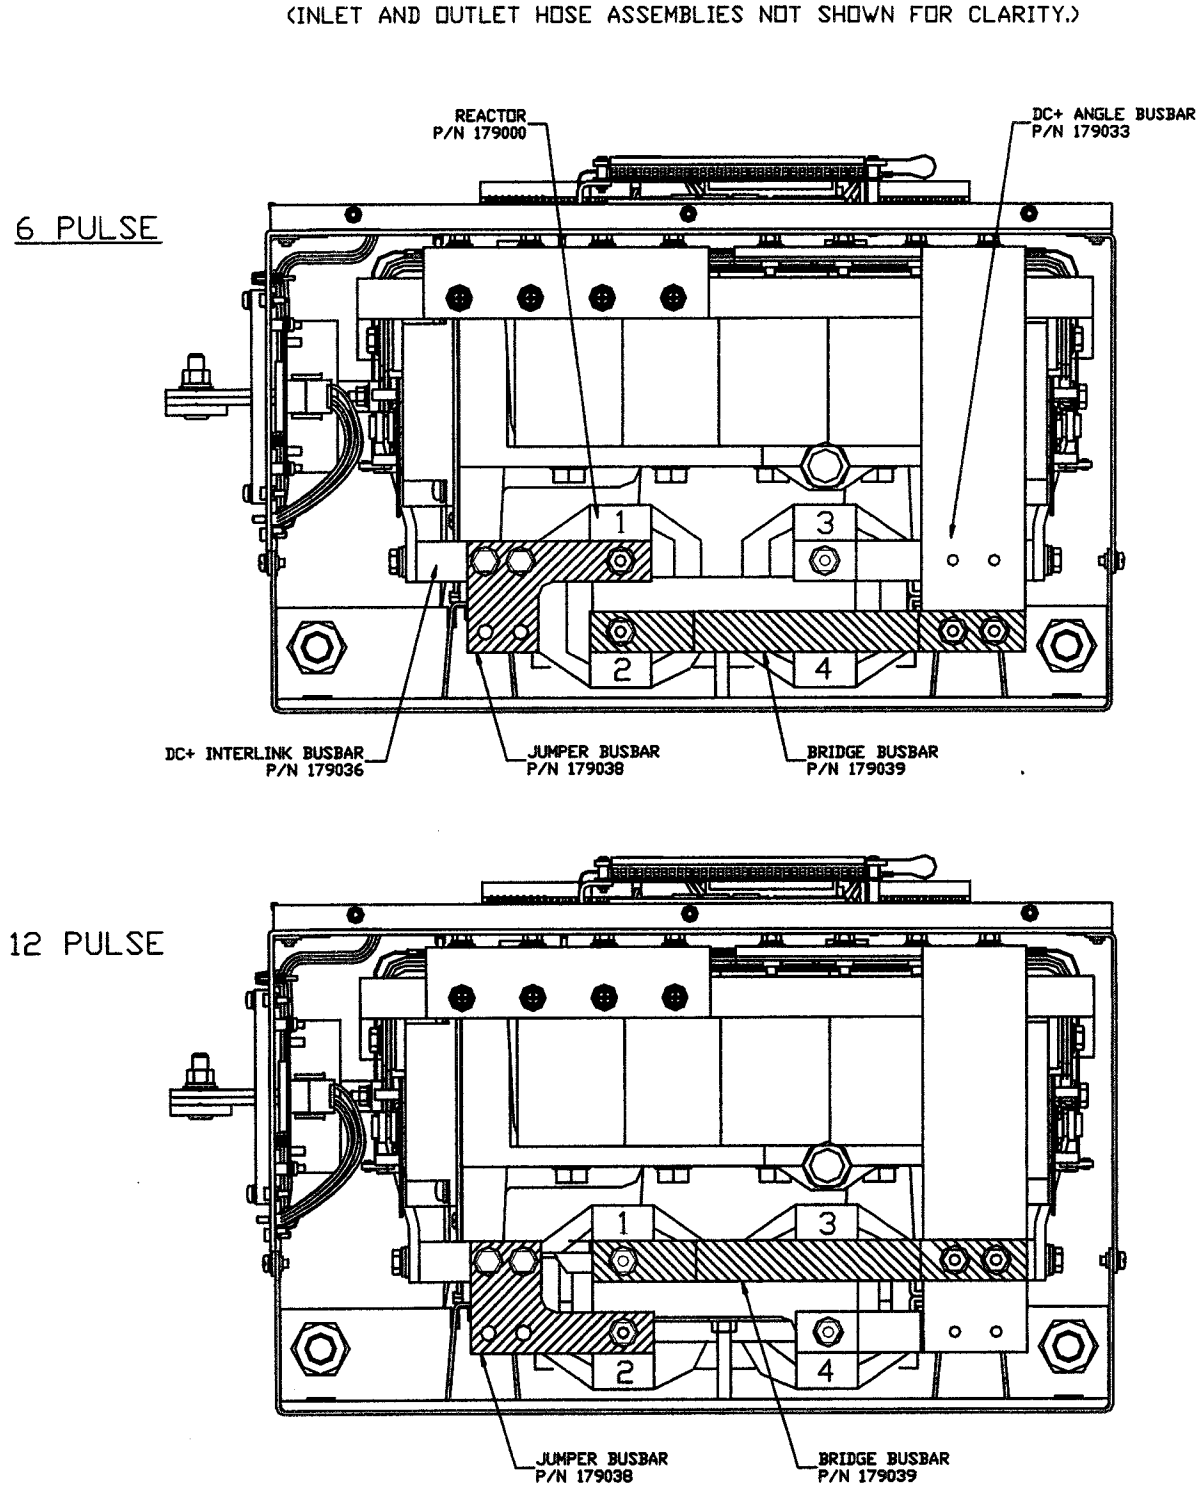
A. Remove and save two M8 screws, one M8 Nut and associated hardware from the Jumper bussbar P/N 179038.

B. Remove and save three M8 Nuts and associated hardware from the Bridge bussbar P/N 179039.

2. Reinstall Jumper Bussbar on Drive:

A. Rotate by 180° Jumper bussbar P/N 179038 and reinstall on DC+ Interlink bussbar P/N 179036 and on Reactor P/N 179000, Terminal 2.

B. Reinstall M8 Hardware. Tightening torque is 90 to 110 inches-pounds.



3. Reinstall Bridge Bussbar on Drive:

A. Reinstall Bridge Bussbar P/N 179039 to the Upper Set of Studs on DC+ Angle Bussbar P/N 179033 and on Reactor P/N 179000, Terminal 1.

B. Reinstall M8 Hardware. Tightening torque is 90 to 110 inches-pounds.

Conversion From 12-Pulse To 6-Pulse Is The Opposite Of This Procedure.

Figure 10 – 6 Pulse – 12 Pulse Conversion

(6) Connecting Power Wiring

THIS SECTION DESCRIBES THE INPUT AND OUTPUT POWER TO THE CABINET.

Cabinet Input Disconnect

⚠ WARNING
THE USER IS RESPONSIBLE FOR CONFORMING TO ALL APPLICABLE LOCAL, NATIONAL, AND INTERNATIONAL CODES. Failure to observe this precaution could result in damage to, or destruction of, the equipment.

An input disconnect circuit breaker is factory-installed in the cabinet. Verify that the available fault is less than the interrupting rating on the circuit breaker nameplate, which are 65,000 amps at 480 VAC.

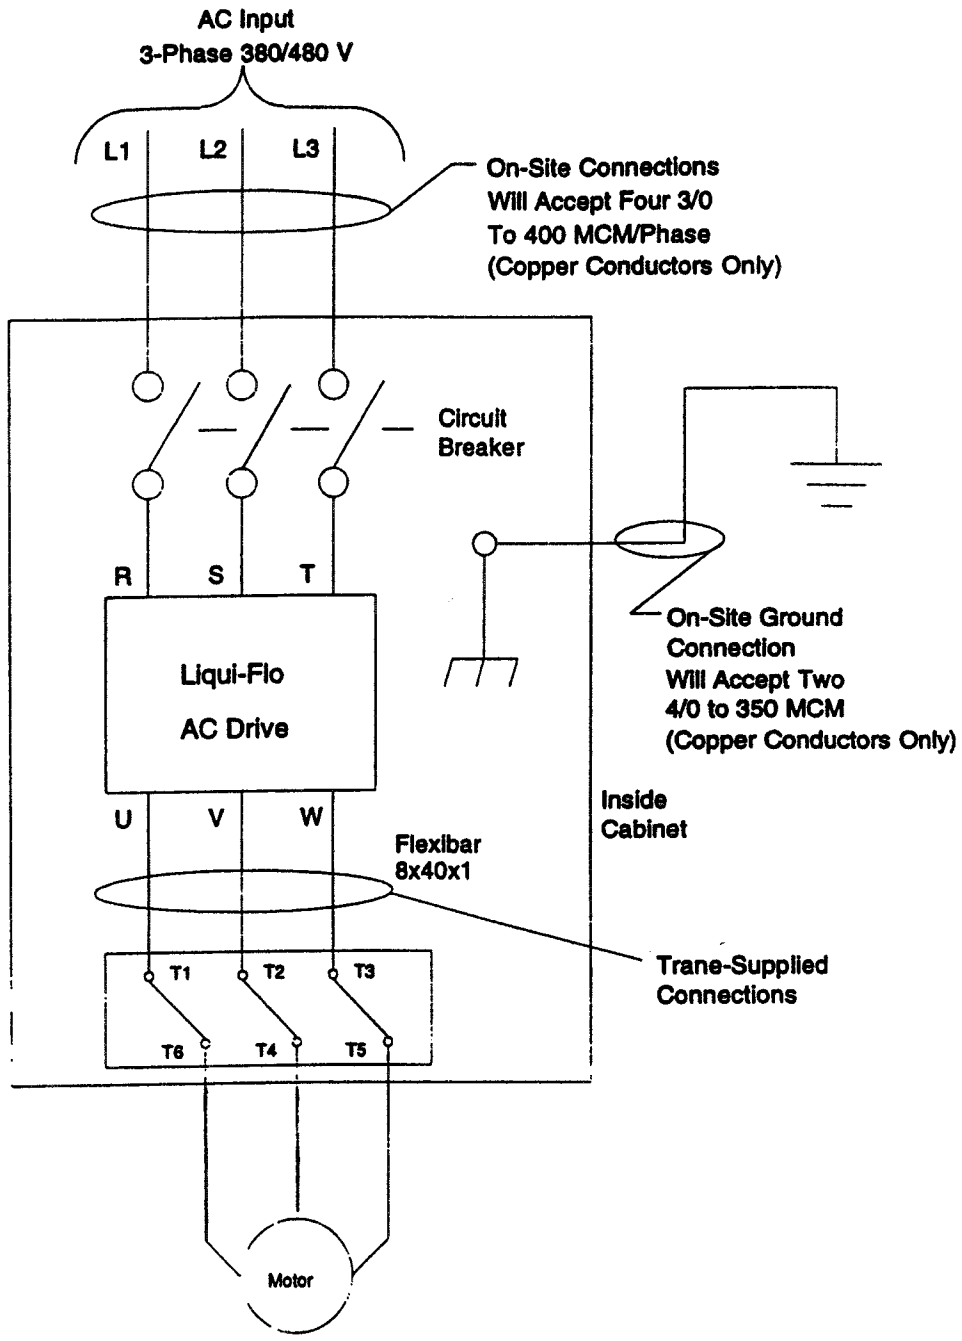
Installing Input Power Wiring (6-Pulse Rectifier) Standard Cabinet

⚠ WARNING
THE USER IS RESPONSIBLE FOR CONFORMING TO ALL APPLICABLE LOCAL, NATIONAL, AND INTERNATIONAL CODES. Failure to observe this precaution could result in damage to, or destruction of, the equipment.

Use the following steps to connect AC input power to the cabinet:

Step 1. Remove the top panel of the cabinet.

IMPORTANT: *Care must be taken to prevent debris from falling into the cabinet while performing this installation.*



Step 2. Drill the wire routing holes in the panel. Note that the wire routing hole patterns shown in Figure 8 are recommendations only. These wire routing holes are the only entry points for input power wiring into the cabinet.

Step 3. Install the appropriate conduit hubs.

Step 4. Reinstall the cabinet's top panel.

Step 5. Connect the three-phase 480 VAC input power leads to circuit breaker terminals L1, L2, and L3. See Figure 11. Tighten these connections to 30 foot-pound. Use only copper-conductors for the input power leads.

Figure 11 - Trane Cabinet Electrical Connections (6-Pulse Rectifier) Standard

(6) Connecting Power Wiring

Installing Input Power Wiring (12-Pulse Rectifier Cabinet) S12 Isolation Transformer (Harmonic Attenuation)

⚠ WARNING
THE USER IS RESPONSIBLE FOR CONFORMING TO ALL APPLICABLE LOCAL, NATIONAL, AND INTERNATIONAL CODES. Failure to observe this precaution could result in damage to, or destruction of, the equipment.

Use the following steps to connect AC input power to the cabinet:

Step 1. Remove the top panel of the cabinet.

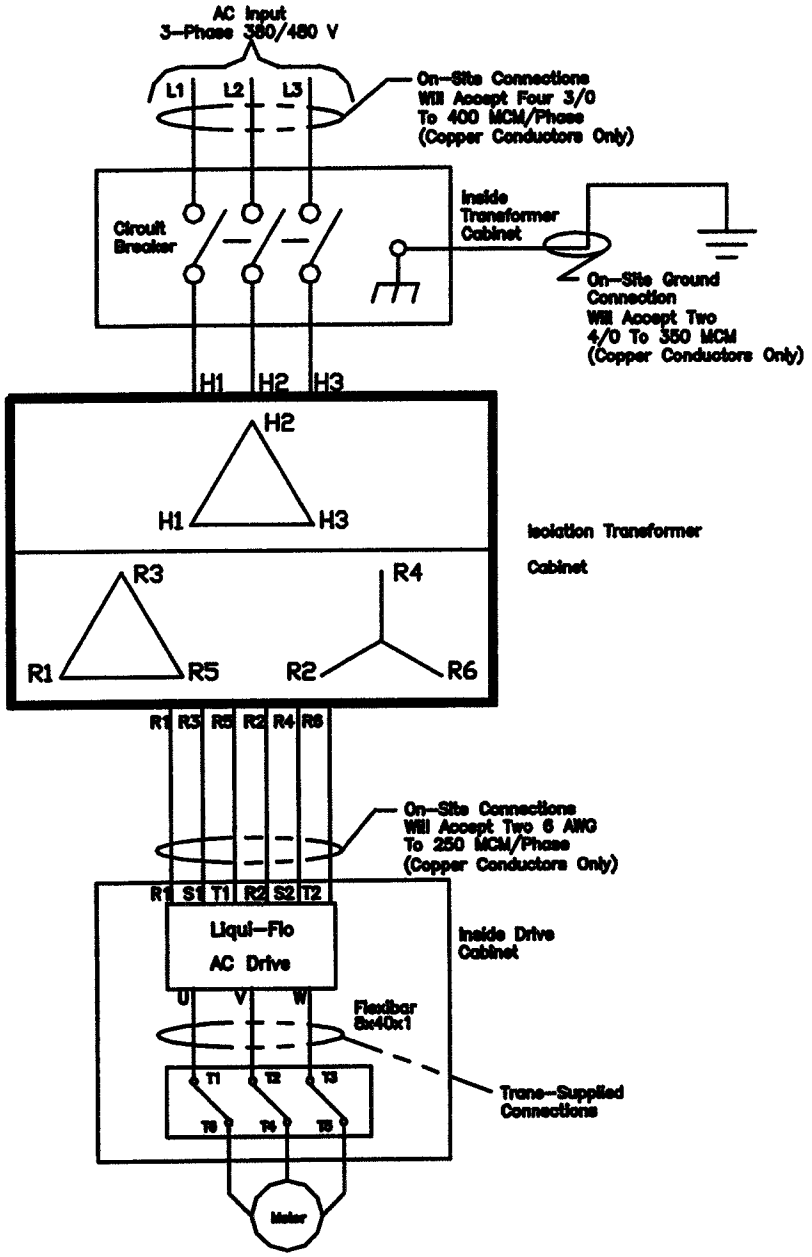
IMPORTANT: *Care must be taken to prevent debris from falling into the cabinet while performing this installation.*

Step 2. Drill the wire routing holes in the panel. Note that the wire routing hole patterns shown in Figure 9 are recommendations only. These wire routing holes are the only entry points for input power wiring into the cabinet.

Step 3. Install the appropriate conduit hubs.

Step 4. Reinstall the cabinet's top panel.

Step 5. Connect the three-phase 480 VAC input power leads to circuit breaker terminals L1, L2, and L3. See Figure 12. Tighten these connections to 30 ft-lb. Use only copper-conductor for the input power leads.



Step 6. Twelve-pulse cabinets require an Isolation Transformer be installed external to the cabinet. Install the Trane-specified transformer by following the installation instructions supplied with it.

Step 7. Connect the load side of the circuit breaker to the R, S, and Terminals on the Isolation Transformer. Tighten these connections to 30 ft-lb.

Step 8. Connect the load side of the Isolation Transformer to the S1 through S6 terminals on the AFDB drive. Tighten these connections to 30 ft-lb.

(6) Connecting Power Wiring

Figure 12 - Trane Cabinet Electrical Connections (12-Pulse Rectifier) Isolation Transformer (Harmonic Attenuation)

(6) Connecting Power Wiring

Installing Output Power Wiring (Completed by Trane on Unit Mounted Drives)

⚠ WARNING
THE USER IS RESPONSIBLE FOR CONFORMING TO ALL APPLICABLE LOCAL, NATIONAL, AND INTERNATIONAL CODES. Failure to observe this precaution could result in damage to, or destruction of, the equipment.

Use the following steps to connect the cabinet's output power wiring from the drive to the chiller motor:

Step 1. Connect the Trane-supplied Flexibar (8 x 40 x 1) conductors to the drive's U, V, W output terminals using the Trane-supplied hardware. See Figures 8, 9, 11 and 12.

Step 2. Tighten these connections to Trane specifications.

Step 3. Connect the Flexibar conductors to the T1, T2, and T3 motor connection studs using the Trane-supplied hardware. See Figures 8, 9, 11 and 12.

Step 4. Tighten these connections to Trane specifications. Refer to Table 5.

Regulator Board Wiring

The cabinet's start/stop wiring on the Regulator board's terminal strip is factory-wired as shown in the wiring diagram.

(7) Liquid Cooling Connections

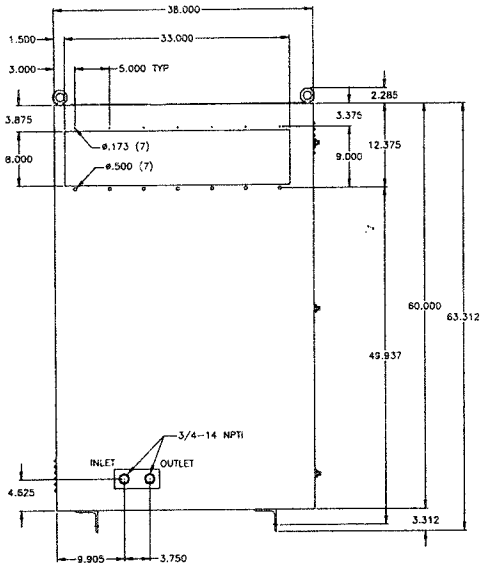
Liquid-Cooling Connections (Factory Connected on Unit Mounted Drives)

External coolant lines connect to the cabinet through two bulkhead fittings. The bulkhead fittings are located on the rear panel of the cabinet as shown in Figure 13. If you have removed the liquid cooling lines for field disassembly when repairing. Use the following steps to connect the coolant lines to the cabinet:

Step 1. Be sure the threads of the bulkhead fittings and the CenTraVac® chiller's tubing connectors are free of dirt, burrs, and excessive nicks.

Step 2. Place two layers of Teflon Pipe Sealant on the threads of the CenTraVac chiller's tubing connectors. More than two layers of sealant may distort or crack the bulkhead fitting. Screw the connectors into the cabinet's bulkhead fittings until they are finger-tight. See Figure 14.

Step 3. Use a wrench to further tighten the connectors 1.5 to 2.5 turns. Do not hold the bulkhead fitting with a pipe wrench when tightening the connectors as the fitting may be damaged. The bulkhead fitting has a built-in anti-rotation feature and will not turn as the connector is screwed in.



CAUTION
THE CABINET'S BULKHEAD FITTINGS MAY BE DAMAGED IF THEY ARE HELD WITH A PIPE WRENCH. DO NOT HOLD THE BULKHEAD FITTING WITH A PIPE WRENCH. THE BULKHEAD FITTING HAS A BUILT-IN ANTI-ROTATION FEATURE AND WILL NOT TURN AS THE CONNECTOR IS SCREWED IN. Failure to observe this precaution could result in damage to, or destruction of the equipment.

Step 4. Check the connections for leaks.

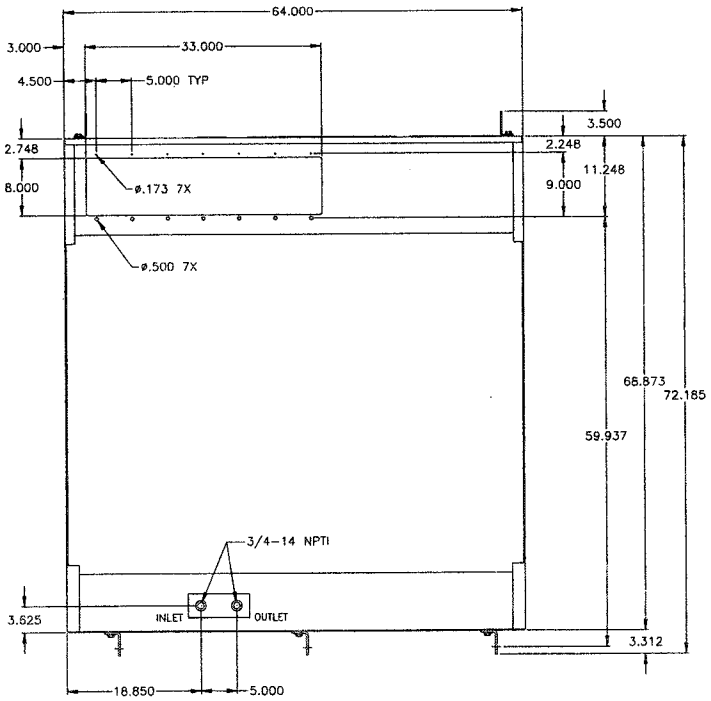

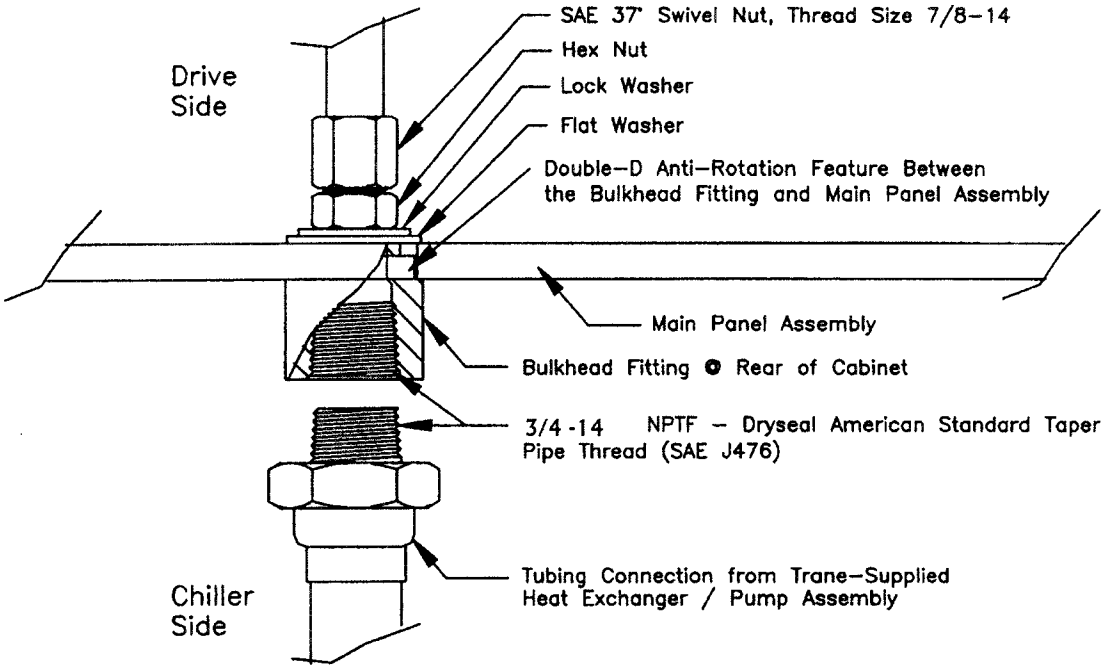

Figure 14 - Liquid Cooling Connections

THIS SECTION DESCRIBES HOW TO REMOVE THE AFDB DRIVE FROM THE CABINET AND PROVIDES A LIST OF REPLACEMENT PARTS.

Follow the procedures below if you are removing a AFDB drive from a 6-pulse (Standard) rectifier cabinet or a AFDB drive from a 12-pulse rectifier (S12 Isolation Transformer) (Harmonic Attenuation) cabinet.

REMOVING THE DRIVE FROM A 6-PULSE RECTIFIER (STANDARD) CABINET

USE THE FOLLOWING PROCEDURE TO REMOVE A AFDB DRIVE FROM A 6-PULSE RECTIFIER CABINET:

⚠ WARNING

DC BUS CAPACITORS RETAIN HAZARDOUS VOLTAGES AFTER INPUT POWER HAS BEEN DISCONNECTED. AFTER DISCONNECTING INPUT POWER, WAIT TEN (10) MINUTES FOR THE DC CAPACITORS TO DISCHARGE AND THEN CHECK THE VOLTAGE WITH A VOLTMETER TO ENSURE THE DC BUS CAPACITORS ARE DISCHARGED BEFORE TOUCHING ANY INTERNAL COMPONENTS. Failure to observe this precaution could result in severe bodily injury or loss of life.

Step 1. Turn off and lock out AC input power to the cabinet.

Step 2. Place the circuit breaker in the Off position. Wait 10 minutes.

Step 3. Verify that there is no voltage at the drive's input power terminals.

Step 4. Check the DC bus potential with a voltmeter to ensure that the DC bus capacitors are discharged.

Step 5. Drain the drive's coolant and disconnect the coolant lines.

a. Use a ball valve at the inlet connection to drain the coolant while running the pump for 1 to 2 minutes.

b. Connect one end of a drain hose to the accumulator on the closed loop coolant system.
Connect the other end of the hose to a drain.

c. Connect a shop air line to the closed loop coolant system at the quick disconnect fitting.
Pressurize the line to 60-90 PSI for 1 to 2 minutes to flush all of the coolant out of the drive.

d. Remove the basket from the Y-strainer and check for any debris.

e. From inside the cabinet, disconnect the coolant lines from the panel using a 1-1/16" wrench on the swivel nut connected to the bulkhead fitting. A crow's foot wrench is recommended. Verify that no residual coolant remains in the drive.

Step 6. Disconnect the Flexibar conductors at the drive's U, V, and W output terminals.

a. Remove the two 3/8"-16-UNC-2B nuts from the clamp holding the Flexibar to the AC output busbar at output terminals U, V, and W.

b. Remove the load plate and the clamps.

c. Save this hardware for reassembly.

Step 7. Remove the rigid buswork that connects the load side of the circuit breaker to the drive.

a. Remove the 1/12"-13 bolts and washers from each of the drive's AC input input terminals (L1 through L6).

b. Remove the two 3/8"-16 bolts, washers and nuts from each of the six circuit breaker input busbar connections.

c. Save this hardware for reassembly.

Step 8. Disconnect the 12-position terminal connection located on the lower left side of the drive. Cut the wire tie on the wire mounting base leading to the panel.

Step 9. Disconnect the leads from each of the three current transformers (CTs). Wrap the CT leads around the AC output busbar to keep them from being damaged. Cut the wire ties on the wire mounting bases.

Step 10. Disconnect the AC busbar support from the AC input busbar.

a. Remove the six M5 hex screws that connect the AC input busbar (L1 through L6) to the busbar support.

b. Save this hardware for reassembly.

Step 11. Remove the removable plate and wire entry panels. See Figure 1.

a. Remove the four 1/4" screws and washers from the upper-right corner of the cabinet that hold the removable plate in place. Remove the removable plate, which will expose a 2" gap in the lip of the cabinet.

b. Remove the eight 1/4" screws that hold the wire entry panel to the top of the cabinet.

c. Save the panels and hardware for reassembly.

Step 12. Install two eyebolts into the drive to serve as lifting points.

a. Two 3/4" nuts are welded to the drive's baseplate. Screw the eyebolts (recommended: 2" eye I.D., 6" long shank) into the nuts.

b. Connect 18" (nominal) of chain between the eyes, securing them with a clevis clamp.

Step 13. Using an overhead or portable hoist (minimum 1/2 ton rated capacity), bring a free-fall chain into the cabinet through the access panel and the wire entry panel.

Step 14. Attach the free-fall chain to the chain secured to the eyebolts. Take up any vertical slack in the chain.

Step 15. Remove the four 1/2" bolts that secure the baseplate of the drive to the cabinet. Save this hardware for reassembly.

Step 16. Using the hoist, lift the drive slightly to take the load off of the cabinet's panel studs. Pull the drive off of the studs and up through the wire entry and access panels until it is clear of the cabinet enclosure. Note that drive's center of gravity is forward of the hoist, which will result in the top of the drive titling forward during removal.

Step 17. Move the drive to a horizontal pallet for servicing or shipment. The eyebolts and the chain between them do not need to be removed.

Step 18. Reinstall the drive by following steps 17 to 1 in reverse order.

a. During reinstallation, tighten the hardware to the torque values shown in Table 5.

b. Visually inspect the insulation of the wiring and bus work to ensure that it was not damaged.

c. Refill the drive with coolant.

Step 19. Test the drive for proper operation by following the startup procedures in instruction manual D2-3410.

Table 5 - Hardware Tightening Torque

Hardware	Maximum Recommended Tightening Torque
1/4" – 20 UNC Screws	75 In-Lb.
1/2" – 13 UNC - 2B Nut	45 Ft-Lb.
3/8" – 16 UNC – 2B Nut	19 Ft-Lb.
IO Terminal Block Screws	4.5 In-Lb.

REMOVING THE DRIVE FROM A 12-PULSE RECTIFIER ISOLATION TRANSFORMER (HARMONIC ATTENUATION) CABINET

USE THE FOLLOWING PROCEDURE TO REMOVE A AFDB DRIVE FROM A 12-PULSE RECTIFIER ISOLATION TRANSFORMER (HARMONIC ATTENUATION) CABINET:

⚠ WARNING

DC BUS CAPACITORS RETAIN HAZARDOUS VOLTAGES AFTER INPUT POWER HAS BEEN DISCONNECTED. AFTER DISCONNECTING INPUT POWER, WAIT TEN (10) MINUTES FOR THE DC CAPACITORS TO DISCHARGE AND THEN CHECK THE VOLTAGE WITH A VOLTMETER TO ENSURE THE DC BUS CAPACITORS ARE DISCHARGED BEFORE TOUCHING ANY INTERNAL COMPONENTS. Failure to observe this precaution could result in severe bodily injury or loss of life.

Step 1. Turn off and lock out AC input power to the cabinet.

Step 2. Place the circuit breaker in the Off position. Wait 10 minutes.

Step 3. Verify that there is no voltage at the drive's input power terminals.

Step 4. Check the DC bus potential with a voltmeter to ensure that the DC bus capacitors are discharged.

Step 5. Drain the drive's coolant and disconnect the coolant lines.

a. Use a ball valve at the inlet connection to drain the coolant while running the pump for 1 to 2 minutes.

b. Connect one end of the drain hose to the accumulator on the closed loop coolant system. Connect the other end of the hose to a drain.

c. Connect a shop air line to the closed loop coolant system at the quick disconnect fitting. Pressurize the line to 60-90 PSI for 1 to 2 minutes to flush all of the coolant out of the drive.

d. Remove the basket from the Y-strainer and check for any debris.

e. From inside the cabinet, disconnect the coolant lines from the panel using a 1-1/16" wrench on the swivel nut connected to the bulkhead fitting. A crow's-foot wrench is recommended. Verify that no residual coolant remains in the drive.

Step 6. Disconnect the Flexibar conductors at the drive's U, V, and W output.

a. Remove the two 3/8"-16-UNC-2B bolts and washers from the clamp holding the Flexibar to the AC output busbar at output terminals U, V, and W.

b. Remove the load plate and the clamps.

c. Save this hardware for reassembly.

Step 7. Disconnect the AC input wiring at the drive's AC input terminals (L1 through L6) and at the circuit breaker's line and load terminals.

a. Loosen all of the pressure lugs.

b. Bend the individual wires vertically within the cabinet.

Step 8. Disconnect the 12-position terminal connection located on the lower left side of the drive. Cut the wire tie on the wire mounting base leading to the panel.

Step 9. Disconnect the leads from each of the three current transformers (CTs). Wrap the CT leads around the AC output busbar to keep them from being damaged. Cut the wire ties on the wire mounting bases.

Step 10 Remove the removable plate. See Figure 3.

a. Remove the four 1/4" screws and washers from the upper-right corner of the cabinet that hold the removable plate in place. Remove the removable plate which will expose a 2" gap in the lip of the cabinet.

b. Save the panel and hardware for reassembly.

Step 11. Place the lifting support bar in the cabinet's stainless steel C-channel brackets. The support bar's pipe support should face you.

a. Screw two 3/4" screws through the pipe support into the 3/4" nuts, which are welded to the drive's baseplate.

b. Hand tighten the screws.

Step 12. Remove the four 1/2" nuts and washers that secure the drive's baseplate to the cabinet. Save the hardware for reassembly.

Step 13. Tighten the two 3/4" screws to remove the load on the baseplate. Slide the support bar along the C-channel brackets until it reaches the cabinet's front seal lip.

Step 14. Using an overhead or portable hoist (minimum 1/2 ton rated capacity), attach a free-fall chain to the 1.5" hole in the support bar. Take up any vertical slack in the chain.

Step 15. Vertically lift the support bar and the drive 3" to 4".

a. Rotate the support bar to the right side, towards you, and slip the support bar/drive assembly out of the cabinet.

Step 16. Move the drive to a horizontal pallet for servicing or shipment. The support bar and screws do not need to be removed.

Step 17. Reinstall the drive by following steps 16 to 1 in reverse order.

a. During reinstallation, tighten the hardware to the torque values (± 10) shown in Table 5.

b. Visually inspect the insulation of the wiring and bus work to ensure that it was not damaged.

c. Refill the drive with coolant.

Step 18. Test the drive for proper operation by following the start-up procedures in instruction manual D2-3410.

(9) UCP2-Parameter Information

Control and Logic Discussion

Variable speed impeller control is used to improve CenTraVac® efficiency at part load. This occurs because the chiller's inlet guide vanes (IGVs) open further than a constant speed machine to compensate for capacity reductions associated with impeller speed decreases. Increased IGV opening reduces the vane's aerodynamic losses, which increases chiller efficiency. This approach allows the chiller to run more efficiently as well as close to the operating condition known as surge. A surge occurs when the compressor can no longer support the differential pressure required between the evaporator and condenser. This transitory pressure breakdown between the high and low side results in an audible noise.

The UCP2 control of the vanes and impellers has two control priorities. The highest control priority is to maintain the chilled water set point. The second priority attempts to optimize unit efficiency by operating the compressor's impellers at the lowest speed possible while avoiding surge. If a surge is detected, an adaptable surge avoidance routine makes adjustments to move away from and to avoid surge at similar conditions in the future.

Install and Enable

Table 6 lists all the parameters that must be reviewed prior to start-up. These parameters are set from the factory, but may need to be changed based on module replacement or desire of customer to allow more aggressive optimization. Following the table is a more detailed description followed by several examples.

Table 6 - List of All UCP2 Parameters

Parameter Name	Default	Proper Setting
Starter Type	Y-Delta	AFDB
Condenser Pressure Sensor Option	Not Installed	Installed
AF Adjustable Speed Control Algorithm Enable	Enable	See Note 1
AF Leaving Water Standard Deviation	1.0	See Note 1
AF Pressure Coefficient Constant	800	See Note 2
AF Re-optimization Factor	0.30	See Note 1
AF Re-optimization Timer	24	See Note 1
AF Boundary Pressure Coefficient Y Intercept	0.40	See Note 1
AF Boundary Pressure Coefficient Y Intercept Maximum	2.00	See Note 1
AF Pressure Error Deadband	0.030	See Note 1
AF Proportional Speed Gain	50	See Note 1

Note: 1. Default is acceptable. Change only as necessary. Refer to examples.
2. This value must be calculated. Refer to next page.

(9) UCP2-Parameter Information

The following descriptions give detailed explanations for the parameters and their adjustment. This should only be changed by a qualified service technician. To get the AFDB control option to function it must first be installed. To install the AFDB control press the Service Settings key and then the Previous key to get to the Machine Configuration Group. **To enter the Machine Configuration Group** type the password keystroke combination of

+ - + - + - followed by the <Enter> key. In this group make sure to do the following:

- **Verify the starter type is set to AFDB.**
- **Verify the condenser pressure sensor option is installed.**

Changing the starter type to AFDB sets up the parameters required by the Trane AFDB and sets up all of the displays associated with the AFDB control option in the UCP2. Once these steps are complete exit out of the Machine Configuration Group, by pressing the Service Settings key again. The AFDB control algorithm is now installed. To make the AFDB control operational, it must be enabled. See CVHE-CLD-1 or latest revision for other chiller/starter parameters.

To enable the AFDB control algorithm enter the Field Start-up Group. This group is also found by pressing the Service Settings key. The password keystroke combination to enter the Field Start-up Group is followed by the <Enter> key. All the AFDB control in Field Start-up Group. The AFDB control algorithm set point values are shown below. These values are found toward the end of the menu listing so that pressing the previous key is the quickest way to get to them. Enter the following data and record in the start-up log.

1. AF Adaptive Speed Control Alg

To get the AF control algorithm to work it must be enabled. Press the + or — key to change the setting to enable and then press the <Enter> key.

2. AF Leaving Water Standard Deviation

This value indicates the standard deviation permitted in evaporator leaving water temperature from the chilled water setpoint to allow speed decreases. The smaller the value, the more stable the ELWT must be before allowing speed decreases to occur. The Standard Deviation is adjustable from 0.5 to 4.0 Deg F, in increments of 0.1. The default value is 1.0 Deg. F.

3. AF Pressure Coefficient Constant

This value is used to normalize the PC (Pressure Coefficient) calculation. The value takes into account specific compressor parameters such as the number of compressor stages and average impeller diameter. The value entered at the UCP2 is shown in the following:

PC constant = (1,316,000)/(# of stages # Avg Dia ^2)

Example: Number of stages = 3,
Avg Dia = 24 inches

(This is nameplate – CPIM/10)
PC constant = 761.6, and is entered as 762.

The PC (Pressure Coefficient constant is adjustable from 0 to 2000, in increments of 1. The default is 800.

4. AF Re-Optimization Factor

The re-optimization factor is a magnitude-based parameter for clearing the Surge flag. It is helpful to think of this value relative to the size of the pressure error deadband.

For example, since the default deadband is 0.03, a re-optimization factor of 0.3 would be 10 x the deadband. Encountering a pressure error greater than 10 x the deadband during operation would imply that operating conditions have changed enough to clear the surge flag. This permits the Boundary Pressure Coefficient (BPC) Y-intercept to be increased if conditions allow, creating a more efficient operating condition.

Setting the re-optimization factor large will cause this re-optimization feature to operate using the time-based parameter. This factor is adjustable from 0.03 to 1.0, in increments of 0.01. The default value is 0.3.

5. AF Re-Optimization Timer
The re-optimization timer is time-based parameter for cleaning the surge flag. The timer begins to decrement from the front panel set point as soon as surge occurs. The timer counts down as long as the UCP2 is powered. This value indicates how aggressively the chiller will try and re-optimize for efficiency.

For example, if the re-optimization timer is set to 1 hr, the surge flag will be cleared 1 hour after being set. This permits the Boundary Pressure Coefficient (BPC) Y-intercept to be increased if conditions allow creating a more efficient operating condition. The re-op timer is adjustable from 1 to 255 hours, in increments of 1. The default value is 24 hours.

UCP2 Parameter Information

6. AF Boundary PC Y-Intercept
The Boundary Pressure Coefficient (BPC) Y-intercept value is used to determine the location of the BPC. This front panel value is unique because it can be changed by the user as well as internally by the control algorithm. The BPC Y-Intercept is adjustable from 0.01 to 2.0 in increments of 0.01. The default value is 0.4.

7. AF Boundary PC Y-Intercept Maximum
The Boundary Pressure Coefficient (BPC) Y-intercept is never allowed to exceed a maximum value. This value is a manual way to control the aggressiveness of the efficiency optimizing procedure.

For example, as this value is lowered the probability of encountering a surge decreases but so does the potential efficiency improvement at a given operating condition. The Boundary Pressure adjustable from 0.01 to 2.0 in increments of 0.01. The default value is 2.0.

8. AF Pressure Error Deadband

Anytime the PC is inside the pressure deadband, no further speed reductions are allowed. Thus the pressure deadband establishes a region where no background speed decreases will occur. Setting this value large will tend to make the AFDB control less aggressive at optimizing efficiency. The pressure error deadband is adjustable from 0.001 to 1.000 in increments of 0.001. The default value is 0.030.

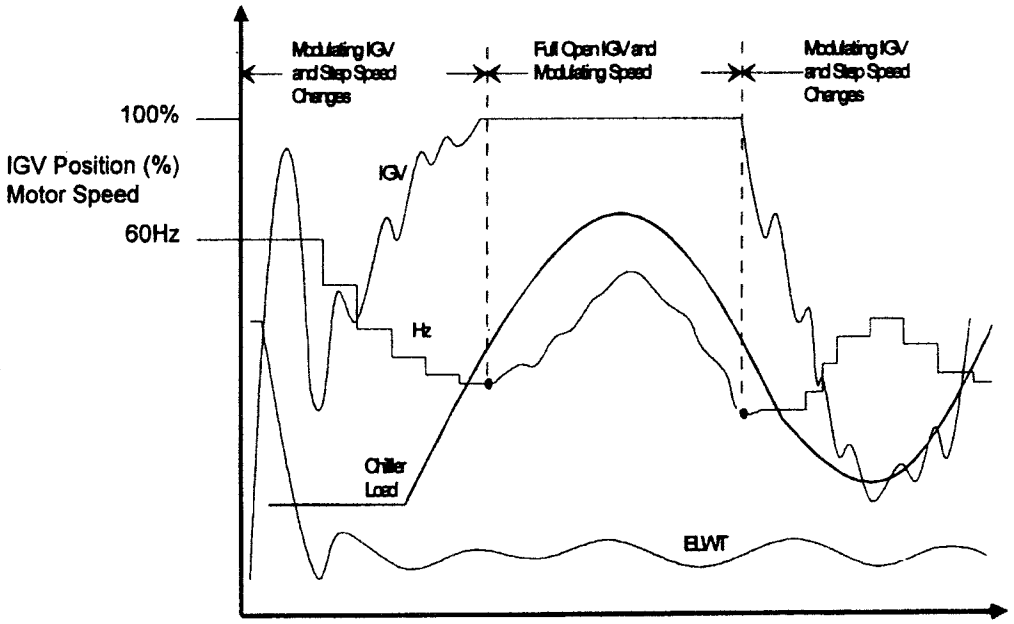
9. AF Proportional Speed Gain

The proportional speed gain is used to convert from pressure error to delta Hz. The proportional speed gain is adjustable from 1 to 100 in increments of 1. The default value is 50.

Table 7 shows parameter settings to achieve two different operating criteria. The first is to aggressively move the operating conditions towards the surge line to achieve operating efficiency. The second is intended to avoid frequent surging but maintain operating efficiency.

Table 7 - List of Parameter Settings and Operating Criteria

Parameter Name	Aggressive	Surge Minimization
Starter Type	AFDB	AFDB
Condenser Pressure Sensor Option	Installed	Installed
AF Adjustable Speed Control Alg Enable	Enable	Enable
AF Leaving Water Standard Deviation	1.0	1.0
AF Pressure Coefficient Constant	See Note	
AF Re-optimization Factor	0.25	0.30
AF Re-optimization Timer	12	48
AF BPC Y Intercept	0.40	0.40
AF BPC Y Intercept Maximum	2.00	1.50
AF Pressure Error Deadband	0.025	0.030
AF Proportional Speed Gain	50	50



Note: This value must be calculated.

Adaptive Frequency™ Drive Control

Two very distinct operating modes make up the AFDB control within UCP2. In one operating mode, unit capacity is modulated by controlling inlet guide vane position, while impeller speed may be changed based on a time interval. In the other operating mode, unit capacity is modulated by controlling impeller motor speed with the inlet guide vanes held full open.

A graphical illustration of the various AFDB operating modes is shown in Figure 15. The illustration shows typical operating profiles for the various parameters involved as the system load slowly increases and then decreases.

Figure 15 - Operating Modes as Chiller Load Varies Over Time

Typical Sequence of Operation

The AFDB/Chiller sequence of operation is very similar to standard chiller operation. Table 8 shows the steps in control logic that UCP2 follows in the operation sequence. This can be used with Figure 15 to gain overview of the control operation.

Table 8 - Steps in Control Logic in UCP2 Operation Sequence

Display	Event	Action Timing
Auto	Call for Cooling as required	
PreLube	Start Oil Pump	Bearing lubricated prior to start, 30 secs.
AFDB Cooling Pump	Start: **Note: The Water Pump turns on when the Oil Pump is started.**	
Starting	Accelerate to 60 Hz	
	Start Condenser Water Pump	
Unit is Running	Sample water temp., adjust IGV	Every 5 seconds
	Stable water temp., adjust speed, Adjust IGV as required	Every 5 minutes Every 5 seconds
	Achieve full open IGV-modulate speed only	Every 5 seconds
	Load drops below capacity at minimum speed and full open IGV	Loading done by speed increases on 5 second intervals. Unloading done by IGV on 5-second Intervals until 70% open.
	Load varies Stable water temp., adjust speed Adjust IGV as required	Every 5 minutes Every 5 seconds
Unit is Preparing to Shutdown	Load is satisfied	Close IGV's, then stop compressor
Postlube	Compressor Is stopped	Bearings lubricated on coast down, 2 minutes
AUTO	Oil Pump AFDB Cooling Pump are de-energized	
STOP	Condenser Water Pump is de-energized	
AUTO	Chilled water pump is de-energized	

Sequence of Operation Detail

The most efficient operating mode for a centrifugal chiller is controlling speed with the inlet guide vanes full open. Thus, after meeting the chilled water setpoint requirement, the secondary goal of the AFDB control is to drive the chiller toward this more efficient operating mode. To do this, the controller attempts to reduce impeller speed during operation, in a background control loop, executed every 5 minutes. A reduction in impeller speed causes a reduction in chiller capacity. Reduced chiller capacity means the chiller is not meeting load requirements, which increases the leaving water temperature error. To reduce this error, the inlet vanes open further as a natural response to the leaving water temperature control. The AFDB controller attempts to continue this process of background speed reduction until the IGVs reach full open. When the inlet vanes reach full open, operation transitions to capacity control by modulating impeller motor speed, and in this mode, the chiller is running as efficiently as possible. Depending on operating conditions, the chiller may or may not be able to enter into this mode.

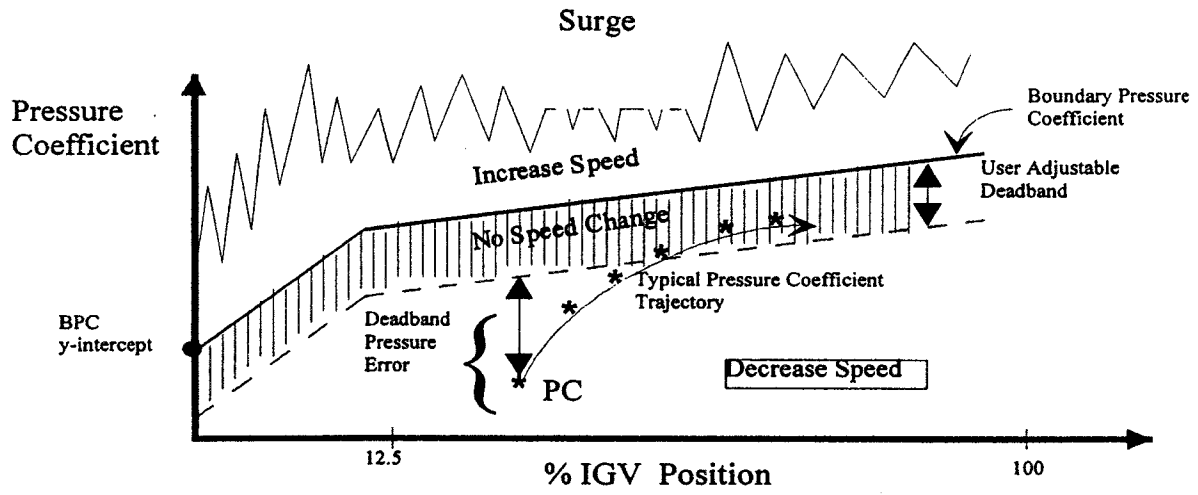
Operating Mode 1

At unit start up, the compressor's motor speed is normal line frequency of 60 Hz. The standard leaving water temperature control is executed every 5 seconds, and modulates inlet guide vane position as on a constant speed machine. Modulating inlet guide vane position varies unit capacity so the leaving water temperature can be maintained to within a deadband (as set by the AF Leaving Water Standard Deviation) about the desired chilled water set point.

Once the Evaporator Leaving Water Temp Set Point is met and in steady state (or pull down is complete). A slower background control loop is executed every 5 minutes, to try and improve efficiency by reducing impeller speed. At each 5-minute sample period, three conditions must be satisfied for a speed reduction to take place. These conditions are:

1. The Evaporator IGV Water Temperature must be in steady state.

2. There must be a negative deadband pressure error. (The compressor is not predicted to surge).



3. The unit must not be surging, and the surge timer must be zero.

The non-dimensional Pressure Coefficient (PC), illustrated in Figure 16, is derived from enthalpy change across the compressor, and compressor parameters such as average impeller diameter (in inches), speed, and AF Pressure Coefficient Constant.

If all three of the above criteria are satisfied, a background speed reduction can occur. The magnitude of a speed reduction is directly proportional to the deadband pressures error. (The maximum reduction is 2 Hz). Once a speed reduction takes place the inlet guide vanes open further in natural response to an increasing leaving water temperature error. In addition, the PC tends to move closer to the Boundary Pressure Coefficient (BPC) value.

Assuming constant operating conditions, Figure 16 illustrates a typical trajectory for the pressure coefficient during background speed reductions.

Figure 16 - Variables Involved in Desirable/Undesirable Compressor Operation

If the PC remains in the deadband no speed changes are allowed. If the PC rises above the BPC value a speed increase is performed in proportion to the error. This is done to force the PC back into the deadband away from surge. As long as the PC lies below the pressure deadband a speed reduction can occur.

Operating Mode 2

The most efficient operating mode for a centrifugal chiller is controlling speed with the inlet guide vanes full open. Thus, after meeting the chilled water setpoint requirement, the secondary goal of the AFDB control is to drive the chiller toward this more efficient operating mode.

In Operating Mode 1, the controller attempts to reduce impeller speed during operation, in a background control loop, executed every five minutes. A reduction in impeller speed causes a reduction in chiller capacity. Reduced chiller capacity means the chiller is not meeting load requirements, which increases the leaving water temperature error. To reduce this error, the inlet guide vanes open further as a natural response to the leaving water temperature control.

The AFDB controller attempts to continue this process of background speed reduction until the IGV's reach full open. When the inlet guide vanes reach full open (Operating Mode 2), operation transitions to capacity control by modulating impeller motor speed. In this mode, the chiller is running as efficiently as possible. Depending on operating conditions, the chiller may or may not be able to enter into this mode.

This control mode uses the same leaving water temperature control algorithm as in Operating Mode 1, but with an appropriate scaling factor to convert from IGV motor steps to Hertz. When a transition occurs, the commanded impeller speed at that time is remembered by the control algorithm.

This value, referred to as the "transition in value" (or HzTrans), sets the bottom end of the modulating range. Any of three conditions below will cause a transition out of this operating mode:

1. Modulating lower than 0.6 hertz below Hztrans.

2. Encountering a forced unload limit condition.

3. Detecting a surge.

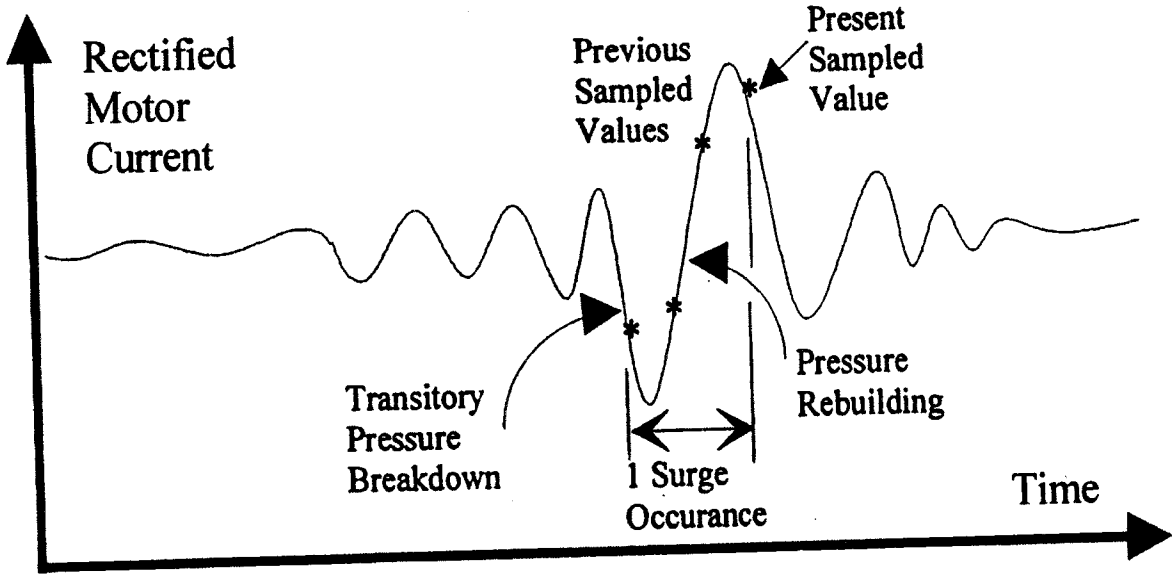
In the *inverter-modulating mode,* commanding impeller speed below Hztrans – 0.6 will cause a transition to Operating Mode 1. This is because the probability of encountering surge increase as impeller speed falls below the Hztrans value. To guarantee that the vanes handle additional unloading, a flag is set. Setting this flag causes any further unloading to go to the inlet guide vanes and any loading to the impeller speed. The flag is not cleared until the inlet guide vanes go below 70% of full open. Once cleared, the control algorithm can begin to do background speed decreases again.

The detection of a *forced unload limit condition* will cause a transition to Operating Mode 1. The inload request is exercised by the inlet guide vane actuator, while motor speed is held constant. Motor speed is not increased to avoid worsening the limit. Conversely, motor speed is not decreased to avoid surge.

The *detection of a surge* will cause a transition to Operating Mode 1.

Surge Detection

Surge detection control logic monitors changes in compressor motor current. A surge occurrence leaves a characteristic motor current signature as shown below in Figure 17. This signature is formed because the transitory pressure breakdown between the condenser and evaporator causes a sudden reduction in compressor motor load. As the pressures equalize, the compressor begins to quickly load, increasing motor current.



Rectified and filtered motor current is sampled every 0.2 seconds. A 30% change is required between the present sampled value and the previous three values to be considered a surge occurrence. Two surge occurrences are required within one minute to denote a unit in surge. This logic is intended to catch all audible surge occurrences. If a surge is detected, control logic will simultaneously increase motor speed by 2.0 hertz terminating the existing surge condition. Motor speed is increased to terminate the present surge condition. Additionally, the logic will "remember" the surge condition and will avoid future occurrences by not allowing operation, and preventing further speed reductions, at these conditions.

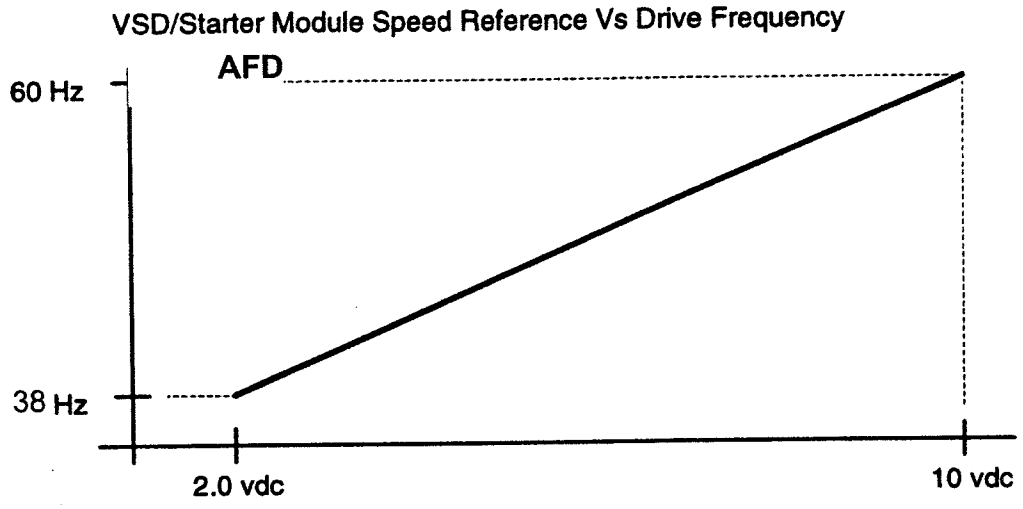
UCP2 Interface to Adaptive Frequency Drive

The UCP2 provides a "Start" contact closure output to command the Adaptive Frequency Drive to begin its start sequence. A 2-10 VDC analog speed signal output is provided by the UCP2 to provide a speed reference to the AFDB. The UCP2 also provides both "Fault" and "Up-to-Speed" (transition complete) contact closure inputs for variable frequency drive starters.

At start of the compressor motor a signal corresponding to normal line frequency (Full Speed) is applied to the speed signal input of the drive.

Figure 17 - Motor Current Signature Representing Surge

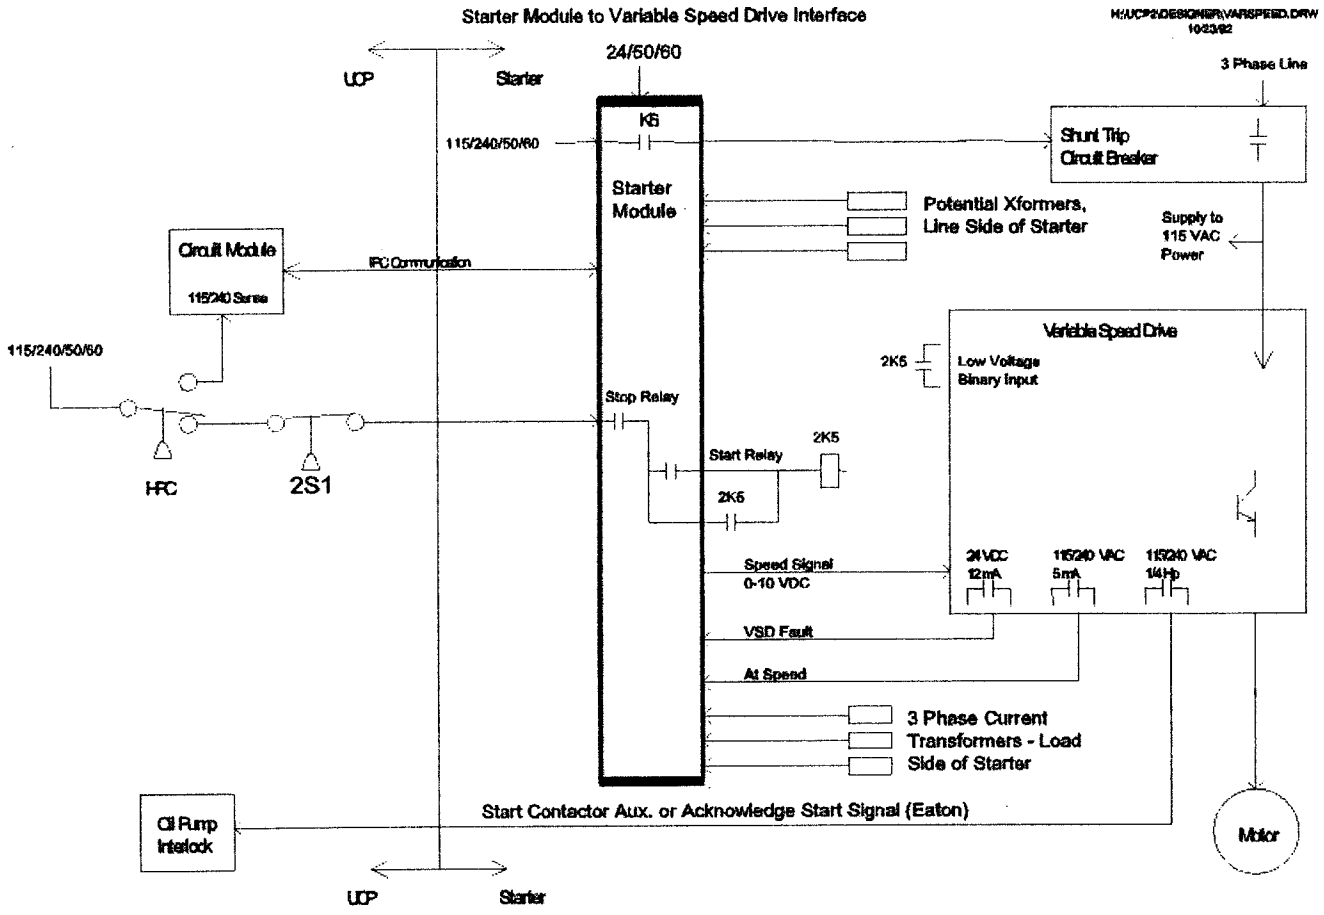
A contact opening at the "Fault" input to the Starter Module shall cause removal of the "Start"



A contact opening at the "Fault" input to the Starter Module shall cause removal of the "Start" signal and the generation of a MANUAL RESET (NMR) diagnostic. The Starter module waits a minimum of 15 seconds for the currents to go away on a shutdown before a contactor failure diagnostic is called.

As illustrated in Figure 18, the speed reference signal shall be set-up such that 2-10 vdc corresponds to 38-60 Hz, respectively.

Note: Unlike electromechanical starters, the phase currents cannot be expected to rise above 85 percent RLA prior to 1.6 seconds following the closing of the "Start" contact and remain above 85 percent RLA until the compressor motor has come up to speed. The "Up-to-Speed" contact operation cannot be tied to the motor currents falling below 85% RLA.



Therefore, regardless of motor current the "Up-to-Speed" contact closure input will be expected to close before the Maximum Acceleration Timer times out, otherwise a MANUAL RESET (MMR) diagnostic shall occur.

Figure 18 - Drive Frequency vs. Speed Reference Signal

The block diagram, Figure 19, shows the communication of the starter module to Unit Mounted Inverter Interface.

Figure 19 - Starter Module to Unit Mounted Inverter Interface Block Diagram

The Oil Pump Interlock load is 115VAC, 1/4 HP.

Figure 20 - 1000 HP Only (Cooling Water Pressure Control (2S1)

1. Loss of Voltage between 2TB1-4 and 2TB1-5 as shown on 2303-5223 schematic for the Unit-Mounted AFDB.

   a. If voltage is present at 1U2 J26-2 (Wire 277B) the UCP2 will latch out and indicate a "High Condenser Pressure".

   b. If no voltage is present at 1U2 J26-2 the UCP2 will latch out and assume a "Phase Loss". (Momentary Power Loss is disabled on a VFD).

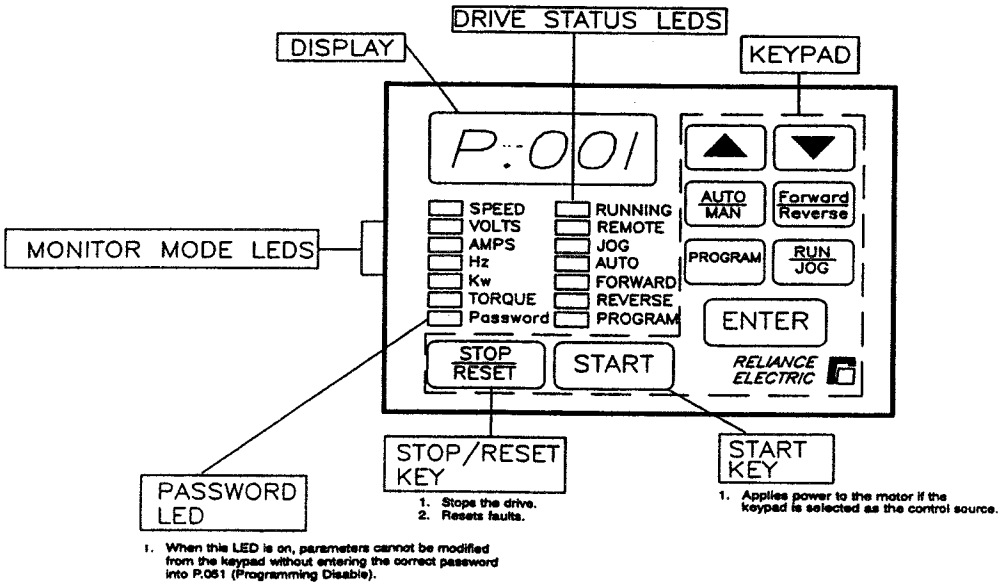
   c. Unit will not restart until Water Pressure Switch (231) is manually reset.

(11) Keypad Introduction

THIS SECTION DESCRIBES USING THE KEYPAD/DISPLAY TO PROGRAM, MONITOR AND CONTROL THE DRIVE.

The AFDB keypad unit controls and primary operator interface. All keypad setup functions come factory set and do not require field setup. Reference Figure 20 showing the keypad.

The Front panel keypad/display is used to program, monitor and control the drive. It operates in two (2) modes: the monitor mode and program mode. The functions available at the keypad depend on what mode the keypad/display is and what has been selected as the drive control source.



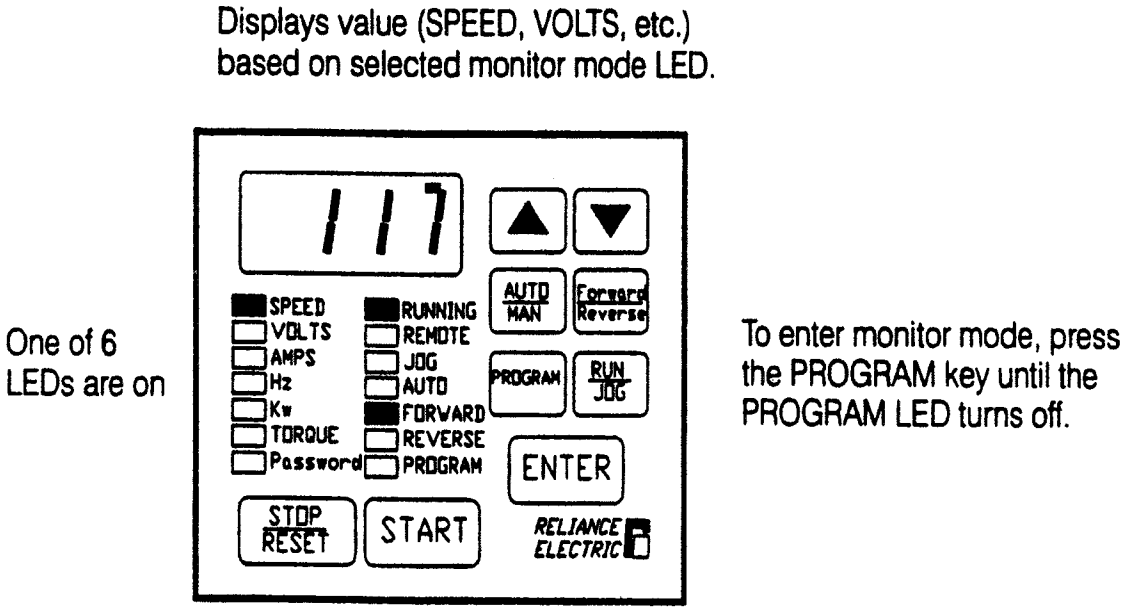
In the MONITOR mode, (the default mode), you can monitor specific drive outputs as well as enter the speed or frequency reference for the drive. The drive speed and hertz can be observed as well in the UCP2 compressor report.

In the PROGRAM mode, you can view and adjust the drive parameter values, and examine the error log.

THE UCP2 PANEL SHOULD BE USED TO START AND STOP THE DRIVE, NOT THE AFDB KEYPAD.

Using the Key Pad/Display to program, monitor and control the drive. The following sections describe monitor and program mode in more detail. The keypad, display, and LEDs are described later in this chapter.

Figure 20 - Key Pad/Display



Monitor Mode

Monitor mode, see Figure 21, is the keypad/displays default mode during drive operation or it is entered by pressing the PROGRAM key until the PROGRAM LED turns off. The following output data can be displayed in monitor mode:

- Speed
- Volts
- Amps
- Hz
- KW (output)
- Torque (vector regulation only)
- Selected reference (speed or torque)

To select a value to monitor, press the ENTER key until the LED turns on next to the desired display item. Pressing the ENTER key will advance you through each of the displays. (Note that all of the LEDs will turn on to indicate the selected reference display).

Figure 21 - Example of a Monitor Mode Display

Displaying the Selected Reference

In monitor mode, you can display the speed reference (speed or frequency) or the torque reference the drive is using while it is running (RUNNING LED is on, JOG LED is off). Follow these steps to display the selected reference:

Step 1. If you are not already in monitor mode, access it by pressing the PROGRAM key until the PROGRAM LED turns off.

Step 2. Press the ENTER key repeatedly to advance through each of the monitor mode LEDs. All of the monitor mode LEDs will then turn on at once and the reference will be displayed. Note that the displayed speed reference value is scaled based on parameter P.028. The torque reference value is displayed in percent.

If the selected reference is negative and its value is greater than 999, the SPEED LED will flash.

Pressing the ENTER key again will advance you to the SPEED monitor display.

Entering the Manual Speed Reference

You can change the manual speed reference at any time while in monitor mode regardless of the control source. Follow these steps to enter the manual speed reference:

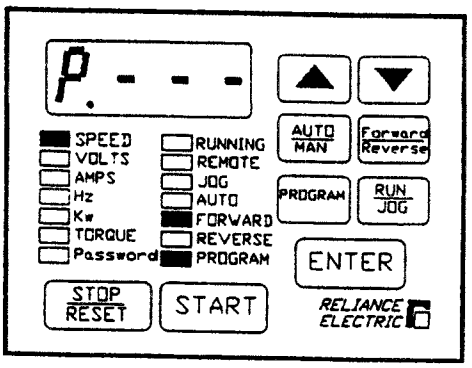
Step 1. From monitor mode, press the UP ARROW key or the DOWN ARROW key once. The monitor modes LEDs will all turn off, and the current manual speed reference value will be displayed.

Step 2. Press the UP ARROW key or the DOWN ARROW key to change the displayed value of the desired manual speed reference. Note that the speed reference is in the units defined in parameter P.028

Step 3. Press the ENTER key or wait approximately 5 seconds without pressing the UP ARROW or DOWN ARROW keys to return to monitor mode. (If the drive is not running, you must press the ENTER key to return to monitor mode).

Program Mode

Program mode, see Figure 22, allows you to display and modify drive parameter values. To enter program mode, press the PROGRAM key until the PROGRAM LED turns on. The following can be displayed in program mode:



- Parameter numbers
- Parameter values
- Error log information

If the Programming Disable parameter (P.051) has been set to prevent parameter modification from the keypad, the PASSWORD LED will also be on before any parameter values can be modified, you will have to access parameter P.051 and enter the password (a factory-set value) to re-enable programming. When programming has been enabled, the PASSWORD LED will turn off.

Note that CONFIGURABLE parameters can be changed only when the drive is stopped. See Section "Parameter Types" in this manual.

Figure 22 - Example of a Program Mode Display

Display shows
menu selections:
P.---
H.--- (if P.048 = U-H)
U.--- (if P.048 = UEC)
r.--- (if the optional RMI
board is installed)
or
Err (Error Log)

PROGRAM
LED IS ON

The Display

The display portion of the keypad/display is a four-character, sever-segment LED. At drive power-up, SELF is displayed as the drive performs power-up diagnostics. During drive operation, the display indicates parameter numbers; parameter values, fault or alarm codes, and drive output values. Figures 21 and 22 show sample displays.

Display Range

Normally, a minus (-) sign is used as one of the four characters in the display to indicate a negative value. If a value (including the minus sign) exceeds four characters, the display will drop the minus sign and display four digits. In this case, the SPEED LED will flash to indicate that the displayed value is a negative number. Refer to the examples below in Table 9.

Note that a decimal point to the right of the last digit in the display indicates there is further resolution (example D) unless a decimal point already appears as part of the number displayed (example F). In either case, the system uses the full resolution of the number for drive control, not the displayed value.

Table 9 – Display Examples

Example	If the actual number is...	It will appear on the display as...	And the SPEED LED will...
A	-999	-999	Not flash
B	-1000	1000	Flash
C	-99.9	-99.9	Not flash
D	-1000.5	1000.	Flash
E	-9.99	-9.99	Not flash
F	-100.25	100.2	Flash
G	-9.999	9.999	Flash

This does not apply for the speed display. For the speed display, the FORWARD or REVERSE LEDs indicate actual speed reference polarity.

(11) Keypad Introduction

The Keypad

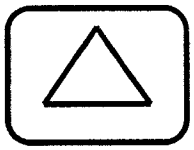
The drive's keyboard has nine (9) membrane keys that are used to monitor, program, and control the drive.

The AUTO/MAN key is used to switch between the auto speed reference and the manual speed reference as shown in Table 10 below: This is set in P.052 to "ON" (which disables the AUTO/MAN key).

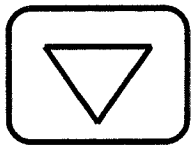
Table 10 – Auto/Man Key Reference

AUTO/MAN Status	Control Source (P.000)	Speed Reference Source
AUTO selected	Local keypad/display (P.000 = LOCL)	Terminal strip
	Terminal strip remote Inputs (P.000 = rE)	Terminal strip
	Option port (P.000 = OP)	Network
	Serial port (P.000= SerL)	Terminal strip
MAN selected	Local keypad/display (P.000= LOCL)	Local keypad/display or OIM
	Terminal strip remote Inputs (P.000=rE)	Local keypad/display or OIM
	Option port (P.000=OP)	Local keypad/display or OIM
	Serial port (P.000=SerL)	Local keypad/display or OIM

If the control source is changed, the AUTO/MAN selection may be changed as well. When the control source is changed to OP or rE, the AUTO/MAN selection will be forced to AUTO. If the control source is changed to LOCL or Serl, the AUTO/MAN selection will be forced to MANUAL. However, if the control source is changed from LOCL to SerL or vice versa, the AUTO/MAN selection will not be changed.



Refer to the P.000 parameter description for more information on control source selection.



Note: *This key is not active if the control source is SerL.*

Refer also to the P.053 (Manual Reference Preset Enable) parameter description.

⚠ WARNING
WHEN SWITCHING FROM AUTO TO MANUAL, OR MANUAL TO AUTO, THE DRIVE WILL RAMP TO THE REFERENCE LEVEL PROVIDED BY THE NEW SOURCE AT THE RATE SPECIFIED IN P.0001 (ACCEL TIME 1), P.002 (DECEL TIME 1), P.17 (ACCEL TIME 2), OR P.018 (DECEL TIME 2). BE AWARE THAT AN ABRUPT SPEED CHANGE MAY OCCUR DEPENDING UPON THE NEW REFERENCE LEVEL AND THE RATE SPECIFIED IN THESE PARAMETERS. Failure to observe this precaution could result in bodily injury.

(11) Keypad Introduction

The UP and DOWN arrow keys are used to:
Step through the drive parameter menus and error log when the keypad/display is in program mode.
Increase (or decrease) a numeric value (such as the reference or a parameter value).

The ENTER key is used to:
Display a parameter (or a selection) value in program mode.
Save a value
Move through each monitor display item when in monitor mode.

The PROGRAM key is used to move between program and monitor modes. The PROGRAM LED will turn on when the keypad/display is in program mode and turn off when the keypad/display is in monitor mode.

Not active on the AFDB. P.000 is set to REMOTE which deactivates this function.

Not active on the AFDB. P.000 is set to REMOTE, which deactivates this function.

(11) Keypad Introduction

Not active on the AFDB. P.000 is set to REMOTE, that deactivates this function.

If the drive is running (RUNNING LED is on), the STOP/RESET key will stop the drive. If the drive is not running (RUNNING LED is off), pressing this key will reset drive faults.

(12) Drive Status LEDs

The keypad contains eight LEDs that show the present drive status. The list below describes what each drive status means.

RUNNING	On	Output power is being applied to the motor.
	Off	Output power is not being applied to the motor.
REMOTE	On	The drive is being controlled from a source other than the keypad.
	Off	The drive is being controlled from the keypad.
	Flashing	The network connection is lost.
AUTO	On	The drive is receiving its speed reference from the terminal strip input or network option.
	Off	The drive is receiving its speed reference from the local keypad or serial port (OIM or CS3000), i.e., uses a manual reference.

NOTE: *If the speed reference is zero (0), pressing the FORWARD/REVERSE key (or toggling the FWD/REV input) will not alter the state of the FORWARD or REVERSE LEDs.*

PROGRAM	On	The keypad/display is in program mode.
	Off	The keypad/display is in monitor mode.
PASSWORD	On	Parameters cannot be modified from the keypad without entering the correct password into P.051 (Programming Disable). Note that disabling program changes by means of P.051 will not prevent parameter changes being made from the serial port or the network.
	Off	Parameters can be modified from the keypad.

Table 11 describes the values that will be displayed when the corresponding monitor mode LED is on.

Table 11- Monitor Mode LEDs

Monitor Mode LED	Corresponding Display When LED is On (Actual Values)
SPEED	Motor speed is displayed. This value is scaled in parameter P.028.
VOLTS	Drive output volts are displayed. This value is **not** DC bus volts.
AMPS	Drive output amps are displayed.
HZ	Drive output frequency in hertz is displayed.
KW	Output power of the drive in kilowatts is displayed. Note that this is intended for display purposes as a general indication of kilowatt output and should not be used for control or exact metering purposes.
TORQUE	Motor output torque is displayed in percent. (Valid only for vector regulation).
ALL LED's	Selected speed reference (in P.028 units) or torque reference (in %) is displayed.

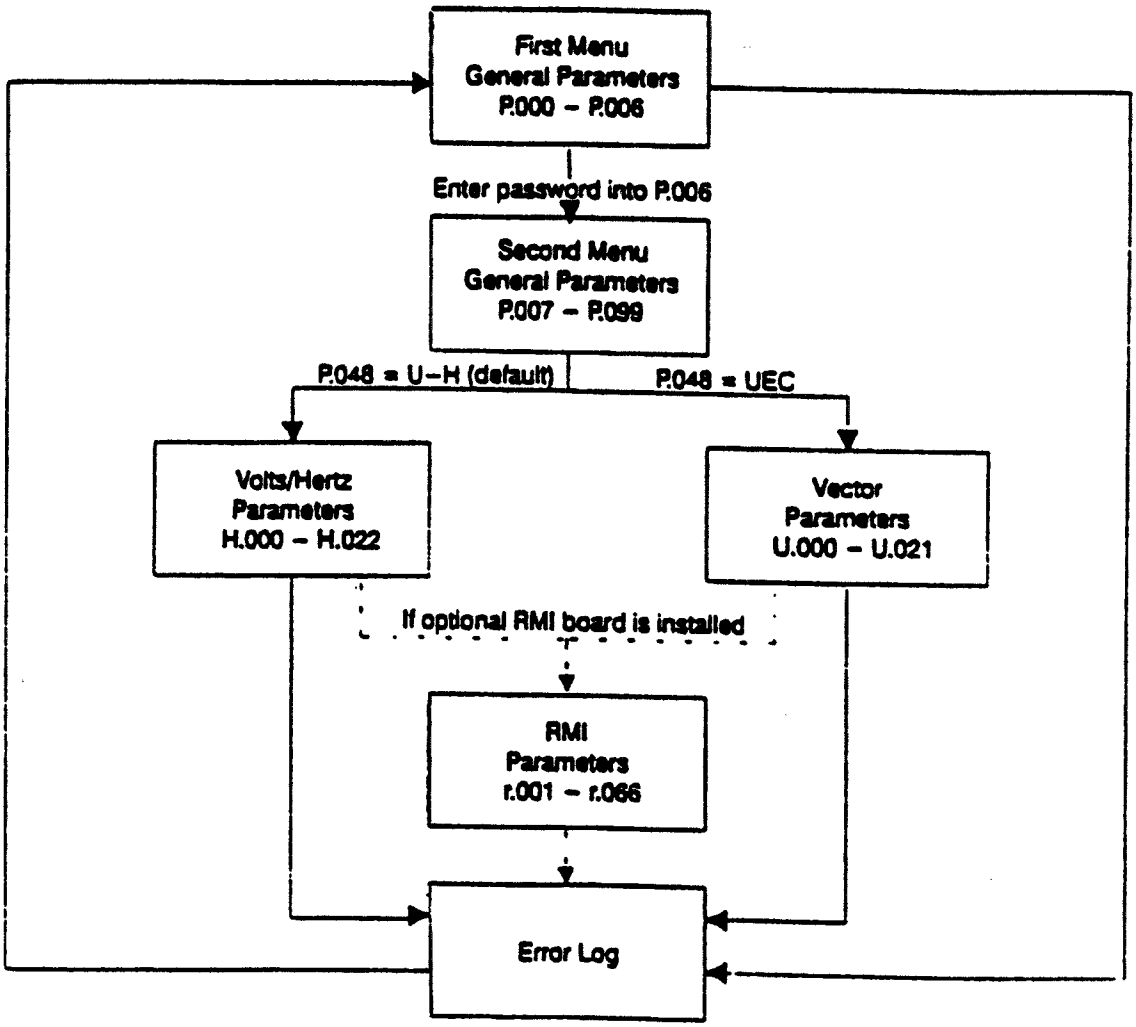
Programming Reference

To program the drive for a specific application, you display the approaching parameter and adjust it an overview of the parameter menus as well as detailed descriptions of each parameter. This chapter also describes how to access, display, and modify parameters.

Parameter Menus

To simplify the configuration process, the drive software parameter list is divided into two menus: the FIRST menu and the SECOND menu. These are shown in Figure 23 and described below.

The FIRST menu contains General parameters (P.000 through P.006) which are commonly used for simple applications.



The SECOND Menu contains parameters that allow drive adjustment for more complex applications. These functions can be safety related and should be used only with a thorough understanding of how they may affect motor operation.

Within the SECOND Menu are:

- General parameters (P.007 through P.099). These parameters apply to both vector and V/Hz applications.
- Volts/Hertz parameters (H.000 through H.022). These parameters are used only for V/Hz applications and are displayed if U-H is selected in parameter P.048 (Volts/Hertz or Vector Regulation).
- Vector parameters (U.000 through U.021). These parameters are used only for vector applications and are displayed if UEC is selected in parameter P.048.
- RMI parameters (r.001 through r.066). These parameters are displayed only if an optional Remote Meter Interface board (M/N 2SI3000) is installed in the drive.
- The error log. The error log is shown as Err on the display.

Access to the SECOND menu parameters is enabled/disabled using the Second Menu Password parameter (P.006).

Figure 23 - Parameter Menu Structure

(13) Parameter Types

⚠ WARNING
ONLY QUALIFIED ELECTRICAL PERSONNEL FAMILIAR WITH THE CONSTRUCTION AND OPERATION OF THIS EQUIPMENT AND THE HAZARDS INVOLVED SHOULD START AND ADJUST IT. READ AND UNDERSTAND THIS MANUAL IN ITS ENTIRETY BEFORE PROCEEDING. Failure to observe this precaution could result in severe bodily injury or loss of life.

THERE ARE THREE TYPES OF PARAMETERS:

CONFIGURABLE: These parameters can be adjusted or changed only while THE DRIVE IS STOPPED.

TUNABLE: These parameters can be adjusted or changed while the drive is RUNNING OR STOPPED.

READ ONLY: These parameters CANNOT BE ADJUSTED.

EACH PARAMETER IS DESCRIBED IN DETAIL IN THIS CHAPTER. THE FOLLOWING INFORMATION IS PROVIDED FOR EACH PARAMETER:

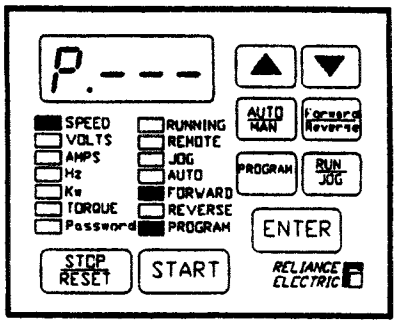
Parameter Number: The unique number assigned to a specific parameter. The number is preceded by P, H, U, or r to identify it as a General, Volts/Hertz, Vector, or optional RMI parameter, respectively. The parameter number is displayed on the drive's keypad/display.

Parameter Name: The name assigned to a parameter number. The parameter name is not displayed when programming the drive using the keypad/display. The parameter name is only visible when using the CS3000 software or Operator Interface Module (OIM).

Parameter Description: A description of the parameter's function.

Parameter Range: The pre-defined parameter value limits or selections.

Default Setting: The factory default setting.



Parameter Type: Identifies whether the parameter is tunable, configurable, or read only.

Refer also to parameters: A list of associated parameters that may provide additional or related information.

Figure 24, on the following page, provides steps on how to display or change parameter values.

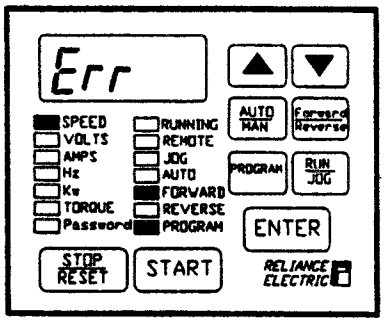


Figure 24 - Procedure to Display or Change Parameter Values:

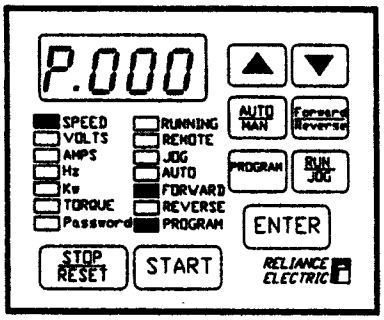
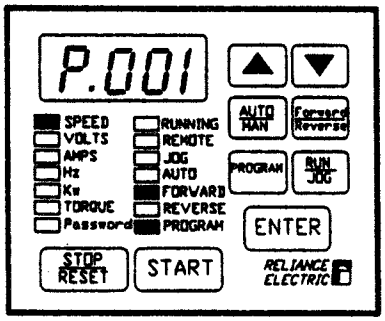
Step 1. Press the PROGRAM key until the PROGRAM LED turns on to enter program mode.



One of the main parameter menus (P.---, H.---, U.---, Err, etc.) will be displayed.

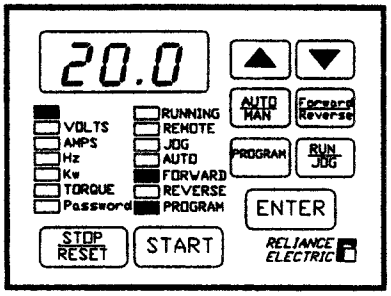
Step 2. Use the ↑ key or the ↓ key to move through the menus.



Note that if P.--- and Err are the only two menu selections displayed, access to the Second Menu parameters has been restricted. A password must be entered into parameter P.006 in order to access the Second Menu parameters.

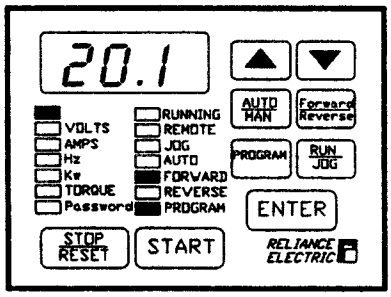
Step 3. Once the desired menu is displayed, press the ENTER key to select it.

The first parameter number in the menu or the last parameter number previously accessed from that menu will be displayed.



Step 4. Press the ↑ key or the ↓ key to move through the parameters.

Each parameter number will be displayed as you move through the parameters.

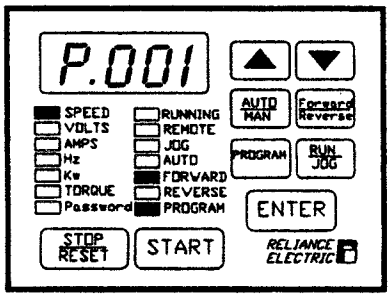


Continued examples of Parameter Values

Step 5. Once the desired parameter is displayed, press the ENTER key to access it.

The parameter value will be displayed.

Step 6. Press the ↑ key or the ↓ key to change the value.



Note that if programming is disabled in parameter P.051 (Programming Disable), or if the parameter is configurable and the drive is running, the value will not change.

Step 7. Press the ENTER key to save the changed value.

- OR -

Press the PROGRAM key to exit the parameter without changing the value.

The parameter number will be displayed again.

NOTE: *The value will not be written into memory unless the ENTER key is pressed.*

To display or change additional parameters within this menu, repeat steps 4 through 7.

To display or change parameters in a different menu, press the PROGRAM key to return to the main menu selections. Then repeat steps 2 through 7.

To exit program mode, press the PROGRAM key until the PROGRAM LED turns off.

NOTE: *Parameter values and the local keypad status are retained through a line dip or power shutdown.*

Protecting Parameter Values

Parameter values can be password-protected using parameter P.051 (Programming Disable). When programming is disabled, parameter values can be displayed but cannot be modified from the keypad unless the correct password is entered in P.051. Note that disabling program changes by means of P.051 will not prevent parameter changes being made from the serial port on the network.

⚠ WARNING
IT IS THE USER'S RESPONSIBILITY TO DETERMINE HOW TO DISTRIBUTE THE PASSWORD. THE TRANE COMPANY IS NOT RESPONSIBLE FOR UNAUTHORIZED ACCESS VIOLATIONS WITHIN THE USER'S ORGANIZATION. Failure to observe this precaution could result in bodily injury.

Use the following procedure to disable/enable parameter programming.

Step 1. Select parameter P.051 from the Second Menu General parameters. P.051 will appear on the display.

Step 2. Press the ENTER key to access the parameter. A zero will be displayed.

Step 3. Use the ↑ key to increment the value to 26. This is the password number.

Step 4. Press the ENTER key to save the value. P.051 will be displayed.

Parameter programming is disabled when the PASSWORD LED is on and enabled when the PASSWORD LED is off.

To prevent unauthorized password use, a zero value (not the saved password value) is displayed whenever this parameter is accessed.

Note: *Parameter values and the local keypad status are retained through a line dip or power shutdown.*

First Menu Parameters

The First Menu contains General parameters that are most commonly used for simple applications. No password is required to access them. These parameters apply only to both vector and V/Hz programming.

First Menu General Parameter Descriptions (P.000 to P.006)

P.000 Control Source

This parameter selects the drive control source. The drive will respond to the reference start commands (inputs) only from the source selected in this parameter.

Parameter Range: LOCL = Local keypad/display
rE = Terminal strip remote inputs
OP = Option port

SErL = Serial port (CS3000 or OIM)*

Default Setting: LOCL

Parameter Type Configurable

Refer also to parameters: P.007 Terminal Strip Digital Inputs Configure
P.008 Terminal Strip Speed Reference Source
P.063 Option Port: Network Reference Source

⚠ WARNING
IN V/HZ REGULATION, IF P.000 (CONTROL SOURCE) IS SET TO OP (OPTION PORT), AND P.062 IS SET TO 1 (HOLD LAST REFERENCE), AND THE DRIVE LOSES COMMUNICATION WITH THE NETWORK, THE DRIVE WILL MAINTAIN THE LAST FREQUENCY COMMAND SENT TO IT. ENSURE THAT DRIVEN MACHINERY, ALL DRIVE-TRAIN MECHANISMS, AND APPLICATION MATERIAL ARE CAPABLE OF SAFE OPERATION AT THE MAXIMUM OPERATING SPEED OF THE DRIVE. Failure to observe this precaution could result in bodily injury.

The selected drive control source is determined primarily by the value in P.000. However, if P.000 = rE, then the REM/LOC input may toggle the control source between the local keypad and the terminal strip. See P.007 (Terminal Strip Digital Inputs Configure).

Depending on the control source selected, the AUTO/MAN key can be used to switch between speed reference sources as shown below in Table 12:

Table 12 - Control Source Displays/Speed Reference Source Displays

Control Source (P.000)	AUTO/MAN Status	Speed Reference Source
Local Keypad/display (P.000=LOCL)	AUTO selected	Terminal strip
	MAN selected	Local keypad/display or OIM
Terminal strip remote inputs (P.000 = rE)	AUTO selected	Terminal strip
	MAN selected	Local keypad/display or OIM
Option port (P.000=OP)	AUTO selected	Network
	MAN selected	Local keypad/display or OIM
Serial port (P.000-SErL)	AUTO selected	Terminal strip
	MAN selected	Local keypad display or OIM

Set P.000 = OP to select the DeviceNet™ Network option board or the AUTOMAX® Network option board as the drive control source.

Note: *The REMOTE LED will turn on if any control source other than the local keypad is selected.*

*For more information about the Control and Configuration Software (CS3000), refer to instruction manual D2-3348. For more information about the GV3000 OIM (Operator Interface Module, M/N 2RK3000), refer to instruction manual D2-3342.

P.001 Accel Time 1 (RAMP 1)

For V/Hz regulation, this parameter specifics the time in which the motor goes from zero speed to Maximum Speed (P.004).

For vector regulation, this parameter specifics the time in which the motor goes from zero speed to Motor Top Speed (U.017).

Parameter Range: 1.0 to 999.9 seconds (V/Hz)
0.1 to 999.9 seconds (vector)

Default Setting: 8.0

Parameter Type: Tunable

Refer also to parameters: P.004 Maximum Speed
P.005 Current Limit
U.017 Motor Top Speed

The time the motor takes to make any speed increase is directly proportional to the value in this parameter.

If the motor load inertia is high, or the Current Limit (P.005) setting is too low, actual motor acceleration time will be longer than the time set in P.001. If Accel Time 1 is set too short, an overcurrent fault may occur.

P.002 Decel Time 1 (RAMP 1)

For V/Hz regulation, this parameter specifies the time in which motor speed decreases from Maximum Speed (P.004) to zero speed.

For vector regulation, this parameter specifies the time in which motor speed decreases from Motor Top Speed (U.017) to zero speed.

Parameter Range: 1.0 to 999.9 seconds (V/Hz)
0.1 to 999.9 seconds (vector)

Default Setting: 18.0

Parameter Type: Tunable

Refer also to parameters: P.004 Maximum Speed
P.025 Stop Type
U.017 Motor Top Speed

The time the motor takes to make any speed decrease (except a coast-to-rest stop) is directly proportional to the value in this parameter.

Note: *Motor load inertia and input line conditions can extend the deceleration time to a value greater than the preset time. With very fast deceleration times, regenerative motor voltage may charge up the DC bus voltage, causing a high bus voltage (HU) fault. To avoid a fault condition, extend the deceleration time for a period. If a deceleration time faster than the acceptable range is required, installing an optional Snubber Resistor Kit or Regenerative Braking Module Kit may prevent the fault.*

For V/Hz regulation with dynamic braking (Snubber Resistor) disabled (H.017=OFF), the deceleration time may be extended to prevent a high bus voltage (HU) fault from occurring.

P.003 Minimum Speed

This parameter limits the speed reference to the drive. Regardless of what speed reference is supplied, the regulator will not command a speed less than the value in P.003.

Parameter Range: 0.5 to P.004 Maximum Speed (V/Hz)
0 to P.004 Maximum Speed (vector)

Default Setting: 38 Hz (V/Hz)
2280 RPM (vector)

Parameter Type: Tunable

Refer also to parameters: P.004 Maximum Speed

⚠ WARNING
THE DRIVE CAN OPERATE AT AND MAINTAIN ZERO SPEED. THE USER IS RESPONSIBLE FOR ENSURING SAFE CONDITIONS FOR OPERATING PERSONNEL BY PROVIDING SUITABLE GUARDS, AUDIBLE OR VISUAL ALARMS, OR OTHER DEVICES TO INDICATE THAT THE DRIVE IS OPERATING OR MAY OPERATE AT OR NEAR ZERO SPEED. FAILURE TO OBSERVE THIS PRECAUTION COULD RESULT IN SEVERE BODILY INJURY OR LOSS OF LIFE.

Note: *In V/Hz regulation, the drive may decrease the output frequency below P.003 (but not below 0.5 Hz) to avoid an overcurrent fault.*

P.004 Maximum Speed

This parameter limits the speed reference to the drive. Regardless of what speed reference is supplied, the regulator will not command a speed greater than the value in P.004.

Parameter Range: 15.0 Hz to H.022 Overfrequency Limit (V/Hz)
10 RPM to U.017 Motor Top Speed (vector)

Default Setting: 60.0 Hz (V/Hz)
3600 RPM (vector)

Parameter Type: Tunable

Refer also to parameters: P.028 Speed Display Scaling
H.022 Overfrequency Limit
U.017 Motor Top Speed

⚠ WARNING
THE USER IS RESPONSIBLE FOR ENSURING THAT DRIVEN MACHINERY, ALL DRIVE-TRAIN MECHANISMS, AND APPLICATION MATERIAL ARE CAPABLE OF SAFE OPERATION AT THE MAXIMUM OPERATING SPEED OF THE DRIVE. OVERSPEED DETECTION IN THE DRIVE DETERMINES WHEN THE DRIVE SHUTS DOWN. FOR VECTOR REGULATION, THIS IS FACTORY SET TO 130% OF MAXIMUM SPEED. FOR VOLTS/HERTZ REGULATION, THIS IS FIXED AT THE FREQUENCY LEVEL SET IN PARAMETER h.022 (OVERFREQUENCY LIMIT). Failure to observe this precaution could result in bodily injury.

For V/Hz regulation, this parameter specifies the maximum allowed speed in hertz. The drive is equipped with configuration overspeed protection at the frequency level set in H.022 (Overfrequency Limit).

For vector regulation, this parameter specifies the maximum allowed speed in RPM. The drive is equipped with fixed overspeed protection at 130% of Maximum Speed.

P.005 Current Limit

This parameter provides the means to limit motor stator current while running at constant speed or during acceleration.

Parameter Range: 50 to 110%* (V/Hz)
U.006 to 150% (vector)

Default Setting: 100% (V/Hz)
140% (vector)

Parameter Type: Tunable

Refer also to parameters: P.095 Power Module Output Amps
H.002 Motor Nameplate Amps
U.004 Motor Nameplate Amps
U.006 Magnetizing Current Percent

*For M/N 125R4140, the maximum Current Limit setting is 100% when P.047 = 8 kHz carrier frequency.

For V/Hz regulation: Current limit is set as a percentage of the Power Module rated amps with a maximum value of 110% current limit equals the current value in parameter P.095 (Power Module Output Amps).

When the output current attempts to exceed the preset current limit, the output voltage and frequency will be lowered as the drive reduces output current.

For vector regulation: Current limit is a percentage of the value entered in U.004.

The output current will be limited to the current limit value, which may result in motor speed decreasing or the acceleration/deceleration time being extended.

P.006 Second Menu Password

This parameter is used to enable/disable access to Second Menu General (P), Vector (U), Volts/Hertz (H), and RMI (r) parameters.

Parameter Number: P.006

Parameter Range: 0 to 9999; 107 = PASSWORD

Default Setting: N/A

Parameter Type: Tunable

Refer also to parameters: N/A

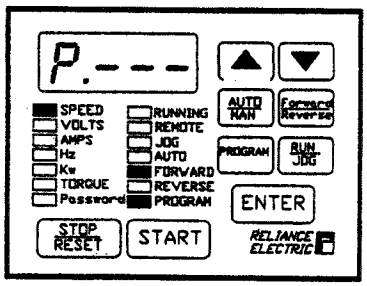
Note: *If the password is entered to enable access to the Second Menu parameters, the password must then be re-entered to disable access.*

Second Menu Parameters

The second Menu contains parameters used for more complex applications. Within the Second Menu are General (P.---) parameters that apply to both vector and V/Hz programming and Vector (U. --) or volts/Hertz (H .---) parameters. If an optional RMI board is installed in the drive, RMI (r. ---) parameters are also contained in the Second Menu. (A detailed description of RMI parameters can be found in the RMI instruction manual, D2-3341 which ships with the drive.

Access to the Second Menu parameters is enabled/disabled using the Second Menu Password parameter (P.006).

Access to the Second Menu parameters is enabled/disabled using the Second Menu Password



Entering the Second Menu Password

The second Menu Password parameter (P.006) is used to enable/disable access to the Second Menu parameters. When access is disabled, the Second Menu parameters cannot be displayed or changed (refer to Figure 25). To enable access, a factory-set password is entered into P.006. Access to the Second Menu parameters will then remain enabled until the password is entered into P.006 again.

Follow the steps shown in Figure 25, to enter the Second Menu Password.

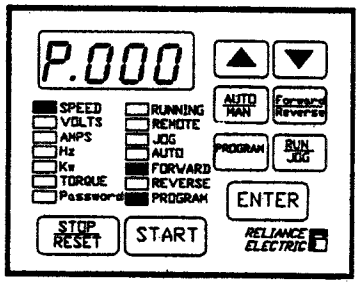


Figure 25 – Entering the Second Menu Password

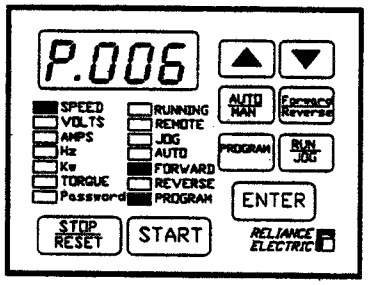
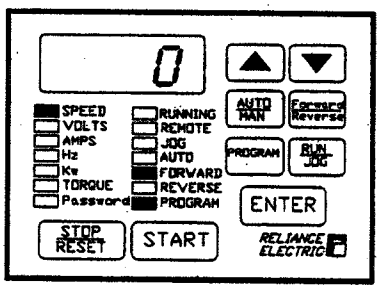
Step 1. Press the PROGRAM key until the PROGRAM LED turns on to enter program mode.



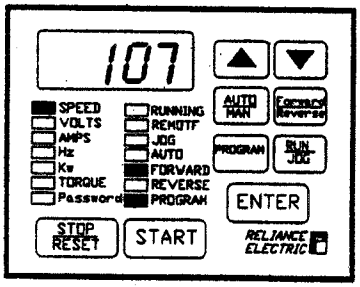
If P.--- is not displayed, press the ↑ key or the ↓ key until it is.

Step 2. Press the ENTER key.

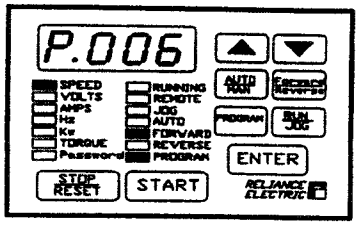


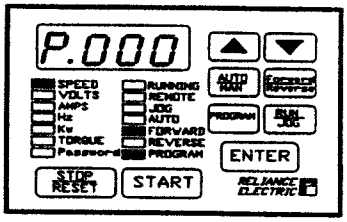
The first parameter number in the First Menu General parameters (P.000) or the last parameter number accessed will be displayed.

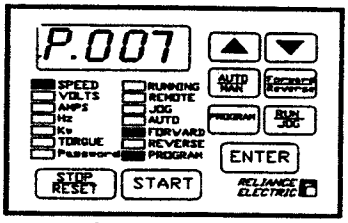
Step 3. Press the ↑ key to increment the parameter numbers until P.006 is displayed.



NOTE: *If you are able to display parameter P.007, access to the Second Menu is enabled. Continue with this procedure only if you wish to disable access to the Second Menu.*







Step 4. Press the ENTER key to access the parameter.

Zero will be displayed.

Step 5. Press the ↑ key to increment the value until 107 is displayed. This is the password. (Holding down the ↑ key will increase the scroll speed.)

Step 6.	Press the ENTER key to select the password.		P.006 is displayed.
Step 7.	Press the ↑ key to verify the access status.	 Access disabled  Access enabled	

To prevent unauthorized password use, a zero value (not the saved password number) is displayed whenever this parameter is accessed.

AFDB Field Accessible Parameters

Number	Name	*Type	Setpoint
P.000	Control/Source	C	RE
P.001	Accel Time 1 (ramp 1)	T	8.0 sec
P.002	Decel Time 1 (ramp 1)	T	18.0 sec
P.003	Minimum Speed	T	2280 RPM (38 Hertz)
P.004	Maximum Speed	T	3600 RPM (60 Hertz)
P.005	Current Limit	T	140%
P.006	Second Level Password	T	107

***Type = C (Configuration)**
T (Tunable)

AFDB Non-Field Accessible Parameters

The remaining parameters P.007 to P.099: U.000 to U.048: R.001 to R.066 are non-field accessible and read only if the Passwords are turned on in P.006 and P.051.

Of these parameters the following need these specified default values.

No.	Parameter Name	Parameter Type	Default Value
P.009	Terminal Strip Analog Input Offset	T	-213
P.010	Terminal Strip Analog Input Gain	T	1.25
P.011	Terminal Strip Analog Input Configure	C	2.0
P.027	Forward/Reserve Configuration	T	1
P.042	Line Dip Ride - Through Time	C	500 ms
P.048	Vector Regulation	C	VEC
P.051	Programming Disable	T	26
P.052	Auto/Main Key Disable	T	ON
P.055	Stop/Reset Key Disable	T	OFF
U.001	Encoder PPR	C	SE
U.012	Speed Regulator Proportional Gain	T	10.0
U.013	Speed Regulator Integral Gain	T	2.0
r.030	Digital Input Configuration	C	0
r.035	Relay Output 1 (N0) Configuration	T	9
r.036	Relay Output 2 (N0/NC) Configuration	T	1
r.037	Relay Output 2 (N0/NC) Configuration	T	3

Of these parameters the following will be down loaded based on compressor motor amps at Full (100%) load.

No.	Parameter Name	Parameter Type
P.028	Speed Display Scaling	T
U.002	Motor Poles	C
U.003	Motor nameplate Base Frequency	C
U.004	Motor Nameplate Amps	C
U.005	Motor Nameplate RPM	C
U.006	Magnetizing Current	C
U.007	Motor Nameplate Volts	C
U.016	Field Weakening Start RPM	C
U.017	Motor Top Speed	C
U.018	AC Line Volts	C
U.022	Motor Nameplate Horsepower	C

(15) Troubleshooting Using Error Codes

The drive can display two kinds of error codes, alarm and fault codes, to signal a problem during self-tuning or drive operation. Fault and alarm codes are shown in Tables 15 - 18. A special type of fault code, which occurs rarely, is the fatal fault code.

An alarm is signified by a two-or three-letter code flashing on the display. The drive will continue to operate during the alarm condition. The user should investigate the cause of the alarm to ensure that it does not lead to a fault condition. The alarm code will remain on the display only as long as the alarm condition exists. The alarm will automatically be cleared when the condition causing it is removed.

A fault condition is also signified by a two-or three-letter code flashing on the display. In the case of a fault, the drive will not continue to operate, but will coast to stop. The RUNNING LED will turn off when this happens. The first fault that occurs will be maintained flashing on the display, regardless of whether other faults occur after it. The fault code will remain on the display until it is cleared by the operator using the STOP/RESET key, or the fault reset input from the control source selected in P.000.

The drive automatically stores all subsequent fault codes that may occur in the system error log, which is accessible through the keypad, the OIM, or the CS3000 software. Using the keypad, the error log can be accessed in program mode after moving through all the parameter menus. There is no visual indicator that other faults are in the log, or that the log is filled and no more errors can be logged. The user must access the error log to view the other faults that occurred and should clear it often.

A maximum of ten fault codes can be stored in the log. The last fault that occurred is the first one to appear on the display when accessing the error log. The last fault will be identified with the highest number (up to 9).

The first fault that occurred will appear as the last one in the log. The number 0 will identify the first fault.

For each entry in the error log, the system can also display the day and time that the error occurred. The day data is based on a relative 247-day counter (rolls over after 247.55). The time is based on a 24-hour clock. The first two digits of the clock data represent hours. The last two digits represent minutes. The clock can be reset using P.030 (Elapsed Time Meter Reset).

All the entries in the error log and the day and time data will be retained, even if power is lost. If the error log is full, more entries can be added by the system only if the log is cleared. To clear the error log press the ↓ key while you are viewing any entry in the log until the display shows **CLr.**
Press ENTER to clear the error log. All entries will be cleared. For more information, refer to pages 5-6 and 5-7 of Section 5.3 of the Reliance instruction manual, D2-3410 that ships with the drive.

Identifying Alarm Codes and Recovering

Drive alarm codes are shown in Table 13. Note that the alarm code will only be displayed for as long as the problem exists. Once the problem has been corrected, the alarm code will disappear from the display.

Table 13 - List of Alarm Codes

Code	Alarm Description	Alarm Cause	Corrective Action
I-Ac	V/Hz identification procedure active	V/Hz identification procedure is enabled and in progress	1. Allow identification procedure to finish. 2. Press keypad STOP/RESET to cancel identification procedure if desired.
I-En	V/Hz identification procedure enabled	H.020 = On; V/Hz identification procedure has been enabled but not started	1. Proceed with V/Hz identification procedure, start drive and allow procedure to begin. Display will change to I-Ac when drive is started. 2. Change H.020 to OFF to cancel identification and clear I-En if desired.
LIL	Low AC input line	AC input line is low	1. Adjust line voltage parameter (H.021) to match actual AC line voltage.
PSEn	Power-up start sequence enabled.	P.054 = On; power-up start sequence has been enabled.	1. Allow power-up start sequence to finish.
S-Ac	Vector self-tuning active	Vector self-tuning is enabled and in progress	1. Allow vector self-tuning procedure to finish. 2. Press keypad STOP/RESET to can vector self-tuning procedure if desired.
S-En	Vector self-tuning enabled	U-.008 = On; vector self-tuning has been enabled but not started.	1.Proceed with vector self-tuning, procedure to begin. Display will change to S-Ac when drive is started. 2. Change U.008 to OFF to cancel self-tuning and clear S-En if desired.

Identifying Fault Codes and Recovering (Continued)

Fault Codes are shown in Tables 14, 15, 16 and 17.

Table 14 - List of Fault Codes (Continued)

Code	Fault Description	Fault Cause	Corrective Action
bYC	DC bus charging bypass contactor	Charging bypass contactor not closed at line voltage ON.	Check for loose connections on ribbon cables between Regulator and Bus Control boards, and between Power Module Adapter and Bus Control boards. Also, measure/check DC Bus voltage.
CHS	Default parameter restore (checksum error)	During drive operation: Regulator board failure.	Contact Trane Service or replace Regulator board.
		After Regulator board replacement:	Contact Trane Service.
EC	Earth current failure (ground fault)	Unintentional grounding.	Check isolation between ground and output terminals. Possible leakage, current sensor defects; replace sensor.
EEr	NVRAM write failure	Failure on write to non-volatile memory, bad NVRAM.	Connect CS3000 software to upload parameters. Then replace Regulator board. Parameter values will be lost when power is cycled.
EL	Encoder loss	Drive is not detecting feedback from the encoder.	Check the connection between the encoder and the drive. Check the encoder/motor coupling.
FL	Function loss	Function loss input on control terminal is opened	Check external interlocks at terminals 16, 20.
Hld	High time identification aborted	Identification process for V/Hz has been aborted.	See H.019 for identification result.
HIL	High line voltage	Input voltage more than 15% above configured value. (Note that this is not tested for in 1-150 HP Power Modules configured for vector control).	Check actual line voltage against U.018 or H.021.
HU	High DC bus voltage	DC bus voltage too high (capacitor protection).	Check input line voltage; if necessary, add transformer.
		Deceleration time too short	Check input line voltage; if necessary, add transformer.
IPL	Input phase loss	Voltage ripple on DC bus due to missing input phase or an imbalance between phases.	Verify that proper voltage is being applied to the drive. Check all phases.
LIL	Line input low (V/Hz)	AC powers supply interrupt or line dip. Alarm at ride through status.	Drive will continue to run after line voltage is restored. Check value of Line Voltage (P.044, U.018 or H.021). Check input voltage for dip. At high three-phase line reactors.

Identifying Fault Codes and Recovering (Continued)

Table 15 - List of Fault Codes (Continued)

Code	Fault Description	Fault Cause	Corrective Action
LU	Low DC bus voltage	DC bus voltage too low. Line dip too long (P.042).	Check input voltage, line fuses. If necessary, add transformer. Check value of Ride Through Time (P.42), Line Voltage (H.021, U.018).
nCL	Network comm loss	Communications with the AutoMax network have been lost.	Check network cabling from network master to network option board. Check that network master is operating properly.
nId	Identification Request not yet performed (V/Hz only)	Drive started but Identification Result = Zero.	Reset fault. Perform Identification Request. Restart drive.
OC	Overcurrent (steady state). Trips at 137% load (based on inverter type current) check Power Module rating.	Output phase-to-phase short.	Check isolation between each output line.
		Bus voltage line-to-line.	Check transistor modules for correct output. If incorrect, possible board defect; replace. Possible Hall effect current sensor defective; replace.
		Ground fault.	Check isolation between ground and output terminals. Possible leakage current sensor defect; replace sensor.
		Momentary overload	Check for motor overload; reduce load on motor.
		Bad Motor	Check motor for overload; reduce load on motor.
		Torque boost/V/Hz too high (V/Hz).	Check parameters H.001, H.002, and/or H.003. Enable Identification Request (H.020).
		Parameter settings (vector)	Check Encoder PPR (U.001), Motor Poles (U.002), Base Frequency (U.003), Motor Nameplate Amps (U.004), Magnetizing Current (U.006), Speed Regulator Prop. Gain (U.012).
		Encoder wired incorrectly, wrong PPR	Check encoder wiring. Perform vector self-tuning.

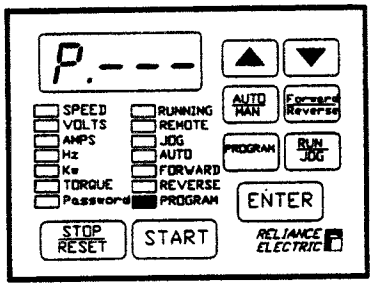
Identifying Fault Codes and Recovering (Continued)

Table 16 - List Fault Codes (Continued)

Code	Fault Description	Fault Cause	Corrective Action
OCA	Overcurrent (at acceleration)	Acceleration time too short.	Increase encoder acceleration time (P.001, P.017, P.021).
OCb	Overcurrent (at DC braking)	DC voltage too high.	Check parameters H.006, H.007
OCd	Overcurrent (at deceleration)	Deceleration time too short.	Increase deceleration time (P.002, P.018, P.022).
OF	Overfrequency	Drive has exceeded max allowable output frequency. Regenerating energy is too high. Stability or slip compensation circuit adds freq. Ref. If H.016 ON, searching current is too high. Motor is too small.	Vector: check parameters Encoder PPR (U.001), Motor Poles (U.002), Base Frequency (U.003).
			V/Hz: check DC bus voltage; increase decelerating time. Check values Maximum Speed (P.0004) / Overfreq. (H.022). Check slip compensation (H.004). If H.016 ON, check motor size versus Power Module Size, recheck setting of P.005 (too high).
OH	Drive overtemperature	Cooling fan failure.	Check ambient temperature, cooling fan, and minimum clearances around drive.
OL	Motor overload	Excess motor current. V/Hz: Torque boost too high, therm. Overload level too low.	Vector: Check actual/Motor Rated Nameplate Amps (U.004). V/Hz: Check actual current/Torque Boost (H.003). Check that power Module is sized correctly. Reduce load on motor (e.g. at low frequency).
		Excess load on motor, e.g., at too low speeds	Check that Power Module is sized correctly. Reduce load on motor (e.g., at low frequency).
		Loss of phase connection	Check output lines to the motor.
OPL	Motor output phase loss	Phase lost between drive and motor.	Check connections and cable of all 3 phases and motor windings. Replace any damaged cable.

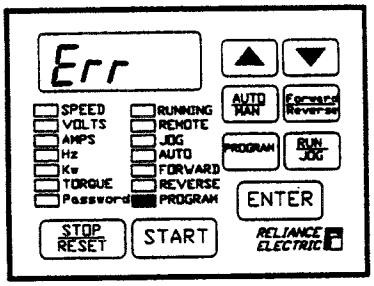
Identifying Fault Codes and Recovering (Continued)

Table 17 - List of Fault Codes



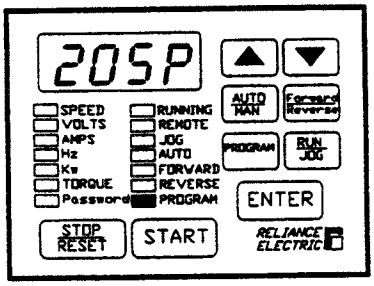
Code	Fault Description	Fault Cause	Corrective Action
OSP	Overspeed (Vector only)	RPM above 130% Maximum Speed (P.004), speed regulator response not optimized.	Check encoder PPR (U.001), Motor Poles (U.002), Base Frequency (U.003), Motor Nameplate RPM Speed (U.005). Check Reg. Proportional (U.012) Integral Gain (U.013)
Puc	Missing Power Module ID connector	Bad or disconnected cable between Regulator and Power Module.	Check cables between Regulator board and Power Module
PUn	Power Module not identified	Drive parameters have been restored to power-up defaults. Regulator has not been configured to match Power Module.	Power Module must be configured by Trane service personnel.
PUo	Drive power electronic overload	Power Module overloaded. Too high DC Braking Voltage (H.007) or Torque Boost (H.003).	Check load to Power Module. Check Power Module sizing versus application. Check DC Braking Voltage value (H.007). Check Torque Boost (H.003).
SF	Self-tuning status (Vector only)		See parameter U.009
SrL	Communication loss between Regulator/PC/ OIM	Serial port communication cable, PC or OIM communication port setup.	Check connection cable and communication port setup.
UAr	Spurious host PC comm interrupt	Regulator board failure.	Replace Regulator board.
UbS	Asymmetrical bus charge	Bad Power Module	Contact Reliance.

Error Log



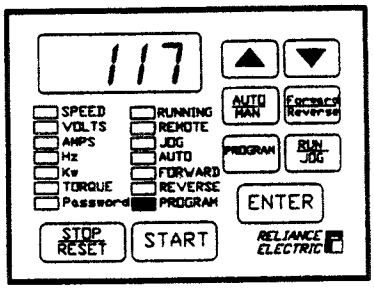
Note that you cannot clear a single entry from the error log. The entire log, including all of the fault codes and the day and time stamp of each fault will be cleared simultaneously using this procedure. See Figure 26.

Figure 26 - Accessing, Reading, and Clearing Faults in the Error Log

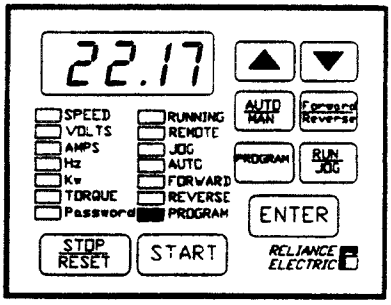


Step 1. Press the PROGRAM key. The First Menu General parameters are displayed. The PROGRAM LED will turn on.

Step 2. Press the DOWN ARROW key until Err is displayed.



Step 3. Press the ENTER key. If no faults have occurred, Err will be displayed again. If only one fault has occurred, the fault code will be displayed as the first entry in the log. If more than one fault has occurred, the first entry is the latest fault that occurred.

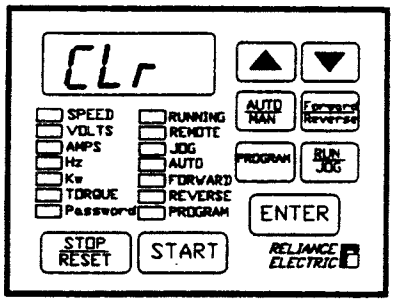


Step 4. Press the UP ARROW key or the DOWN ARROW key.

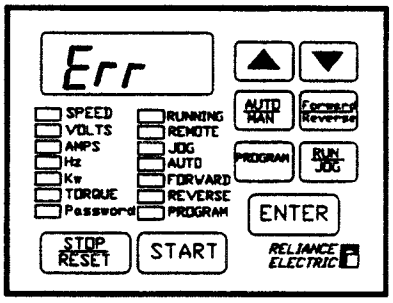
The display steps through the error log entries, which are numbered 0-9 (maximum).

Step 5. Press the ENTER key. The display shows the day stamp, which can range from 0-248 days.

Step 6. Press the DOWN ARROW key. The display shows the time stamp, which is based on a 24-hour clock. Use the arrow keys to move between the day and time data.



Step 7. Press the PROGRAM key, which displays the error log entries again.



The display shows the error log entry viewed prior to or associated with the last viewed time stamp.

Step 8. Repeat steps 4-7 for each additional error log entry to view the the time and date for each error log entry.

Step 9. When you have viewed all the entries, you should clear the error log. Press the DOWN ARROW key while you are viewing any entry in the log until the display shows CLr. Press ENTER to clear the error log. All entries will be cleared.

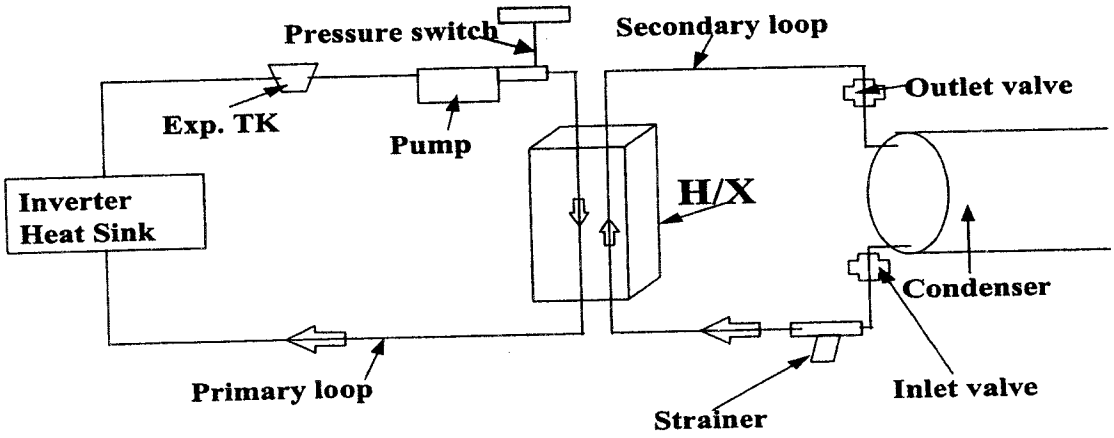
Step 10. Err will be displayed again to indicate that the log is empty.

Step 11. Press the PROGRAM key to access program mode again.

Recovering from Fatal Fault Codes

The letter **F** preceding the code distinguishes fatal fault codes. They normally indicate a malfunction of the microprocessor on the Regulator board. In some cases, fatal fault codes can be reset and the drive can be re-started. Table 18 lists the fatal fault codes, which can be reset. If any other fault code appears on the display, you will need to replace the Regulator board.

Table 18 - Fatal Fault Codes that can be Reset



Code	Fault Description	Fault Cause	Corrective Action
F 3	Encoder power-up	Encoder voltage is less than 10 V.	Turn off power to the drive. Disconnect the encoder wiring from the terminal strip. Turn power to the drive back on. If the F3 error does not occur again, the problem is in the wiring between the drive and the encoder. If the F3 error does occur again, the problem is in the Regulator board which should be replaced.
F 60	Option port identification error	The option board could not be identified by the regulator.	Check the ribbon cable between the Regulator board and the option board. For M/N 50R41xx, 50T41xx, 75R41xx, 75T41xx, and 125R41xx drives, check the option port jumpers on the option board. Refer to the appropriate option board instruction manual for more information about the option board.
F 61	Option board power-up diagnostic failure	Option board has failed one or more power-up diagnostics.	Check the ribbon cable between the Regulator board and the network option board. Replace the option board if necessary. Refer to the appropriate option board instruction manual for more information about the option board.
F 62 or F 26	Option board runtime error.	During operation, the option board watchdog failed or handshaking with the drive failed.	If intermittent, check for causes of noise, for proper grounding, and that outputs are not exceeding rated current capacities. Replace the option board if necessary. Refer to the appropriate option board instruction manual for more information about the option board.

(17) AFDB Cooling Circuit

1. List of Serviceable Parts

The cooling circuit consists of two loops. Figure 27 of the Schematic for the cooling circuit shows the primary and the secondary loops as well as the Pressure Switch.

Figure 27 – Schematic of the Cooling Circuit

The following main parts are present in the cooling circuit for the unit mounted inverter.

1. Cooling loops-hoses
2. Pump
3. Brazed plate heat exchanger
4. Strainer

The details of these parts are shown below.

2. Part Details

Hose Details

Type	Hydraulic Hose Synthetic Rubber with Double Wire Braid-Reinforcement
Hose I.D.	.75 inch
Hose O.D.	1.10 inch
Hose I.D.	1.0 inch
Hose O.D.	1.42 inch
Max Oper.	500 psi
Min. Burst	10000 psi
Min. Bend Radius	6 Inches
Oper. T Range	-40°F to +212°F

(17) AFDB Cooling Circuit

2.1 Pump Details

Type	Regenerative Turbine Pump, close coupled
Liquid	Distilled Water plus Inhibitor
Suction	3/4" NPT
Discharge	3/4" NPT
Max T	230F
Max sys P	300 psi
Flow	5 gpm
TDH	97 ft
Rated BHP	0.25 hp
NPSHrequ	6 ft
Impeller	Bronze
Cover	Bronze
Shaft	316SS
Motor Bkt	Bronze
Seal	
O-rings	EPR
Motor bearing	

2.3 Motor Data

HP	1/3
RPM	3450
Voltage	115/230
Phase	1
Hertz	60
Enclosure	Open Drip Proof
Frame	56
Thermal overload protection built in to motor	
Agency Certification	UL

2.4 Heat Exchanger Details

Type	Brazed Plate
Plates/Connections	AISI 316 SS
Solder	Copper
Max P	450 psig
Max T	365 °F

2.5 Standard Operating Conditions 350-600 HP

	Condenser Side	Inverter Side
Flow Rate	5 GPM	5 GPM
Calculated Pressure Drop	091 psi	2.44 psi
Fluid	Cooling Tower Water	Distilled Water + Inhibitor
Connections	3/4" NPT	3/4" NPT

2.5.1 Standard Operating Conditions 1000 HP

	Condenser Side	Inverter Side
Flow Rate	4.75 GPM	8.00 GPM
Calculated Pressure Drop	0.74 psi	2.24 psi
Fluid	Cooling Tower Water	Distilled Water + Inhibitor
Connections	1" NPT	3/4" NPT

2.6 Strainer Details

Type	Y-Type Strainer
Material	Bronze Shell
Filter Screen	Stainless Steel
Mesh Size	20 Mesh
Size	1.5-Inch Diameter

3. Recommended Service Procedures

3.1 Service Requirements during Normal Operation

The only components in the cooling circuit that can be monitored during operation are the cooling loops. All other components can be serviced only after the unit is shut down. Therefore, regular maintenance and service procedures for all other components are described in the section titled "Service requirements during shutdown".

3.1.1 Inhibitor Solution for Primary Loop

In order to prevent corrosion in the primary loop, an inhibitor solution must be used. The solution shall be a mixture between 5000ppm to 13000ppm of inhibitor solution and distilled water. Mixing concentration shall be (3) oz. of concentrated inhibitor solution (shipped in a bottle with unit) to the primary water loop of distilled water for 350-600 HP sizes. The 1000 HP uses a different inhibitor and a different concentration. The inhibitor solution shall be mixed to the proper concentration prior to filling the primary loop. If necessary to replace/purchase inhibitor solution contact the local Trane Parts office.

3.1.2 Cooling Loops

It is essential that the amount of cooling medium be maintained in the primary and secondary loops. The amount of cooling medium in the primary loop can be monitored by the level of the ball in the expansion tank sightglass. This ball will be at the center of the sightglass when the level of the cooling medium in the expansion tank is sufficient. The loop holds 1-3 gallons of water; care needs to be exercised that the loop is not overfilled. Therefore, it is essential that the ball in the sightglass is visible. The level of the cooling medium in the cooling loop must be monitored at periodic intervals (not to exceed 2 months) by ensuring that the ball in the sightglass is visible. The level of the cooling fluid may be decreased by draining through the valve at the back of the inverter. The coupling at the top of the expansion tank is used as the fill point.

No special maintenance procedures are needed for the secondary loop. Water flow through the secondary loop is automatic. Debris in the cooling water tower is removed by the strainer. The cleanout procedures for the strainer are described in a later section.

3.1.3 Cooling Loop Pump Operations

The primary loop must be filled in such a way that will always keep the pump seal surrounded by water. To fill the primary loop, remove the water fill connection and bleed connection at the top of the expansion tank. Fill the primary loop with the inhibitor solution until the ball in the expansion tank sight glass floats. When the chiller is first started, watch the ball in the expansion tank sight glass and fill immediately when the inhibitor solution level decreases. The unit should be run for several minutes to allow air to be removed from the primary loop.

CAUTION
DO NOT OPERATE THE PUMP WITHOUT WATER. Failure to operate the pump without water may result in the seal being permanently damaged.

3.2 Service Requirements during Shutdown

The unit must be shut down using shutdown procedures described in the literature. Prior to performing any service on the secondary loop, the isolation valves on the condenser must be closed end, the cooling tower pump must be shut off.

3.2.1 Cooling Loops

The primary loop of the inverter cooling circuit shall be charged with the inhibitor solution during normal operation of the inverter. **If the chiller is in an unconditioned mechanical room during shutdown periods, the primary loop needs to be drained of tap water, blown out with and refilled with a 100% propylene glycol solution. Normal shutdown procedures used with the condenser need to be followed for the secondary loop.**

Draining and refill procedure

Opening the valve at the back of the inverter drains the primary loop. The coupling on top of the expansion tank is used for filling. It is recommended that the pump be run for approximately two minutes after the charging. The cap on the charging process (on top of the expansion tank must be opened to let out any air in the system.) The charging process may be stopped when the ball in the sightglass is visible at the center of the sightglass indicating the proper level of the glycol.

Checking cooling loop integrity

Some situations will require that the hoses be disconnected at the connections. In these situations, teflon pipe sealant must be applied on the threads of all mating parts before they are assembled. Leaks in the cooling loop must be avoided since they can lead to reduction in the inverter life. Therefore, it is essential that the loops be tested for leak each time they are disconnected at any joints or connections. Once the loop has been filled with the coolant medium, they should be tested for leaks by applying liquid soap on the exterior surface of hoses and the connections. It is recommended that the cooling pump be running at the time of the test since this will detect leaks that occur during water flow but are absent in a static situation. The hoses must be replaced if the leak is substantial. If there is leaks at the fittings, these fittings must be disconnected, re-threaded and tested again. Teflon pipe sealant must be applied if needed. If the leak continues, the fittings will need replacement. REFER TO CVHE-IN-3B, DISSASSEMBLY AND REASSEMBLY MANUAL, FOR ADDITIONAL INFORMATION.

3.2.2. Pump (See Pump Manual Section on Maintenance and Service)

3.2.3. Heat Exchanger

The heat exchanger can be serviced only after the unit is shut down. The heat exchanger is susceptible to two mechanisms, which can cause reduction in the performance of the unit: fouling and corrosion. Some basic concepts on these two mechanisms are explained below:

3.2.3.1. Fouling

Fouling in brazed plate heat exchangers can be classified into two types based on the effect that they have on the heat exchanger.

Pressure Drop Fouling

This is caused by fibers or other particles (<1 mm) getting stuck in the plates of the heat exchanger. This can be more of a problem in units connected to cooling towers exposed to environments containing airborne particles such as dust and cottonwood seeds. This issue has been addressed with the strainer in the secondary loop. The primary loop contains **distilled water** , which is not expected to have solid particles in it. However, backflushing is a method, which can be used to address this situation. For backflushing, disconnect the inlet and outlet connections, connect the inlet connection to the drain and the outlet connection to a city water connection and flush the heat exchanger with city water for 2-3 minutes. Please note that the city water pressure should not exceed 150 . psi.

I. Surface Fouling

One or more of the following can cause surface fouling: Sticky products such as oil and grease.

In situations where this is an issue, ***commercial detergents such as P3 T6560 from Henkel may be used. Laundry detergents or dishwashing detergents must be avoided. However, if they are the only alternative, a water treatment specialist needs to be consulted before usage.***

II. Scaling

Solubility of salts such as copper sulfate in water decreases with increase in water temperature. This can be a problem in high temperatures. This is not expected to be a problem in temperatures of less than 45°F, which is the case in this application. Scaling can be removed by backflushing with dilute (5%) solutions of sulphamic acid, phosphoric acid and citric acid (NEVER USE HYDROCHLORIC ACID, SULFURIC ACID OR MURIATIC ACID). It is recommended that a concerned user consult a water treatment specialist.

III. Algae, Fungi or Bacteria

Algae cannot grow in regions where there is no light. However, they may grow in cooling towers, which are open to light. Danger of algae growth may be reduced by treating the cooling towers with algaecide (AVOID BIOCIDES OR ALGAECIDES WITH CHLORIDES). In this application, the issue has been further addressed through the strainer, which will filter any algae present in the secondary loop.

Bacteria and fungi can attack sulfates causing sulfuric acid, which would consequently lead to sulfuric acid corrosion. They can also feed on nitrogen or phosphor to form slime. Bacteria are also known to feed on iron present in water forming a viscous mass of oxide. All these occurrences will cause a reduction in heat transfer capability accompanied by an increase in pressure drop. ***Chlorophenols, potassium permanganate, sodium dichromate or sodium chromate can be used to clean the system in cases where bacterial or fungal presence in the water is anticipated. Chlorine usage is strongly discouraged since it will cause pitting of the heat exchanger surface.***

IV. Deposits of Sand

This is sometimes found in cooling tower water. Sand may accumulate in the heat exchanger plates at very low velocities. This is not a concern in this application since the heat exchanger is designed for high velocities in the channel. Also, the strainer will filter out particles less than 1/32" in diameter.

V. Barnacles or Larvae

This is a concern only in brackish or seawater. ***This application is not designed for this type of water and must not be used with seawater, river water or brackish water***

3.2.3.2 Corrosion

The heat exchanger used in the application is stainless steel which is resistant to pitting and micro-galvanic corrosion in most conditions of operation. However, one can never do enough to completely prevent corrosion. Therefore we have provided guidelines for water quality that would minimize the risk of corrosion and fouling. ***It must be noted that the heat exchanger and components of the cooling loops must be cleaned and rinsed without fail immediately after shutdown.***

In addition, corrosion of copper components can be reduced if the pH of the water is maintained between 7.5 and 9.0, oxygen content is maintained below 0.1 PPM. Compounds such as hydrogen sulfide, ammonia and compounds with chlorides must be avoided at all costs in the cooling loops. Water containing hydrazine is very good for prevention of corrosion of iron and copper. It must be noted that ammonia cannot be used in cooling tower water for this application.

Recommended concentration limits for impurities in water to prevent microgalvanic corrosion of unalloyed or galvanized iron is mentioned in Table 19. It must be noted that these values are only recommended values and cannot be considered as guarantees. Water quality specialists should be consulted for ultimate authority.

Table 19 - Concentration Limits of Impurities in Water

Ph SO_4- Total hardness Fe^{3+}	7.5-9.0 <90 PPM 4.0-8.0 dH <0.3 PPM
H_2S $PO_4^{\ 3}$ NH_3 HCO_3-/SO_4	<50 ppb <2.0 PPM <0.5 PPM >1.25
Cl- Temperature Oxygen content Total dissolved solids Free chlorine	<100 PPM <45°C <0.1 PPM 500 ppm of $CaCO_3$ <0.4 PPM

3.2.4 Strainer

The strainer will catch all the debris that the cooling tower water has that is larger than 1/32" in diameter. This strainer is cleanable and cleaning is recommended every 1-3 months in order to avoid clogging of the filter screen. Clogging of the filter screen will cause reduction in flow through the heat exchanger, which will in turn increase the temperature of the water flowing through the inverter. The screen of the strainer can be removed from the shell by unscrewing the nut on the leg of the Y strainer. This can only be done after the isolation valves on the inlet and

outlet of the heat exchanger are closed and the unit is shut down. The refrigerant charge can remain in the unit during the clean out procedure. Cleanout of the screen can be done with tap water or **distilled water.** Oils or other lubricants should not be used. Commercial cleaners may be used but they must be thoroughly removed from the screen before the screen is put back into the shell. Cleaners which remain on the screen may go on to the heat exchanger and cause scaling or corrosion and therefore must be thoroughly rinsed.

(18) AFDB Startup Procedure

THE WATER COOLED ADAPTIVE FREQUENCY DRIVE IS UNIT MOUNTED ON A CVHE/F/G UNIT. IT IS COMPLETELY FACTORY INSTALLED AND PROGRAMMED. THE FOLLOWING PROCEDURES SHOULD BE FOLLOWED WHEN STARTING THE WATER CHILLER AND DRIVE.

1. The CenTraVac® control panel (UCP2) is the prime controller and is used to start, stop and monitor all unit and AFDB run functions.

   1.1. Complete all The Commissioning Checklist and Start-up procedures for the CVHE/F/G as called out in the operation maintenance manual CVHE-OM-8 or other applicable manual.

   1.2. Complete the "CenTraVac Adaptive Frequency Drive Startup Log" located in this section.

2. Check the following on the drive:

   2.1. 460/480 volt input wiring to the drive is sized correctly and hooked up as noted in this manual.

   2.2. Check the drive ground connection as detailed in the "Wire Routing" Section (5) of this manual, check cabinet wire routing and grounding. A suitable grounding conductor unbroken must be run from the cabinets ground stud to the motors ground terminal (factory connected) and then to earth ground (field) responsibility.

3. Check all drive wiring and connections in the drive to make sure they are tight and free of any shipping damage.

4. AFDB cooling circuit:

   4.1. **The primary water loop (See Figure 27) on the AFDB cooling circuit must be charged with Distilled water plus inhibitor solution prior to starting. It requires approximately 2-3 gallons of water. Fill the circuit using the connection provided on the primary circuit expansion tank. Fill the tank until the ball in the expansion tank sight glass is visible at the center of the sight glass. Because air will still be trapped in the drive after initially filling the primary loop, the following procedure must be followed to properly remove the air. If this air is not removed the pump will not function properly and the drive will overheat and shut the chiller down.**

   Leave the fill connection at the top of the expansion valve open, start the primary circuit pump by running the oil pump in the manual mode. When the water level lowers the ball in the sight glass expansion tank, refill the tank until the ball is visible in the center of the sight glass. Repeat this process until the ball remains in the center of the sight glass. The tank may need to be refilled several times before all of the air is removed from the system. Close the top of the tank after all of the air is removed from the primary side.

   4.2. Water Pump Operation. Check the water Pump operation by going to the Service Test Menu and running the oil pump in the "MANUAL" mode.

   4.3. Re-enable Password security in P.006 and P.051 to lock in the settings after completing the Program settings.

5. AFDB control checkout: Reference Section 14, "Ensuring Program Security" on AFDB field accessible parameters and non-field accessible parameters.

   5.1. Check out all setpoints in P.000 through P.006. These are general setpoints that are the same on all AFDB water-cooled drives. See Section 14, "Ensuring Program Security".

   5.2. Verify setpoints on all the remaining parameters, P.007 to P.099: U.000 to U.048 and R.1030 to R.037. See Sections 12, "Drive Status Leds" and Section 14, "Ensuring Program Security". These parameters are specific to your unit/motor combination. in the drive.

   5.3. Re-enable Password security in P.006 and P.051 to lock in the settings after completing the Program settings.

Note: *If the set values do not match, contact the La Crosse Business Unit Technical Service Department. The correct values are listed on the drive parameters settings shipped with each unit.*

6. If you are not already in the monitor mode of the AFDB Display, access it by pressing the program key until the Program LED turns off. You will then be able to press the ENTER key to advance through each of the monitor mode when the drive is running.

7. Start the drive from the UCP2 panel.

8. Check the AFDB chiller drive response to the UCP2. Initially, the drive will go to 60 hertz and stay there until the CenTraVac® vanes go wide open based on load. The drive will decrease the speed from there based on load demand.

START-UP PROCEDURES
TRANE LIQUI-FLO VARIABLE FREQUENCY DRIVE
PRE START-UP CHECKLIST AND SERVICE REQUEST

Use this form to check for proper installation of the Rockwell Automation Liqui-Flo VFD. For start-up service, please fax this completed form to: **Rockwell Automation – LaCrosse, WI FAX: 1-608-781-7182** to schedule start-up. Please allow three weeks to arrange for start-up services.

JOB LOCATION_____INSTALLING CONTRACTOR_____

STREET_____CONTRACTOR CONTACT_____

CITY_____CONTACT PHONE_____

PRE START-UP CHECKLIST

PRIOR TO ROCKWELL AUTOMATION BEING ON SITE, CONFIRM THAT THE FOLLOWING ACTIONS HAVE BEEN COMPLETED (OR WILL BE COMPLETED PRIOR TO THE SCHEDULED START-UP):

	YES
1. The Trane Liqui-Flo VFD is mounted and wired per the CVHE-OM-8 Operation & Maintenance manual and/or wiring diagram (if separately supplied).	☐
2. The A-C primary line voltage is the proper voltage.	☐
3. The Trane chiller is ready to start and operate under load conditions. All preliminary start-up checks have been completed as detailed in the appropriate Installation Operation Maintenance manual, such as (evacuation, charging, all wiring & electrical work, chiller and AFD control settings checked, etc...).	☐
4. The Personnel have been selected to assist the Rockwell Automation service representative with the operation of the equipment and the facility layout.	☐

REQUEST FOR SERVICE REPRESENTATIVE

I acknowledge that all four of the above items have been completed. I understand that if upon job inspection these requirements are not met, no start-up work will be performed and travel time and mileage will be charged at current hourly rates.

Notice

The Trane Company urges that all HVAC servicers working on Trane equipment, or any manufacturer's products, make every effort to eliminate, if possible, or vigorously reduce the emission of CFC, HCFC and HFC refrigerants to the atmosphere resulting from installation, operation, routine maintenance, or major service on this equipment. Always act in a responsible manner to conserve refrigerants for continued use even when acceptable alternatives are available. Conservation and emission-reduction can be accomplished by following recommended Trane service and safety procedures published in Trane General Service Bulletin CTV-SB-81. The information and procedures provided in CTV-SB-81 supersedes those published in this manual. Copies of this bulletin may be obtained by contacting your local Trane commercial product representative.

Specifications

Electrical Power Requirements
103-127 VAC, 60 Hz, 1-Phase, 8 Amps.
99-121 VAC, 50 Hz, 1-Phase, 8 Amps.

Fault Relay Output Rating
120 VAC, 1 Amp

Operating Environment
40 F to 120 F; 5% to 95% relative humidity, non-condensing.

Storage Environment
-40 F to 150 F; 5% to 95% relative humidity, non-condensing.

Mounting
Direct-mounted on condenser shell above liquid level of highest condenser.

Dimensions (approx.)
25 1/2" high x 24 3/4" wide x 18 3/4" deep, with filter-drier.

Weight
115 pounds with filter-drier.

Model Number Description

The operating components and options for any Trane Purifier Purge are assigned a multiple-character alphanumeric model number that precisely identifies each unit. An explanation of the identification code that appears on the unit nameplate is shown here.

Use of the service model number will enable the owner/operator, installing contractors, and service technicians to define the operation, components and options for any specific unit.

Sample Model Number

Model No.	P	R	G	C	A	0	0	1	A	A0		A

B = None

General Information

About this Manual

This manual discusses the Purifier Purge system operating concepts, operator interface, maintenance requirements and procedures, and basic troubleshooting procedures.

Literature Change History

PRG-OM-3 (December 1990)

Original issue of manual, describing operation, control, start-up, maintenance and troubleshooting of the Trane Purifier Purge unit. This manual applies to Model PRGA design sequence "1C" purge units only.

PRG-OM-3A (January 1992)
Manual revised to:

- Replace PDS description with unit model number descriptions, show updated nameplate, add HCFC-123 to Figure 2
- Correct operational description
- Update Troubleshooting chart

PRG-OM-4 (November 1992)
Manual revised to:

- Model PRGB
- Incorporate HFC-134a Condensing Unit
- Redesigned purge tank
- Separate filter-drier canister
- Revised control panel configuration

PRG-OM-5 (July 1993)
Manual revised to:

- Model PRGC
- Incorporate UCP2 microprocessor control with adaptive operating mode and improved diagnostic capability
- Incorporate tank float switch

PRG-OM-5 (October 1993)
Manual revised to:

- Clarification of existing information.

PRG-OM-6 (November 1995)
Manual revised to:

- Incorporate improved pumpout circuit.
- Redesigned filter-drier assembly.

Incorporate Purifier Plus.

PRG-OM-6A (July 1997)
Manual revised to:

- Update General Assembly
- Expand Troubleshooting Section

Warnings and Cautions

Notice that **warnings** and **cautions** appear at appropriate intervals throughout this manual. Warnings are provided to alert installing contractors and other personnel to potential hazards that could result in personal injury or death, while cautions are designed to alert personnel to conditions that could result in equipment damage.

Proper chiller performance and the personal safety of operating and service personnel depend upon strict observance of these precautions. The Trane Company assumes no liability for installation or service procedures performed by unqualified personnel.

Purge Nameplate

The nameplate is located on the control panel. Always provide the model number, serial number and product description information from the nameplate when making inquiries or ordering parts or literature for the purge unit. (See Figure 1 for an example of a nameplate).

TRANE

ORDER NO:
MODEL NO: PRGCA011AA0A
SERIAL NO:
RATED VOLTAGE: 110/50/1,115/60/1
TOTAL UNIT AMPS: 8 AMPS
MIN CKT AMPACITY: 10 AMPS
MAX OVERCURRENT
PROTECTIVE DEVICE: 15 AMPS
FACTORY CHARGED: .500 LBS OF HFC-134A
DESIGN PRESSURE: HIGH SIDE 235 PSIG
LOW SIDE 140 PSIG
UNIT SUITABLE FOR USE WITH REFRIGERANT-11 OR 123 SEE PRG-OM-6A
MANUFACTURED UNDER ONE OR MORE OF THE LISTED U.S. PATENTS OWNED BY AMERICAN STANDARD INC.: 5,031,410

Figure 1
Typical Purge Nameplate

Operating The Purge

Introduction

The incorporation of a microprocessor into the purge control system greatly enhances the flexibility of operation of the unit. The operator may adjust various setpoints, select an operating mode, and receive information on system operating status, current and cumulative purging activity, and any active fault diagnostics via a human interface.

There are two basic types of purges covered by this manual:

- UCP2 based display purges
- Purge based display purges

The primary difference between these two types of purge units is the human interface - the device through which the purge is controlled by the operator. The human interface provides the means to adjust operating parameters and setpoints, and is the means by which the purge module reports purge unit function and performance data.

For UCP2 based display purges, the human interface is the UCP2 chiller main panel. For purge based display purges, the human interface is a separable unit which may be mounted in any convenient location on or near the chiller.

The operation of these two types of human interfaces is somewhat different. Each is described fully in the following sections. The operator should reference the section appropriate to the unit being worked on.

The following sections describe in detail the features and operation of the two versions of the purge human interface:

- UCP2 Human Interface
- Purge Based Human Interface

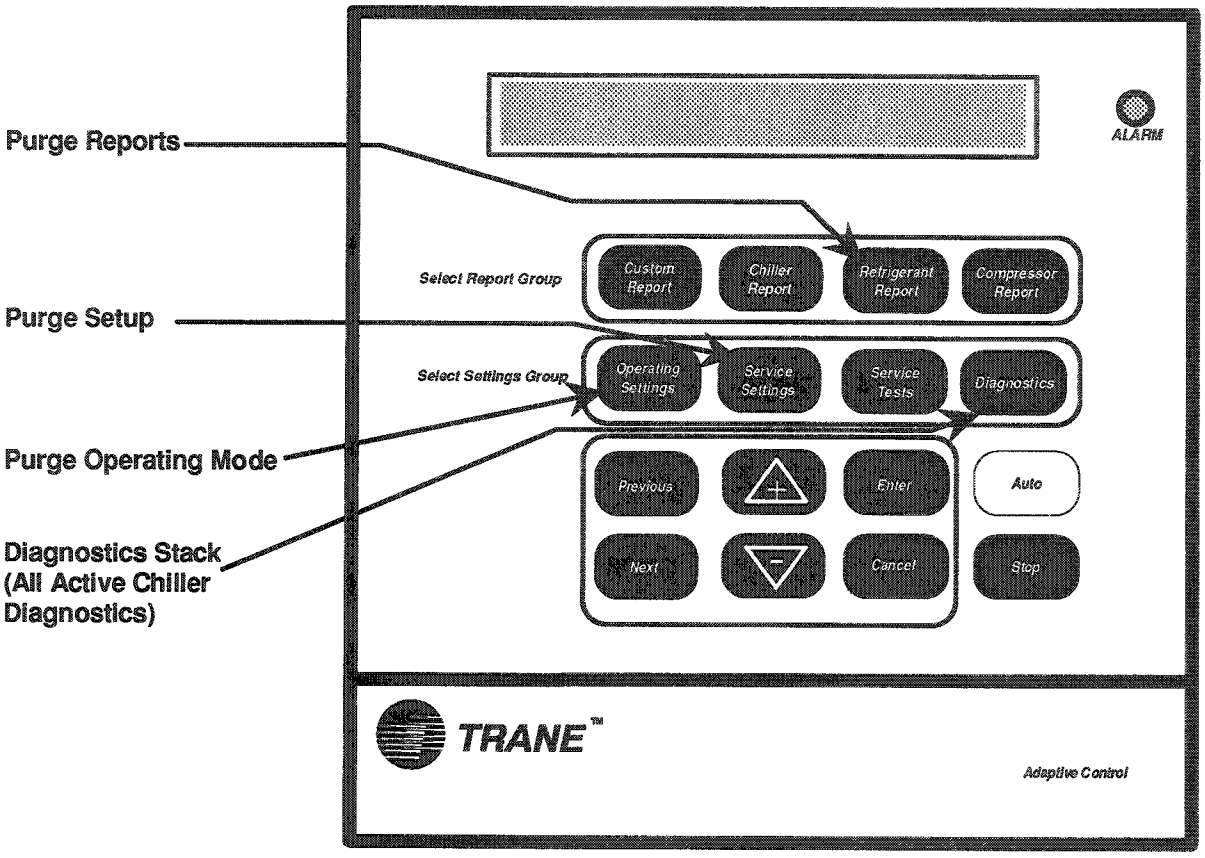
Note: Complete descriptions of operating modes, reports, and diagnostic messages are contained in the UCP2 Human Interface section. The Purge Based Human Interface section contains more abbreviated descriptions, with references to the more detailed information contained in the UCP2 Human Interface section.

These two specialized sections are then followed by three general sections on the operation of the purge:

- Operating the Purge
- Purge Start-Up
- Data Logging

UCP2 Human Interface

The UCP2 chiller main control panel is the human interface providing a means of communication between the operator and the purge microprocessor. This is accomplished via a two row alphanumeric screen display. The display panel is illustrated below. The keys which will be used for purge control are indicated. The applicable screens related to the setup of purge operating parameters, the selection of operating mode, and the review of performance reports are shown in the following sections. The left column of each set illustrates the screens as they actually appear, while brief explanatory notes are given in the right column.



UCP2 screens for the setup, selection of operating mode, and reporting functions of the purge, while grouped together for convenience, are in reality a subset of the larger set of screens used for the control of the centrifugal water chiller. They are accessed through the UCP2 panel via the keys on that panel. The purge setup screens are accessible within the "Field Startup" group found under the "Service Settings" key on the main panel. The purge operating mode screen is accessible using the "Operator Settings" key on the main panel. The report screens may be displayed using the "Refrigerant Reports" key on the main panel. The sections entitled "Setup", "Operating Mode", and "Reports" which follow explain in detail the various required screens and how to access them.

Note: Purge based display purges utilize a different type of human interface. While functionally similar, details of its menu structure and command set are different. See the section "Purge Based Human Interface" for a detailed discussion of this interface.

The following sections describe in some detail the features and operation of the microprocessor controlled UCP2 based display purges:

- Setup
- Operating Mode
- Reports
- Restarting the Purge Following a Latching Diagnostic

UCP2 Based Display

Setup

The operator may establish the desired operating parameters of the Purifier Purge via the human interface by indicating the purge type, the desired operating mode, and various setpoint values.

For the UCP2 based display purge, operating parameter setup is accomplished by pressing the "Service Settings" key on the panel. The "Next/Previous" keys scroll down and up through all available service settings. Scroll to the "Field Startup" screen. Entering the password gains entry to the required area for establishing purge operating parameters. The password is entered by pressing the sequence (+)(+)(-)(-)(+)(+) followed by the "Enter" key. Within the field startup area the "Next/Previous" keys scroll down and up through all available field startup screens. These include the screens required for setting up the purge operating parameters. The "+/-" keys scroll through available options or increment numerical values within a given field startup screen. The "Enter" key enters the displayed value into the microprocessor.

The following sections describe purge setup in the following categories:

- Type
- Service Log Reset
- Setpoints

Type

Purge Control/Type: 01-Micropurge	01-Micropurge = standard

The current Purifier Purge type is 01-Micropurge. Setting to any other type will suppress all purge screens

Service Log Reset

A service log is provided as a convenience to the operator. This service log accumulates pumpout time and elapsed calendar days since the log was last reset. The purpose is to provide a means for the operator to track purge operation relative to any required service intervals. For example, the optional Purifier Plus requires service after a given number of elapsed pumpout minutes or a given number of elapsed calendar days. This service log provides a convenient means to monitor these parameters.

Service Log: Press (enter) to reset Purge Pumpout Time: X,XXX.X Min	Service log reset Displays current value of log
Service Log: Press (enter) to reset Time Since Last Reset: X,XXX Cal Days	Service log reset Displays current value of log

Two reset entries are available. These are:

Purge Pumpout Time

This is to reset service log cumulative pumpout time to zero. The current log value is displayed.

Time Since Last Reset

This is to reset service log cumulative calendar days to zero. The current log value is displayed.

Setpoints

The operation of the purge is constrained by specifying the following setpoints:

Purge Max Pumpout Rate: XXX.X Min/24 hrs "Press (+) (-) to Change Setting"	Range is 1 to 100 minutes Default is 20
Purge Disable Pumpout Alarm for: XX hrs "Press (+) (-) to Change Setting"	Range is 1 to 72 hrs, displays the remaining time as it counts down
Purge Low Liquid Temp Limit: enable,disa "Press (+) (-) to Change Setting"	Enable / disable for low liquid temp limit (next setpoint). Default is ENA
Prg Low Liquid Temp Inhibit Setpt:XX.X F "Press (+) (-) to Change Setting"	Range is 32-50 F (0-10 C). Default is 40. Will display only if enabled

Purge Maximum Pumpout Rate

The maximum allowable minutes of pumpout activity in a 24 hour period. This value may range from 1 to 100 minutes.

Purge Disable Pumpout Alarm For XX Hrs

The alarm indicating pumpout activity has exceeded the set maximum value may be disabled for a given number of hours. This setpoint may be activated if it is anticipated that a large amount of air is in the unit due to service, etc. This value may range from 1 to 72 hours.

Purge Low Liquid Temp Limit: Enable, Disable

Purge pumpout activity may be inhibited if the chiller condenser saturation temperature falls below a set value as established below. This setpoint enables or disables the low temperature inhibit. This setpoint should be enabled for chillers with a free cooling operating mode or ice storage chillers, or any time chiller condenser temperatures are below 50°F, to avoid the pumpout of refrigerant when the purge is in the ON or ADAPTIVE mode.

Purge Low Liquid Temp Inhibit Setpoint

Purge pumpout activity may be inhibited when the chiller condenser saturation temperature is too low to assure effective purging. This setpoint establishes the minimum condenser saturation temperature below which pumpout activity is to be inhibited. Values of this setpoint may range from 32° F to 50° F. This setpoint becomes effective when it is enabled by the preceding setpoint.

Operating Mode

The operator may establish the desired operating mode of the Purifier Purge via the human interface.

For the UCP2 based display purge, operating mode selection is accomplished by pressing the "Operator Settings" key on the panel. The "Next/Previous" keys scroll down and up through all available operator settings. The "+/-" keys scroll through available options within a given operator setting screen. The "Enter" key enters the displayed value into the microprocessor.

Purge Operating Mode: [Mode] "Press (+) (-) to Change Setting"	[Mode] = STOP, ON, AUTO, ADAPTIVE

The purge system operating mode indicates the desired mode of operation. Available operating modes are:

Stop

The condensing unit will not run.

On

The purge system is in the normal operation state and runs continuously regardless of chiller operational status.

Auto

The purge system runs in the normal operation state when the chiller is running.

Adaptive

In this mode, purge operation is totally dependent on past purge activity.

With the chiller operating in powered cooling, the purge module will keep track of the last 30 days of chiller operation and will store the amount of pumpout time and the amount of run time for the chiller. Using the data for all days of chiller operation, the average pumpout time is computed. If the last day's pumpout time is greater than 5 times the average, the last day's pumpout activity will be used to determine the purge off cycle duration; otherwise the average will be used. The purge will start when the chiller starts, and will continue to operate until 60 consecutive minutes of operation without pumpout occur. The purge will then shut down for a period of time based on the average pumpout time.

Average pumpout with chiller running	Purge off cycle duration
< 1 minute	4 hours
1 to 3 minutes	3 hours
3 to 5 minutes	2 hours
5 to 8 minutes	1 hour
> 8 minutes	no off cycle

The purge module will store the accumulated pumpout time for the first 3-hour period during the last 5 chiller shutdowns. A time period will be calculated based on the average amount of pumpout occurring for these last 5 cycles. This time period represents the amount of chiller run time permitted before the purge will run at chiller shutdown. When this amount of chiller run time elapses, the purge will be run the next time the chiller is shut down.

Average pumpout, last 5 shutdowns	Chiller run time to next purge run at shutdown
< 2 minutes	80 hours
2 to 4 minutes	40 hours
> 4 minutes	20 hours

If it is determined that the purge is to run at chiller shutdown, the purge will start after the chiller shuts down. The purge will continue to run for 3 hours or until 30 consecutive minutes of run time without pumpout are recorded.

The purge module will calculate the average pumpout time for the last 30 days of extended chiller off periods. This average is used to determine an allowable number of consecutive off days that may elapse before purge operation is required.

Average pumpout during extended chiller off periods	Number of consecutive off days before the purge runs
< 1 minute	14 days
1 to 2 minutes	10 days
2 to 3 minutes	6 days
3 to 4 minutes	4 days
4 to 5 minutes	3 days
5 to 8 minutes	2 days
> 8 minutes	1 day

If it is determined that the purge is to run during a chiller off cycle, the purge will continue to run until 60 minutes of consecutive run time without pumpout are recorded.

Reports

The current and cumulative operating status of the purge is reported via the human interface. This report includes any current system diagnostics.

For the UCP2 purge, reports on status of operation, any active diagnostics, current performance data, and 30 day summary data may be viewed by pressing the "Refrigerant Report" key on the panel. The "Next/Previous" keys scroll down and up through all available chiller reports, including those on purge activity.

For the UCP2 purge, diagnostics may be reviewed and reset by pressing the "Diagnostics" key on the panel. The "Next/Previous" keys scroll down and up through all active chiller diagnostics, including those on purge activity.

The following sections describe purge reports in the following categories:

- Status of Operation
- Performance Data
- 30 Day Summary Data
- Diagnostics

Status of Operation

The purge status indicates the current operating status.

Purge Operating Mode:	Adaptive	See "Operating Mode"
Purge Status:	Running	See "Status of Operation"

Values of operating status are:

Idle

Condensing unit is off.

Running

Condensing unit is on.

Pumpout

Condensing unit is on, pumpout initiated by purge refrigerant compressor suction temperature.

Service Pumpout

Pumpout initiated by service switch (manual).

Running - Pumpout Inhibited By Low Temp

Condensing unit is on, pumpout inhibited by low condenser saturation temperature.

Pumpout Maximum Rate Disabled

Condensing unit is on, maximum pumpout rate alarm has been disabled by the operator. See PURGE DISABLE PUMPOUT ALARM FOR XX HRS in "Setpoints" under "Setup".

Performance Data

Purge Suction Temp: XXX.X F Purge Liquid Temp: XXX.X F	Purge refrigerant comp suction temp Chiller condenser saturation temp
Purge Pumpout Rate: XXX.X Min/24Hrs Purge Max Pumpout Rate: XXX.X Min/24Hrs	Current purge pumpout rate Max pumpout rate setpoint
Purge Total Pumpout Time: XX,XXX.X Min Purge Total Run Time: XX,XXX.X Hrs	Log of total accumulated pumpout and run time since installation
Purge Adapt Cycle T/Chlr On : XXX.X Hrs Time to Purge Remaining: XXX.X Hrs	Adaptive mode off-interval/time-to-run based on pumpout history
Purge Adapt Cycle T/Chlr Off: XXX.X Hrs Time to Purge Remaining: XXX.X Hrs	Adaptive mode off-interval/time-to-run based on pumpout history
Service Log: Reset log in field start up Purge Pumpout Time: X,XXX Pumpout Min	Accumulated service interval run time
Service Log: Reset log in field start up Time Since Last Reset: X,XXX Cal Days	Accumulated service interval calendar time

Current operating performance data includes:

Purge Suction Temp

The current purge refrigerant compressor suction temperature. This temperature is monitored to initiate and terminate pumpout activity. Pumpout is initiated at 18F and terminated at 22 F.

Purge Liquid Temp

The current chiller condenser saturation temperature. For UCP2 purges, this is reported from the chiller sensors. For purge based display purges, this data is acquired from an additional sensor mounted on the purge liquid return line (to the chiller condenser).

Purge Pumpout Rate

Current pumpout rate expressed in minutes of activity in a 24 hour period.

Purge Max Pumpout Rate

The current maximum allowable pumpout rate established as user entered data. When the current pumpout rate exceeds the maximum, an alarm diagnostic is generated.

Purge Total Pumpout Time

Log of accumulated pumpout activity over the life of the unit to this point.

Purge Total Run Time

Log of accumulated purge system run time over the life of the unit to this point.

Purge Adaptive Cycle Time/Chiller On

The purge off cycle time computed by the adaptive mode based on cumulative pumpout history for chiller on operating periods. Shown only when adaptive mode is active

Purge Adaptive Cycle Time/Chiller Off

The purge off cycle time computed by the adaptive mode based on cumulative pumpout history for chiller on and off operating periods. Shown only when adaptive mode is active.

Time To Purge Remaining

The time remaining from the Purge Adaptive Cycle Time until purge activity resumes. Shown only when adaptive mode is active.

Service Log: Purge Pumpout Time

A cumulative log of purge pumpout time since this log was last reset. This output is provided to help the operator track desired service intervals which are dependent upon purge activity.

Service Log: Time Since Last Reset

A cumulative calendar day log since this log was last reset. This output is provided to help the operator track desired service intervals which are dependent upon elapsed time.

30 Day Summary Data

Historical data is available via the human interface for a number of variables for the previous 30 calendar days, independent of whether the chiller or purge was run. This historical data is used by the ADAPTIVE mode to adjust purge operational parameters to optimize purge performance. The operator may study this data to analyze chiller leak patterns.

30 Day Purge Pumpout Avg: XXX.X Min/Day Chiller Average Run Time: XXX.X Hrs/Day	Pumpout activity indicative of total chiller leak picture
30 Day Purge Pumpout Avg, Chiller Running: XXX.X Min/Day	Pumpout activity indicative of chiller running leaks
Last 5 Cycle Pumpout Avg, Interval From Shtdn to 3 Hrs after shtdn:XXX.X Min/Day	Pumpout activity indicative of chiller air storage during operation
30 Day Pumpout Avg, Interval From 3 Hrs after Shtdn to next start: XXX.X Min/Day	Indicative of seal, o-ring, etc leakage during chiller off periods

The summary data includes:

30 Day Purge Pumpout Average

Average pumpout activity per 24 hour period over the last 30 days.

Chiller Average Run Time

This is the summation of chiller run time in hours divided by the number of days of available data.

30 Day Purge Pumpout Avg, Chiller Running

This summary includes all pumpout data for periods when the chiller is running. Large service pumpouts are not included if they occurred more than 7 days in the past.

Last 5 Cycle Pumpout Avg, Interval From Shutdown To 3 Hours After Shutdown

Data is available for the previous 30 calendar days for pumpout data during the first 3 hours following chiller shutdown. Large service pumpouts are included. From this data, the average for the last 5 shutdown cycles is reported here.

30 Day Pumpout Avg, Interval From 3 Hours After Shutdown To Next Start

This summary includes all pumpout data for extended chiller shutdowns (beyond the 3 hour period covered above). Large service pumpouts are not included if they occurred more than 7 days in the past.

Diagnostics

Faults that occur during the operation of the purge result in the generation of a diagnostic message indicating the nature of the fault. These diagnostic messages are communicated via the human interface. Chiller operation is unaffected by purge diagnostics.

When a diagnostic is detected, the display will automatically go to the "Diagnostics" menu and the following screen will appear:

A New Warning Has Been Detected Press (Next) For More	A new diagnostic has been detected

This is a "one-time" screen that will not reappear. Pressing "Next" causes the following screen to appear:

Diagnostic Report Follows Press (Next) For More	Scroll down to review diagnostic messages

The next screen will be:

Press (Next) to Display Operating Mode at Time of Last Diagnostic	Display chiller operating mode at time of diagnostic

Pressing "Next" will display the chiller operating mode at the time the diagnostic was generated. Following that screen, all active chiller diagnostics will be displayed in order of occurrence from newest to oldest. Diagnostics are displayed on 2 screens. The first screen contains the diagnostic message itself, along with a sequence number and a brief help message. An example purge diagnostic message is:

[sn] Max Pumpout Rate Exceeded (Prg) Purge Inoperative: See Purge OM Manual	Example diagnostic/help message

The second screen for each diagnostic message contains the sequence number and a date and time stamp. The form of this screen is:

[sn] Occurred at HH:MM xm Mon xx, 199x	Example diagnostic/help message time and date stamp

Following the active diagnostics may be a series of diagnostics labeled "historic only." These are diagnostics for which corrective action has been taken and which have been cleared. A buffer containing up to 20 of these historic diagnostics is retained for reference only

Diagnostics are either "latching" or "non-latching". Latching diagnostics force the purge to the STOP state. The purge may only be restarted by clearing these latching diagnostics after appropriate corrective action has been taken. See the section "Restarting the Purge Following a Latching Diagnostic" for more information on clearing latching diagnostics and restoring purge operation.

Non-latching diagnostics are cleared when the fault causing the diagnostic is corrected. No reset is required.

Operating The Purge (Continued)
UCP2 Based Display

Available purge diagnostics are as follows:

Purge Cprsr Suction Temp Sensor

The purge compressor suction temperature sensor has failed, the connection has been broken, or a short has occurred in the wiring. This latching diagnostic is set on a short or open.

Chlr Sat Cond Temp Sensor (Purge)

The chiller condenser liquid temperature sensor has failed, the connection has been broken, or a short has occurred in the wiring. This diagnostic is operational only in a purge based display application, and then only if low chiller liquid temperature protection is enabled. This latching diagnostic is set on a short or open. See Table 2 for Sensor Resistance Values.

Max Pumpout Rate Exceeded-SVC (Prg)

The pumpout rate timer exceeded the maximum pumpout rate setpoint while the service pumpout switch was in the service position. This is a latching diagnostic. When this diagnostic is cleared the pumpout rate timer will be reset to zero.

Max Pumpout Rate Exceeded (Prg)

The pumpout rate timer exceeded the maximum pumpout rate setpoint while the service pumpout switch was in the auto position (normal purge operation). This is a latching diagnostic. When this diagnostic is cleared the pumpout rate timer will be reset to zero.

Purge Liquid Level Too High

The liquid level sensor indicates liquid refrigerant is filling the primary purge tank. This is a latching diagnostic. Fault on open.

Purge: Loss of Comm With Chiller

Communications with the human interface (chiller module) have been lost for 15 consecutive seconds. This is a non-latching diagnostic.

Purge: Loss of Comm With Starter

Communications with the starter module have been lost for 15 consecutive seconds. This diagnostic is active for UCP2 applications only. This is a non-latching diagnostic. The diagnostic will be cleared when communications resume.

Purge: Loss of Comm With Stepper

Communications with the stepper module have been lost for 15 consecutive seconds. This diagnostic is active for UCP2 applications only. This is a non-latching diagnostic. The diagnostic will be cleared when communications resume.

Purge Memory Error III

A shadow RAM memory error was detected. This diagnostic is active for UCP2 applications only. No setup parameters were lost. This is an informational diagnostic only. Occurrence of this diagnostic should be an isolated event. If this diagnostic occurs repeatedly, the purge module should be replaced.

Purge Memory Error Type I: NOVRAM

A NOVRAM memory error was detected. This diagnostic is active for purge based display applications only. The purge module is operating on engineering ROM default setup parameters. Check all setup parameters and continue to operate purge. Replace the purge module at the first opportunity.

Purge Memory Error Type II: Shadow RAM

A Shadow RAM memory error was detected. This diagnostic is active for purge based display applications only. No setup parameters were lost. Compressor starts and hours were lost for not more than the last 24 hours. This is an informational diagnostic only. Occurrence of this diagnostic should be an isolated event. If this diagnostic occurs repeatedly, the purge module should be replaced.

Purge Memory Error Type III

A Shadow RAM error was detected. This diagnostic is active for purge based display applications only. Setup parameter changes made within the last 24 hours were lost. Check the operating parameters and update as required. Compressor starts and hours were lost for not more than the last 24 hours. This is an informational diagnostic only. Occurrence of this diagnostic should be an isolated event. If this diagnostic occurs repeatedly, the purge module should be replaced.

Restarting the Purge Following a Latching Diagnostic

All latching diagnostics force the purge to the STOP state. An alarm relay available for use by the operator is activated. The purge may only be restarted by clearing these latching diagnostics after appropriate corrective action has been taken.

Latching diagnostics are cleared by a command from the human interface in the "Diagnostics" area. See the illustration of the UCP2 Based Display on page 6.

If any active purge diagnostics are present, the following screen will appear at the end of the "Diagnostics" section below all active and historic diagnostic messages:

Press (Enter) to Clear Purge Diagnostics	Message to clear active purge diagnostics

Pressing "Enter" at this point will clear active purge diagnostics, and the following screen will be displayed for 4 seconds:

Purge Diagnostics Have Been Cleared Diagnostic Report is Being Reset	Message stating diagnostic reset has occurred

Following this display, the purge will restart automatically.

Note: Do not press "Enter" when the following screen is displayed:

Press (Enter) to Clr Active Diagnostics and Shutdown / Reset System	Chiller reset. **Do not use to clear purge diagnostics**

Pressing "Enter" at this point will shut down the chiller and reset all system operating parameters.

Continue to scroll down until the screen specifically intended to clear purge diagnostics is encountered.

Purge Based Human Interface

Purifier Purge units supplied as purge based display purges have a different human interface than UCP2 based display purges on Trane CenTraVac chillers.

UCP2 based display purges have access to the chiller main panel for input and report screen display. In general, purge based display purges will not have a compatible main panel display available. For this reason, purge based display purges are supplied with their own interface. The interface ships attached to the microprocessor panel as shown in Figure 4, but may be easily separated and mounted in any convenient location on or near the chiller.

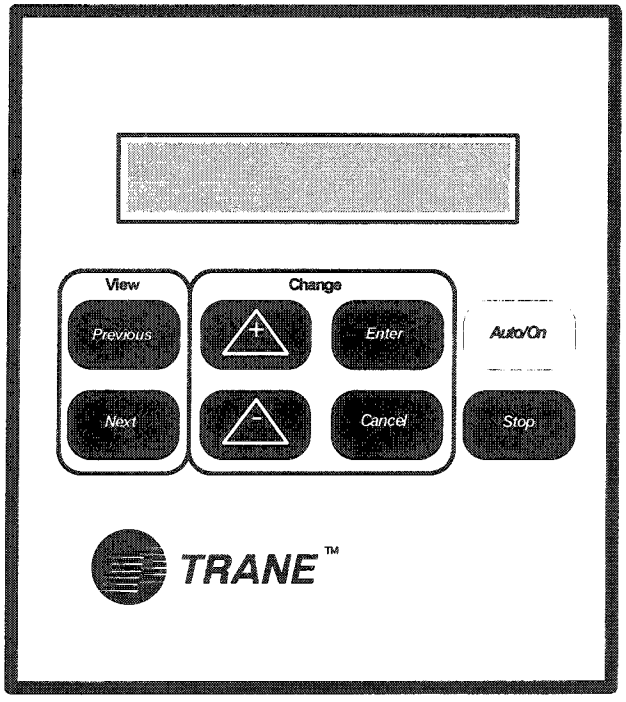
There are two primary differences between the UCP2 human interface and the purge based human interface:

1. Because of a smaller screen display area, the messages outlined in the preceding sections "Setup" and "Reports" are somewhat abbreviated for display on the purge based human interface.
2. Because the purge based human interface is a free-standing unit not linked to the main chiller panel, its function is wholly dedicated to control and operation of the purge. Since the screens do not form a subset of a larger group of screens, the menu structure is simpler and more direct.

The following sections explain the menu concept and slightly modified command set of the purge based human interface.

Display Overview

The purge based human interface contains 8 keys and a 2 x 16 character display on the front panel. A display backlight will illuminate when the display keys are pressed. The information displayed on the purge based human interface is constantly updated from the purge control module inside the purge control box.



The keys on the human interface are functionally grouped to start and stop the purge, "change" the purge setpoints, and "view" the contents of the purge menus.

- The "view" keys include the <Next> and <Previous> keys. These keys will display the next or previous menu entry.

- The "change" keys include a <+> and <-> key to change the operator setpoints in the SETTINGS report and an <Enter> and <Cancel> key to either accept or reject the changed setting.

- The <Stop> key is used to stop the purge. The <Auto/On> key is used to return the purge to an active state after the stop key is pressed. The <Auto/On> key will place the purge into the mode set up in the SETTINGS report for "Purge Control Mode".

Purge Based Display

Menu Overview

The purge based human interface uses a major menu structure with entry points into side menus (see the following chart entitled "Purge Based Human Interface Menu Structure"). The <NEXT>, <PREVIOUS> keys are used to navigate vertically through the menus. If the side menus are not accessed, only the major menu entries are displayed (those shown on the left column of the chart entitled "Purge Based Human Interface Menu Structure"). The side menus are accessed by pressing the <ENTER> key at the entry points into the side reports. Once a side menu is accessed, the <NEXT>, <PREVIOUS> keys are used to navigate vertically through the screens. The <NEXT>, <PREVIOUS> keys will return to the major menu loop once the side menu is exhausted.

A brief description is given in the chart for each menu entry. Additional explanation may be found in the referenced UCP2 human interface section.

Alarm Messages

If an alarm is active, an alarm message will display alternately with the alarm heading. The list of alarm messages that may be displayed for the purge based human interface are:

> Suction Temp Sensor Fail
> Liquid Temp Sensor Fail
> Liquid Level Too High
> NOVRAM Error 1
> NOVRAM Error 2
> NOVRAM Error 3
> Lost Communication
> Max Pumpout Rate Exceeded
> Max Pumpout Rate Exceeded - Service

A further explanation of these alarm diagnostics may be found in the "Diagnostics" section for the UCP2 human interface.

As indicated in the above referenced section, some diagnostics are latching, that is, they force the purge to the STOP state, and some are non-latching. Non-latching diagnostics are cleared when the fault causing the diagnostic is corrected. No reset is required, and purge operation resumes automatically. Latching diagnostics are cleared by pressing the <+> key after appropriate corrective action has been taken. The purge will then restart.

Status Messages

Valid status messages for the purge based human interface are:

> IDLE - Condensing unit is off
> RUNNING - Condensing unit is on
> PUMPOUT - Temperature initiated pumpout is active
> SVC-PUMP - Pumpout initiated by the service switch
> LOW TEMP - Pumpout inhibited by a low liquid temperature
> SVC-OVRD - Max pumpout rate alarm is disabled

A further explanation of the status displays may be found in the "Status of Operation" section for the UCP2 human interface.

Default Displays

After 20 minutes of inactivity a default screen is displayed. The default screen consists of either an alternating status display or an alternating alarm display if an alarm is currently active. The alternating status display consists of the Mode/Status screen and the Last 24 hour pumpout rate screen. The alarm display consists of an alarm screen and an alarm message. The backlight will flash when the alarm screen is displayed and an alarm is active.

Operating The Purge (Continued)
Purge Based Display

Purge Based Human Interface Menu Structure

Major Menu	Side Menus	Description/Ranges
Mode: ADAPTIVE Status: RUNNING		Purge operating mode [STOP, ON, AUTO, ADAPT] Purge Status See "STATUS MESSAGES"
Last 24 Hr Pump Rate: XXXX.X Min		Current purge pumpout rate for the last 24 hours
**** ALARM! **** Press + to Reset		Alarm status - Backlight will flash when in alarm (See "ALARM MESSAGES"
1 TEMP Report <Enter> to View		Entry point into the **TEMPERATURE** Report
	Prg SUCTION Temp = XXX.X F	Purge refrigerant compressor suction temperature
	Prg LIQUID Temp = XXX.X F	System refrigerant liquid temperature returned to the chiller from the purge
2 RUNTIME Report <Enter> to View		Entry point into the **RUNTIME** Report
	PUMP Time Last 24 hr=XXXX.X min	Current purge pumpout rate for the last 24 hours
	PUMP Time Total = XXXXX.X min	Log of total purge pumpout time since installation
	PURGE Run Time Ttl= XXXXX.X hrs	Log of total purge run time since installation
	ADAPT Cycle Time w/CHLR ON= XXhrs	Adaptive mode "off-interval" - for use when chiller is running (varies from 0 to 4 hrs).
	ADAPT Cycle Time w/CHLR OFF=xxxhr	Adaptive mode "off-interval" - for use when chiller is off (varies from 1 to 14 days, displayed in hours).
	Time until Purge Runs: =XXX.X hrs	Amount of time left on the adaptive cycle timer until the purge runs
	LOG <+> to Reset XXXXmin XXXXdays	Service log - accumulated pumpout time and calendar days since the log was last reset.
3 30 Day Report <Enter> to View		Entry point into the **30 DAY** Report
	Avg 30 Day Pump = XXXX.X min/day	Last 30 day pumpout activity - indicative of total chiller leak picture
	Avg 30 Day Chlr Run=XX.X hrs/day	Last 30 day chiller run activity
	Avg Pmp;CHLR RUN = XXXX.X min/day	Last 30 day pumpout activity while the chiller was running - indicative of chiller low side leakage
	Avg Pmp;CHLR OFF = XXXX.X min/day	Last 30 day pumpout activity while the chiller was off - indicative of low and high side leakage
	Avg Pmp;CHLR DWN =XXX.Xmin/Shtdwn	Pumpout activity during 3 hours after chiller shutdown - indicative of air storage during operation
4 SETTINGS Reprt <Enter> to View		Entry point into the **SETTINGS** Report
	Purge Control Mode = ADAPTIVE	Operator entry to select purge operational mode. Mode may be set to [ON, AUTO, ADAPTIVE]
	Max Pump Rate = XXX min/24 hr	Operator entry for 24 hour maximum pumpout. Range from 1 to 100 minutes, Default is 20 min.
	Disable Pump Alarm for XX hrs	Max pumpout rate override. Range is from 0 to 72 hours. Display will count down as time elapses.
	Low Liquid Temp Protect= DISABLE	Enable / disable for low liquid temp limit (next setpoint)
	Low Liquid Temp Limit = XX F	Pumpout is disabled when liquid temperature falls belo this setting (range is 32 to 50 F when enabled).
	Display Units = ENGLISH	Select units display "English" or "SI".
	Language Setting ENGLISH	Select language (entries are - English = Standard
	Prg Control/Type 01-Micropurge	01-Micropurge = standard

Operating the Purge

The basic purpose of the Purifier Purge is to remove non-condensibles from the chiller. The available ADAPTIVE mode allows this to be accomplished in the most efficient manner. The AUTO and ON modes are available to allow alternate operating modes better suited to certain applications and in chiller service environments.

The ability to monitor current and historical purge activity via the purge reports allows the operator to monitor chiller leakage, resulting in an effective means to protect the chiller's refrigerant charge.

Purge pumpout minutes are used to :

- Allow the operator to determine and set appropriate PURGE MAXIMUM PUMPOUT RATE setting
- Allow the ADAPTIVE mode to determine the most effective pumpout schedule for the individual chiller
- Determine if the chiller leak rate has increased

The microprocessor monitors the pumpout activity of the purge system and alerts the operator if an unexpectedly high level of activity is present by shutting down the purge via a diagnostic.

The pumpout timer is used to sense and accumulate pumpout time within a 24-hour sliding window. It does this by determining the length of each pumpout cycle and adding that time increment to an accumulation buffer. In order to accumulate time within the 24-hour constraint, the pumpout time measured 24 hours previously is erased from the buffer. When the accumulated time in the buffer exceeds the PURGE MAXIMUM PUMPOUT RATE setting as specified at the purge human interface, a purge latching fault is generated and the purge is disabled. The 24 hour buffer is cleared and the purge is allowed to resume operation after the operator clears the MAX PUMPOUT RATE EXCEEDED diagnostic. The PURGE MAXIMUM PUMPOUT RATE setting is selectable at the human interface. The selectable range is from 1 to 100 minutes per 24 hours. The factory setting is 20 minutes. Since individual chillers operate at differing temperature conditions, run schedules, and air-leak rates, the chiller operator may need to set a rate more appropriate for his particular system.

At initial startup, the operator should log the purge pumpout activity to develop a short history for his machine. After gathering this pumpout data, the operator should set a PURGE MAXIMUM PUMPOUT RATE that will protect the chiller from any sudden increases of pumpout activity but will not result in nuisance trips under what is normal pumpout activity for his machine.

Note: Be certain that any normal increases in pumpout activity due to extended chiller off cycles (normal duty rotation or week-ends) are taken into account.

The MAX PUMPOUT RATE EXCEEDED diagnostic may be disabled when known large quantities of air must be removed from the chiller (such as after major chiller servicing). The PURGE DISABLE PUMPOUT ALARM FOR XX HRS setting is programmable from the purge human interface. The disable interval may be selected from 1 to 72 hours. The remaining time for the disable mode may be determined by monitoring the human interface. The displayed interval will decrease as time elapses. The set point for the disable mode may be modified at any time by modifying the disable time and entering the new value.

Note: Since the purge has no fault protection in the disable alarm mode, it is recommended that this mode be used sparingly and only when the purge and controls are known to be operating properly.

Purge Start-Up

Before the Purifier Purge is operated for the first time, be sure to perform the following procedures:

If the purge unit is equiped with a replaceable filter drier core, perform the following steps, beginning with step 1. If the purge unit is equipped with a replaceable filter drier assembly begin with step 3.

1. Remove the cover from the filter-drier canister and install the two (2) filter-drier cores that shipped with the purge. Refer to "Filter-Drier Core Replacement" in "Service Procedures" section.

Note: The drier cores adsorb moisture from ambient air, so they are shipped in sealed containers. Keep the cores sealed prior to installation.

2. Replace the filter-drier canister cover, positioning the drain at the bottom of the canister and tighten the bolts evenly.

Note: Be sure all internal components are in the proper position when replacing the canister cover (See Figure 10).

3. Perform the "Purge Pumpout and Fault Check" as described in the "Service Procedures" section.

4. Open the purge tank isolation valves on the purge tank inlet and liquid return lines.

5. Program the purge control mode to AUTO or ADAPTIVE for normal operation.

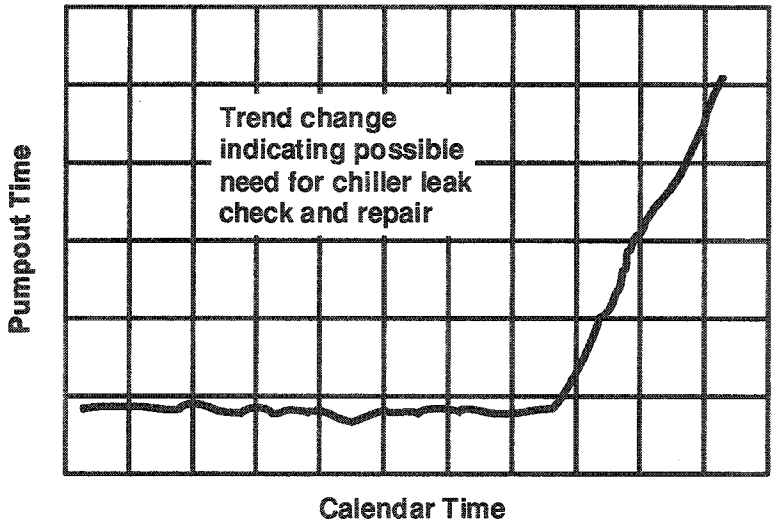
6. Check maximum pumpout rate setting. Factory setting is 20 minutes/24 hours. Adjust setting as needed later, based on purge system pumpout requirements.

7. If there is an excessive amount of air in the chiller:

a. Temporarily bypass the pumpout restrictor (see "Bypassing Pumpout Restrictor")

b. Program the PURGE DISABLE PUMPOUT ALARM for 24 hours.

Data Logging



One of the most valuable features of the microprocessor based purge is the ability to use stored purging data to monitor the condition of the chiller. It is strongly recommended that the operator maintain a log on a daily or weekly basis, recording at least the following data:

- Purge pumpout last 24 hours
- 30 Day purge pumpout average
- 30 Day purge pumpout average, chiller running
- Last 5 cycle pumpout average, interval from shutdown to three hours after shutdown
- 30 Day pumpout average, interval from three hours after shutdown to next start.

A sudden change in the trend of this data, which cannot be accounted for by a change in chiller operational patterns, may indicate the need for a chiller leak check and repair. See the example chart below.

A graphical data log will be easier to interpret than a tabular log.

PURGE DATA TREND

Purge System Overview

Introduction

A purge system is required on all low pressure centrifugal water chillers to remove air, moisture and other non-condensibles that may leak into the machine. The Purifier Purge system is designed to accomplish this task efficiently.

Trane centrifugal chillers utilizing low pressure refrigerants CFC-11, CFC-113 and HCFC-123 operate at less than atmospheric pressure. This is in contrast to the high pressure refrigerants CFC-12 and HCFC-22 which are used in refrigeration systems that operate above atmospheric pressure. Figure 2 compares the pressure/temperature relationship between low and high pressure refrigerants and indicates the temperatures at which chiller system pressures are negative with respect to atmosphere.

Figure 3 illustrates the low pressure areas of a typical Trane CenTraVac (model CVHE shown) when the unit is running. Air and moisture may leak into the machine through these low pressure areas. Once it enters the chiller, the air will accumulate in the condenser during machine operation. The air in the condenser increases condensing pressure, thereby reducing the chiller's efficiency and cooling capacity.

The Purifier Purge is a device mounted externally to the chiller. It consists basically of a tank, inlet and outlet valves, and a refrigeration system. The purge tank is connected to the chiller condenser by supply and return lines through which refrigerant may freely flow. The purge refrigeration system has its evaporator located inside this tank. The purge evaporator coil presents a cold condensing surface to the chiller refrigerant contained in the tank. When the purge is running, chiller condenser refrigerant is attracted to the cold surface of the purge evaporator. When the gaseous refrigerant contacts the surface of the purge evaporator it condenses into a liquid, leaving a partial vacuum behind. More condenser refrigerant vapor migrates to fill this vacuum. As the refrigerant condenses into a liquid, any non-condensibles present in the chiller are left behind to fill more and more of the space in the tank. The liquid refrigerant returns to the chiller condenser via the liquid return line. Increasing quantities of non-condensibles present in the purge tank reduce the heat transfer capability of the purge evaporator coil, and the purge compressor suction temperature decreases. This temperature is monitored to activate the pumpout compressor to remove the accumulated air. When enough air has been removed, the increasing purge refrigerant compressor suction temperature terminates the pumpout cycle.

The Purifier Purge will track the pumpout activity for a given machine as an indicator of air leakage into the chiller. This feature is provided to inform the machine operator of purge activity. The ability to monitor purge operation is an important feature of the Purifier Purge unit.

IMPORTANT: "Normal" average pumpout time for PRGB and PRGC model purges installed on typical CFC-11 or HCFC-123 chillers is approximately 15 minutes per day for a one week period. This value, however, will vary widely depending on chiller size, operating conditions, and operating schedule. The purge activity for each individual chiller should be carefully monitored for an appropriate period of time (one week or more) in order to establish a baseline value for PURGE MAXIMUM PUMPOUT RATE appropriate for that individual installation. The PURGE MAXIMUM PUMPOUT RATE should be set high enough to avoid nuisance trips, but low enough to trigger an alarm diagnostic should the pumpout rate suddenly increase. The "Troubleshooting" section and the chiller purge history should be carefully reviewed before a decision is made to shut down the chiller for leak testing and repair.

Purifier Purge Subsystems

From a functional standpoint, the purge system can be divided into four subsystems of components. There are:

- Heat Transfer Circuit
- Purge Tank
- Pumpout System
- Purge Control System

These four subsystems and their component parts are shown in Figure 4 and discussed in the following material.

Figure 2
Temperature/Pressure Relationship for Common Refrigerants

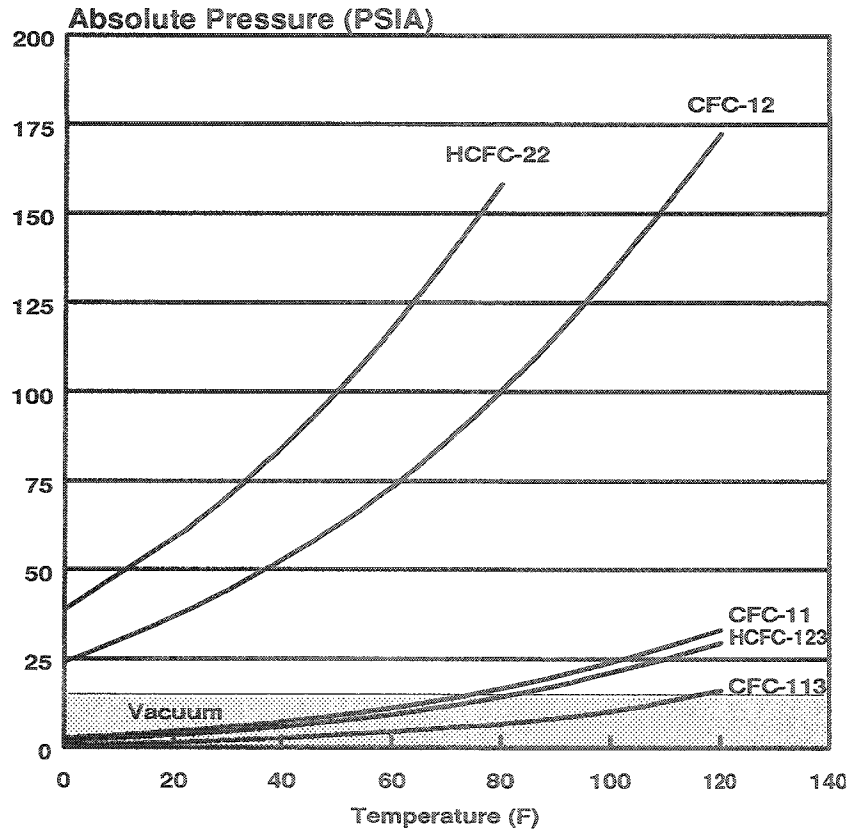


Figure 3
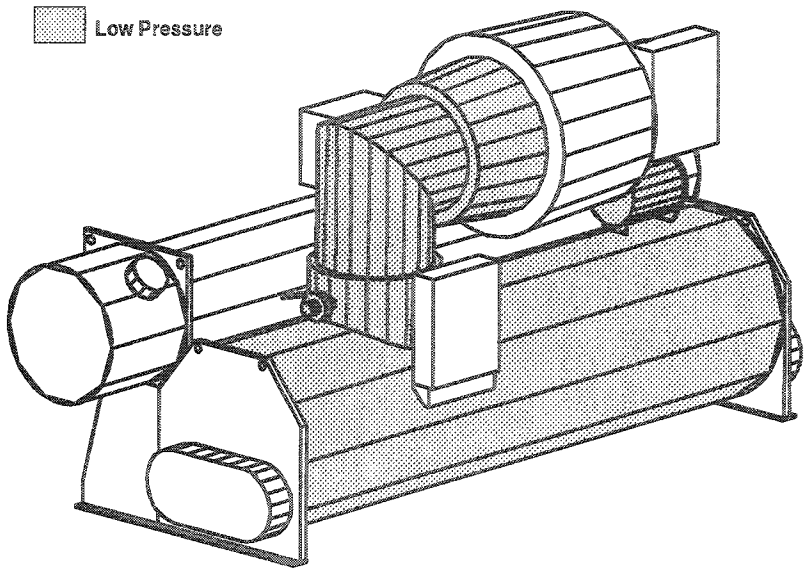
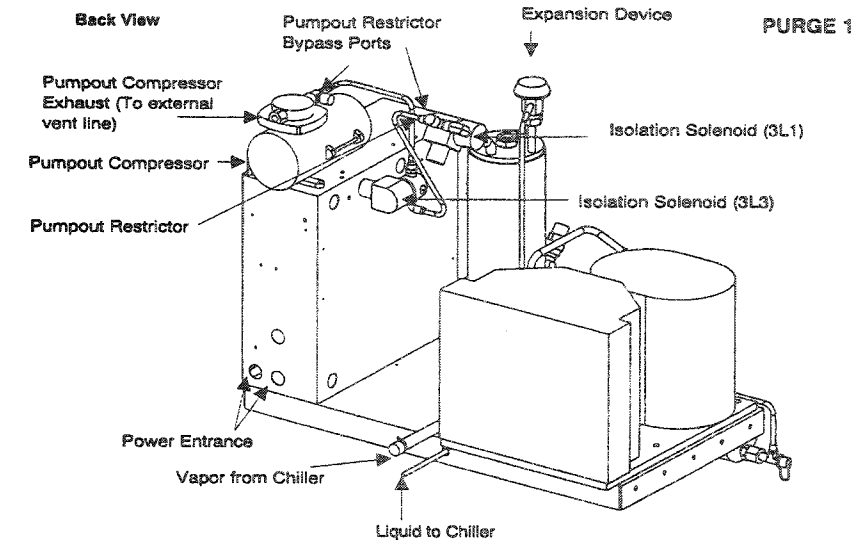
Low Pressure Areas of Operating CVHE Unit





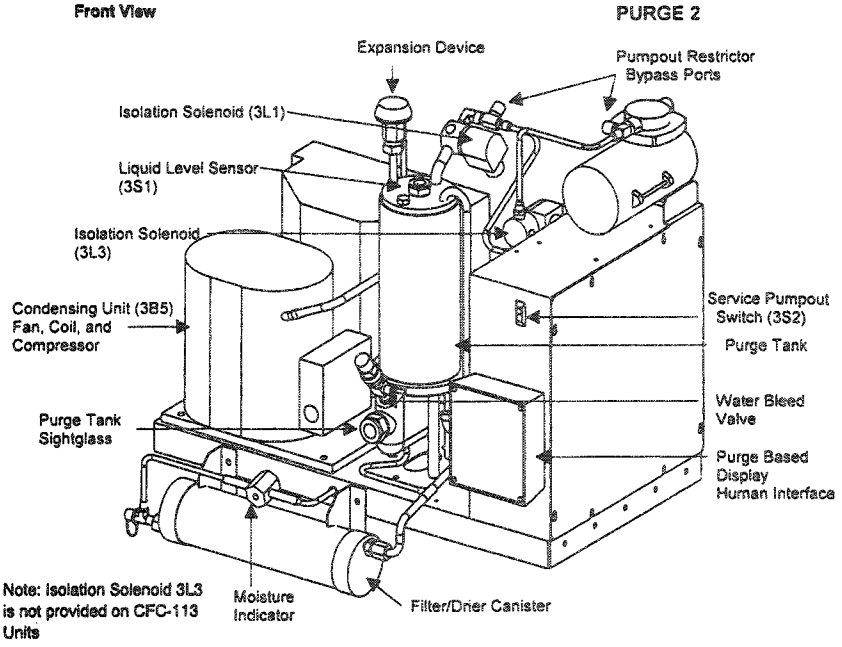


Figure 4 Purifier Purge Component Layout

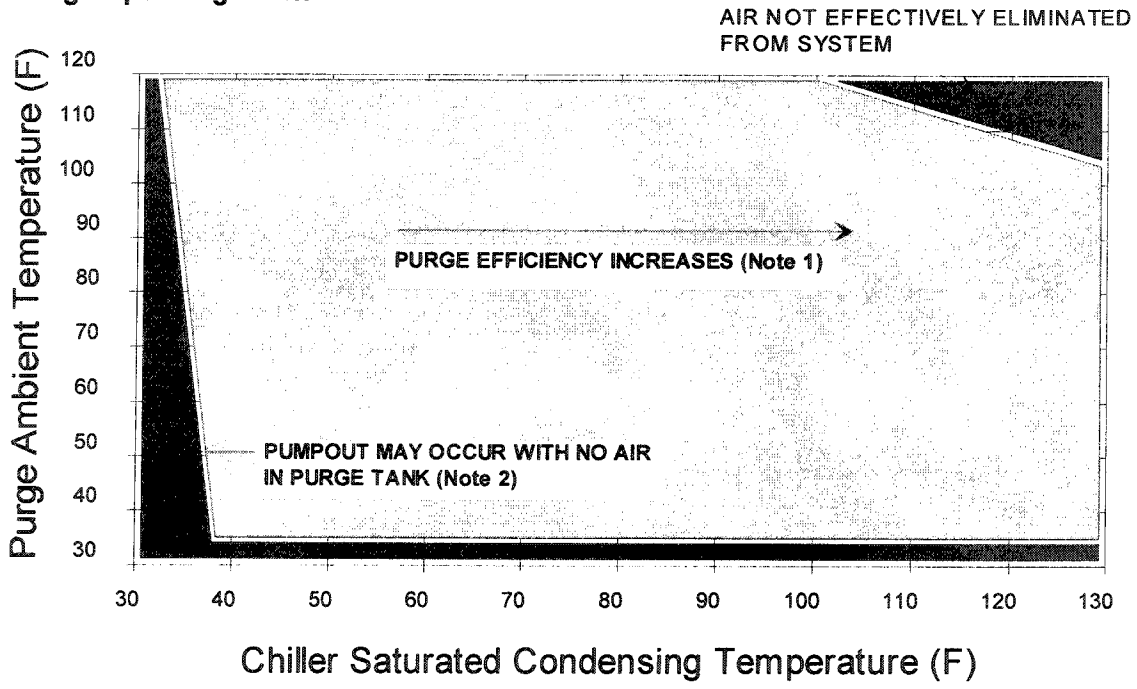
Heat Transfer Circuit

The portion of the purge that removes heat from the circulating purge refrigerant and transfers it to the atmosphere is the heat transfer circuit. This is an enclosed refrigerant circuit consisting of an air-cooled condensing unit (compressor, fan and condensing coil), an expansion device, and a coil in the purge tank (evaporator).

The air-cooled condensing unit provides cooling for the purge coil (3/8-inch copper tubing coil in the purge tank). In conjunction with the purge coil, it is the cooling source that draws the refrigerant from the chiller condenser for the separation of non-condensibles.

The coil in the purge tank acts as an evaporator from the standpoint of the heat transfer circuit, and as a condenser from the standpoint of the chiller refrigerant.

The condensing unit operates effectively over an ambient temperature range of 40°-120° F. As ambient temperature increases, condensing unit capacity decreases, reducing the rate at which the purge will remove air from the chiller (Figure 5).



Note: Because the Purifier Purge utilizes an air-cooled condenser, it is operable whether the chiller is running or not. No additional cooling source is required (e.g. water hookup).

IMPORTANT: No water connections are required to the Purifier Purge.

⚠ WARNING

HOT SURFACES
SURFACE TEMPERATURES MAY EXCEED 150 F ON CONDENSING UNIT
Contact of bare skin with hot surface may result in minor to severe burns.

Figure 5
Purifier Purge Operating Limits

Notes:
1. Lowest amount of refrigerant loss during pumpout.
2. Low Liquid Temperature Inhibit protects against operation under these conditions.

Purge Tank

The purge tank consists of a cooling coil, water separation tube, sight glass, connections for the refrigerant gas from the chiller condenser and a liquid refrigerant return line to the chiller condenser, and a water bleed valve and air discharge port. Air and water are separated from the refrigerant vapor and accumulated in the purge tank.

The purge tank is a condenser from the perspective of the chiller, but serves as a DX-type evaporator in the purge refrigerant circuit.

Heat is transferred out of the chiller vapor, condensing it, and is transferred into the colder refrigerant of the purge circuit, first evaporating and then superheating it.

Air within the tank decreases the effectiveness of this heat transfer, decreasing the exit superheat of the purge refrigeration circuit. When the superheat decreases to 18° F, enough air is deemed to be present to initiate a pumpout cycle.

The water separation tube assembly (Figure 7) serves as both a trap to prevent the "short circuiting" of chilled vapor through the purge tank, and as a means to separate excessive quantities of water which may be present. This trapped water may be removed via the water bleed valve in the sump. Dissolved water remaining in the liquid refrigerant is removed in the filter-drier.

Pumpout System

The pumpout system consists of a small pumpout compressor, two isolation solenoids, and a restriction device located at the pumpout compressor suction connection. When the purge control system detects the presence of air in the purge tank, the isolation solenoids are opened and the pumpout compressor is turned on. The compressor and a restriction device, shown in Figure 6, cause the purged air to be removed slowly. This slow air removal process enhances the efficiency of the purge system. The standard pumpout compressor is compatible with both CFC-11 and HCFC-123. An alternate pumpout compressor and restrictor are available for CFC-113 applications.

Note: Trane recommends using 3/8-inch copper tubing to connect the purge pumpout compressor exhaust to the chiller rupture disc vent line. If the optional Purifier Plus is installed, 3/8-inch copper tubing should be used to connect the purge pumpout compressor exhaust to the Purifier Plus, with 3/8-inch copper tubing from the Purifier Plus to the chiller rupture disc vent line.

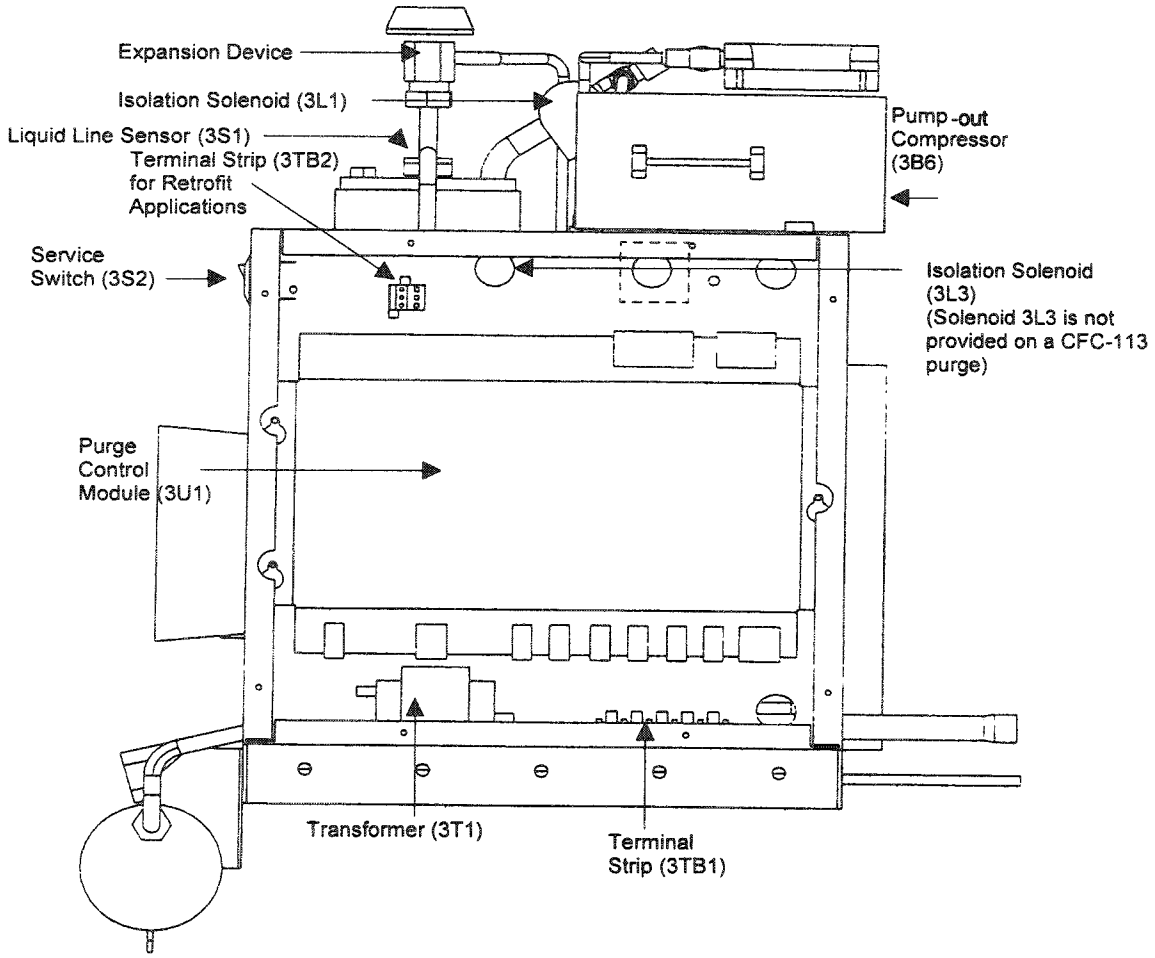
Purge Control System

The purge control system is comprised of a microprocessor control module mounted in the purge control box and a human interface. For purges operating with UCP2 controls, purge information is displayed on the UCP2 human interface. For purge based display installations, a separable purge display panel is provided. This purge based display human interface may be remotely mounted from the purge in any convenient operating location.

A service switch is mounted on the purge control box. This manual switch will start the pumpout system. All other control functions and data access are controlled through the purge human interface.

Purge operating controls located inside the purge control panel are:

- Microprocessor module
- Transformer
- Terminal strip



Purge operating controls not located inside the purge control panel are:

- Service switch 3S2 for manual operation of pumpout system
- Isolation solenoid valves 3L1 and 3L3
- Purge based display human interface
- Liquid level sensor 3S1
- Temperature sensors 3RT2

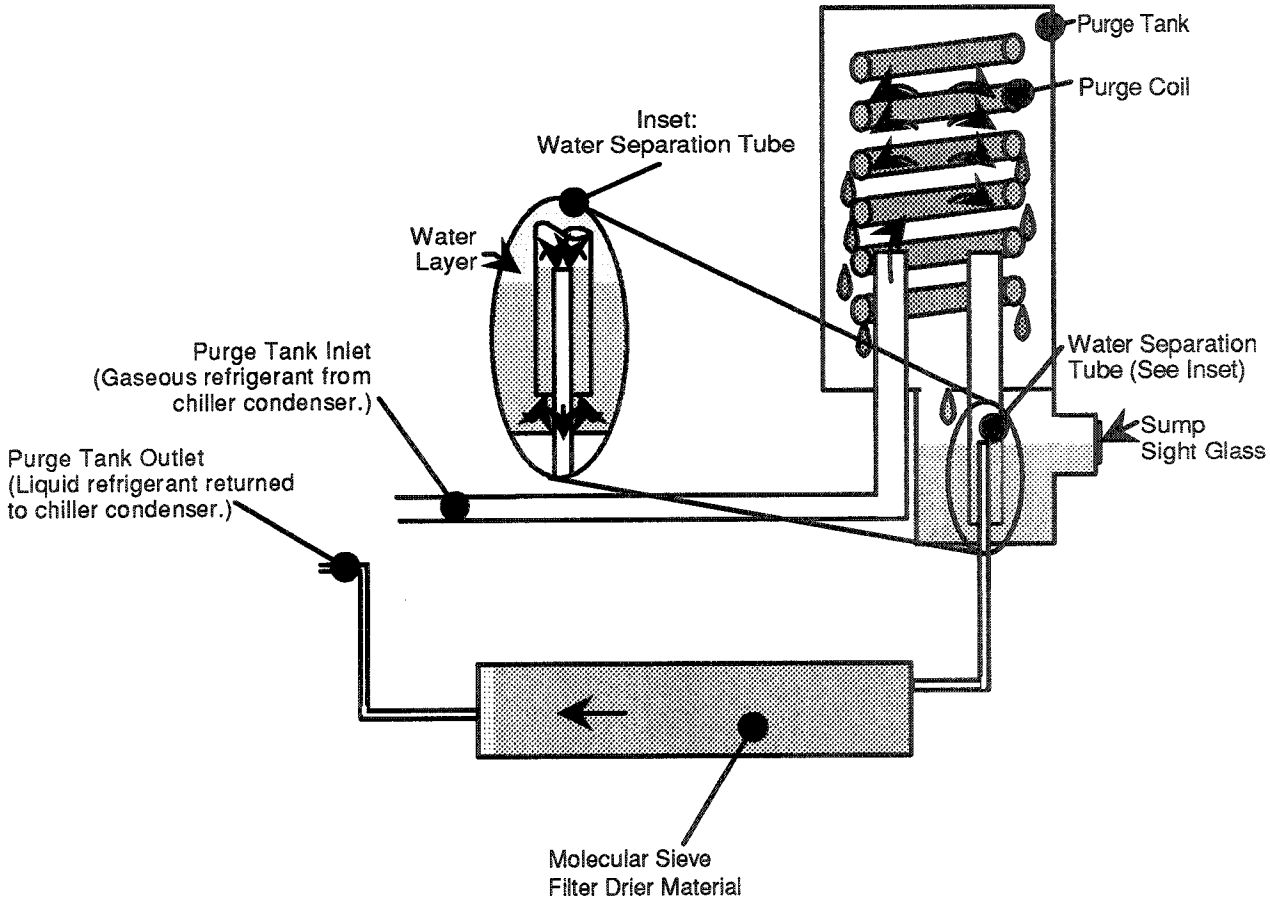
The location of these items is shown in Figures 4 and 6.

Note: Solenoid valve 3L3 is not used on CFC-113 Purifier Purge units.

Figure 6
Purifier Purge Control Box Layout

Operating Principles

General



The purge is active when the purge condensing unit is powered. The condensing unit is used to condense refrigerant vapor in the purge tank. The condensing refrigerant lowers the pressure in the tank, drawing vapor from the chiller condenser. The vapor carries non-condensibles and moisture into the purge tank.

Refrigerant vapor enters the purge tank through a 5/8-inch line connected at the bottom of the purge tank (Figure 7). Once inside the tank, the refrigerant vapor condenses on the purge tank coil and falls to the bottom of the tank. Non-condensibles accumulate in the purge tank only when there is air in the chiller condenser.

A layer of liquid refrigerant is maintained in the bottom of the purge tank during purge operation. The refrigerant liquid level is determined by the height of the liquid refrigerant standpipe in the purge tank. When the purge is running, the liquid level is visible in the purge sump sight glass.

Note: Free water in the purge sump is an uncommon occurrence. Liquid water is less dense than liquid refrigerant and will "float" on top of the liquid refrigerant. It may be seen during purge start-up, if major leaks occur, or if the filter drier is saturated.

Figure 7
Purge Tank Refrigerant Flow

Operating Cycle

The following discussion describes the Purifier Purge unit operating cycle at typical conditions (70 F ambient, 8 psig chiller condensing pressure). Figure 8 illustrates the cycle of the active purge (condensing unit compressor running). The conditions that should exist at points 1 through 5 in Figure 8 are:

- Point 1 = 0 F
- Point 2 = greater than 22 F
- Point 3 = 140 F
- Point 4 = 85 F
- Point 5 = 75 F

The purge condensing unit compressor suction temperature varies with the amount of air in the purge tank. When the amount of air present in the purge tank limits the available condensing surface in the tank, the condensing unit compressor suction temperature will fall. The purge module will initiate a pumpout cycle when the suction temperature reaches 18 F. The air in the purge tank is then vented from the purge tank. As air is removed from the purge tank, condensing unit compressor suction temperature increases to terminate the pumpout cycle.

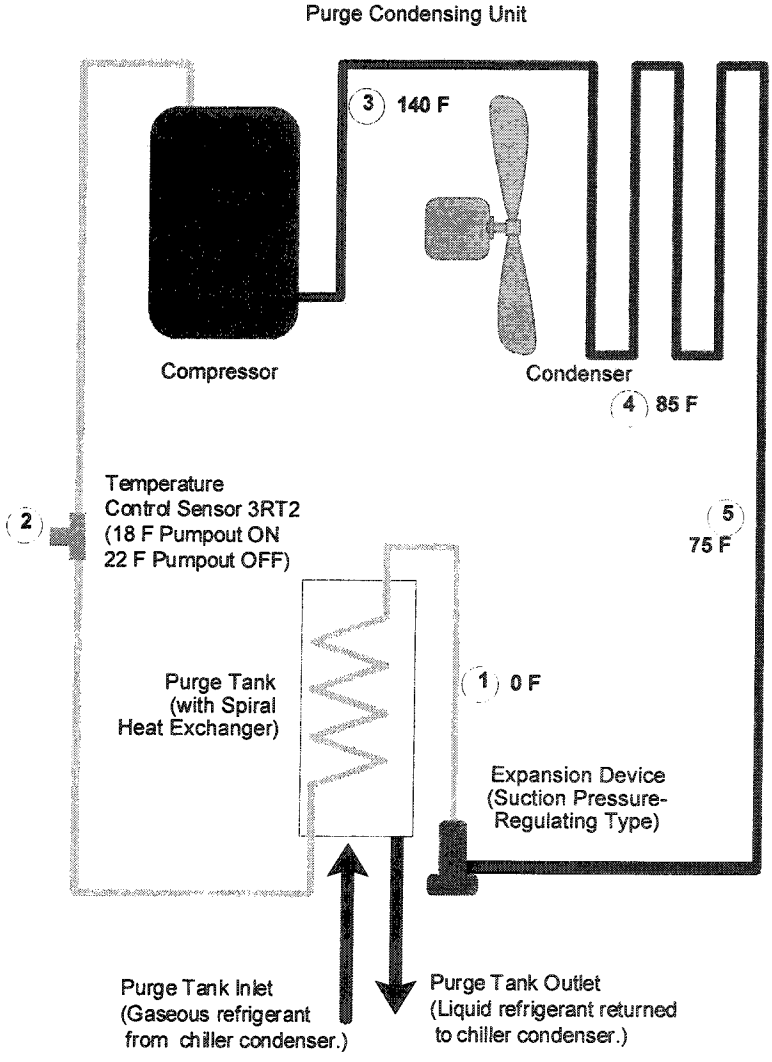


Figure 8
Purifier Purge Refrigerant Circuit Schematic

Operating Limits

Purge efficiency is dependent upon the chiller condenser pressure. Purge efficiency increases as the chiller condenser pressure increases. Figure 5 illustrates the purge operating limits and relative efficiency.

The Trane Purifier Purge can operate with a chiller saturated condensing temperature between 40 - 130 F (Figure 5).

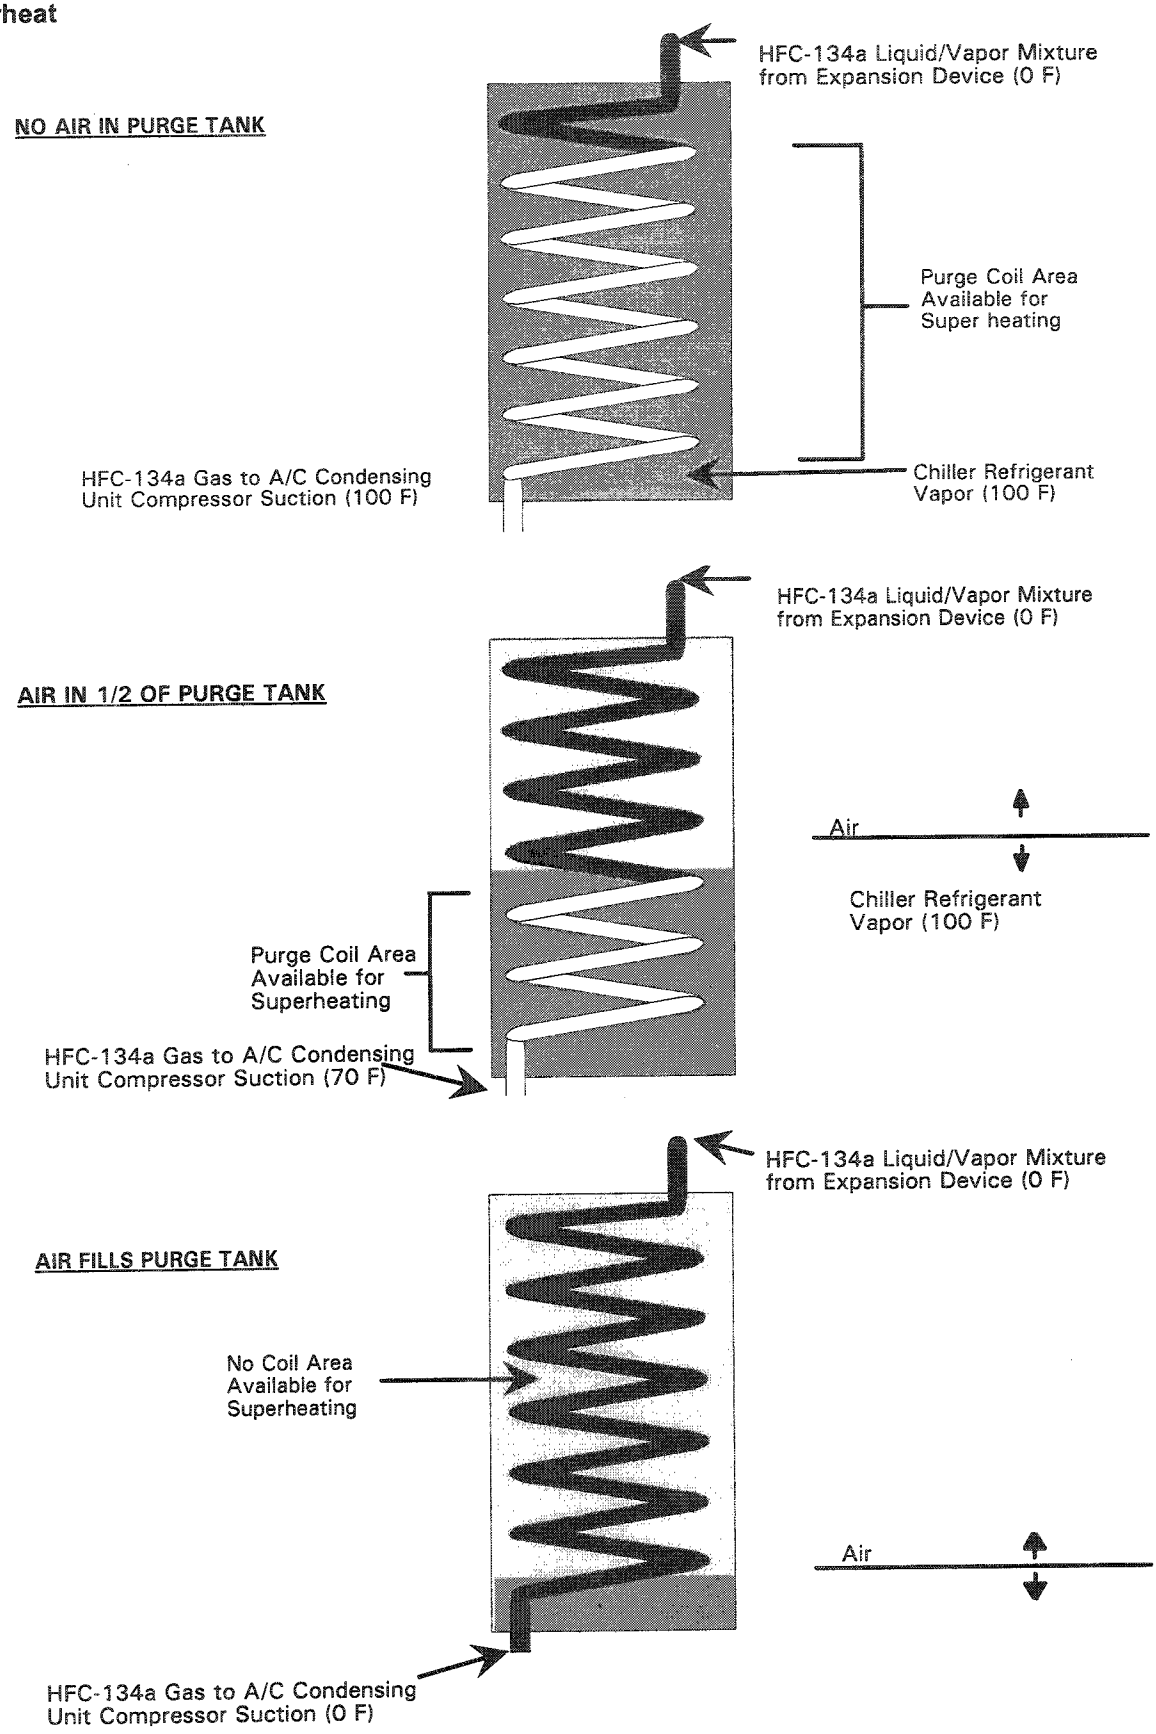
Higher saturation temperatures and corresponding higher chiller condensing pressures result in less refrigerant lost to the atmosphere when air is purged.

Lower saturation temperatures result in more refrigerant loss when air is purged, decreased suction superheat to the condensing unit compressor, and increased pressure ratio on the pumpout compressor.

In the AUTO mode, the purge will run whenever the chiller is running. Continuous purge operation (mode set to ON) is intended for use primarily during service procedures as described in "Maintenance". The ADAPTIVE operating mode will run the purge at various times when the chiller is both operational and off. The purpose of the ADAPTIVE control is:

- To limit how often the purge is run (to save energy)
- Run the purge during chiller shutdown to insure air is removed from the chiller
- Keep pumpout statistics to help diagnose chiller leak patterns.

IMPORTANT: Do not operate the purge when saturation temperatures are less than 40 F as seen when ice storage units are turned off or when a chiller is operating in free-cooling mode. The low liquid temperature setting provides automatic lockout based upon saturated condensing temperature.



Air Removal

Figure 9 illustrates the air removal cycle as air accumulates in the purge tank.

When there is no air in the purge tank, the refrigerant returning to the purge condensing unit compressor suction has a high superheat. As air accumulates in the tank, displacing the refrigerant vapor, the effective coil surface exposed to vapor decreases, reducing available superheat at the purge condensing unit compressor suction.

When condensing unit compressor suction temperature reaches 18 F, the purge control activates the isolation solenoids and the pumpout compressor to remove the accumulated non-condensibles. As air is removed from the purge tank, the coil is once again exposed to refrigerant vapor. The purge condensing unit compressor suction temperature rises and turns off the pumpout system. Pumpout cycle duration is typically 40 to 60 seconds.

Figure 9
Purge Tank Air Vs. Condensing Coil Superheat

Moisture Monitoring and Removal

A moisture indicator is provided in the liquid return line from the purge tank to the chiller condenser. This allows the machine operator to monitor the quality of the liquid refrigerant in the chiller.

Inspect the moisture indicator periodically. The indicator will show "wet" whenever the chiller moisture level exceeds the levels shown in Table 1. Notice that the indicator becomes more sensitive as the temperature decreases. (The moisture indicator normally operates at equipment room ambient temperatures.) A "wet" indication for more than 72 hours typically indicates that the filter drier is saturated and should be replaced.

Consult the moisture indicator only under these conditions:

1. The chiller is operating
2. The purge unit is operating and has been allowed sufficient time to remove system moisture properly (minimum of 72 hours after replacing filter-drier cores).

The filter drier dehydrates the refrigerant passing through the purge and prevents moisture from re-entering the chiller. The nominal life of the filter drier is one year and should be replaced once the cores become saturated, refer to the "Drier Core Replacement" and "Filter-Drier Assembly Replacement" sections of this manual. If the filter drier becomes saturated and the moisture indicator shows "wet" refrigerant, water will accumulate in the purge sump. Due to the small volume of the purge tank sump, free water will typically form a visible layer on top of the refrigerant and be visible in the purge tank sump sight glass. This free water must be removed to avoid corrosive conditions in both the purge and the chiller. To remove moisture from the purge sump refer to the "Service Procedures" section of this manual.

Table 1
Refrigerant Moisture Content As Determined By Moisture Indicator

Refrigerant	CFC-11			HCFC-123		
Moisture Level	75° F	100° F	125° F	75° F	100° F	125° F
Dry	Below 5	Below 10	Below 20	Below 20	Below 30	Below 35
Caution	5-15	10-30	20-50	20-50	30-80	35-100
Wet	Above 15	Above 30	Above 50	Above 50	Above 80	Above 100

Note: Refrigerant Moisture content given in parts per million (ppm)

Maintenance

Periodic Maintenance

The following information describes the maintenance requirements of the Purifier Purge. To assure efficient and reliable purge operation, perform all inspections and procedures at the prescribed intervals. Keep a record of all inspection results to establish proper service intervals and document changes that occur in purge activity that could reflect on chiller performance.

The following sections describe the required periodic maintenance:

- Weekly
- Semi-Annually
- Annually

⚠ WARNING
LIQUID OR VAPOROUS REFRIGERANT
CLOSELY FOLLOW ALL SAFETY PROCEDURES DESCRIBED IN THE MATERIAL SAFETY DATA SHEET FOR THE REFRIGERANT AND TO ALL LABELS ON REFRIGERANT CONTAINERS.
Failure to follow all safety procedures for refrigerant may expose operating and/or servicing personnel to liquid and/or vaporous refrigerant. Inhalation of, or skin exposure to refrigerant can cause injury or death.

⚠ WARNING
HAZARDOUS VOLTAGE!
NEVER OPEN ACCESS PANELS TO INSPECT OR SERVICE THE UNIT WITHOUT FIRST OPENING ALL DISCONNECT SWITCHES.
Failure to open all disconnect switches before inspection or servicing can cause injury or death due to electrical shock.

⚠ WARNING
HOT SURFACES
SURFACE TEMPERATURES MAY EXCEED 150 F ON CONDENSING UNIT.
Contact of bare skin with hot surface may result in minor to severe burns.

Weekly

1. With the purge unit operating, check the purge tank condensing activity by observing the liquid level in the sump sight glass. In addition, liquid refrigerant flow should be visible in the moisture indicating sight glass located in the liquid line immediately after the filter drier canister. The liquid refrigerant flow and level in the sump sight glass may vary.
A lack of refrigerant flow in the drain line sight glass indicates:

- a pumpout cycle is necessary, or,
- a problem exists with the purge heat transfer circuit (air-cooled condensing unit, expansion device or purge tank coil), or,
- a problem exists with the purge control circuit, or,
- refrigerant vapor from the chiller condenser to the purge tank is restricted.

2. Check the moisture indicator on the purge liquid return line. If moist refrigerant is indicated, replace the filter-drier. Refer to "Filter-Drier Replacement" in the "Service Procedures" section.

Note: The need for frequent change of the filter drier indicates the possibility of significant chiller tube or air leaks.

3. Check refrigerant in the purge tank sump for water. If water is present, there will be a visible line of separation between the water and the refrigerant in the tank. Remove any free water from the purge tank. (Refer to "Service Procedures" in this section).

Note: The need for removal of water indicates the possibility of significant chiller tube or air leaks

Semi-Annually

Inspect the air-cooled condenser coil and clean as needed. Clean the coil from the fan side using compressed air or coil cleaner. A fouled coil will reduce purge efficiency and capacity.

Annually

1. Perform the purge system control check described in "Control Circuit Test" in the "Troubleshooting" section.

2. Perform "Purge Tank Checkout and Water Removal" as described in the "Service Procedures" section of this manual.

Service Procedures

This section describes specific procedures that must be performed as part of the maintenance program of the purge system.

The following sections describe the required service procedures:

- Purge Tank Checkout and Water Removal
- Drier Core Replacement
- Filter Drier Assembly Replacement
- Purge Pumpout and Fault Check
- Purge Operation After Major Chiller Repairs
- Bypassing Pumpout Restrictor

Purge Tank Checkout and Water Removal

1. Isolate the purge by closing the valves on the purge vapor inlet and liquid return lines (between the chiller condenser and the purge tank).

2. With the purge condensing unit turned off, pressurize the purge tank through the water bleed valve located on the tank sump to a maximum of 15 psig and test the solenoid valves to insure they seal properly.

3. Check the purge tank sump sight glass for water.

If no water is visible, proceed to "Drier Core Replacement" or "Filter-Drier Assembly Replacement".

If a layer of water is visible on the refrigerant in the purge sump sight glass:

a. With the purge tank isolated from the chiller, pressurize the purge tank through the water bleed valve with dry air or nitrogen to a maximum of 15 psig. Close valve to contain pressure within purge. Disconnect nitrogen and connect a refrigerant hose from the angle valve to a suitable approved containment vessel. Open water bleed valve. The water and a small amount of refrigerant will flow into the containment tank.

⚠ WARNING

EXCESSIVE PRESSURE
DO NOT PRESSURIZE THE PURGE TANK IN EXCESS OF 15 PSIG.
Exceeding 15 psig can damage the unit and/or result in personal injury or death.

Note: An alternative to pressurizing the purge tank is to draw a vacuum on a suitable containment vessel and use the pressure differential to draw the water out of the sump.

b. Connect a suitable vacuum pump to the containment tank with the pump discharging back into the chiller or another suitable container. Pull a vacuum to 25 inches of mercury on the refrigerant and water mixture. The refrigerant will boil off, leaving only the water in the vessel.

Note: Do not pull a vacuum deeper than 25 inches of mercury as this will cause the water to also boil.

Drier Core Replacement

Following are maintenance instructions for **replaceable filter drier cores.**

Two high-water-capacity filter drier cores are inside the canister (Figure 10) located on the front of the purge unit. The following procedure should be followed when installing or changing the cores.

1. Isolate the purge unit from the chiller.

2. Drain the canister of liquid refrigerant prior to opening. Use available pressure differential whenever possible or use nitrogen to raise the pressure inside the purge to slightly higher than chiller condenser. Connect a refrigeration hose to the 1/4 in. schrader drain fitting (Figure 10) on the end of the canister and also to a service valve on the chiller evaporator. Open the chiller valve and drain the canister.

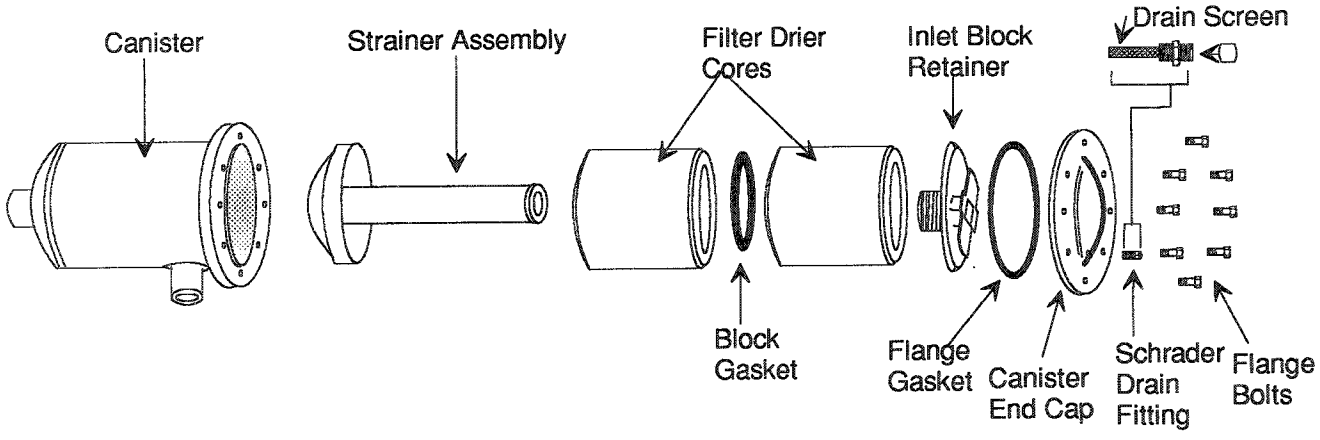
3. Remove the refrigerant vapor inside the canister by connecting the suction side of a vacuum pump to the schrader drain fitting and the pump discharge to the chiller. Pull a vacuum for approximately 30 minutes.

Note: Due to the slow out-gassing of refrigerant from the cores, it will not be possible to pull and hold a deep vacuum.

4. Remove the canister end cap (Figure 10) and remove the cores. Butyl gloves are recommended when handling cores because of direct contact with refrigerant. Immediately after removing the cores, they should be placed in a sealable container for storage and disposal in accordance with local regulations.

5. Clean the inside of the canister and the drain screen (Figure 10) as necessary.

6. Install new cores and gaskets making sure the canister cover is installed with the drain at the bottom.



Note: The drier-cores adsorb water vapor from ambient air, so they are shipped in sealed containers. Do not open them until immediately before they are installed and sealed in the canister.

7. Pressurize the purge with dry air or nitrogen to 10 psig through the water bleed valve and check for leaks. Release the pressure.

8. Set mode to ON and wait for the pumpout compressor to start.

9. Open the valves on the purge vapor tank inlet and liquid return lines at the chiller.

Figure 10
Filter-Drier Canister Assembly

Filter-Drier Assembly Replacement

Following are maintenance instructions for **filter drier assembly replacement**.

1. Isolate the purge unit from the chiller.

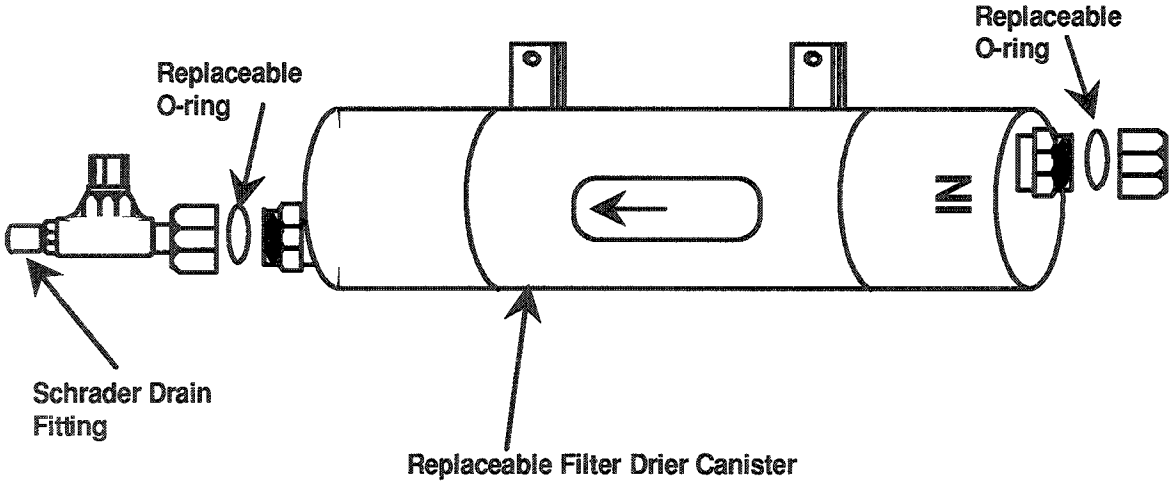
2. Drain the filter drier of liquid refrigerant prior to opening. Use available pressure differential whenever possible or use nitrogen to raise the pressure inside the purge to slightly higher than chiller condenser. Connect a refrigeration hose to the 1/4 in. schrader drain fitting (Figure 11) located at the outlet end of the filter drier and also to a service valve on the chiller evaporator. Open the chiller valve and drain the filter drier.

3. Remove the refrigerant vapor inside the filter drier by connecting the suction side of a vacuum pump to the schrader drain fitting and the pump discharge to the chiller. Pull a vacuum for approximately 30 minutes.

Note: Due to the slow out-gassing of refrigerant from the filter drier, it will not be possible to pull and hold a deep vacuum.

Note: The filter drier adsorbs water vapor from ambient air, so it is shipped with caps on each end. Do not remove these caps until immediately before installation.

4. Remove the screws connecting the filter drier brackets to the Purifier Purge base. Loosen the nuts at each end of the filter drier and slide it out from the adjacent tubing. Immediately cap the two ends with the caps from the replacement filter drier. Dispose of the old filter drier in accordance with local regulations.



5. Install new filter drier using new o-rings supplied with assembly.

6. Pressurize the purge with dry air or nitrogen to 10 psig through the water bleed valve and check for leaks. Release the pressure.

7. Set mode to ON and wait for the pumpout compressor to start.

8. Open the valves on the purge vapor tank inlet and liquid return lines at the chiller.

Figure 11
Filter-Drier

Purge Pumpout and Fault Check

This procedure tests the ability of the purge to remove non-condensibles from the chiller. This is done by isolating the purge from the chiller, adding air to the purge tank, and then using the purge pumpout compressor to remove the air again. Perform the following procedure to verify proper purge pumpout sequencing:

1. Close the shutoff valves on the purge tank inlet and liquid return lines to isolate the purge from the chiller.

2. Disconnect the 1/4-inch line from the inlet of the pumpout compressor.

3. Record current maximum pumpout rate setting, and temporarily change maximum pumpout rate to 2 min/24 hrs.

4. Temporarily shut off power to the purge and disconnect the liquid level sensor 3S1 from the microprocessor unit 3U1. Restore power and set operating mode to ON. The condensing unit should not start.

5. Temporarily shut off power to the purge and reconnect liquid level sensor 3S1 to 3U1. Restore power. The condensing unit should start.

6. Press and hold service switch 3S2 in the MOMENTARY ON position for at least ten seconds, energizing the pumpout solenoids and pumpout compressor. The purge will draw air into the purge tank back through the isolation solenoid valves. Repeat this procedure until sufficient air is drawn into the purge tank to reduce the compressor suction temperature to 18 F as indicated on the human interface. At this point the pumpout compressor should start and run.

7. Set operating mode to STOP. Reconnect the 1/4-inch line at the inlet of the pump-out compressor and tighten to 5-7 ft-lbf. Open the shutoff valves on the purge tank inlet and liquid return lines.

8. Set operating mode to ON. Monitor compressor suction temperature. The pumpout compressor should stop when the compressor suction temperature reaches 22 F.

9. Continue to monitor pumpout time. When the total pumpout time reaches 2 minutes, the unit should display a MAX PUMPOUT RATE EXCEEDED diagnostic and stop.

10. Restore the maximum pumpout rate setting to its original value and reset the MAX PUMPOUT RATE EXCEEDED diagnostic. Set the operating mode to the desired value.

Purge Operation After Major Chiller Repairs

This section describes specific procedures that must be performed when the chiller refrigerant system has been opened to atmosphere.

In those situations where air has entered the chiller during servicing, it will have to be removed before the chiller can be started. The purge will do this in two stages; the "continuous-operation" stage and the "intermittent-operation" stage.

Go to the setup menu and set the PURGE DISABLE PUMPOUT ALARM FOR XX HRS to an appropriate value (programmable from 1 to 72 hours in 1 hour increments). Typically, 24 hours is sufficient.

This mode will allow the purge to pump-out for extended periods of time without signaling a diagnostic for excessive pump-out time. The PURGE DISABLE PUMPOUT ALARM FOR XX HRS mode will automatically de-energize after the selected time period.

The restrictor present in the pumpout circuit may be bypassed to decrease required pumpout time. It is recommended that this be done during initial startup of the purge or chiller and whenever a service procedure may have resulted in excessive air in the unit. Refer to "Bypassing Pumpout Restrictor" in this section.

When large amounts of non-condensibles are present in the chiller, purging efficiency can be enhanced by increasing refrigerant pressure in the purge tank. This can be done by operating the chiller as soon as practical or by circulating warm water (less than 100 F) through the chiller evaporator tube bundle. The amount of time that the purge pumpout compressor operates continuously will vary, depending on the initial pressure level and the quantity of non-condensibles in the chiller. Initially, the pumpout compressor operates continuously due to the large amount of non-condensibles and relatively small amount of refrigerant being drawn into the purge tank. It may be several hours before the pumpout compressor cycles off for the first time.

Excessive continuous pumpout may be caused by:

- Large amounts of non-condensibles in the chiller
- Leaks in the tubing between the purge tank and the pumpout compressor. Leak check tubing and bypass restrictor to remove excess air.

Once the level of non-condensibles present in the chiller falls to a point where increasing amounts of refrigerant are entering the purge tank, the temperature control in the purge control system will begin to cycle the pumpout compressor on and off. As the refrigerant in the system becomes less contaminated with non-condensibles, purge pumpout is activated less frequently.

If the chiller is suspected to contain excessive amounts of moisture, several filter-drier cores or filter-drier assemblies may be required to completely remove the moisture.

Bypassing Pumpout Restrictor

The pumpout restrictor may be bypassed to accelerate non-condensible removal. However, this is a manual operation that will reduce the air separation efficiency of the purge. To bypass the restriction device:

Remove the caps on the two pumpout restrictor bypass ports shown in Figures 4 and 6 and temporarily connect a bypass hose.

Note: This should be done for only a short period since bypassing the pumpout restrictor reduces purge separation efficiency. Ensure that the caps on the bypass ports are reinstalled tight and leak free before returning purge to normal operation.

Troubleshooting

Troubleshooting Procedures

If operational difficulties are encountered, use the diagnostic chart and checkout procedures to determine the cause and correct the problem.

The following sections provide troubleshooting resources:

- Troubleshooting Chart
- Refrigerant System Diagnostic Procedure
- Control Circuit Test

⚠ WARNING

LIQUID OR VAPOROUS REFRIGERANT
CLOSELY FOLLOW ALL SAFETY PROCEDURES DESCRIBED IN THE MATERIAL SAFETY DATA SHEET FOR THE REFRIGERANT AND TO ALL LABELS ON REFRIGERANT CONTAINERS.
Failure to follow all safety procedures for refrigerant may expose operating and/or servicing personnel to liquid and/or vaporous refrigerant. Inhalation of, or skin exposure to refrigerant can cause injury or death.

⚠ WARNING

HAZARDOUS VOLTAGE!
NEVER OPEN ACCESS PANELS TO INSPECT OR SERVICE THE UNIT WITHOUT FIRST OPENING ALL DISCONNECT SWITCHES.
Failure to open all disconnect switches before inspection or servicing can cause injury or death due to electrical shock.

⚠ WARNING

HOT SURFACES
SURFACE TEMPERATURES MAY EXCEED 150 F ON CONDENSING UNIT.
Contact of bare skin with hot surface may result in minor to severe burns.

Troubleshooting Chart

The chart that follows is provided to help identify malfunctions that could occur. The chart has three columns:

- the Symptom column describes what the unit is doing
- the Cause column identifies possible sources of the problem
- the Solution column describes what must be done to correct the problem

Symptom	Cause	Solution
Purge diagnostic MAX PUMPOUT RATE EXCEEDED, purge not running, condensing unit iDLE (pumpout operates too long)	Air Infiltration rate into chiller too high. Excessive purging required	Leak-check chiller. Repair Leaks
	Maximum pumpout rate set too low	Determine proper value for chiller and reset. See "Setup"
	Leakage in purge interconnecting pumpout tubing	Check flare nuts for tightness. Tighten to 5-7 ft-lbf. Leak-test and repair tubing
	Chiller refrigerant temperature too low (pumpout below 40 F saturation temperature is not effective)	Do not operate purge unit at or below 40 F saturated refrigerant temperature. Set the low liquid temp inhibit to ENABLE and program setpoint to a higher value
	Isolation solenoids 3L1 or 3L3 fail to open or are restricted. Air is not removed	Repair or replace solenoid coils or valves
	Isolation solenoids 3L1, 3L3 both fail to close and chiller is at a low temperature (air leaks into chiller)	Repair or replace solenoid coils or valves
	Purge isolation valves closed	Open isolation valves
Purge fails to pump out non-condensibles. Running chiller indicates high head pressure i.e., measured condenser pressure is greater than refrigerant saturation pressure corresponding to measured condenser refrigerant temperature and/or chiller surges at start up	Depending on the chiller type and operating conditions, air may accumulate in the chiller condenser away from the purge gas pick-up location	Operate purge with chiller OFF. Any air in chiller will be removed if purge is functioning properly. If a large amount of air is removed, leak-test chiller and repair leaks. Consider using ADAPTIVE mode. This mode will run the purge as required when the chiller is OFF. If non-condensible removal is required during chiller operation refer to "chiller gas/liquid connections"
	Pumpout restrictor clogged	Operate purge with pumpout restrictor bypassed (refer to "Bypassing Pumpout Restrictor"). Clean out restrictor orifice with compressed air (preferred) or a small wire.
	Purge condensing unit is overcharged or undercharged	Refer to "Refrigeration System Diagnostic Procedure" to evaluate purge charge level
	Purge expansion valve has failed	Refer to "Refrigeration System Diagnostic Procedure" to evaluate expansion valve performance
	Pumpout circuit fault	Run diagnostic of purge control circuit. Refer to "Control Circuit Test"
	Condenser fan has failed	Replace fan as indicated
	Condensing unit compressor motor winding temperature sensor opened (may go out on high winding temperature)	Replace temperature sensor or compressor as indicated

Troubleshooting (Continued)

Symptom	Cause	Solution
Purge unit does not run or pumpout system does not run	Control circuit problem	Run diagnostic of purge control circuit. Refer to "Control Circuit Test"
Purge continues to operate when chiller is OFF	Purge in ON or ADAPTIVE mode	ON mode should be used only for certain service procedures. ADAPTIVE is a normal operating mode
	Purge mode in the AUTO setting and the chiller RUN signal failed at high voltage	Check chiller RUN signal
Pumpout compressor operates continuously: Suction temperature is less than 18° F	Excessive air in chiller	Temporarily bypass pumpout restrictor to increase rate of non-condensible removal (refer to "Bypassing Pumpout Restrictor")
	Leakage in purge pumpout tubing	Check all connections between purge tank and pumpout compressor for leaks and repair. Tighten flare nuts to 5-7 ft-lbf.
	Pumpout restrictor plugged	Operate purge with pumpout restrictor bypassed (refer to "Bypassing Pumpout Restrictor"). Clean out restrictor orifice with compressed air (preferred) or a small wire.
	Purge sump sight glass leaking	Replace sight galss, apply hand tool removable Loctite to male threads and torque sight glass to 23-25 ft. lbf.
	Gas pick up connection below liquid level	Refer to "chiller gas/liquid connections"
	Gas pick up line restricted	Ensure shut off valves are fully open and remove any restrictions
	Restriction in exhaust lines	a. Disconnect tubing at pumpout compressor discharge port and clean out tubing with compressor air b. Ensure there are no liquid traps in these lines
Pumpout compressor operates continuously: Suction temperature is greater than 18° F	Suction temperature sensor has failed	Replace as required
	Purge control module has failed	Replace as required
Diagnostic PURGE LIQUID LEVEL TOO HIGH	Liquid accumulation in the 5/8" inlet gas line will cause excessive pressure drop, resulting in high liquid level in the purge tank	a. Ensure 5/8" gas line slopes toward chiller for the entire distance to condenser (1"/ft min). b. Insulate 5/8" gas line if needed. c. If problem persists, contact qualified Trane service representative
	Purge liquid drain line restricted	Remove restrictions from drain line
No refrigerant in purge tank sight glass	Liquid refrigerant may evaporate and migrate back into the chiller with the purge off	Liquid should appear within 10 minutes of continuous purge operation

Symptom	Cause	Solution
Refrigerant level rises above purge tank sight glass	Restriction in the purge inlet gas line or liquid return line	a. Check for restrictions in the 5/8" purge tank inlet line and in the 1/4" liquid return line. b. Ensure that shutoff valves for these lines are fully open. c. Ensure that there are no liquid traps in these lines d. Insulate the inlet gas line
	Liquid drain line restricted	a. Open all valves and remove any restrictions b. Ensure filter drier is not plugged
Free water visible in purge tank sight glass	Filter drier may be saturated with water	Refer to "Purge Tank Checkout and Water Removal". Drain water manually or monitor the moisture indicator. If the condition persists, replace the filter-drier. Refer to "Drier Core Replacement" or "Filter Drier Assembly Replacement". **Note:** Multiple changes of filter drier may indicate need for chiller leak testing and/or additional moisture removal systems. Refer to CTV-SB-63A for suggested alternative in-line refrigerant cleaning systems.
Purge based human interface displays: Mode: ON Status: IDLE	Jumper J6 missing on communication block J1 of module (see wiring diagram, Figure 13)	Install Jumper

Refrigeration System Diagnostic Procedure

If there is concern that one of the components in the purge refrigeration system is not operating correctly, troubleshoot the system by taking surface temperature measurements.

⚠ CAUTION

REFRIGERANT LOSS

TO AVOID REFRIGERANT CHARGE LOSS DO NOT ATTEMPT TO MEASURE PURGE SYSTEM DISCHARGE OR LIQUID LINE PRESSURE.

⚠ WARNING

HOT SURFACES

SURFACE TEMPERATURES MAY EXCEED 150 F ON CONDENSING UNIT.

Contact of bare skin with hot surface may result in minor to severe burns.

The critical temperature measurements needed to diagnose the system properly are shown on the figure below. The temperature at Point 1 may be obtained by moving aside a small portion of the insulation covering the tubing. The condensing unit suction temperature, Point 2, is a part of the purge control system and may be read directly from the purge human interface. The condenser temperature, Point 4, may be measured by reading the surface temperature of the second or third condenser tubing U-bend from the top on the side of the coil opposite the discharge gas inlet.

Note: Use an accurate (±1 F) temperature probe with a range of -10 F to 200 F to take temperature readings. Fasten the sensor of the probe tightly against the tubing surface. Insulate around the probe for accurate results.

The following sections describe diagnostic procedures for these elements of the refrigeration system:

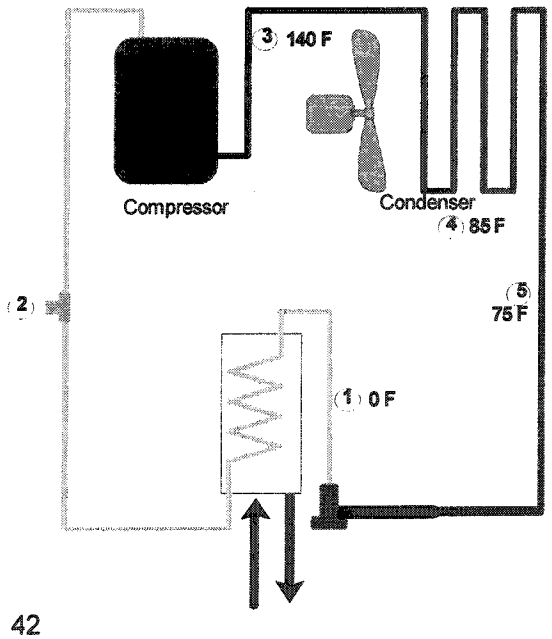
- Charge Level
- Expansion Valve

Charge Level

The purge refrigeration system must have a proper HFC-134a charge before any other refrigerant circuit components may be evaluated.

Suction pressure is not a good indicator of proper charge. The best method to determine charge level is to measure surface temperature at various points on the refrigerant circuit. These points are shown on the figure below.

With the purge condensing unit running, take temperature measurements at Points 4 and 5. The difference between these two values is the subcooling. This value should be between 5 and 15 F with the proper refrigerant charge in the system.



- A subcooling value of less than 5 F indicates a refrigerant undercharge and a probable leak
- A subcooling value greater than 15 F indicates a refrigerant overcharge

Expansion Valve

With the purge condensing unit operating, the expansion device will reliably regulate the low side of the purge refrigerant system, even with a relatively wide range of variation in refrigerant charge.

The purpose of the expansion valve is to regulate refrigerant flow to maintain a constant pressure within the purge tank coil. To determine if the expansion valve is operating properly, measure temperature at Point 1 on the figure below. An optimum constant temperature of 0 F should be measured at this point. However, depending upon operating conditions and or measurement error a measurement between -5 F and 10 F is acceptable.

Critical Temperature Measurement Locations

Chiller Gas/Liquid Connections

Gas/Liquid connections must be properly located on the chiller condenser to ensure correct purge operation.

During chiller operation air will accumulate in the coldest, calmest spot in the condenser above the liquid level. This location is typically just under half-way up the condenser shell above the condenser sump.

During Chiller OFF cycles air may rise to higher elevations within the chiller. However, with the purge operating a continuous thermal syphon exists which will draw non-condensibles into the purge tank.

In addition to the correct pick-up location the lines must be sloped a minimum of 2 inches per foot off horizontal or vertical to ensure no liquid or vapor traps exist.

Control Circuit Test

The incorporation of a microprocessor into the purge control system integrates many functions and eliminates most of the electro-mechanical control elements found in earlier purges. It is therefore difficult to test components and functions in isolation.

This procedure uses an approach of stepping through a thorough test of the entire control system, allowing evaluation of individual components and functions along the way. Problems noted at any point will indicate required service.

Refer to Figures 11 and 12 in the "Electrical System" section.

⚠ WARNING

LIQUID OR VAPOROUS REFRIGERANT
CLOSELY FOLLOW ALL SAFETY PROCEDURES DESCRIBED IN THE MATERIAL SAFETY DATA SHEET FOR THE REFRIGERANT AND TO ALL LABELS ON REFRIGERANT CONTAINERS.
Failure to follow all safety procedures for refrigerant may expose operating and/or servicing personnel to liquid and/or vaporous refrigerant. Inhalation of, or skin exposure to refrigerant can cause injury or death.

⚠ WARNING

HAZARDOUS VOLTAGE!
USE EXTREME CAUTION WHEN SERVICING UNIT WITH CIRCUITS ENERGIZED.
Failure to use caution when working on the unit with circuits energized can cause injury or death due to electrical shock.

Test procedure:

1. Record current maximum pumpout rate setting, and temporarily change maximum pumpout rate to 2 min/24 hrs.

2. Turn the chiller OFF and remove the purge power fuse located in the chiller control panel.

3. Each time purge power is removed in this test procedure, confirm that there is no power between 3TB1-1 and 3TB1-3.

4. Remove power from J16, 1-3. This will disable the external alarm relay circuit, if used.

5. For purge based display purges, disconnect and isolate the RUN signal lead that connects the chiller control panel to J26, 1-2.

6. Close the shutoff valves on the purge tank inlet and liquid return lines to isolate the purge tank from the chiller.

7. Disconnect the 1/4-inch copper line between the pumpout compressor 3B6 and isolation solenoid valve 3L3.

8. Disconnect the float switch 3S1 from P3B, 5-6.

9. Restore power to the purge and set operating mode to ON. The purge unit should not start.

10. Remove power from the purge and reconnect float switch 3S1 to P3B, 5-6.

11. Restore power to the purge. The purge unit should start.

Note: Successful completion of these steps verifies function of:
- float switch circuit
- microprocessor
- condensing unit

12. Press and hold service switch 3S2 in MOMENTARY ON position for approximately 10 seconds. Isolation solenoids 3L1 and 3L3 should energize, and pumpout compressor 3B6 should start. Air will be drawn into the purge tank through the open isolation valve 3L3 outlet.

13. Release service switch 3S2. It should return to OFF position. Isolation solenoids 3L1 and 3L3 should de-energize, and pumpout compressor 3B6 should stop.

Note: Successful completion of these steps verifies function of:
- service switch 3S2
- isolation solenoids 3L1, 3L3
- pumpout compressor 3B6

14. Repeat Steps 12 and 13 until sufficient air is drawn into the purge tank to reduce the compressor suction temperature to 18 F. At this point, the isolation solenoids 3L1 and 3L3 should energize and pumpout compressor 3B6 should start.

15. Set operating mode to STOP. Reconnect the 1/4-inch copper line between the pumpout compressor 3B6 and isolation solenoid valve 3L3 and tighten to 5-7 ft-lbf. Open the shutoff valves on the purge tank inlet and liquid return lines.

16. Set operating mode to ON. Pumpout compressor 3B6 should start. Monitor compressor suction temperature. The pumpout compressor should stop when the compressor suction temperature reaches 22 F.

Note: Successful completion of these steps verifies function of:
- microprocessor
- refrigeration compressor suction temperature sensor
- pumpout control circuit

17. Continue to monitor pumpout time. When the total pumpout time reaches 2 minutes, the unit should display a MAX PUMPOUT RATE EXCEEDED diagnostic and stop. It may be desirable to use the service switch 3S2 to hasten the accumulation of sufficient pumpout time to check this diagnostic and confirm remote fault indication relay closure at J16, 1-3.

Note: Successful completion of this step verifies function of:
- microprocessor
- remote fault relay indication

18. Restore the maximum pumpout rate setting to its original value and reset the MAX PUMPOUT RATE EXCEEDED diagnostic. Verify the remote fault indication relay has de-energized

19. For purge based display purges, complete the following steps:

a. Remove power from the purge.
b. Bring a 115 VAC power source with a momentary on switch to the RUN signal input J26, 1-2.
c. Restore power to the purge and set operating mode to AUTO. Purge should not start.
d. Press the momentary ON switch, supplying a simulated chiller RUN signal. The purge should start. Repeat several times.
e. Remove power from the purge and remove simulated RUN signal power source.

Note: Successful completion of these steps verifies function of:
- microprocessor
- run signal input

20. Remove power from the purge.

21. Enable the external alarm relay circuit, if used.

22. Check all flare connections for tightness on the 1/4-inch copper lines, between the pump-out compressor (3B6) and isolation solenoid valve 3L1. Correct tightness is 5-7 ft-lbf.

23. Restore power to the purge. Check to be sure all settings have been restored to their original values and all diagnostics generated by this test procedure have been reset.

24. For UCP2 based display purges, set the mode to AUTO and verify that the purge starts at the next chiller start. Following this verification, restore the mode to its desired value.

Note: Successful completion of these steps verifies function of:
- microprocessor
- condensing unit
- pumpout system
- float switch circuit

All test procedures are complete and the chiller is ready to be restarted and/or purged as needed.

Electrical System

Control Components

This section identifies and explains the operation of the major systems and individual components of the Purifier Purge electrical control circuit. Refer to Figures 4, 6, 11, and 12.

The following sections cover the major systems and components of the electrical system:

- Microprocessor Module
- Pumpout System
- Service Pumpout Switch
- Chiller Liquid Refrigerant Temperature
- Liquid Level Sensor
- Isolation Solenoids
- External Alarm Relay

Microprocessor Module

The Purifier Purge unit is controlled by microprocessor module 3U1. The operation of the purge is coordinated with chiller operation in both a UCP2 and purge based display system. In a UCP2 module system (as installed on new Trane chillers and older chillers which have been retrofitted with UCP2 controls), data is shared with the purge module via the interprocessor communication link (IPC). This link conveys chiller operating information to the purge and purge operational parameters to the UCP2 human interface. For purge based display installations, data transfer to the purge human interface is accomplished via the IPC link. However, chiller information is gathered via an additional binary (chiller running) and analog (purge liquid temperature) input to the purge module.

Purge operating mode is selected in the menu on the human interface (see the "Operating Mode" section for more details) -

- Purge Mode set to STOP

This mode will not allow the purge condensing unit to run. This mode is accessed by pressing the STOP key on the Purge Human interface or by selecting the STOP mode on the UCP2 human interface.

- Purge Mode set to ON

The purge will run continuously. Use of the ON switch position is recommended only for certain service procedures.

- Purge Mode set to AUTO

The AUTO mode will run the purge when the chiller is running. This mode is one of the recommended purge operating modes. The AUTO position interlocks purge operation with a chiller-generated "cooling/run" signal. For UCP2 chiller systems, this signal is transmitted as data on the IPC link. On purge based display purges, this voltage signal input is located on connection point J26.

- Purge Mode set to ADAPTIVE

This mode commands the purge to run depending on the pumpout history developed over the previous 30 days of operation. This mode is explained more fully in the section "Operating Mode"

Pumpout System

The refrigerant compressor suction temperature sensor 3RT2 is used to control the pumpout cycle to remove air from the purge tank. As air and non-condensibles accumulate in the purge tank, the refrigerant compressor suction temperature falls. When this temperature reaches 18 F a pumpout cycle is initiated by energizing solenoid 3L3 and pumpout compressor 3B6 followed by solenoid valve 3L1. The pumpout cycle is terminated when the refrigerant compressor suction temperature rises to 22° F.

Service Pumpout Switch

A service pumpout switch (3S2) is provided in the purge-mounted control panel. This switch is used to manually open the solenoid valves and energize the pumpout compressor when conducting service procedures or operational checks of the purge system. The switch is a normally open momentary rocker switch, momentarily closed to initiate pumpout.

Chiller Liquid Refrigerant Temperature

The pumpout cycle may be inhibited when the chiller condenser saturation temperature is low. The input value on UCP2 control systems is condenser liquid temperature (chiller on) or evaporator refrigerant temperature (chiller off), and is transmitted to the purge module via the IPC link. For purge based display installations, the input value is provided by a temperature sensor mounted to the bottom of the filter-drier canister and connected to purge module 3U1 at connection points J3-1 and 2. The minimum allowable condenser saturation temperature for purge pumpout may be set via the human interface. The pumpout inhibit may be enabled and disabled via the human interface.

Liquid Level Sensor

A liquid level sensor (3S1) is mounted in the top of the purge tank. This sensor will generate a latching fault if the purge tank fills with liquid. This condition can arise from purge lines that are plugged or have closed valves, or a purge suction line that contains a trap which accumulates liquid.

Isolation Solenoids

The isolation solenoid valves (Figure 4) are used to control purge exhaust from the purge tank. The operation of 3L1 and 3L3 is controlled by purge module 3U1. Two pumpout solenoid valves are provided since their function in the system is a critical factor when the purge tank is at a positive pressure.

Note: Solenoid 3L3 is not used for CFC-113 applications.

External Alarm Relay

An external alarm relay is provided for operator use. This relay is activated whenever a purge latching diagnostic occurs. This relay is located in the J16 output block of the 3U1 microprocessor. See Figures 11 and 12 in the "Purifier Purge Electrical Configurations" section.

Purifier Purge Electrical Configurations

There are two available electrical configurations for the Purifier Purge. Each is illustrated by the electrical schematics shown in Figures 12 and 13. These configurations are:

1. UCP2 based display purge (Figure 13)

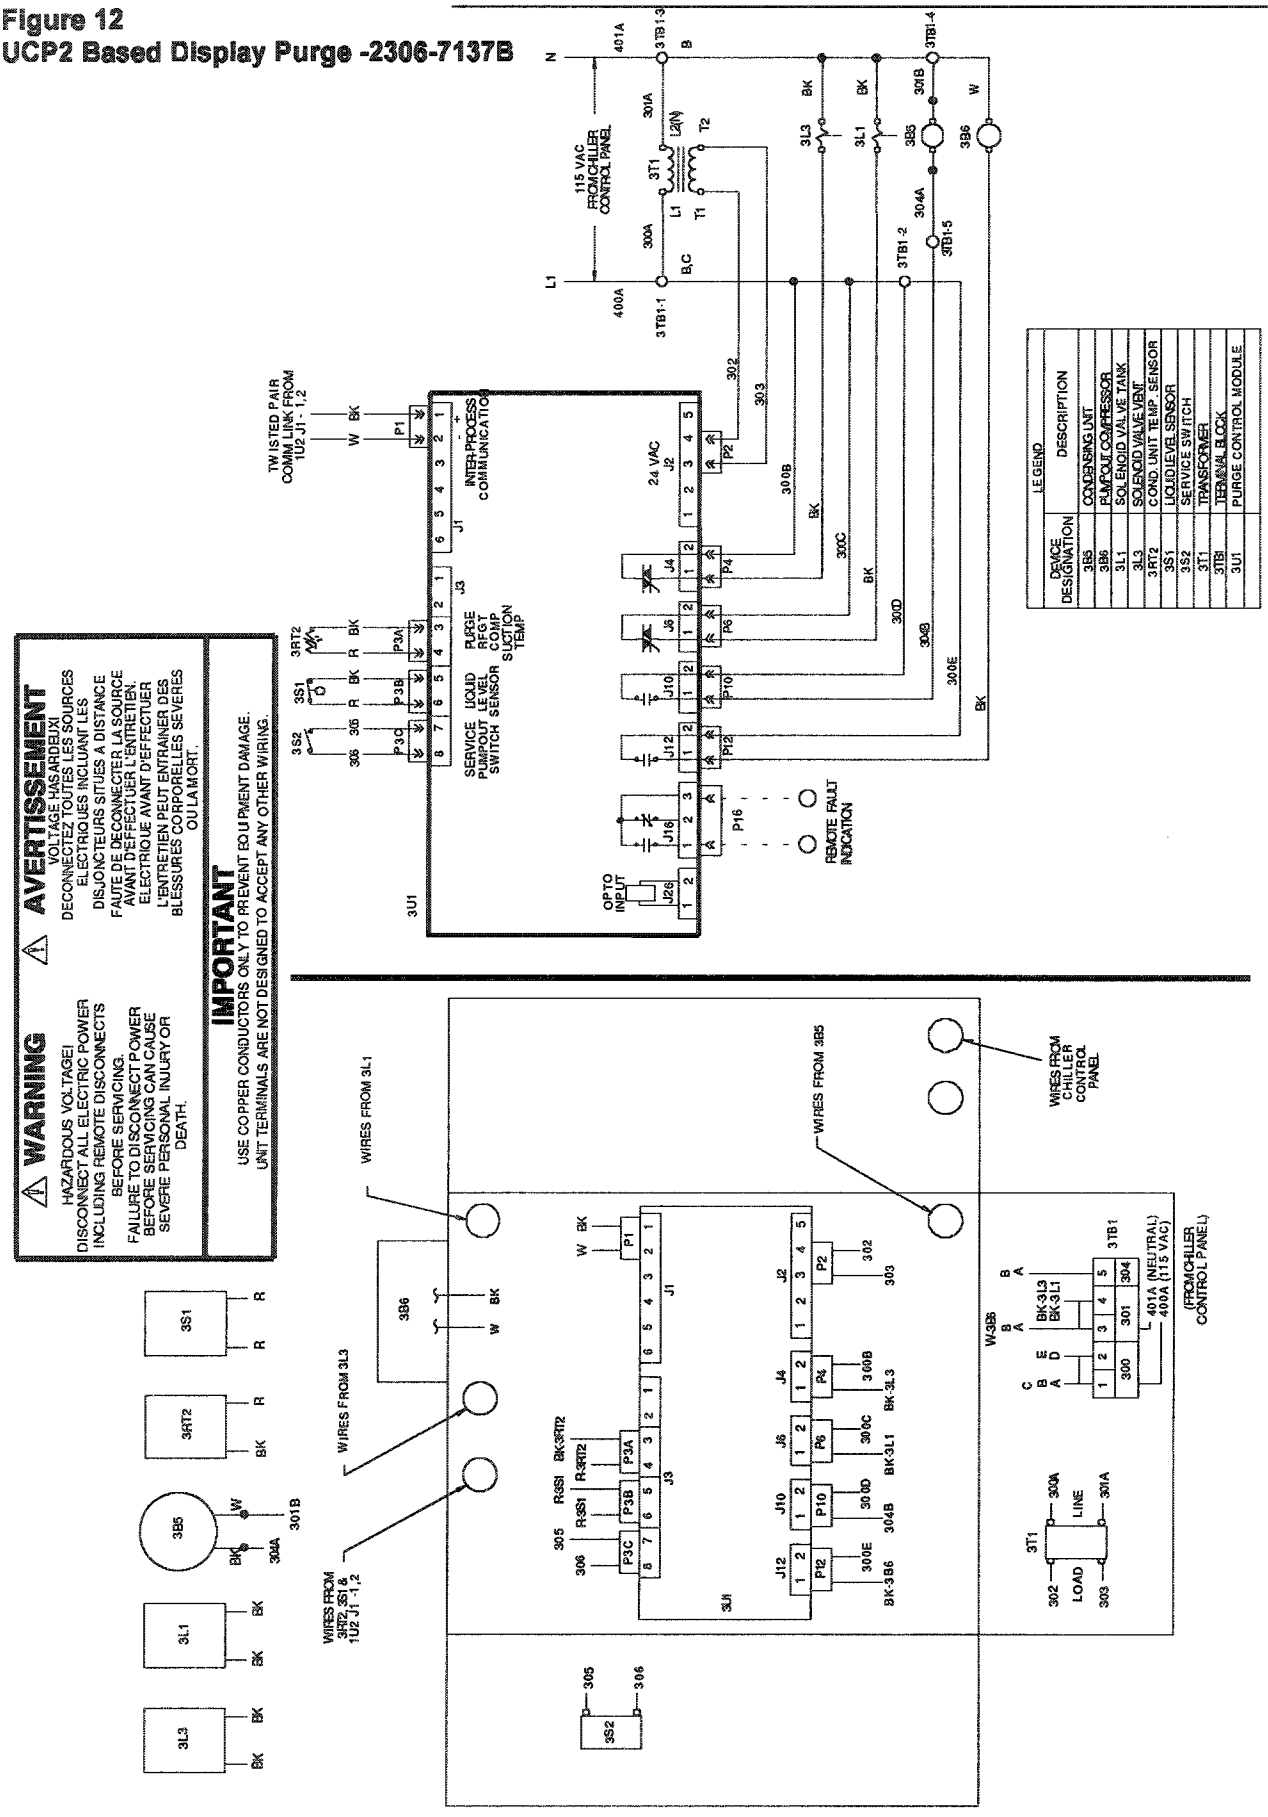
2. Purge based display (field-installed) purge (Figure 13)

UCP2 based display purges are part of an integrated UCP2 control system. As part of an integrated control system, appropriate information is shared between the chiller modules and the purge module via a communication link. Purge based display or field-installed purge purges have a dedicated human interface and additional binary and analog input and output.

For purge based display purges mounted in inaccessible locations, the purge human interface may be remote mounted (Figure 4). The interface may be removed from the purge platform and placed at the chiller control panel or other convenient location.

Purge units designed for chillers using CFC-11 and HCFC-123 use two pumpout solenoid valves (3L1, 3L3). Purge units designed for chillers using CFC-113 do not have solenoid valve 3L3. See Figures 11 and 12.

Figure 12
UCP2 Based Display Purge -2306-7137B



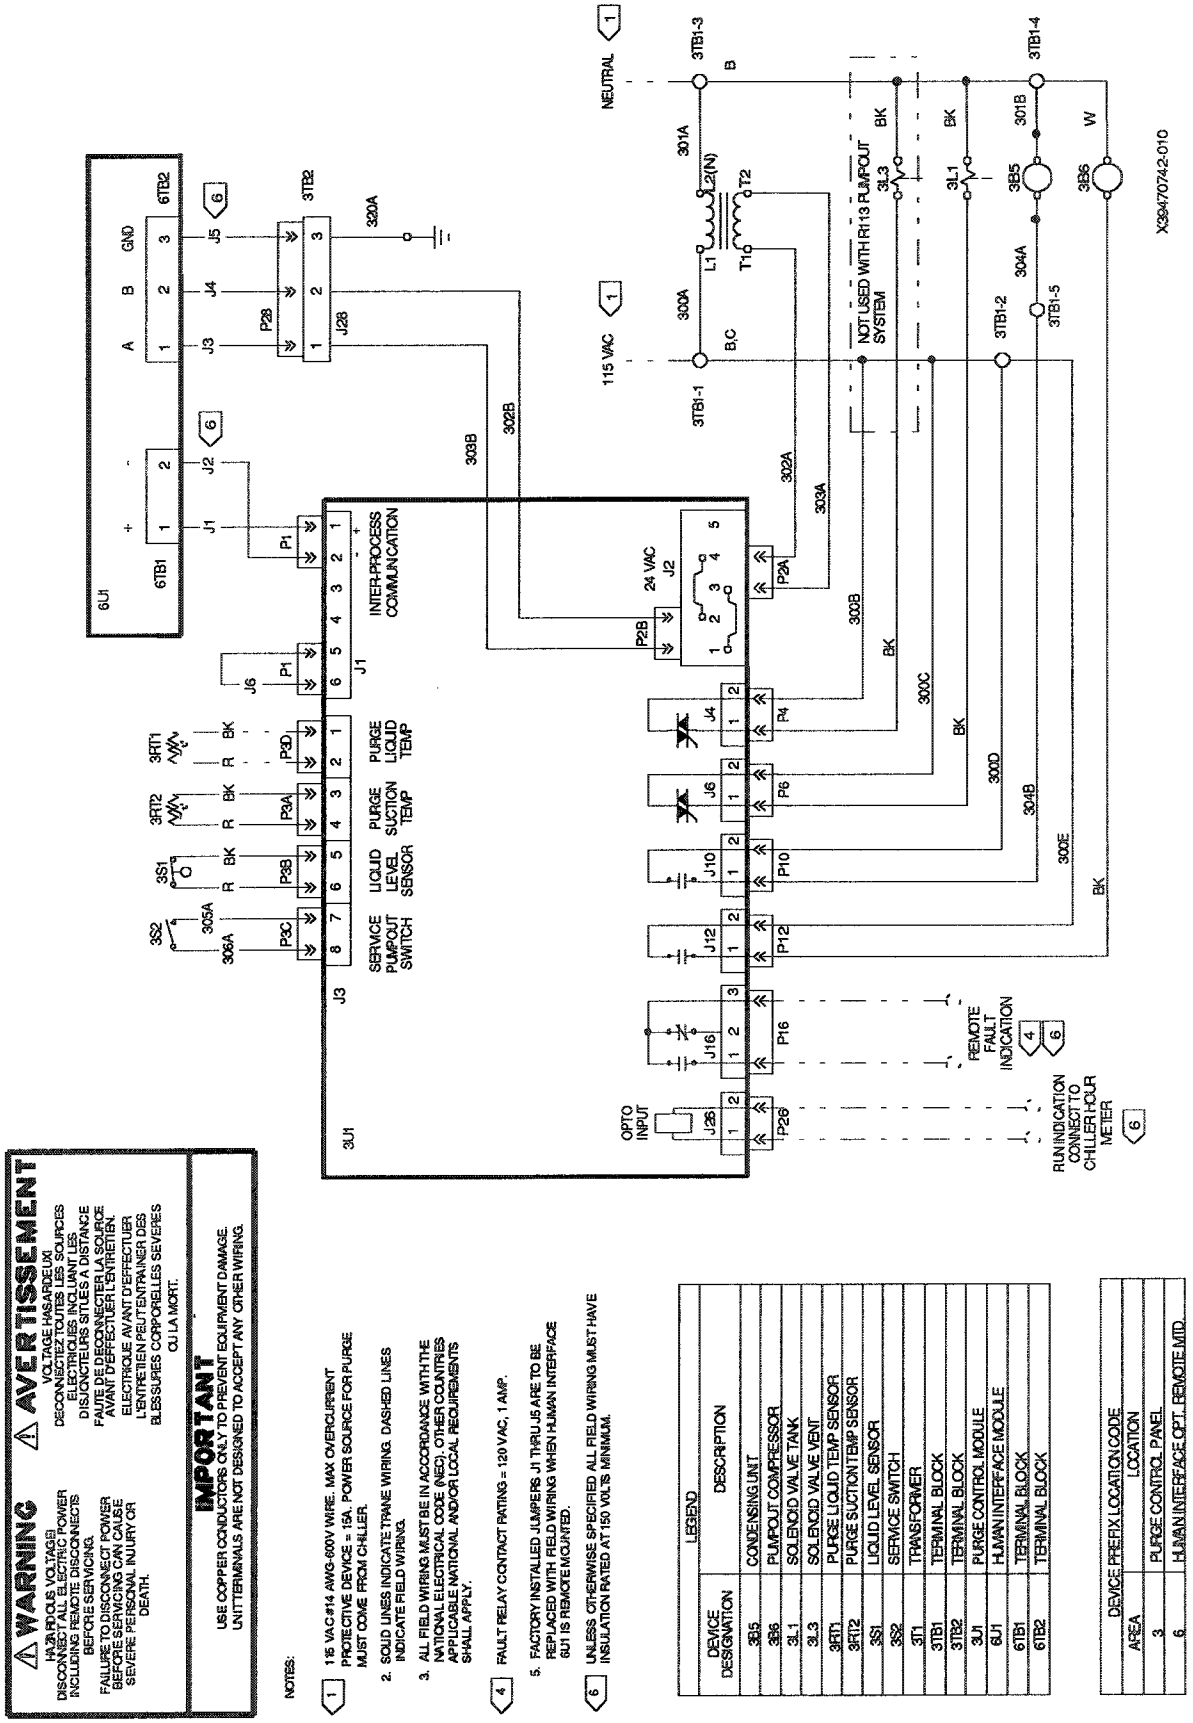


Figure 13
Purge Based Display (Field Installed) Purge

Sequence of Operation

Power is supplied to hot terminal 3TB1-1.

The microprocessor 3U1 controls purge operation according to the mode set by the operator. This control includes initiation and duration of purge operation. Input is also received from the liquid level sensor 3S1 and from a device indicating chiller condenser saturation temperature. Communication with the operator is via a human interface.

Pumpout is initiated and terminated by purge compressor suction temperature sensor 3RT2. Pumpout may be manually initiated by the momentary contact service switch 3S2.

General Information

The Purifier Plus purge emission collection canister is installed in the exhaust line of the Trane Purifier Purge, (Figure 14). The canister contains activated carbon which "filters" the refrigerant from the purge exhaust and holds it for recovery at a later date.

The Purifier Plus requires no service other than periodic replacement. When the carbon is saturated, the canister must be removed and returned for regeneration. During regeneration the refrigerant is extracted from the carbon and recycled. The canisters are cleaned and tested to insure proper performance and made available for re-use.

Tank Replacement

The saturation level of the activated carbon in the canister is directly related to the accumulated pumpout time on the Purifier Purge. When the pumpout time on the Purifier Purge timer reaches the value listed in line "A" or the date on line "B" of the Change Purifier Plus Canister label (Figure 16), the carbon is saturated and the canister needs to be replaced.

Receiving the Replacement Kit

Upon receipt of the unit, inspect the shipping carton for signs of visible damage. Report any damage to the carrier.

Store unit in a dry, secure place prior to its installation and use.

Carefully remove the collection canister from the shipping containers. Inspect it for signs of visible shipping damage. If any damage is found, report it to the local Trane Sales Office immediately. Do not install or operate a damaged unit without sales office approval. The Purifier Plus replacement kit consists of:

- Qty 1, Regenerated Purifier Plus Canister
- Qty 1, Return shipping package and shipping instructions.

⚠ CAUTION

DO NOT CONTAMINATE THE PURIFIER PLUS CANISTER WITH THE WRONG REFRIGERANT. Before installation, verify the refrigerant type marked on the replacement Purifier Plus canister is the same as the refrigerant in the chiller.

Installing the New Canister

The refrigerant vapor in the purge exhaust line can be pumped into the canister before removing the connecting lines by:

1. Disconnect and plug the 1/4" line entering the pumpout compressor so that air cannot enter the chiller when the solenoids are activated.

2. Turn on the pumpout system using the purge service switch for ten to fifteen seconds. This will pull room air into the pumpout compressor and force purge exhaust into the Purifier Plus canister.

3. Disconnect the lines from the full canister (Figure 14 and 17).

4. If these lines are non-copper, switch the fittings between the full canister and the replacement canister. The original fittings are specially adapted to current production purge lines. Ensure that the fittings which have been moved to the full canister are tightly capped.

5. Install replacement canister and update all label information as follows:

a) Install the Change Purifier Plus Canister label (Figure 16) on the Purifier Purge over the existing label. Add the applicable value from Table 3 to the current value of purge total pumpout time. Record this number on line A. Add three years to the installation date and record on line B.

b) Record the requested information on the canister nameplate of both old and new canisters. (See Figure 15)

6. Reconnect the purge lines.

7. Reconnect the tubing removed in Step 1.

Note: The purge exhaust lines are made from a special engineering copolymer material with UV stabilizers. This material is fully compatible with R-123 and is suitable for the industrial environment associated with chiller use. The tubing is dimensioned specifically to match the special fittings used in this installation. If these lines should ever need replacement for any reason, they must be replaced with comparable material obtained from the Trane Company, or replaced with copper (this will require new fittings).

IMPORTANT NOTICE!
The contents of this canister must be reclaimed at a Trane authorized facility. Disposal of the canister or the contents in any other way may be a violation of Federal CFC/HCFC venting regulations.

Return Instructions

The replacement Purifier Plus shipping box should be used to ship the saturated Purifier Plus canister back to Trane for regeneration. Upon receipt of the Purifier Plus canister at the Trane regeneration site, core deposit dollars will be credited to the appropriate customer account. **TO RECEIVE CORE DEPOSIT CREDIT DOLLARS, THE SATURATED PURIFIER PLUS CANISTER MUST BE RETURNED TO TRANE FOR REGENERATION.**

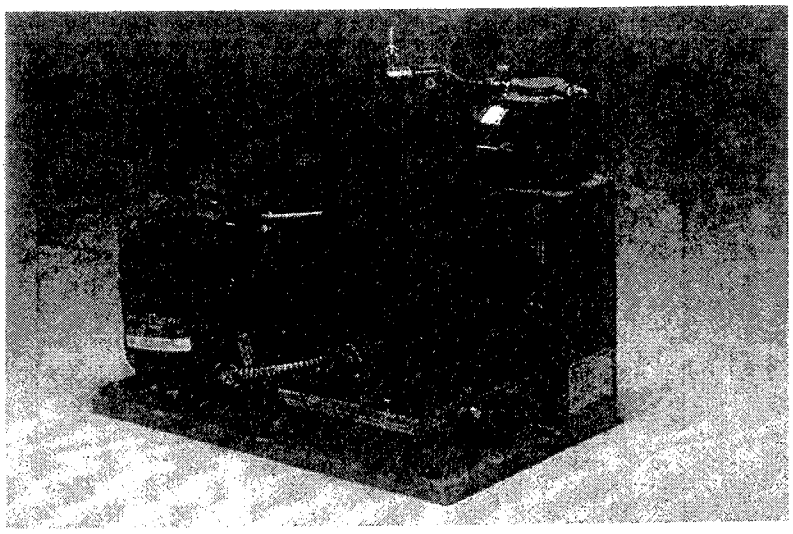
Follow these instructions for easy Purifier Plus returns:

1. **Inspect it!** Upon receipt of the replacement canister, confirm the following items were received.

Qty	Description
1	Purifier Plus Canister
1	UPS Authorized Return Service Label

2. **Package it!** Remove the new canister and place the saturated Purifier Plus into the shipping carton.
3. **Seal it!** Seal the carton with heavy-duty shipping tape. Please do not use masking or cellophane tape These are not strong enough for proper seal.
4. **Label it!** Enter your address and ZIP code in the space provided on the UPS A.R.S. label and apply it on top of the existing mailing label, located on top of the carton. Do not place label over tape or seams. Retain the detachable receipt for your records. (Complete shipping instructions are included on the back of the label.)
5. **Send it!** Bring the package to any location where a UPS driver makes a regular pickup or delivery or to any UPS Customer Counter. Your A.R.S. package will be accepted free of charge. You do not need to call for pickup or record the package in a pickup record book.

Maintenance



No maintenance is required for the canister. Keep the canister clean and dry in a corrosive free environment.

⚠ CAUTION

DO NOT PAINT THE TANK. The performance of the carbon is tracked by weight. Any added weight will invalidate the tank data.

INTRODUCTION

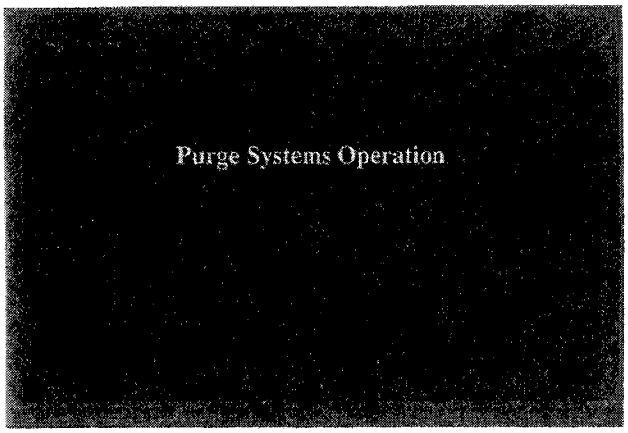

Figure 1

(Figure 1) In this section, we will introduce the operational aspects of the various purge systems utilized over the years by The Trane Company.

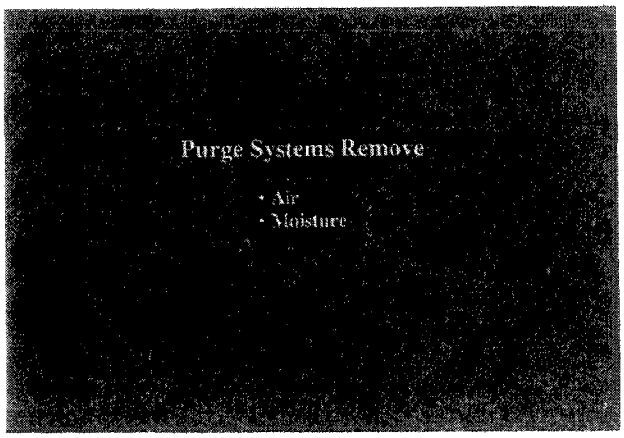

Figure 3

(Figure 3) The primary noncondensables requiring purge systems are air and moisture. While both air and moisture are collected by the purge systems, only air can be removed automatically from the system by means of some form of bleed or relief valve. Moisture or water must be removed manually through a blow-down valve system or methods using water absorbing materials.

WHY PURGE SYSTEMS ARE NEEDED

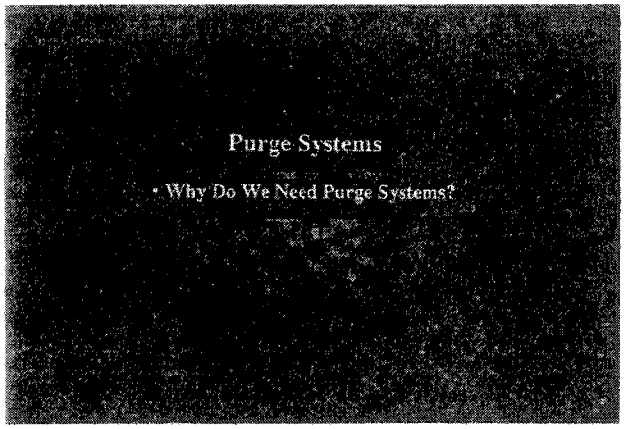

Figure 2

(Figure 2) Why do we need purge systems? Because many centrifugal chillers operate in a vacuum, there is an opportunity for contaminates to get into the system from any leaks or minor servicing errors. These contaminates are classified as noncondensables requiring a method for disposal. This is known as purging.

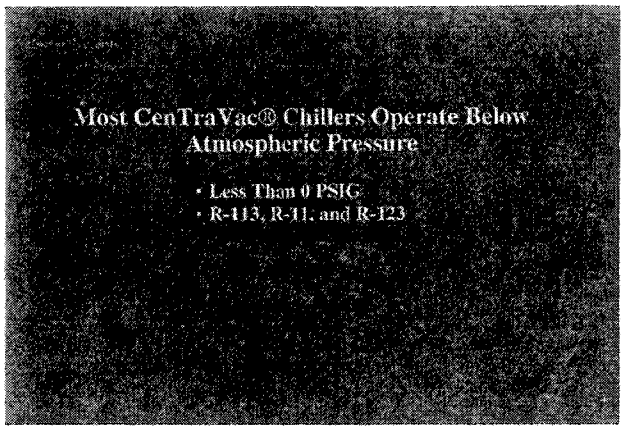

Figure 4

(Figure 4) All low pressure centrifugals operate completely or partially below atmospheric pressures. These machines use low pressure refrigerants such as R-113, R-11 or the new replacement refrigerant, R-123.

Because the system operates below atmospheric pressure, there is the possibility for refrigerant contamination by way of leaks in the system. While some people may consider purge systems to be a nuisance, they actually play an important part in maintaining centrifugal chiller system integrity.

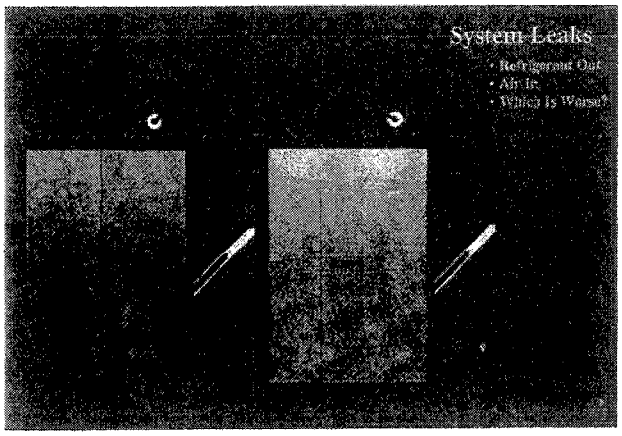

Figure 5

(Figure 5) This figure illustrates the difference between a low pressure and a high pressure system. It also may help you to understand why a purge system is used only on low pressure systems.

In the example on the left, an operating high pressure system is represented using Refrigerant-12. The high and low operating range for this refrigerant is indicated as positive pressures (PSI above atmospheric pressure). The example on the right with Refrigerant-11 is operating in a negative or partial vacuum measured in inches of mercury.

If a leak were to occur with either of these systems, what would be the result? The high pressure refrigerant machine would probably lose all of its charge if the leak were not discovered in time. A leak of this type is hazardous to personnel and may result in injury. The low pressure machine would simply leak air into the machine.

By simply monitoring the frequency of the purge relieving noncondensable gases, the operator could spot the increasing leak rate in the low pressure machine. The actual loss of refrigerant, then, depends only on the efficiency of the purge in separating air from refrigerant in the purge process.

Since there is increased interest in reducing atmospheric emissions of all refrigerants to an absolute minimum, the importance of an efficient leak prevention program will become paramount for all chiller systems, regardless of the type of refrigerant being used.

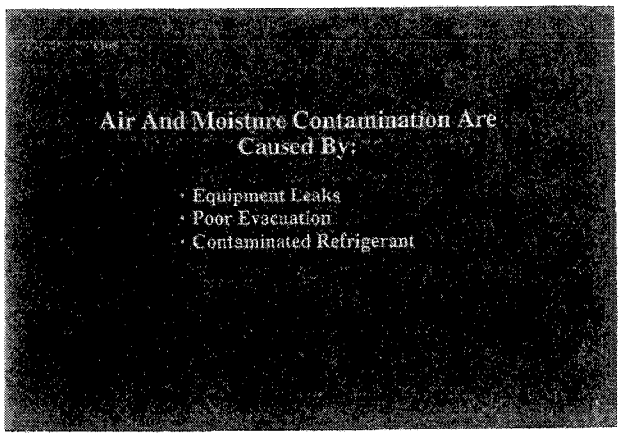

Figure 6

(Figure 6) Generally, we can isolate air and moisture contamination to three areas: equipment leaks, poor service evacuation practices and contaminated refrigerants. All of these conditions can be improved by increased attention to the fundamentals of machine operation and maintenance, and a strong educational program.

Improper or limited evacuation by service personnel is usually the result of haste in completing the job of restarting a machine after servicing. The service technician may opt for inadequate evacuation in the interest of time and the mistaken belief that the purge can handle all the air and moisture remaining in the chiller following major work.

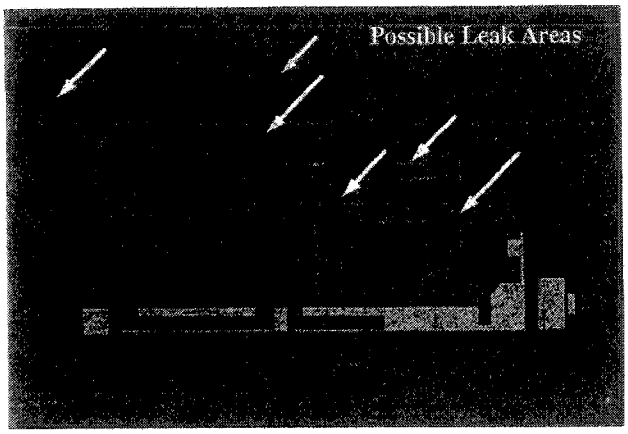

Figure 7

(Figure 7) Leaks can adversely affect the operating capacities and efficiencies of any air conditioning or refrigeration equipment. In large centrifugal chillers such as the Trane CenTraVac® chiller, the low pressure areas are most suspect when purge operation rates increase, indicating an increase of noncondensable gas being relieved.

Leaks are most likely to occur around the low pressure flanged or gasketed areas, tube and pipe fitting areas, and wherever control linkages must connect to the compressor inlet guide vanes.

High pressure leaks are also possible past the compressor's first stage in the flange areas and at pressure taps. These leaks will occur when the chiller is running and will not be detected with the increased purging rate. It is useful, therefore, to monitor the machine room air for traces of refrigerant gas and periodically leak check these areas simply to minimize these types of refrigerant losses.

HOW THE PURGE ELIMINATES AIR

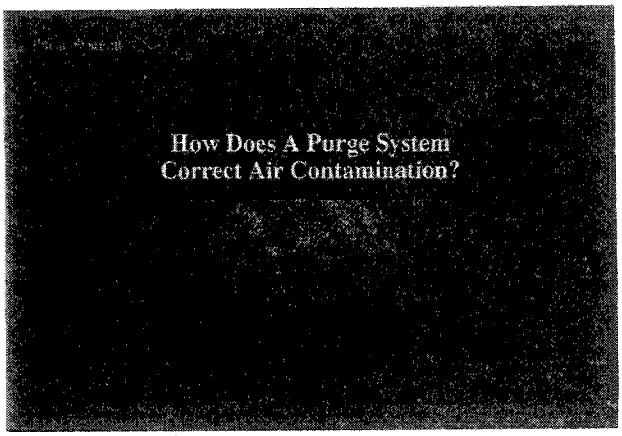

Figure 8

(Figure 8) How the purge eliminates air from the chiller is the subject of the next area of discussion.

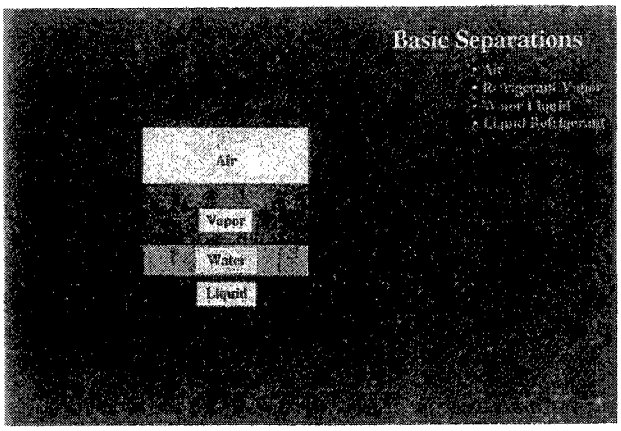

Figure 9

(Figure 9) The first step to understand a purge system is to know how the noncondensables and refrigerant separate in a closed container. The container in Figure 9 shows the separation or stratification process of liquids and gases based on their different weights.

Since air is the lightest of the components shown here, it will always rise to the top. Next in sequence is refrigerant vapor, water and finally refrigerant liquid. Because air is lightest, and is at the top of the container, it is a simple process to slowly release that air by means of a relief valve (provided that the container gases are not stirred or mixed in any way).

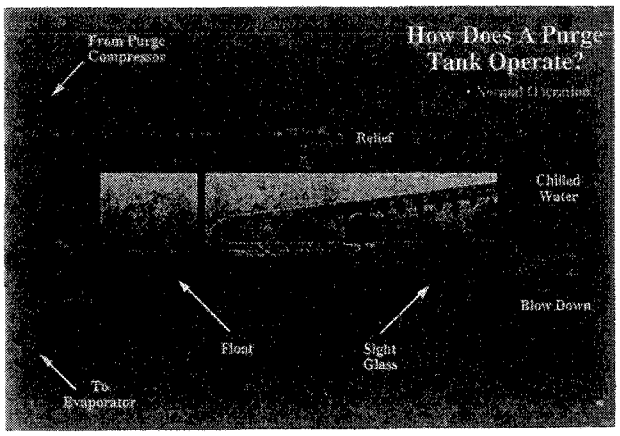

Figure 10

(Figure 10) Using the basic separation process just covered, let's look at a typical purge condenser tank that is found on many chillers manufactured from the 1950's through the 1980's. First we will assume that noncondensables are not present.

Refrigerant vapor comes from the chiller's condenser via a purge compressor and is directed to the purge condenser tank. The higher pressure gas comes into contact with a coil which acts as a condenser. Using cool water flowing in the coil, the purge condenser transforms the refrigerant gas to a liquid and it drops to the bottom of the tank.

A liquid level is maintained by a float-valve which meters the liquid back to the chiller's evaporator. Since noncondensables did not enter the purge condenser tank with the refrigerant vapor, the pressure of the refrigerant in the purge tank will stay fairly close to the saturation temperature imposed by the cooling water in the coil.

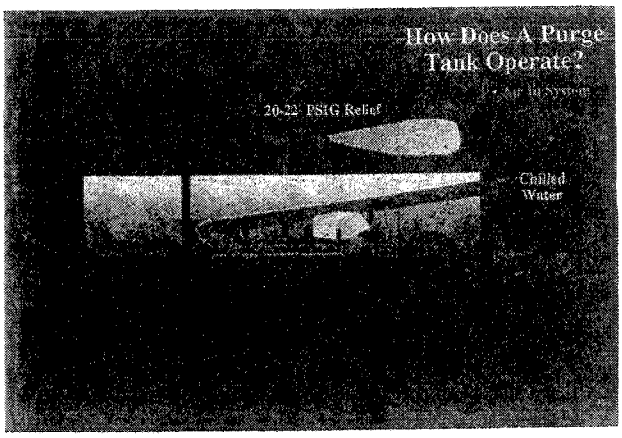

Figure 11

(Figure 11) This figure shows a system contaminated with air. The contaminated refrigerant and air mix is drawn from the unit condenser via the purge compressor and again is directed to the purge condenser tank. The gas mixture comes into contact with the purge condenser coil. With the mixture of gases, only the refrigerant portion will condense to a liquid.

The remaining air becomes trapped within the purge condenser tank and will accumulate. Because pressures of dissimilar gases have an additive effect, the combined gas pressures reach the release pressure of the relief valve located on top of the purge drum, and the valve vents the air mixture.

Because refrigerant vapor is present in the purge condenser tank when the relief valve is activated, some refrigerant can be lost with the air being vented. The efficiency of this method of purge depends, in part, on the condensing temperature in the purge drum. The temperature should be as low as possible to lower the distillation temperature of the refrigerant-air mixture. This will minimize the percentage of refrigerant vapor volume relative to the air volume in the drum while gases are being vented.

WHEN TO PURGE A UNIT

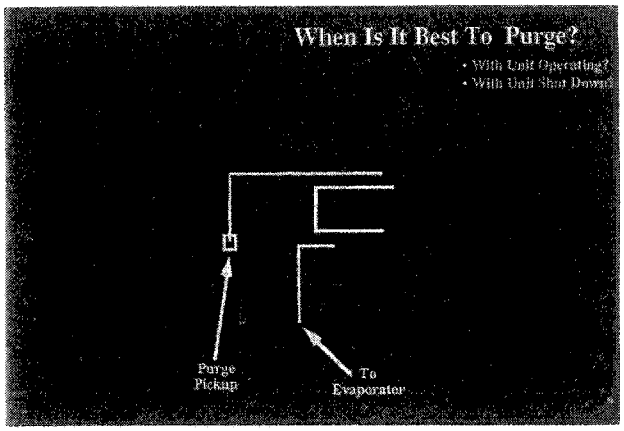

Figure 12

(Figure 12) Is it best to purge when the unit is operating or when the unit is shut down? It depends on where the purge pickup is located on the machine. Referring to Figure 12, note that the pickup is about halfway down the condenser tube bundle. With this form of pickup, an operating machine is more effectively purged than a machine that is standing idle.

With the compressor forcing high velocity discharge gas into the top of the condenser shell, air will be mixed with the refrigerant. A quiet zone is provided at the side of the condenser shell to help trap and hold air to be picked up by the purge compressor. With the unit off, there is a stratification of air to the top of the condenser. The pickup becomes less effective because less air is actually exposed to the pickup point.

Why is the pickup always located in the condenser and not in the evaporator? Air will always tend to be trapped in the condenser. With the unit running, the condenser has a liquid seal at the condenser discharge; air cannot travel past this point. With the chiller off, air in the machine will rise to the top of the condenser. Either way, the evaporator is not an effective source for the point of purge pickup.

HOW PURGE DESIGNS HAVE CHANGED

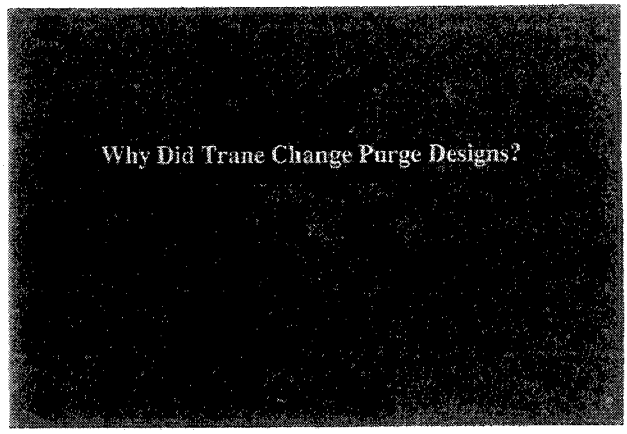

Figure 13

(Figure 13) Trane and other manufacturers of low pressure centrifugal chillers have all changed their design of purge units over time. In the centrifugal chillers of the 1930's, purging was often done by releasing the air-mixed refrigerant directly from the top of the condenser barrel.

The main factors for design changes of the mechanical purge systems were: reducing product costs to be more competitive; extremely low refrigerant costs, which lowered the priority concerns about refrigerant losses; and owner requirements for reducing maintenance time and labor on the purge systems.

These were the priorities before the current concern of reducing refrigerant emissions to the lowest possible levels due to environmental concerns. The design requirements for purge effectiveness have changed!

BELT DRIVE PURGE

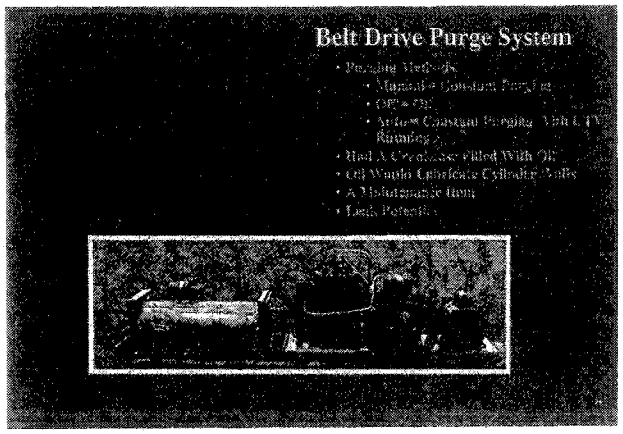

Figure 14

(Figure 14) The belt drive purge was the earliest purge design Trane used. One of the main reasons for using this purge system for so many years was that its endurance record was well proven. It had an open drive type compressor supplied to Trane from several vendors. Other components were the oil separator, purge condenser tank and a fractional horsepower motor which drove the compressor with a belt drive system.

The operation of this type of purge system can be controlled by the operator through the use of a three-position rocker switch. In the **MANUAL** position, the purge unit will run continuously with no respect to the operating mode of the chiller. Occasionally running the purge in the manual position was the preferred method of purging the chiller by many operators because it allowed them to monitor the relief of noncondensables.

In the **OFF** position, the purge unit is totally disabled. In the **AUTO** position, the purge unit would operate continuously when the chiller was on line and running. When the chiller shut down, the purge system would be stopped.

This purge design required careful operation and maintenance to keep the system running effectively. The oil separator, purge drum, float mechanisms, relief valve and purge tank all required cleaning and periodic service. The external components such as the motor and belt drive also had to be maintained. As with all open drive compressors, the seals often were subject to leaks and had to be inspected and serviced.

OIL-LESS PURGE

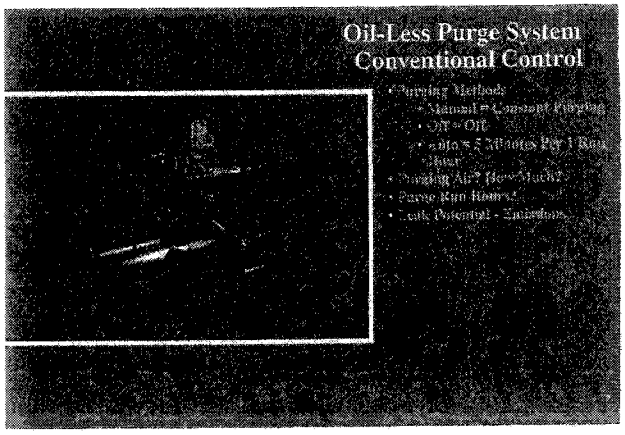

Figure 15

(Figure 15) Shortly after the introduction of the Trane three- stage CenTraVac chiller, the oil-less purge system was introduced. The main feature of this system was that the purge compressor did not utilize an oil-filled crankcase, and because of this, it did not require a oil separator to recover oil. An advantage to this approach was lower maintenance.

However, this design did have a number of drawbacks. For example, continuous purging operations of long duration caused premature wearing of the purge compressor. The oil-less purge system again used a three-position rocker switch to control the purging of the chiller.

In the **MANUAL** position, the purge system would run continuously with no respect to the chiller's operation. In the manual position, it was imperative that chilled water be flowing through the purge condenser. This again was the preferred method of purging by many operators.

In the **OFF** position, the purge system was totally disabled.

In the **AUTO** position, the purge unit would operate for five minutes of each hour that the chiller is operating. This five minutes of purging was sufficient to remove noncondensables; however, the actual amount of noncondensables removed could not be determined in this mode of operation.

This oil-less purge unit, as well as preceding purge units, had no way of maintaining a record of the duration of operations or the number of purges. Without this information, it was difficult to determine both the condition of the system as well as the purge compressor overhaul needs.

OIL-LESS PURGE WITH UCP

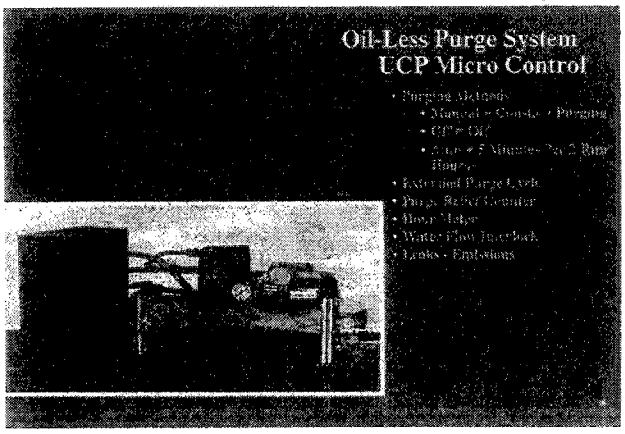

Figure 16

(Figure 16) The next step was to interface the oil-less purge system with the new Trane three-stage CenTraVac unit control panel (UCP). This allowed for better control of the system.

The unit control panel (UCP) oil-less purge system again used a three-position rocker switch to control its operation. In the **MANUAL** position, the purge system operated continuously, regardless of the operating mode of the chiller.

In the **OFF** position, the purge system was totally disabled.

In the **AUTO** position, the purge operated five minutes out of each two hours of chiller operation (assuming that no significant purge gases were present).

Although the basic oil-less purge system was the same, the method of control and recording capabilities were enhanced. This enhancement included the addition of a start counter to count the number of actual purge relief operations and an hour meter that would record the run hours accumulated on the purge compressor.

Another feature was the extended purge cycle, a slightly more flexible approach to purge. This feature increased purging time by an additional four minutes each time a call for relief was required. This increased the ability of the purge system to completely free its system of air and minimize the number of run hours accumulating on the purge compressor and extend the time between purge compressor overhauls.

This unit also had a small purge tank and a solenoid valve controlled by the control panel instead of a relief valve.

PURIFIER PURGE

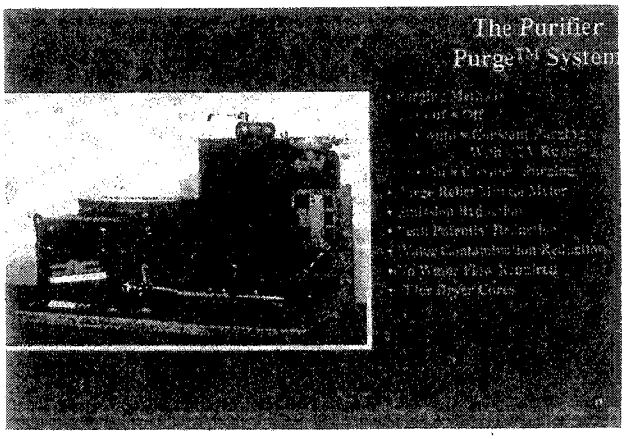

Figure 17

(Figure 17) In 1990, the Purifier Purge™ system was introduced. This style of purge also uses intelligent controls. In addition, it exhibits a whole new concept in purging methods. The net results are more accurate and informative purging.

The features are numerous, the first being that the new system purges by monitoring a refrigerant temperature instead of pressure. It does not need water connections for condensing purposes; therefore the purge system can be operated easily without the chiller running, and there is little chance of water contamination or accidental discharge of the refrigerant.

This system dramatically reduces the amount of refrigerant emissions by about 90 percent. The purifier release of air to refrigerant ratio has been measured at .5 to 1 pound of refrigerant for each pound of air purged from the system. This compares to a ratio of three to seven pounds of refrigerant to each pound of air in the old system.

There are similarities and differences in the operation of this system. For example, when the three-position rocker switch is in the **OFF** position, the purge system is totally disabled, as with previous systems.

When the switch is in the **AUTO** position, the purge system will operate continuously with the chiller in a run mode. When the chiller shuts down, so does the purge system.

When the switch is in the **ON** position, constant sampling is the result, regardless of the chiller's operating mode and discharge noncondensables when needed. It also records minutes of relief operations.

HOW PURGE SYSTEMS WORK

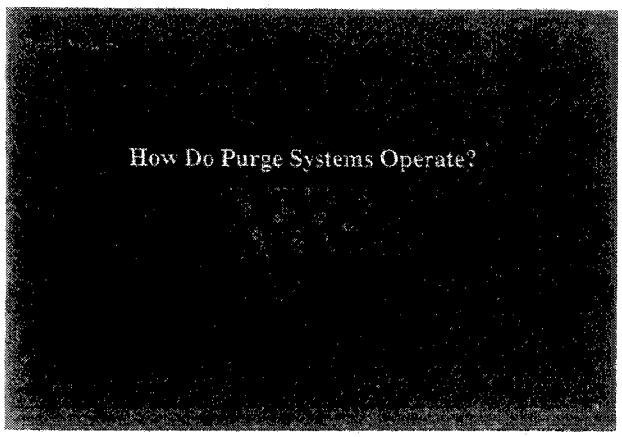

Figure 18

(Figure 18) Now let's take a look at how these four purge systems work.

BELT DRIVE PURGE

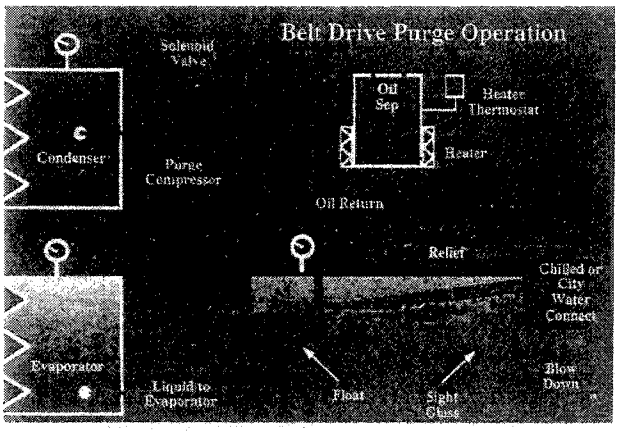

Figure 19

(Figure 19) The belt drive purge system took refrigerant samples from the unit condenser via a solenoid valve that had been energized to allow that sample to be compressed by the purge compressor and sent to the oil separator.

Notice that the purge gas mix must be elevated to a higher pressure in order to develop sufficient pressure for this design of purge system to work.

The oil separator is needed because the purge compressor has a crankcase filled with oil. The oil coming off the crankshaft lubricates the cylinder wall. As the piston comes down on an intake stroke of the compressor, some of the oil lubricating the cylinder wall slips past the piston rings.

The oil will leave the compressor by way of the discharge line on the compression stroke. This oil must be recovered and returned to the crankcase of the purge compressor by an oil separator. The oil separator must be kept warm through the use of heaters to insure the flashing of any refrigerant entrained with the oil.

The higher temperature and pressure refrigerant vapor is then sent to the purge tank, where it's condensed to a liquid. The liquid refrigerant is then returned to the evaporator to do useful work.

OIL-LESS PURGE

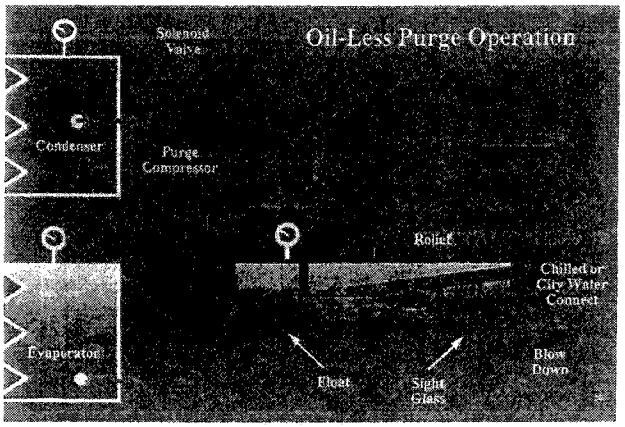

Figure 20

(Figure 20) The oil-less purge operation is very similar to the belt drive purge with one evident exception and that is no requirement for an oil separator. All other purge functions are the same.

It's interesting to note that this compressor was originally designed to operate as an air compressor, but was redesigned to operate in a refrigerant atmosphere. Even though air compressor and refrigerant parts are interchangeable, parts designed for use in refrigerant atmosphere only should be used because of the difference in the life expectancy of the parts.

OIL-LESS PURGE WITH UCP

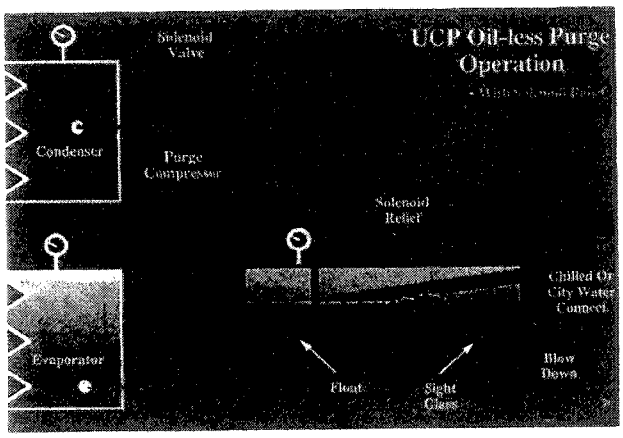

Figure 21

(Figure 21) The unit control panel controlled oil-less purge is the same as the earlier oil-less purge, except that the newer purge system operates on command signals from a higher source and as stated before, offers relief by way of a solenoid valve instead of the standard relief valve.

PURIFIER PURGE™

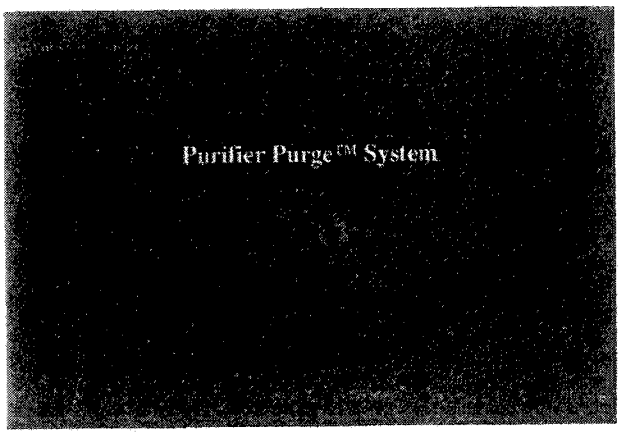

Figure 22

(Figure 22) The Purifier Purge is a new and exciting concept. Its basic purpose is the same as that of all purge systems, but it performs in an entirely different manner.

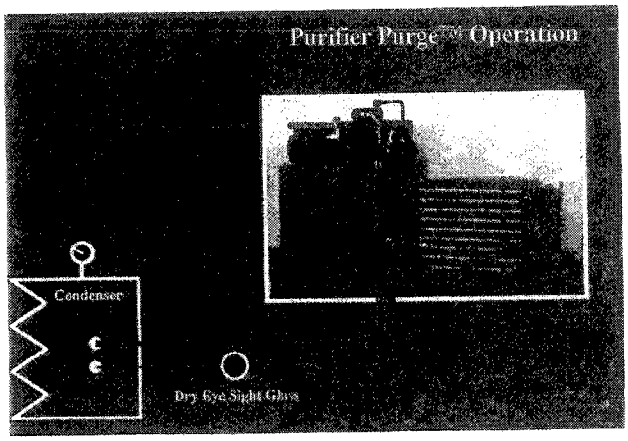

Figure 23

(Figure 23) The initial big change we see is that the purge pickup and purge liquid return are both located in the unit condenser. This system has some advantages in that flow is established through migration of the refrigerant sample from the unit condenser and returns by gravity flow. So, the Purifier Purge™ system must be installed on the top of the condenser. The return flow and moisture content of the refrigerant is monitored by a Dry-Eye™ sight-glass.

This sample process is an improvement because it does not rely on elevated pressure for condensing or refrigerant return. It also reduces the possibility of leaks because fewer components and connections are used, and the refrigerant sample is being taken from and returned to the same vessel.

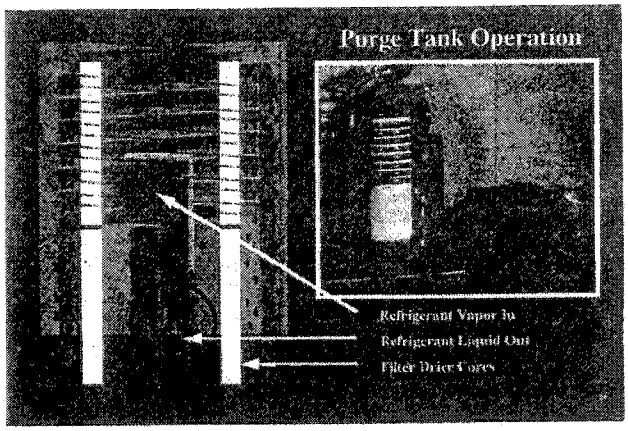

Figure 24

(Figure 24) The refrigerant vapor sample is brought into the bottom of the purge condenser. In the purge condenser there is a vapor inlet and a liquid refrigerant return tube. There also are two filter drier cores installed end to end, the purpose of which is to remove any moisture that may be entrained with the refrigerant sample.

The refrigerant vapor sample, having passed through the filter drier cores, will next encounter a serpentine coil, which acts as a heat exchanger. The serpentine coil cools the refrigerant vapor and causes it to condense to a liquid and allows it to collect in the bottom of the purge tank.

The liquid level rises in the bottom of the tank until it exceeds the height of the liquid refrigerant return tube and then returns the liquid to the unit condenser.

Any water present in the tank is prevented from returning to the unit condenser by a water separation tube that extends below the liquid level isolating the lighter water above the refrigerant, where it will be visible through the sight glass in the purge tank. This visible water line will serve as a cue that service is required and the filter drier cores should be replaced.

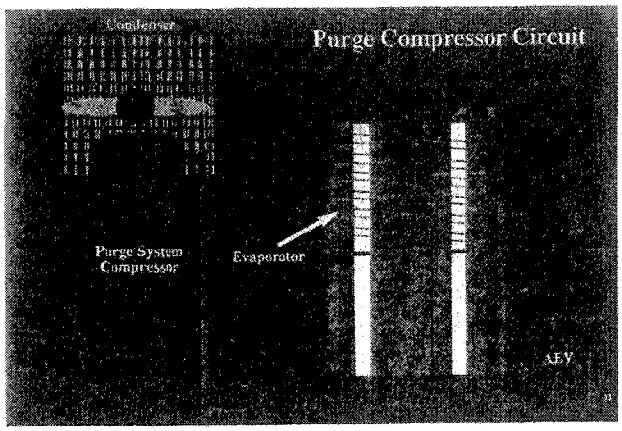

Figure 25

(Figure 25) In order for the purge condenser serpentine coil to act as a heat exchanger, a small refrigeration circuit is used. This refrigeration circuit is much like the one in a home refrigerator.

Its purpose is to supply low temperature refrigerant, approximately 0 F, to the coil by way of an automatic expansion valve. The serpentine coil heat exchanger removes the heat from the refrigerant sample. The low temperature refrigerant supplied by the refrigeration unit now completes its circuit and returns at a higher temperature, sometimes as high as the chiller condensing temperature.

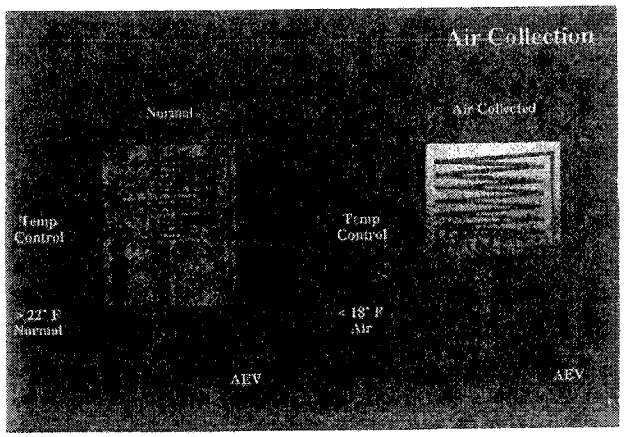

Figure 26

(Figure 26) What happens when air collects in the purge condenser tank? The diagram on the left shows a normal operating purge condenser. We know it's operating because the temperature control is monitoring a return refrigerant temperature of 22 F or greater.

But the diagram on the right is a different story. As more air collects at the top of the tank, the air will begin to insulate the serpentine coil, preventing it from doing its job.

As the volume of air increases in the tank, more and more of the serpentine coil surfaces become inefficient in absorbing heat. The temperature control monitors this condition and senses air is trapped in the purge tank because of the lower return refrigerant temperature.

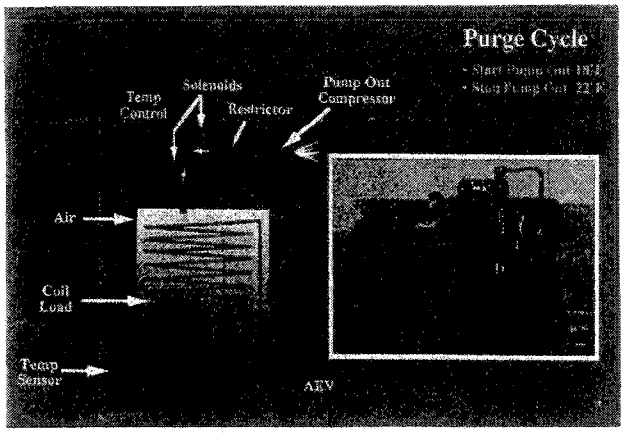

Figure 27

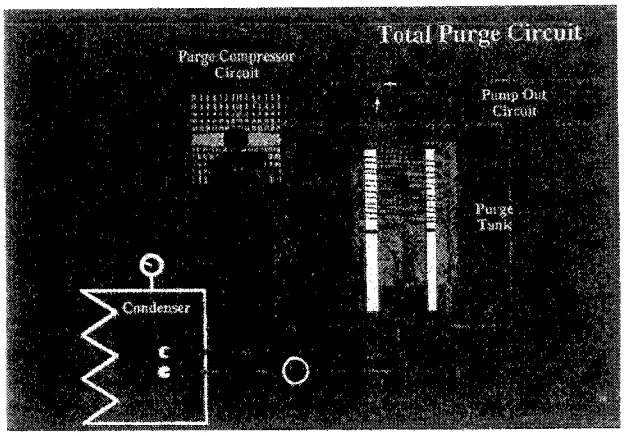

Figure 28

(Figure 27) Once the temperature control has sensed 18 F or below, indicating the presence of air in the purge tank, it will initiate and energize the purge solenoids and the pump out compressor to remove the air. The temperature control will continue monitoring the returning refrigerant temperature from the serpentine coil and when it sees the temperature rise above 22 F, it will discontinue the purge relief cycle.

It should be noted that there is a restricter located between the solenoid valves and the pump out compressor. This restricter's purpose is to slow down the discharge rate of the pump out compressor to prevent excessive release of refrigerant vapor with the trapped air. The slower release of air reduces turbulence inside the tank from the entering vapor.

Also notice that there are two opposing solenoids installed in the pump out line. These solenoids provide a positive seal when they are de-energized to minimize leak potential.

(Figure 28). As discussed, three circuits are involved in the purge system. The refrigeration circuit supplies the low temperature refrigerant for condensing purposes to the purge serpentine coil. The purge pickup and return circuit to the unit condenser supplies the refrigerant sample for testing purposes. The solenoid valves and the pump out compressor reject air from the system.

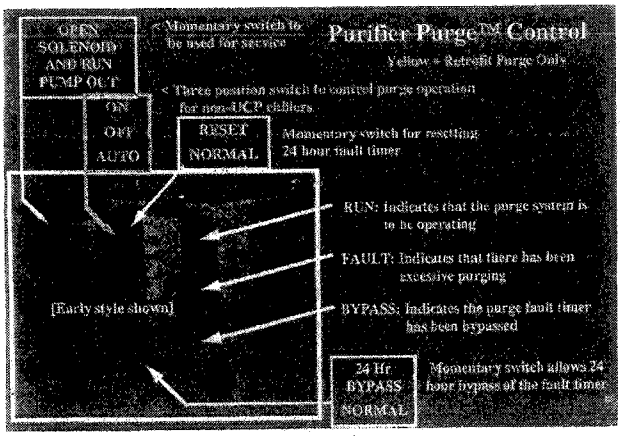

Figure 29

(Figure 29) There are several control schemes involved in the Purifier Purge control system. One of the control schemes relates only to a version which operates only by its own controls for use with older chillers.

Another scheme involves the interfacing of the chiller's microprocessor panel with the purge control system, allowing for a centralized control point. To get an explanation of the full sequence of operation, refer to the applicable operators manual. Be sure to use the correct manual.

This figure shows indicator lights and operational switches. The open solenoid and run pump out switch acts as a momentary service switch. This switch is meant to be used by service personnel to test for operation of the purge solenoid valves and the pump out compressor.

The **ON, OFF/RESET, AUTO** switch is used only with field retrofit of the newest version of the purifier purge system. The purpose of this switch is to reinitialize the internal purifier purge 24-hour smart timer.

There are three indicator lights mounted on the purge control panel:

Run: This light indicates that the purge system is operating. It should be noted that the purifier purge runs continuously as long as the chiller is operating.

Fault: This light will illuminate any time that the actual purge relief has exceeded the time value set in the 24-hour smart timer (factory set at 12 minutes).

Bypass: This light is illuminated when the purge relief 24-hour fault timer has been bypassed intentionally. One reason for this intentional bypass may be because of a service requirement.

The final switch, 24-hour bypass or normal, is a momentary switch and is used to reinitialize the 24-hour bypass fault timer for an additional 24 hours.

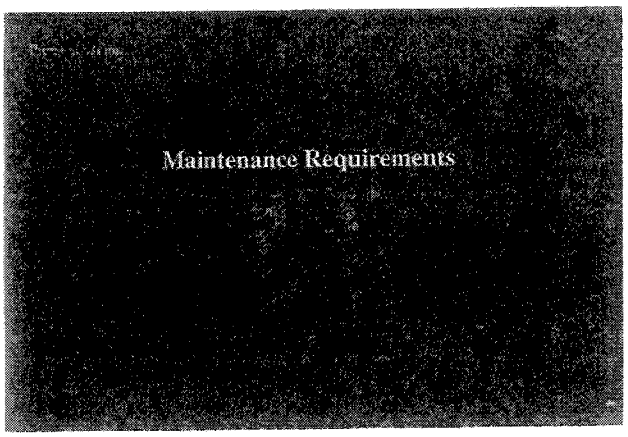

Figure 30

(Figure 30) To get the maximum performance out of any purge system, certain maintenance requirements must be met. In the remainder of this manual, we will cover these necessary steps.

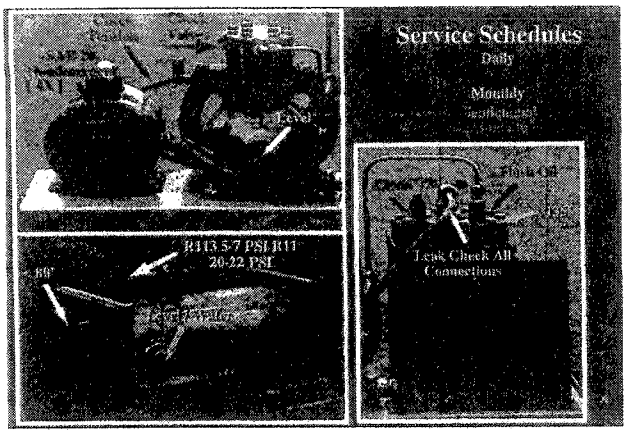

Figure 31

(Figure 31) Performing regular, scheduled maintenance will help assure proper operation of the purge belt drive system. Here are suggested service schedules:

Daily: Check and log operating purge pressures. If the purge compressor has a sightglass, check for oil levels. Check the purge drum for proper level and any indication of moisture. Check the oil separator for proper operating temperature.

Weekly: Operate the purge as required. Check the oil separator heaters for proper setpoints and operating temperature.

Monthly: Leak check all purge components, lines, connections and fittings. Check the purge drum water temperature. (It should be less than 80 F). Check the purge compressor oil level.

Quarterly: Lubricate purge motor bearings.

Semiannually: Check the purge belt drive for wear and proper tension. Clean all water strainers. Flush the oil separator with fresh oil.

Annually: Check the purge relief for the correct relief setting. Inspect, clean and recalibrate (if necessary) all safety and operating controls associated with the operation of the purge system.

Overhaul the purge condenser tank, disassemble, clean the tank, check the float and purge tank baffle. Change the purge compressor crankcase oil. Check the purge compressor valves. Check purge compressor shaft seals. Clean the oil separator and recharge with fresh oil. Leak check all purge system components, lines, connections and fittings.

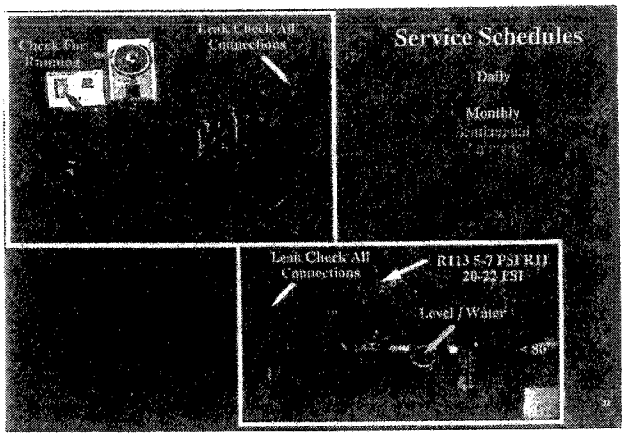

Figure 32

(Figure 32) The oil-less purge system maintenance checks are basically the same, except those items referring to the oil separator. The current recommendation is to overhaul the oil-less purge compressor at 750 hours of accumulated run time. Use only replacement parts which are suitable for operations in a refrigerant atmosphere.

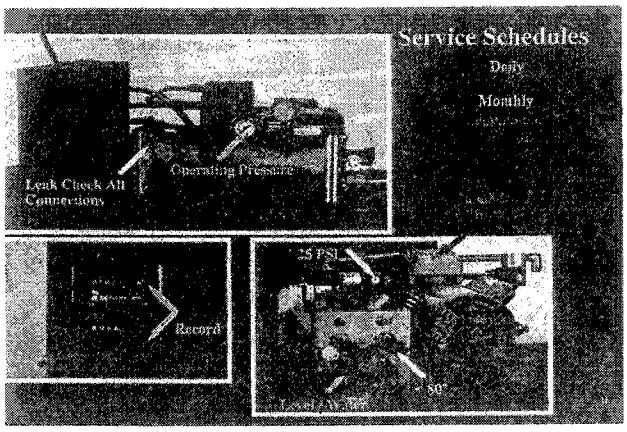

Figure 33

(Figure 33) The service requirements are basically the same for an oil-less purge system which uses unit control panel inputs. In addition, it is necessary to monitor the start counter and the run hour meter daily logs. Doing this will reveal any adverse operating conditions.

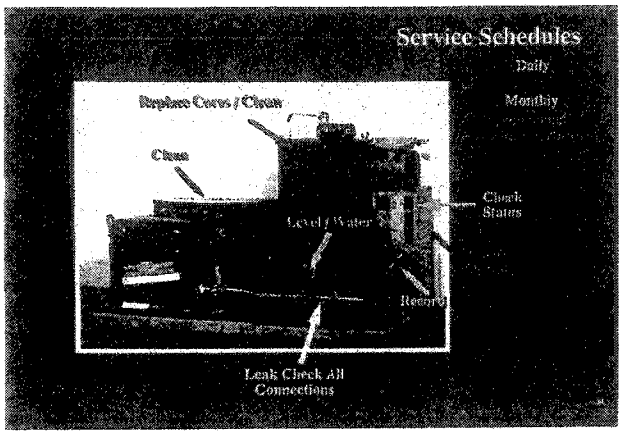

Figure 34

(Figure 34) The Purifier Purge™ has similar checkout requirements for maintenance, although there are some differences we should discuss.

Daily: Check and log the status lights of the purge control panel. Record the minute meter and note any changes in the accumulated time recorded.

If the accumulated minutes setting has changed, be sure to take into consideration the operating schedule of the chiller. Make a visual inspection of the purge tank and liquid line sight glass and note any changes.

Weekly: While the purge is operating, check the purge tank condensing activity at the sight glass. A continuous flow of refrigerant droplets should be visible.

Check the moisture indicator on the liquid return line. If the indicator shows the presence of moisture, it is time to replace the filter drier cores.

Check the purge tank sight glass for the presence of water. If water is present, there will be a visible line of separation between the water and the refrigerant.

The presence of water in the purge tank indicates that service is required. See the appropriate operators manual for a description of the above mentioned conditions.

Monthly/Semiannually: Inspect the air-cooled condenser coil and clean as needed. A fouled coil will reduce purge efficiency and capacity.

Annually: Perform a purge system control check as outlined in the operators manual. Perform purge tank service as described in the operators manual.

SUMMARY

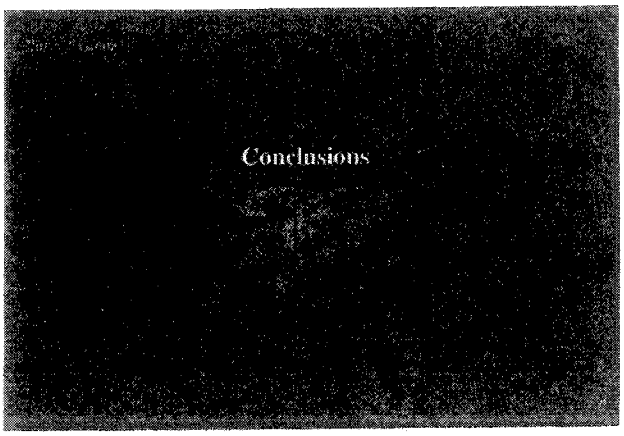

Figure 35

(Figure 35) To summarize, there are different types of purge systems. The new Purifier Purge™ system represents an opportunity for increased control over refrigeration emissions.

Subject: Model PRGA Purifier Purge™ Filter-Drier Core and Smart Timer

Introduction:

The following problems with the PRGA Purifier Purge unit have been identified.

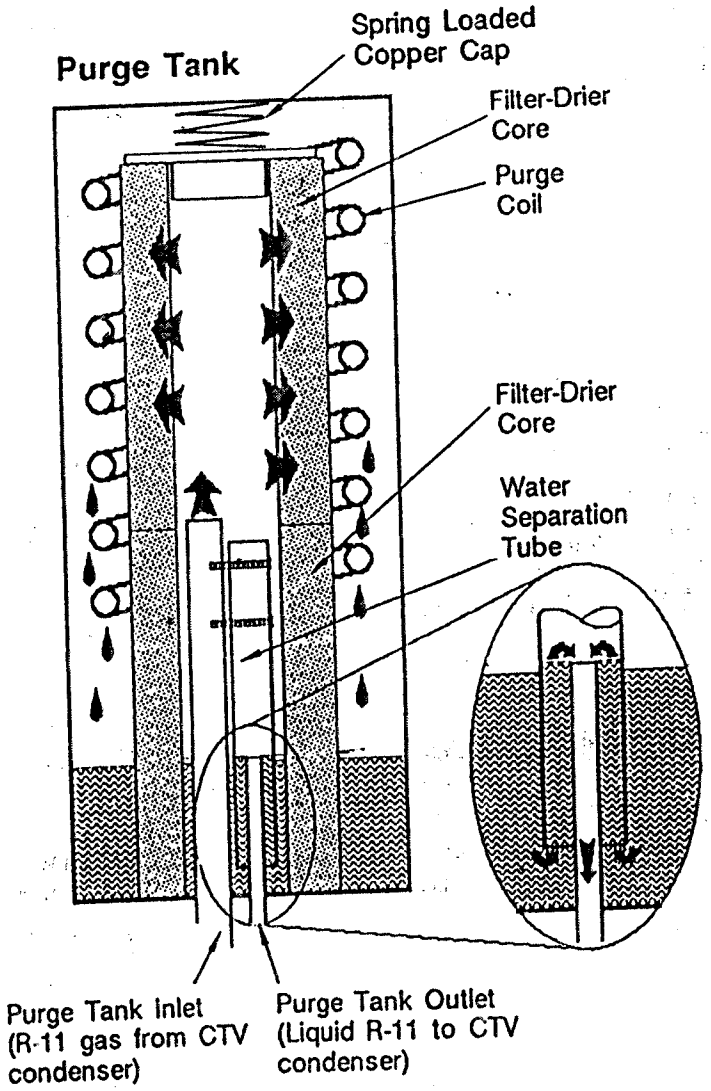
I. - **Filter-Drier Core Movement**
II. - **Filter-Drier Core Disintegration**
III. - **24-Hour Fault Timer Setting**
IV. - **Smart Timer Fault Bypass Premature Reset**

I. Drier Core Vibration Failures:

Discussion:

A number of purge units in the field have been identified as having a problem with excessive wear occuring on the outside surface of the drier core. Evidently, normal unit operating vibration is causing the drier cores to rotate during system operation. This rotation causes the drier cores to rub against the purge coil, damaging the drier cores. Residual material from the drier core either collects at the bottom of purge tank, enters the liquid return line, or floats on the surface of the liquid refrigerant in the bottom of the purge tank.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.



Units Affected:

All Purifier Purge units that were manufactured prior to January 9, 1991 are affected by drier core movement. This includes purges that are factory-mounted on CVHB and CVHE units and purge units that were sold for retrofit applications.

Corrective Action:

To correct this problem, a spring-loaded copper cap is to be installed on top of the drier cores. Refer to Figure 1. The spring-loaded cap will maintain tension on the drier cores, preventing movement. The existing filter cap in the affected units should be replaced with the new cap during routine Purifier Purge maintenance. As of January 1991, all Purifier Purge units are being manufactured with the spring-loaded cap.

Figure 1
Purge Tank with Spring-Loaded Drier-Core Cap Installed

©American Standard Inc. 1991

Parts Ordering Information:

Order one spring-loaded drier-core cap for each purge unit affected using the following part number:

Trane Part No. CAP0282 = Drier-Core Cap; Spring-Loaded

Order from LaCrosse, "Ship from 31".

II. Drier Core Disintegration:

Discussion:

In a number of instances, drier-core disintegration has been discovered on the outside surface of the drier core. Disintegration occurs when the drier cores become saturated with water. This results in a desiccant powder which may flow into, and restrict the liquid return line.

When saturation of the drier cores occur, free water collects in the purge tank. With the presence of free water in the tank, disintegration of the drier cores may occur in one, or both, of the following areas on the drier-core surface:

- Near the bottom of the purge tank, where a layer of liquid refrigerant is maintained. It is in this area where drier-core granules decay from constant exposure to free water which floats on the refrigerant surface.

- If purge tank temperature falls below 32 F during purge operation, the water near the outside surface of the saturated drier cores may freeze next to the purge coil. Freezing will also cause granules of the drier core to decay.

Units Affected:

All Purifier Purge units manufactured to date.

Corrective Action:

Present corrective action for this problem is to stress the importance of periodic inspection of the moisture indicator. On factory-installed purge units, a moisture indicator is provided in the liquid return line from the purge tank to the CenTraVac condenser. This allows the machine operator to monitor the quality of the refrigerant in the system. Refer to "Moisture Monitoring and Removal" in the Trane Purifier Purge operation and maintenance manual. The current Purifier Purge operation and maintenance literature (PRG-OM-3) is being revised regarding moisture in the system and will be reissued as PRG-OM-3A.

Although the Trane Purifier Purge incorporates two high-capacity filter-drier cores for dehydration, they are <u>not</u> designed to remove free water from the purge tank. If there is excessive moisture in the system, remove the drier cores and operate the purge system continously for 24-48 hours. Once all excess water has collected in the purge tank, remove the water, following the procedures in the operation and maintenance literature. If excessive moisture is a persistent problem, it is recommended that a Trane Interclean™ unit be installed to provide continuous moisture removal.

Warning: Do not operate with drier cores installed if free water exists in the purge tank.

Parts Ordering Information:

There is no parts ordering requirement for the drier core disintegration problem.

III. 24-Hour Fault Timer Setting:

Discussion:

The Purifier Purge "smart timer" is a key component for protecting the chiller's refrigerant charge. The desired time setting of the fault timer is operator-selectable on a 10-Bit Dip Switch located on the timer. The factory setting on this timer is 12.8 minutes, and the maximum recommended setting is 20 minutes. However, the purge operation maintenance manual (PRG-OM-3) suggests that any setting within the variable range (0.1 thru 102.3 minutes) is acceptable. This is not true.

Units Affected:

All Purifier Purges, design sequence 1C, that were manufactured between October 1, 1990 and current production are affected. This includes both purges that are factory-mounted on CVHB and CVHE units, and purge units that were sold for retrofit applications.

Corrective Action:

Check the purge fault timer setting. Allowable settings range from 1.0 minute to 20 minutes. Correct the setting of any timer not set within this range. The operation and maintenance literature will be revised to clarify the acceptable range. No labor is authorized for this action.

IV. Smart Timer Fault-Bypass Premature Reset:

Discussion:

The purifier purge unit can be operated in a "fault-protection-bypass" mode. During this mode, the fault timer (3DL2, 6DL2) ignores all purge pumpout activity. A problem has been identified in a number of instances where the 24-hour fault timer resets itself back to the normal fault-protection mode even though it is supposed to be in the bypass mode. This is caused by electrical noise generated by the temperature switch (3S15) and the pumpout solenoid valves (3L1, 3L3).

If the timer resets itself to the normal mode prematurely when a large amount of air or nitrogen is present in the system, the following will occur:

- The purge pumpout compressor will operate until the accumulated buffer time of the fault timer exceeds the setting of the timer.

- Once the buffer time is exceeded, the timer detects a fault and turns the purge unit off.

- The fault condition will remain until timer power is manually cycled for more than 1/2-second.

 ©American Standard Inc. 1991

Units Affected:

All Purifier Purge units, design sequence 1C, that were manufactured between October 1, 1990 and February 18, 1991 are affected. This includes both purges that are factory-mounted on CVHE and CVHB units and purges that were sold for retrofit applications.

Corrective Action:

As a field fix for this problem, a Quencharc surge suppressor should be installed across service switch 3S4. Refer to the electrical schematic in Figure 2. Remove the wire from each side of the service switch. Push the end terminals of the surge suppressor onto the switch and reattach the wires removed from the switch to the piggy-back terminals on the surge suppressor.

Because operation in fault-protection bypass mode is not often required, this problem is not of an urgent nature. The surge suppressor should be installed during routine purge maintenance. No labor is authorized for this procedure. As of February 18, 1991 all Purifier Purge units are being manufactured with the surge suppressor factory-installed. Future plans include replacement of the present fault timer with one that utilizes a built-in surge suppression device.

Parts Ordering Information:

Order one Quencharc Surge Suppressor for each Purifier Purge unit affected using the following part numbers:

Trane Part No. SPS0019 = Quencharc Surge Suppressor

Order from LaCrosse, "Ship from 31".

PRGA-SB-3 (7/92) -- Original Issue

Subject: Purifier Purge Restrictor Rework

Introduction:

The purpose of this bulletin is to provide details and authorization for the retrofit of selected Purifier Purge units, Model PRGA.

Discussion:

It has been determined that selected Purifier Purges built in early May, 1992, may have shipped without a restrictor at the inlet of the purge pump. The omission of this restrictor reduces the separation efficiency of the purge.

Units Affected:

The following units are affected and need to be retrofit.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Purifier Purge™ Human Interface Software Retrofit

Problem Discussion

A software problem has been identified on the Purifier Purge™ with microprocessor controls. The problem causes erroneous alarms to be displayed through the Human Interface while operating in the "Adaptive" and "On" modes. The alarms do not interrupt the normal operation of the purge and any subsequent alarms will take precedence. An EPROM chip change in the Human Interface Module (6U1)is required.

The purpose of this Service Bulletin is to alert you to this problem and to provide instructions to remedy the software problem.

Units Affected

All Retrofit version Model PRGC Purifier Purges shipped between September 24, 1993 and January 5, 1994 are affected. This covers units with Serial Numbers L93J0901 through L93M12630.

Note: PRGC Purges provided on new CVHE/F CenTraVacs are NOT affected.

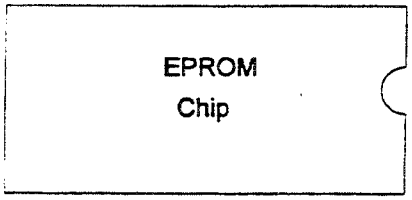
Material Authorization

The following part should be ordered from a Trane Parts Center for each affected purge in your territory.

Item	Part Number	Qty Req'd per Purge
EPROM Chip	CHP0020	1

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

©American Standard Inc. 1994



Repair Instructions

The existing EPROM chip in the Human Interface Module (6U1) must be replaced. Due to the delicate nature of this chip change, it should be performed by a technician familiar with servicing electronic components.

1. Disconnect power from the purge unit.

   WARNING! Failure to disconnect all power to the unit before performing this repair can result in cause equipment damage and/or serious bodily injury or death.

2. Remove the 4 screws on the front of the Human Interface module (6U1) and while touching only the metal faceplate, carefully tilt the module forward.
3. Locate the EPROM chip in the approximate center of the module. Using a chip puller or a small screwdriver, carefully remove the chip from the socket. If using a screwdriver, be sure to evenly pry out the chip to avoid any damage to the socket. Do not attempt to pull the chip out with your bare hands. Remain in contact with the metal faceplate at all times whilereplacing the EPROM chip.
4. Ground yourself immediately prior to removing the new EPROM from the shipping box. Match the notch on the chip to the notch in the socket, carefully line up the pins with the socket and press the new chip in place. Again, remain in contact with the metal faceplate at all times.

Caution: Electrostatic discharge can damage sensitive electronic components such as those located on this circuit board. Always ground yourself by touching a metal object such as the control box of the purge before coming into direct contact with any of the components on the board.

5. Tilt the module back into place in the enclosure and replace the 4 screws.
6. Apply power to the purge. Upon applying power, the display should light and within a few seconds display the words American Standard and the software code number. The proper software code is 6200-0052-02. (This number is also shown on the label on the back of the chip.)

Material Disposition

The defective part should be disposed of in the field.

New Production

All purges shipping after January 5, 1994 include the latest software revisions.

Subject: Unexplained Purge Pumpout

Introduction:

This service bulletin details Unexplained Purge Pumpout conditions that can affect PRGC style Purifier™ purges with HCFC-134a refrigerant. Purges having unexplained pumpout problems exhibit excessive pumpout minutes virtually from the point of startup.

Units Affected:

PRGC Purifier purges with refrigerant HCFC-134a, design sequence CO and DO, could exhibit this problem.

Discussion:

Occasional complaints of Purifier purges experiencing excessive pump-outs have been received. Virtually all such complaints can be resolved with careful examination of the purge and chiller. Common things that can imitate this condition are:

1. Excessive air in the chiller
2. Plugged pumpout restrictor
3. Plugged pumpout tubing
4. Leaks on the pumpout circuit tubing
5. Failed solenoid valve
6. Faulty pumpout compressor

©American Standard Inc. 1997

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Discussion: (continued)

7. Faulty temperature sensor
8. Vapor or liquid connections below the liquid level in the chiller condenser
9. Plugged vapor or liquid lines to the condenser
10. Leaking filter drier canister or cover not on tight
11. Plugged filter drier cores
12. Leaking purge tank around the sight glass
13. Faulty 3U1 module - stuck contacts
14. Plugged purge sump drain line
15. Installation error - retrofit purifier purges
16. If none of the above — Unexplained Pumpout

Whenever there is an excessive pumpout complaint, these possible causes should be investigated. The vast majority of complaints are resolved through discovery of one or more of these factors.

In very rare instances, no apparent cause can be found for the excessive pumpout. Experience has revealed a combination of previously unknown conditions that could cause excessive pumpout complaints for PRGC Trane HCFC-134a equipped Purifier™ purge units. These factors include condensing unit performance, charge and heat exchanger component layout geometry that effect refrigeration system performance.

It is believed that an unusual combination of these factors could cause the unexplained purge pumpout complaints seen on some PRGC purges.

Whenever a "purge fault" pumpout alarm occurs, the operator is encouraged to check for evidence of non-condensibles in the chiller. If evidence of non-condensibles is not found, the operator should not use the "24 hour override" to bypass the pumpout alarm. Instead, a technician should check and rule out all of the fifteen excessive pumpout causes above. In most cases, one or a combination of these causes will explain the problem.

If all common causes of excessive pumpout have been ruled out, the purge should be evaluated to see if its performance characteristics are consistent with the unexplained purge pumpout problem. The unexplained purge pumpout problems on PRGC purges are characterized by:

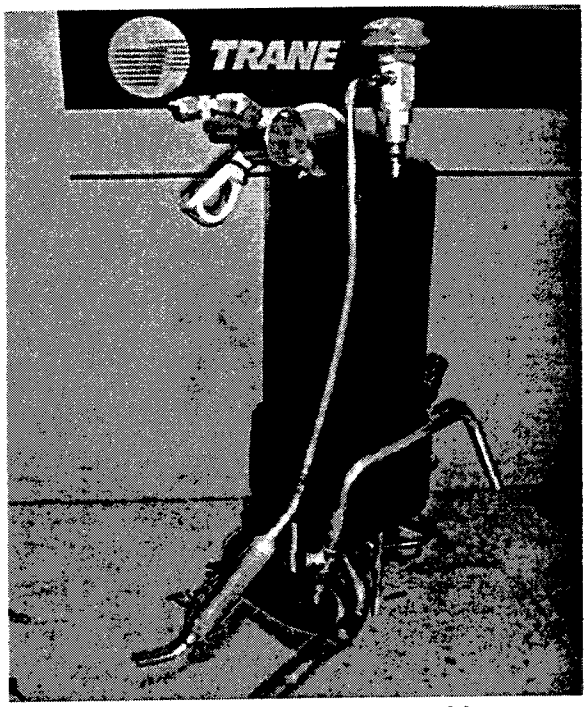
a. Repeated "purge fault" pumpout alarms in the apparent absence of non-condensibles in the chiller. These alarms have been evident from purge startup.

b. These unexplained "purge fault" alarms only occur when the chiller is operating and chiller condensing temperatures are above 80° F.

To verify that a purifier purge has this unusual condition, monitor the chiller's saturated condenser refrigerant temperature during purge operation. The saturated condenser refrigerant vapor provides the load for the purge tank. Adjust the tower water or building load to obtain a 75° F saturated condenser refrigerant temperature and check the purge's suction temperature. Slowly increase the tower water or building load to obtain a 110° F saturated condenser refrigerant temperature and observe the purge suction temperature.

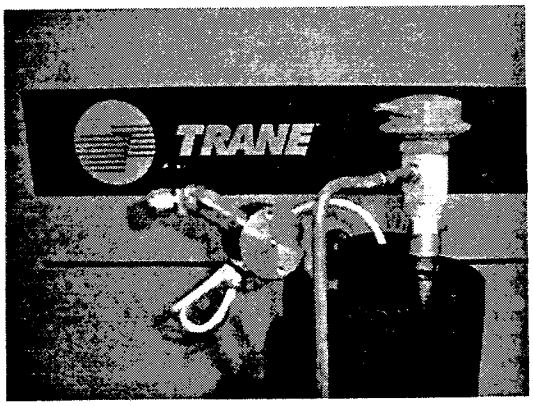
If the purge suction temperature drops to a very low temperature (for example, -6° F) and stays there at any point during this test, an "unexplained pumpout purge" has been identified. Verify by decreasing the saturated condenser refrigerant temperature. The suction temperature of an unexplained pumpout purge will rise and approach the condenser temperature at some point while the saturated condenser refrigerant temperature is lowered.

Material Required:



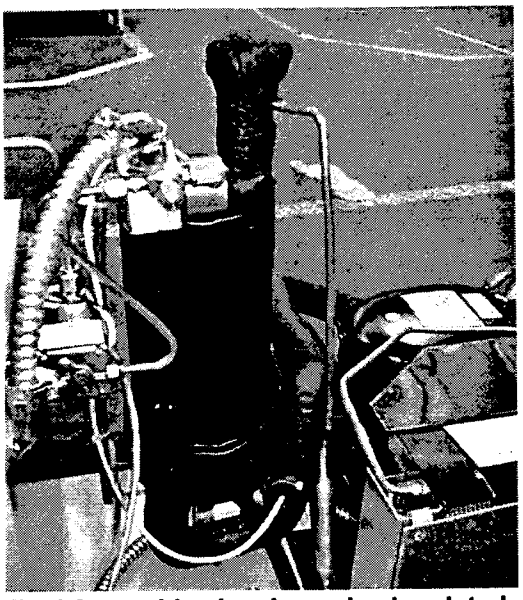
The following parts should be ordered from a Trane Parts Center for each Purifier™ purge that is retrofit.

- Filter Drier - DHY 0294
- Expansion Valve - VAL 4418
- 1/4" copper refrigeration tubing (field supplied)



Repair Instructions:

Rework the Purifier™ Purge using the following steps:



1. Close the chiller refrigerant 5/8" vapor pick-up and 1/4" drain line valves.
2. Recover the R-123 refrigerant from the purge tank using 1/4" access valve on the tank (water drain valve). Dispose / reclaim in accordance with all local, state and federal codes.
3. Remove insulation from the top of the purge tank and remove the 1/4" fusible plug from the top of the tank.
4. On the R-134a system, install a line tap valve or equivalent on the suction and discharge (or liquid) lines and recover the R-134a charge. Dispose / reclaim in accordance to all local, state and federal codes.
5. Remove the line tap valves and permanently braze line access valves (Shrader or equivalent 1/4" size) in their place. Be sure to purge dry nitrogen through the system while brazing, to prevent copper oxides from forming in the refrigeration system.
6. Cut the 3/8" refrigerant line entering the top of the purge tank just below the swaged (belled) connection using a tubing cutter. A short stub of straight 3/8" line should protrude from the top of the tank to allow installation of the new expansion valve. Cut the line or unsweat the filter-drier at the entering connection closest to the condenser. Be sure to flow dry nitrogen through the line if unsweating. This will allow removal of the expansion valve and filter-drier in one section. Dispose of the lines, expansion valve and filter-drier per all local, state and federal codes.
7. Form a new 1/4" copper line as shown in the photographs on the following page. Use refrigeration grade copper tubing.
8. Fit up the new expansion valve, 1/4" line and filter drier. With shrader valve cores removed, flow a small amount of dry nitrogen through the R-134a refrigeration circuit. Introduce the nitrogen through the suction fitting and feel for a slight flow from the discharge or liquid fitting.
9. Flow dry nitrogen into the purge tank R-123 side through the 1/4" access valve on the lower tank. A slight positive flow should be felt from the top of the purge tank at the 1/4" pipe fitting hole where the fusible plug was removed.

Valve Location and Tubing Assembly (Note: Filter Drier should be installed at approximately 45°angle as shown.)

Valve Location

Final Assembly showing valve insulated

10. Braze the expansion valve, 1/4" line and filter drier assembly using a high temperature silver brazing alloy such as BCuP-5 (15% silver), which does not require flux for copper to copper joints. Be sure to use care while brazing the expansion valve to not overheat and disturb surrounding braze joints.

11. After allowing the joints to cool, discontinue the dry nitrogen flow and replace the shrader cores in the valves. Introduce a trace amount of R-22 vapor, 20 psig or so, and charge dry nitrogen to a final pressure of 75 psig into the R-134a refrigeration circuit. Leak check the system using a sensitive electronic leak detector. Repair any leaks found being sure to flow dry nitrogen through the system while brazing.

12. Reinstall the fusible plug in the top of the purge tank. Using R-22, pressurize the purge tank R-123 refrigeration side to 15 psig. Leak check the system using a sensitive electronic leak detector. Repair any leaks found, being sure to flow dry nitrogen through the system if brazing is required to repair the leak.

13. Reinsulate the expansion valve and top of the purge drum as shown in the photograph above.

14. Evacuate the R-123 system at the purge tank access valve to at least 1000 microns.

Evacuate, dehydrate and charge the R-134a system using the following procedure:

1. Attach a vacuum pump to the high and low side of the system, use a micron gage and monitor the vacuum level for at least a 60 minute period. A heat lamp placed on the compressor sump can be used to enhance the dehydration/evacuation process. Values as low as 10-100 microns may occur.

2. Isolate the unit for a 30 second vac rise test and note the result.
   - If the pressure rises steadily to atmospheric, a leak is indicated. Repair the leak and repeat the evacuation and dehydration test.
   - If the pressure initially rises rapidly and then stabilizes with a very slow rate of rise to a value greater than 600 microns but lower than atmospheric at 30 seconds, moisture is still present in the system. Repeat the evacuation and vac rise test. If moisture is not adequately removed using this procedure, a triple evacuation with heat lamps on the compressor sump and purge tank may be necessary.
   - If the pressure initially rises rapidly and then stabilizes with a very slow rate of rise to a value less than or equal to 600 microns at 30 seconds, the unit passes the vac rise test and is ready for charging.

3. Charge the unit with 8 oz of R134a.
   - Replace the micron gage with a vacuum/pressure gage (30 inHg -150 psig) with good accuracy in the 0-10 psig range.
   - Introduce the charge into the purge unit with the condensing unit running. The condenser sub cooling (the difference between the third u-bend and leaving condenser temperatures) should be between 9-10°F with the proper amount of charge in the unit.
   - As charge is introduced, the condensing unit compressor suction temperature may drop, depending on the amount of air remaining in the chiller refrigerant circuit.
   - Observe the pressure gauge after about five minutes. The pressure should fall between 2 - 6 psig.
   - If the pressure is higher than 10 psig, then the expansion is faulty and needs to be changed along with the filter drier. After changing the expansion valve and filter drier, repeat the leak, evacuation and dehydration tests.
   - If the pressure is less than 1 psig after about 1/2 hour one or more of the following may be occurring:
     — a blockage may exist in the refrigerant circuit
     — the expansion valve is faulty
     — the unit is undercharged
     thus inhibiting proper refrigerant metering.
     Repair as required.
   - With the chiller valves open, verify that the suction temperature approaches the chiller condenser saturation temperature. Introduce nitrogen into the purge tank through the water bleed valve and verify that the purge suction temperature drops and a pumpout cycle occurs.

Material Disposition:

The defective materials should be disposed of in the field in accordance with local codes.

New Production:

All purges design sequence EO shipping approximately after June 24, 1997 have the relocated expansion valve.

Model Number and Nameplates

Unit Model Number

For service and replacement purposes, the Trane Model RMWD Refrigerant Monitor is assigned a multiple-character alphanumeric model number that precisely identifies each unit. The model number key is shown here.

Use of the model number will enable the owner/operator, installing contractor, and service technician to define the characteristics of any RMWD unit. Be sure to refer to the model number when ordering replacement parts or requesting service.

Nameplates

The Model RMWD unit nameplate is located on the right side of the monitor (when facing the front). The nameplate includes the service model number, unit serial number and electrical information. Refer to this information whenever making inquiries or ordering replacement parts. A nameplate is shown below in Figure 1. An abbreviated version of the nameplate is also provided on the outside of the shipping package (Figure 2).

General Information

Literature Change History

RMWD-IOM-1 (August 1994)

Original issue of the manual pertaining to design sequence A0.

RMWD-IOM-1A (November 1994)

Manual revised to include:

- Expanded product line for various refrigerants
- Additional audible alarm capabilities
- Recommended alarm levels based on refrigerant type
- Changes to Clear Language Display software from Version 1 to Version 2

RMWD-IOM-1B (March 1995)

Manual revised to include:

- UL Listing

RMWD-IOM-1C (January 1996)

Manual revised to include:

- Minor text clarifications

RMWD-IOM-1D (November 1997)

Manual revised to include:

- Updates of the Factory Default values for refrigerants

Receiving

Upon receipt of the unit, inspect the shipping carton for signs of visible damage. Report any damage to the carrier and note it on the delivery receipt. Unit must be stored in a dry, secure place prior to its installation and use. Store in the original shipping carton.

Unpacking

Carefully remove the monitor from the shipping container. Inspect it for signs of visible shipping damage. If any damage is found, report it to the shipper immediately. Do not install or operate a damaged unit without sales office approval.

Confirm all the loose items shipped with the monitor have been received. Each carton should contain:

Qty
Item

(1) Refrigerant Monitor
(1) Particle filter holder and element (3 additional filters if scanner option is provided)
(2) Power Fuses
(1) Power Jumper
(1) Installation, Operation and Maintenance manual

Note: The particle filter(s), fuses and the jumper are shipped in a small box inside the main monitor shipping carton. Make sure it does not get discarded or lost.

Report any shortages immediately to the local Trane office. Retain the original packing for re-use in the event the unit must ever be returned for service.

Warnings and Cautions

Warnings and Cautions appear at appropriate sections throughout this manual.

⚠ WARNINGS
alert the installer, owner, operator or service personnel to potential hazards that, if not avoided, could result in death or serious personal injury.

⚠ CAUTIONS
are provided to alert personnel to conditions which, if not avoided, may result in minor or moderate injury. It may also alert against unsafe practice causing damage to equipment.

General Information

Unit Description

The TraneTM Model RMWD Refrigerant Monitor circulates room air through a sensing cell to provide a continuous indication of refrigerant vapor concentration. It is intended for indoor use in mechanical equipment rooms which house air conditioning or refrigeration equipment or in areas where bulk refrigerants are stored. The monitor utilizes infra-red photo-acoustic sensing technology, allowing accurate measurement of refrigerant vapors with minimum interference from other chemicals in the vicinity. The instrument is compound-specific and factory calibrated for the specific refrigerant of interest. It is capable of measuring down to 1 ppm and displaying refrigerant concentrations from 0-1,000 parts-per-million (ppm). The monitor can signal alarms at three different concentration levels. These alarms are factory set, but can be easily adjusted in the field. A unit trouble alarm indicates internal problems with the instrument. A level alarm or a trouble alarm condition will cause the display to flash with a diagnostic message and activate a dry contact relay(s) which can be used to control external alarm lights or horns, start emergency ventilation, or signal a building management system. The refrigerant level alarm relays can be configured as latching or non-latching. 0-10 VDC and 4-20 mA analog outputs are provided for connection to a data recorder or building management s ystem. These analog outputs can be scaled as 0-100 ppm or 0-1000 ppm. The standard unit monitors one zone. The optional multi-channel scanner can be factory or field installed to monitor up to 4 zones.

Clear Language Display (CLD)

All setup, alarm, diagnostic, measured concentration and calibration information for the monitor is accessed through an 8 button, 2 line, 16 character backlit clear language display (CLD) mounted in the unit front panel.

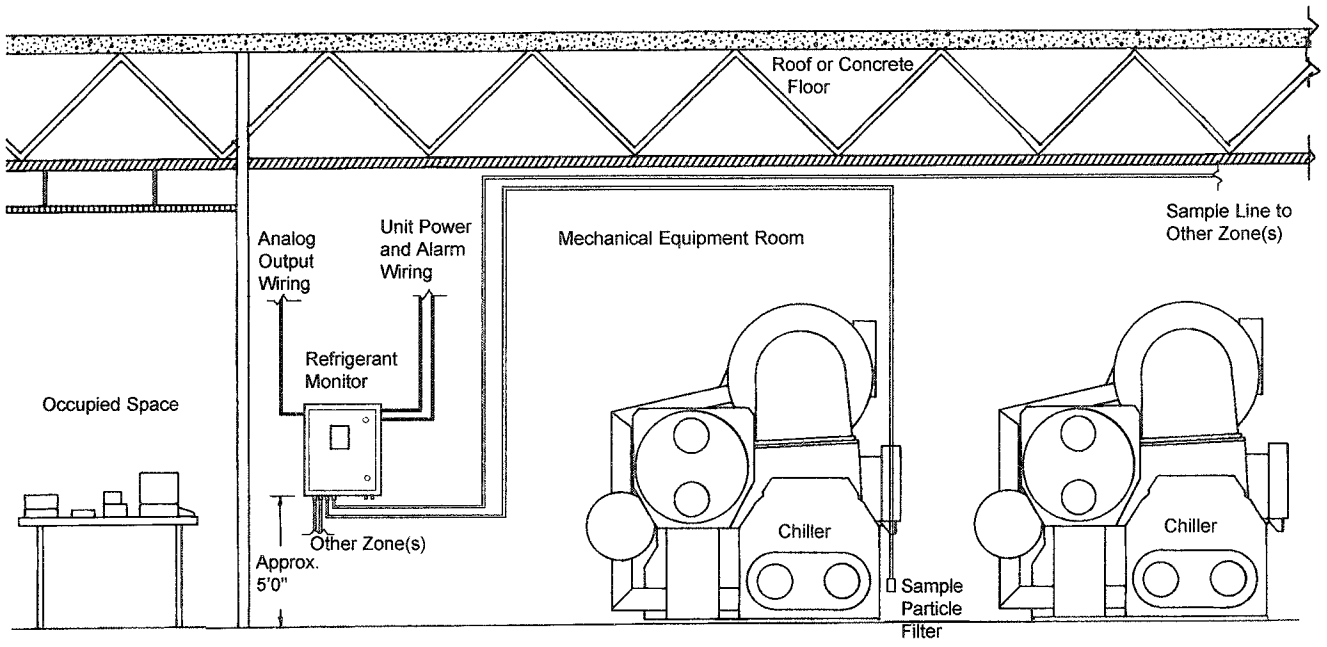
Location of the Unit

The ability of the monitor to properly measure and display the refrigerant concentration is dependent on the location of the monitor and the sensing pick-up point(s).

Locating the Monitor

Items to consider in locating the Refrigerant Monitor include:

- Mount the unit in a location where it will be free from shock and vibration. Avoid mounting to piping or piping supports which may transmit vibration from pumps, chillers, etc.
- Mount the unit so the front panel display can be easily viewed.
- Do not locate the unit near an excessive heat source or in direct sunlight. Mount in an area of stable temperature and humidity conditions.
- Unit must be mounted in a vertical position.
- Locate in an area where it can be easily accessed for service and calibration.



Locating the Sensing Point(s)

Due to the wide variation in equipment room layouts, each situation must be analyzed individually. A sensing point may be remotely located up to 150 feet from the monitor and positioned 12 to 18 inches above the floor in an area where refrigerant vapors are most likely to accumulate.

Note: The 150 feet refers to the total sample and exhaust line length.

The following should be considered when selecting the location for the refrigerant pick-up point(s).

Figure 3
Typical RMWD Refrigerant Monitor Installation

Note: Monitors without scanner option have one sampling port. Those with scanner will have four ports.

Installation

Room Configuration

Since all fluorocarbon refrigerants are three to five times heavier than air, they will concentrate near the floor and in low areas such as pits and stairwells. Large pits and stairwells should be ventilated and monitored.

Airflow Patterns

Airflow patterns can cause areas of the room to become stagnant and refrigerant vapors to accumulate. The sampling point should be between the refrigerant source (typically the chiller) and the ventilation exhaust inlet. Smoke tubes are useful in determining the ventilation patterns.

Equipment Configuration

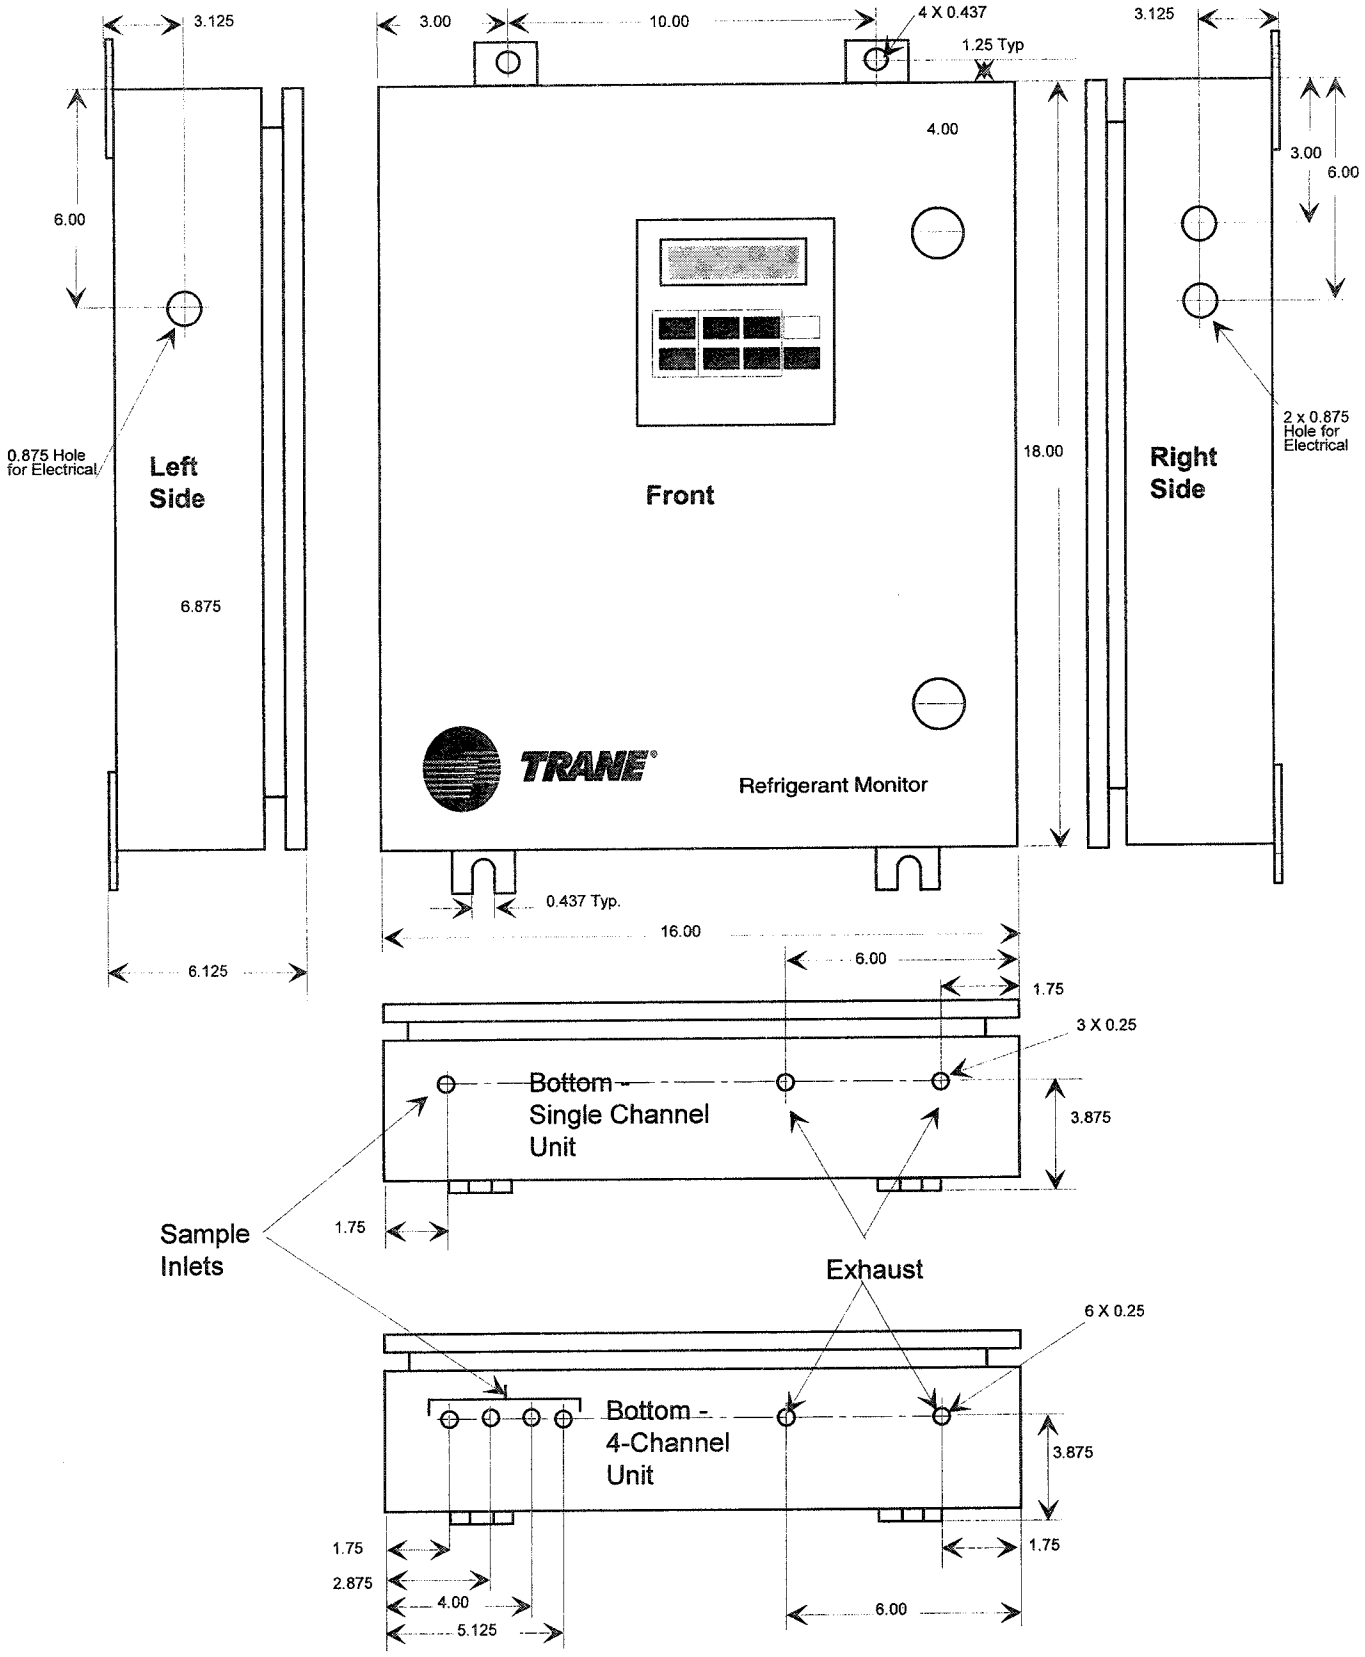
The equipment arrangement in the room can also have an impact on the most effective place to sample. As a general guideline, if there is one chiller in the room, sample at the perimeter of the unit. For two chillers, sample between them. For three chillers, sample at the middle chiller. With four or more chillers, multiple monitors or a single monitor with a multi-point sampling system should be used. Typically, a sensing point can handle a radius of 50 feet; however airflow patterns must always be considered.

Activity in the Room

The expected activities in the room must also be considered when determining the sensing point. As stated earlier, refrigerants will concentrate near the floor. Typically, sampling 12-18 inches above the floor is sufficient for early warning and to provide adequate protection for someone working closely to the floor. If it is expected that an occupant's breathing zone may be less than 12-18 inches off the floor, locate the sampling point accordingly.

Note: Select sampling locations which result in the shortest possible line length to reduce transport time.

For more information on equipment room design and monitoring, refer to Trane Application Engineering Manual REF-AM-3, "Refrigeration System Equipment Room Design" available from your local Trane office.



Mounting

The monitor has four mounting tabs on the back panel of the enclosure. Securely mount the Refrigerant Monitor to the wall or structure using appropriate mounting hardware.

⚠ CAUTION

Do not mount the monitor directly to a chiller or use brackets other than those provided. Unit vibration may affect the operation of the monitor.

Physical Data

Sample Tubing Installation

Sample inlet and exhaust connections for the air sampling system are located on the bottom of the unit. (See Figure 4 for locations of the connections). The connection fittings are self-clamping and require no special tools or additional fittings. They are designed to accept 1/4 inch OD copper tubing.

⚠ Caution:
Insert only clean tubes, cut with a tubing cutter, into the fittings to ensure a smooth, contaminant-free connection.

The sampling line(s) can each be up to 150 feet long using 1/4 inch O.D. tubing.

Note: The maximum total length of the sample and exhaust line(s) is 150 feet.

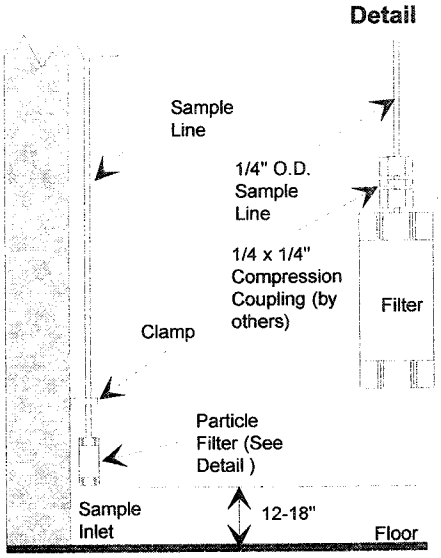
Note: Install line(s) so that they can be easily removed for calibration.

Route the sample tubing to the area to be monitored. 1/4 inch O.D. rigid copper tubing with flare or compression type fittings is recommended. Soldered connections on the sample line(s) should be avoided due to the possibility of the monitor being sensitive to the solvents in the soldering flux paste. Plastic tubing should be avoided due to its tendency to absorb refrigerants which could possibly cause a delayed alarm and/or slowly leak out gas later resulting in a nuisance alarm.

After the line(s) are installed and BEFORE they are connected to the monitor, they should be blown out with compressed air or nitrogen to remove any debris and leak checked to assure they are leak-free. Then connect the line(s) to the sample port(s) on the monitor and install the end-of-line filters as shown in Figure 5.

All unused sample port(s) must have an end-of-line filter installed to avoid debris entering the unit and to retain NEMA-4 integrity.

⚠ Caution:
The end-of-line filters must be in place whenever the monitor's pump(s) are operating. Operation without sample filters will damage the unit.



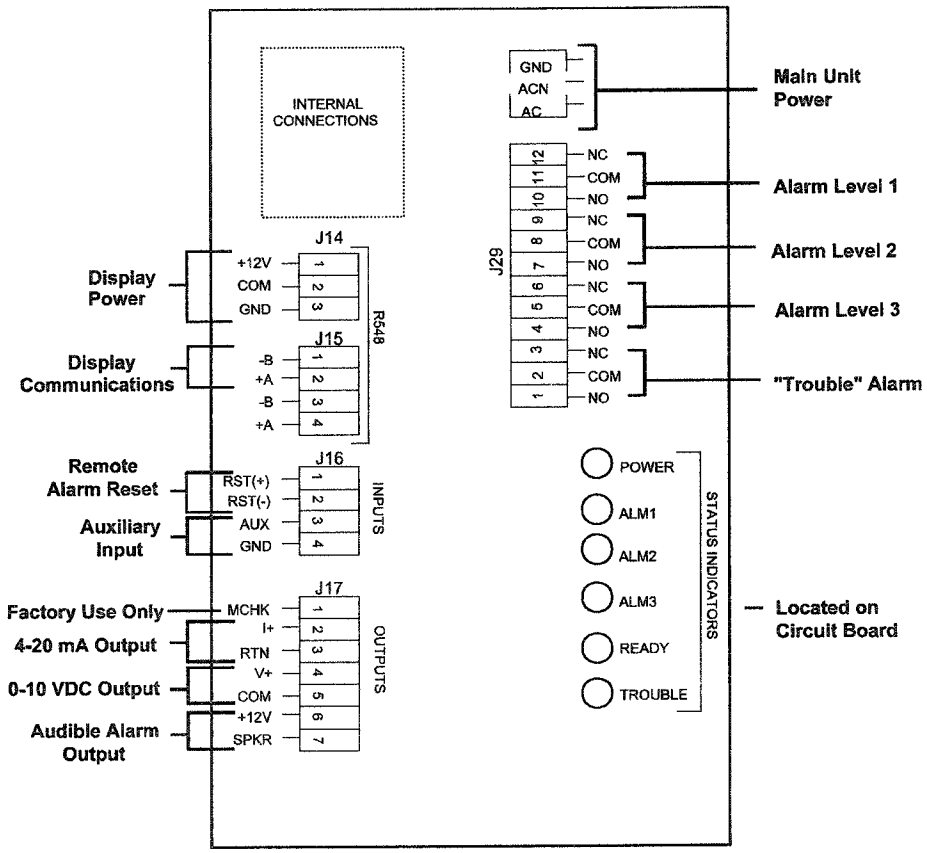
Note: Trane filter element part number is ELM1144.

Exhaust Tubing Installation

The monitor has two exhaust ports. If the monitor is located in the same room as the sample inlet(s), the exhaust can be vented back into the room. If sample is coming from a separate area, the exhaust should be piped back to the same area or to another safe area. If the exhausts are vented to a remote area, the two exhaust lines must be run individually to avoid any possible effects of back pressure on the instrument.

⚠ Caution:
Never connect to a vacuum or pressure source or install in-line devices such as a flow meter in the exhaust lines. Monitor exhausts must vent to atmospheric pressure to avoid damage to the unit.

Figure 5
Typical Filter Installation



Electrical Connections

⚠ WARNING
Open all disconnects before making wiring connections. Failure to do so can result in serious personal injury or death due to electrocution.

⚠ Caution
Do not drill additional holes in the enclosure. Use the openings provided for electrical connections. Metal shavings caused by drilling may short out electronic components causing equipment malfunction.

Two 0.875 inch openings are provided on the right side of the unit and one 0.875 inch on the left side for electrical connections to the monitor. The unit ships with the holes plugged. Open only the holes necessary for your specific installation. To retain the NEMA-4 integrity of the enclosure, appropriate NEMA-4 conduit and connectors must be used for all connections.

Figure 6
Field Electrical Connections

Note: See the "Electrical Connections" Section for additional wiring information.

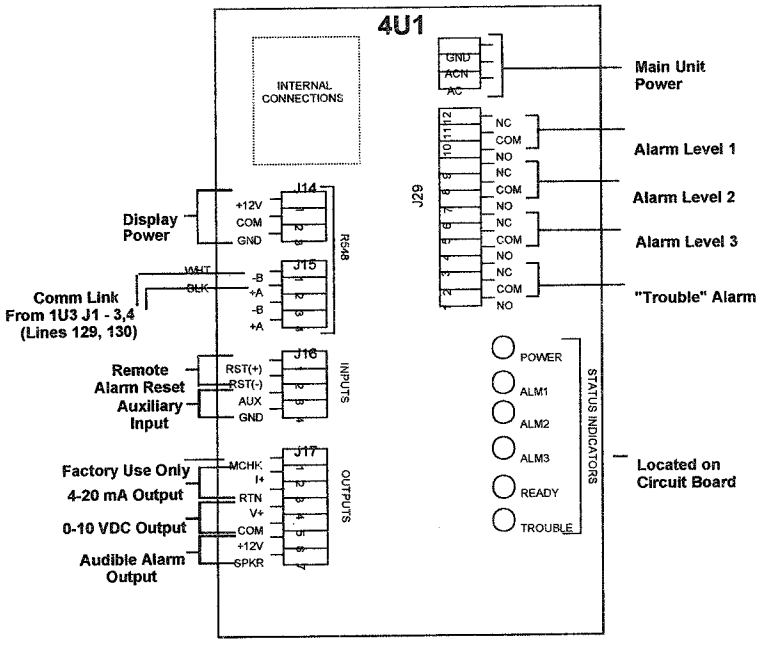
Electrical Connections

Optional Trane Unit Mounted Refrigerant Monitor

The optional Trane unit mounted refrigerant monitor is identical to the remote mounted monitor; however no clear language display (Human Interface) is mounted to the front panel of the monitor. A plain painted front panel, with a pilot light to indicate power is present, replaces the clear language display. The chiller UCP2 Clear Language Display (Human Interface) displays monitor status and information. The UCP2 set-ups, reports, calibration and diagnostic menus are identical to the remote monitor. All monitor setups, inputs, calibration and diagnostic menus are shown in service manual, CVHE-CLD-1.

The unit mounted refrigerant monitor is designated 4U1 on • Trane wiring diagrams as shown in Figure 6A.

⚠ CAUTION



Do not install with high voltage wiring (>30 volts) sharing the same panel entrance hole or conduit with low voltage (<30 volts) wiring. Electrical interference can result.

Unit Power Wiring

A separate, dedicated power source is recommended for the refrigerant monitor to insure that the unit remains powered when other circuits are shut down for servicing, routine maintenance or shift changes.

The monitor utilizes a wide range power supply which can accept AC power from 100 to 240 volts (nominal), 50 or 60 Hz. The power wiring should enter the unit through one of the openings on the right side of the enclosure. Connections are made to the screw terminals labeled "AC", "ACN" and "GND" located in the upper right side of the unit. (See Figure 6 for location).

Figure 6A
Optional Field Electrical Connections

Note: See the "Electrical Connections" Section for additional wiring information.

Electrical Connections

The incoming power provided to the monitor determines the configuration of the fuse(s) and/ or jumper on the main power terminal block. The following tables show the fuse and jumper locations for various voltages.

Note: The monitor ships without fuses or jumpers in place. The unit is non-operational until they are properly configured for the power being applied.

Figure 7

220 Volts AC, 3 Conductor, 50 Hz

GND		GND
ACN	FUSE	ACN
AC	FUSE	AC

Alarm Relay Wiring

Three refrigerant level alarm relay outputs and one trouble relay are provided. All are Form C, SPDT relays which can be wired to either close or open its contacts in an alarm condition. Relay wiring should enter the unit through one of the openings on the right side of the unit. Connections are made at the internal terminal strip labeled J29 located on the right side of the circuit board. (See Figure 6 for location). The terminal portion of the connector can be unplugged from the circuit board for easier wire connections.

Note: It is recommended that the Trouble relay is wired as normally closed (contacts close on loss of power) to provide an alarm if main power is lost to the unit.

Contact Ratings:

Resistive Load

- 7.2 Amps @120 VAC
- 5.0 Amps @ 240 VAC

Inductive Load

- 2.88 Amps Pilot Duty
- 1/3 HP, 7.2 FLA, 43.2 LRA

Analog Output Wiring

Two types of analog outputs, a 4-20 mA and 0-10 VDC, are provided as standard. These voltage and current outputs are proportional to the displayed refrigerant concentration. The scaling of the outputs is software selectable as 0-100 or 0-1000 ppm. Connections are made to terminal strip J17 located on the lower left side of the main circuit board (See Figure 6). Analog output wiring should enter the unit through the hole provided on the left side of unit. The terminal portion of the connector can be removed from the circuit board for easier connection. 18 AWG, shielded twisted pair is recommended; 500 feet maximum length.

4-20 mA

The 4-20 mA output sources current to the module ground. Connections are made to terminals 2 (I+) and 3 (RTN) on J17.

0-10 VDC

The 0-10 VDC output sources voltage to 2 K ohms maximum load. Connections are made to terminals 4 (V+) and 5 (COM) on J17.

⚠ Caution:
Do not install with low voltage wiring (<30 volts) sharing an enclosure opening or conduit with higher voltage wiring (>30 volts). Multiple low voltage wires can however share an opening and/or conduit.

Electrical Connections

Remote Alarm Reset

Latched refrigerant level alarms can be reset through a momentary contact **opening** (normally closed set of contacts). Connections are made to terminal strip J16, terminals 1 and 2 with the wiring entering the enclosure through the hole on the left side of the instrument. The unit ships with a jumper across the reset terminals (J16, 1 & 2). The switch must have signal- level contacts, typically gold flash. The maximum distance from the reset switch to the monitor using 18 AWG shielded wire, is 300 feet. Refer to the section titled "Remote Alarm Reset" in this manual for more information about this feature.

Note: Terminate all wire shields on an appropriate ground at monitor.

Audible Alarm Output

A 12 VDC output is provided to drive an optional low-power (150 mA non-inductive maximum load) piezo-electric horn. Connection is made to terminals 6 (+12V) and 7 (SPKR) on J17. See the Installation Instructions provided with the Alarm Kit for details.

Remote Display Wiring (Optional)

The front panel clear language display can be remotely mounted up to 250 feet from the instrument. An optional blank-off panel kit is required to seal the enclosure and maintain the NEMA 4 integrity after the display is removed. The factory wiring from the display to the circuit board terminals will need to be disconnected and replaced.

Display Power:

18 AWG wire is recommended

Field Wire from:
TB2-1 on display to terminal #1 (+12V) on J14
TB2-2 on display to terminal #2 (Com) on J14
TB2-3 on display to terminal #3 (Gnd) on J14

Display Communications:

18 AWG, twisted pair shielded wire is recommended.

Field Wire from:
TB1-2 on display to terminal #1 (-B) on J15
TB1-1 on display to terminal #2 (+A) on J15

See the Installation Instructions provided with the Remote Display Option for more details.

Auxiliary Input

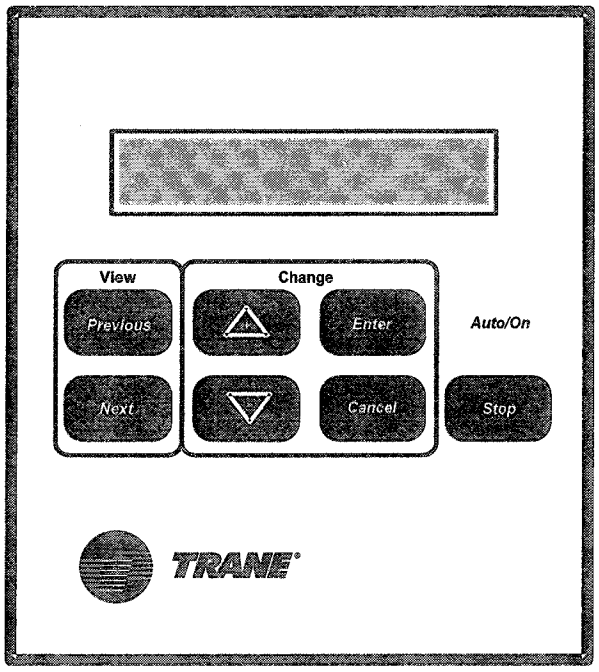
A 4-20 mA analog input can be made to the monitor from another device such as another refrigerant monitor or an oxygen monitor. See the section titled "Auxiliary Input" in this manual for a detailed description of this feature. The input wiring should be brought into the enclosure through the hole on the left side of the instrument and connected to terminals 3 (Aux) and 4 (Gnd) on J16. 18 AWG, twisted pair, shielded wire is recommended. Maximum length of wire run is 250 feet.

⚠ Caution:
All field wiring must be done in accordance with national and local electrical codes.

Operation

Display Overview

The human interface which is mounted to the front panel of the monitor contains eight keys and a two line, 16 character, backlit, clear language display (CLD). The displayed information is updated continuously by the microprocessor-based module located inside the enclosure. In the event of a refrigerant level alarm condition, the backlight will flash and the refrigerant concentration will be displayed. If a unit malfunction occurs, a "Trouble" alarm will be initiated and a service diagnostic message will appear. All operating parameters, setpoints, calibration and refrigerant levels are accessed through the CLD. After 60 seconds of no activity, the backlight will turn off. After 20 minutes of inactivity, (no key press) the screen will default to the first menu screen showing the operating mode, channel if a scanner is installed and the refrigerant concentration.



The keys are functionally grouped into a "View" section and a "Change" section. The "View" group includes the <Next> and <Previous> keys which are used to scroll from one menu to another.

The "Change" group includes <+> and <-> keys which are used to change set-up parameters within a menu. The <Enter> and <Cancel> keys are used to accept or reject a parameter change or to enter a side menu.

Note: The <Enter> or <Cancel> keys must be pressed after a change is made to accept or reject the change(s).

The <Auto/On> and <Stop> keys are not used for operating the Refrigerant Monitor. The monitor is "on" whenever power is applied.

Figure 8
Clear Language Display

Menu Overview

The Monitor display uses a major menu structure with entry points into side menus. (See Figure 9 Menu Flow Schematic.) The <Next> and <Previous> keys are used to navigate vertically through the menus. The side menus are accessed by pressing the <Enter> key at the major menu point. If a side menu is not accessed (entered), only the major menus (those shown in the left column) will appear. After the side menu is accessed, the <Next> and <Previous> keys are used to navigate vertically through those screens. After paging through the entire side menu, the display loops back to the major menu.

A brief description and range information for each menu item is given in Figure 10.

Figure 9
Menu Flow Schematic

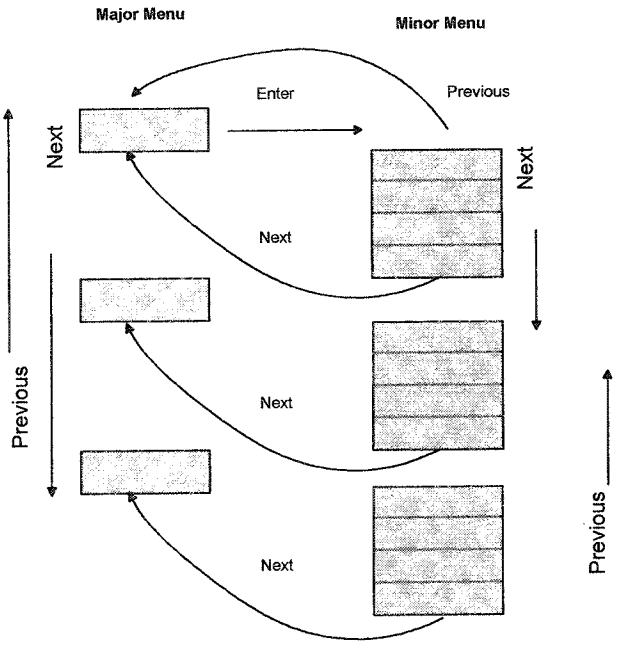


Figure 10—Refrigerant Monitor Menu Screens

Major Menu	Side Menus	Description
READY XXXX ppm R-XXX		Refrigerant Monitor operating mode [WARMUP, READY, MONITOR CHECK, TROUBLE] (Single Channel Unit Only)
CHAN X READY XXXX ppm R-XXX		Refrigerant Monitor operating mode [WARMUP, READY, MONITOR CHECK, TROUBLE] (Channel Scanner Unit Only)
1 STATUS Report < Enter> to View		Entry point into the SAMPLE Report
	Current Sample = XXXX ppm R-XXX	The current refrigerant sample point. (Displayed if channel scanner is not installed)
	Current Chan X = XXXX ppm R-XXX	The current refrigerant sample point. (Displayed if channel scanner is installed)
	Last Channel 1 = XXXX ppm R-XXX	The last value read from Sample Point #1. (Displayed if channel scanner is installed)
	Last Channel 2 = XXXX ppm R-XXX	The last value read from Sample Point #2. (Displayed if channel scanner is installed)
	Last Channel 3 = XXXX ppm R-XXX	The last value read from Sample Point #3. (Displayed if channel scanner is installed)
	Last Channel 4 = XXXX ppm R-XXX	The last value read from Sample Point #4. (Displayed if channel scanner is installed)
	Case Temp= XX.X C Bench Temp= XX.X C	The temperature of the Refrigerant Monitor's Case. The temperature of the Refrigerant Monitor's Optical Bench
	Auxiliary Input = XX.X mA	The current auxiliary mA signal being sent to the monitor. (Displayed if auxiliary input is installed.)
	Clear Lang Dspl Software Ver XXX	The current software version of the Refrigerant Monitor Clear Language Display.
	Rfgt Monitor Software Ver XXX	The current software version of the Refrigerant Monitor.
2 SETTINGS Reprt < Enter> to View		Entry point into the SETTINGS Report
	Alarm Level 1 = XXXX ppm R-XXX	The minimum refrigerant concentration necessary to trigger a Level 1 Refrigerant Alarm (press + to increment, - to decrement) **XXXX ppm** *
	Alarm Level 2 = XXXX ppm R-XXX	The minimum refrigerant concentration necessary to trigger a Level 2 Refrigerant Alarm (press + to increment, - to decrement) **XXXX ppm** *
	Alarm Level 3 = XXXX ppm R-XXX	The minimum refrigerant concentration necessary to trigger a Level 3 Refrigerant Alarm (press + to increment, - to decrement) **XXXX ppm** *
	** Audible Alarm For Rfgt = XXXXX	The refrigerant alarm level which causes the optional Audible Alarm to sound [Off, Alarm1, Alarm2, **Alarm3**]
	** Audible Alarm For Trouble = XXX	Select the optional Audible Alarm to sound for a Trouble condition [**Off**, On]
	Alarm Level 1 = XXXXX	Alarm Level 1 relay configuration [Latching, **Non-Latching**]
	Alarm Level 2 = XXXXX	Alarm Level 2 relay configuration [Latching, **Non-Latching**]
	Alarm Level 3 = XXXXX	Alarm Level 3 relay configuration [Latching, **Non-Latching**]
	Channel Scanner = XXXXX	Select the multi-channel scanner [**Installed**, **Not Installed**] **Default dependent on scanner installation** (only displayed during "Warm-up")
	Scanner Chan 1 = XXXXX	Select Channel 1 Status [**Active**, Inactive] (Displayed if channel scanner is Installed)
	Scanner Chan 2 = XXXXX	Select Channel 2 Status [Active, **Inactive**] (Displayed if channel scanner is Installed)
	Scanner Chan 3 = XXXXX	Select Channel 3 Status [Active, **Inactive**] (Displayed if channel scanner is Installed)
	Scanner Chan 4 = XXXXX	Select Channel 4 Status [Active, **Inactive**] (Displayed if channel scanner is Installed)
	Dwell Threshold = XX %	Select the percentage of Alarm Level 1 necessary to dwell on a channel for an additional 60 seconds 30 - **70%** (Displayed if channel scanner is installed)
	Auxiliary Input = XXXXX	Select Auxiliary Input installation status [Installed, **Not Installed**]

Bold = Factory Default
* See Factory Default Value Chart in Settings Side Menu
** Added to second CLD software version

Figure 10—Refrigerant Monitor Menu Screens (Cont.)

Major Menu	Side Menus	Description
	Aux Input Alarm = XXXXX	Select Auxiliary Input alarm status [**Enabled,** Disabled] (Displayed if Auxiliary Input is Installed)
	Auxiliary Alarm Level = XX.X mA	Select the alarm condition level for the auxiliary input. (Displayed if Auxiliary Input is Installed)
	Aux Input Alarm Direction= XXXXX	The alarm direction for the auxiliary input. [**Below**, Above] (displayed if Auxiliary Input is Installed.)
	* * Audible Alarm For Aux = XXXXX	Select the optional Audible Alarm to sound for an Auxiliary Input Alarm condition [**Off**, On] (Displayed if auxiliary input is installed)
	Analog Output Range 0-1000 ppm	Refrigerant Monitor Analog Output range [0-100ppm, **0-1000ppm**], 0-10VDC & 4-20mA scaling factor.
3 Calibration < Enter> to Cal		Entry point to CALIBRATION report
Enter Password XXXX		Enter 6 digit password "– + – – + + "; Monitor mode changes to Monitor Check.
Chan X Mon Check XXXX ppm R-XXX		Displays current refrigerant concentration. Alarms disabled.
Refrigerant Zero < Enter> to Cal		Entry point to Refrigerant Zero Calibration routine.
	Starting Cal Please Wait	Monitor module preparing for Zero calibration. If scanner is installed, locks onto Channel 1.
	Connect Zero Gas < Next> to Continue	Connect Zero gas canister or Scrubber filter to sample inlet. (Channel 1 if scanner is installed.)
	Open Valve < Next> to Continue	Open Zero gas canister regulator if used
	XXXX ppm R-XXX < Enter> to Adj	Refrigerant Zero concentration sensed.
	Locking Reading Please wait	Locks current reading.
	Refrigerant Zero XXXX ppm R-XXX	Press (+) increase reading or (-) to decrease displayed value to Zero.
	Starting Cal Please Wait	Monitor module preparing for Zero callibaration.
	Successful Calibration	New Zero calibration values accepted.
	Cal Failed < Enter> to retry	Monitor unable to accept new zero value. Reverts back to previous Zero value.
Refrigerant Span < Enter> to CAL		Entry point to Refrigerant Span Calibration routine.
	Starting Cal Please Wait	Monitor module preparing for calibration. If scanner is installed, locks onto Channel 1.
	Connect Span Gas < Next> to Continue	Connect Span gas canister to Sample inlet (Channel 1 if scanner is installed)
	Open Valve < Next> to Continue	Open Span gas canister regulator.
	XXXX ppm R-XXX < Enter> to Adj	Actual Refrigerant Span concentration sensed.
	Locking Reading Please wait	Locks current reading.
	Refrigerant Span XXXX ppm R-XXX	Press (+) increase reading or (-) to decrease displayed Span value.
	Starting Cal Please Wait	Monitor is adjusting calibration values.
	Successful Calibration	New Span calibration values accepted.
	Cal Failed < Enter> to retry	Monitor unable to accept new Span value. Reverts back to previous Span calibration value.
Press < Enter> to exit Cal		Exit Calibration Menu

Bold = Factory Default
* See Factory Default Value Chart in Settings Side Menu
** Added to second CLD software version

Operation

Operating Modes

Modes of operation are:

Warm-up: The warm-up mode will be displayed upon power up of the monitor. It will remain in this mode until the photo-acoustic sensing cell is up to operating temperature. Typically warm-up time is 20-30 minutes

Ready: This is the normal operating mode of the unit.

Monitor Check: This mode is displayed whenever the "Calibration" major menu is accessed or a "Settings" menu item is changed.

Trouble: The unit will go into the trouble mode whenever internal unit malfunction is sensed. Outputs during the "Trouble" mode are unreliable.

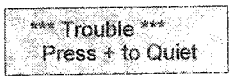
Current Refrigerant Concentration

The currently sensed concentration of refrigerant and the type of refrigerant for which the unit is currently calibrated is displayed.

Alarm Status

If an alarm is active, the backlight on the display will flash. If the alarm is due to the refrigerant concentration exceeding the preset alarm point, an alarm message will be alternately displayed with the current ppm reading and alarm status.

The refrigerant alarm messages that may be displayed are:



Rfgt. Level 1: The sensed refrigerant concentration is above the Alarm Level 1 setting.

Rfgt Level 2: The sensed refrigerant concentration is above the Alarm Level 2 setting.

Rfgt Level 3: The sensed refrigerant concentration is above the Alarm Level 3 setting.

Aux Input Alarm: The auxiliary input current is above/below the Auxiliary Alarm setting.

Trouble Status

This screen will alternate with the diagnostic message. If the problem is due to unit "Trouble" (malfunction), the trouble message and the diagnostic will be displayed. The diagnostic alarm messages that may be displayed are:

Communication Lost With Module: The clear language display is not communicating with the monitor module.

RAM Loss: The monitor module has lost the data in its battery backed RAM.

IR Source Fail: The infrared optical source has failed.

Chopper Fail: The optical bench photo interrupter has failed.

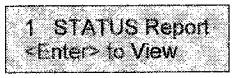
Temp Sensor Fail: The bench temperature sensor has failed.

Bench Flow Loss: Air flow loss to the optical bench. Allow two minutes to reset on units with channel scanner.

Scan Flow Loss: Air flow loss to the channel scanner.

Out of Temp Rng: The refrigerant monitor is out of the temp range where it can measure refrigerant.

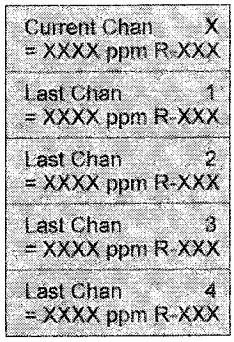
Rfgt Lvl to Low: The displayed refrigerant level is less than - 4 ppm.



Rfgt Mon Fail: An undefined trouble diagnostic from the refrigerant monitor.

Aux Input Fail: Auxiliary input is less than 4 mA or greater than 20 mA with the aux input installed.

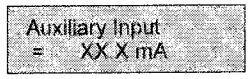
Ext Reset Fail: The external reset switch has failed or the jumper is missing.



Note: See the "Troubleshooting" section for more discussion of service diagnostics.

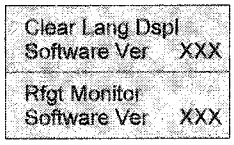
STATUS Side Menu

Current Sample: The current refrigerant concentration will be displayed. This screen will only be displayed if the Channel Scanner is "Not Installed".



Current Channel X: The current refrigerant concentration and the channel being sampled is displayed. This screen will only appear if the Channel Scanner is "Installed".

Last Channel 1 through 4: The value that was displayed the last time that channel was read. These screens will only appear if the Channel Scanner is "Installed".

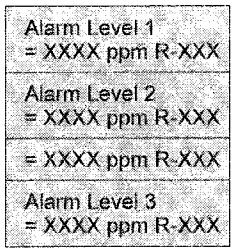


Case Temp. : The internal case temperature (C).

Bench Temp.: The internal temperature of the photo-acoustic bench (C).

Auxiliary Input: Displays the mA current being measured at the auxiliary input. This screen is displayed only if the Auxiliary Input is "Installed".

Clear Language Display Software Version: The software version of the clear language display.

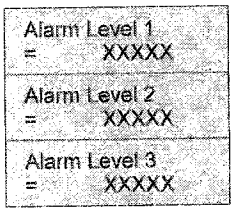


Rfgt Monitor Software Version: The software version of the monitor module.

Entry point into the SETTINGS Side Menu.

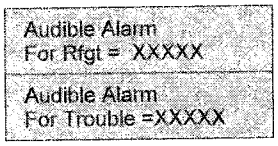
SETTINGS Side Menu

Note: Press <Enter> to save settings, <Cancel> to cancel changes and revert back to previous values.



Alarm Levels 1, 2 and 3 XXXX ppm: The ppm level at which a concentration alarm will be displayed and the appropriate alarm relay activated. Press (+) to increase setting, (-) to decrease setting. (See "Alarm Level Settings" for allowable range of settings).

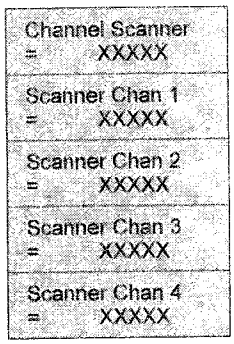
Factory default values are:



Refrigerant	Level 1	Level 2	Level 3
HCFC-123	50	150	500
CFC-11, HCFC-22, HFC-134a, CFC-12, CFC-113, CFC-114, CFC-500, CFC-502	50	150	1000
Ammonia	10	25	50

Note: These are the current recommended alarm level values at the time of printing. They can be easily adjusted as required.

Alarm Level 1, 2 and 3 Relay Configuration: The three alarm relays can be configured individually to "latch" or "unlatch" when the alarm level is exceeded. With "unlatched" alarms, the unit will automatically reset the alarm status, de-energize the alarm relay(s) and revert to normal operation when the refrigerant concentration falls below the preset alarm level. "Latched" alarms will stay activated until acknowledged (reset) by pressing the <+> key on the keypad while viewing the alarm. If the alarm condition remains, the alarm will immediately re-latch. If the alarm condition was cleared, the alarm will clear in about five seconds. Options are "Latched" and "Unlatched". Factory default is "Unlatched". Press (+) to change setting.



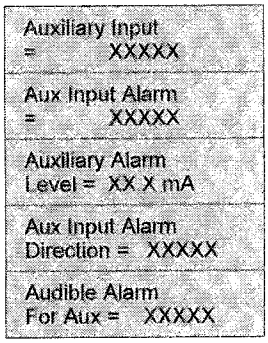
Note: Allow 15 seconds after "Installing" scanner before attempting to view channel settings and dwell threshold.

Audible Alarm For Refrigerant: * The audible alarm is a separate option that is field installed. If this option is ordered, it can be set to sound on alarm level 1, 2 or 3 or left off. The factory default is "Alarm 3". Press (+) to change setting.

Audible Alarm for Trouble: * If the optional Audible Alarm is ordered, it can be set to sound if a "TROUBLE" (malfunction) diagnostic is displayed. Once the alarm clears, the horn is silenced. The factory default is "OFF", but can be changed to "ON" by pressing (+).

*Added to second CLD software version.

Channel Scanner : This setting can only be changed during the "Warm-up" mode. It determines if the scanner set-up screens are displayed. Options are "Installed" and "Not Installed". Press (+) to change setting. If scanner option is provided, the Factory default is "Installed" and Channel 1 = "Active" and Channels 2,3 and 4 = "Inactive".



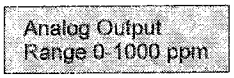
Scanner Chan 1 through 4 : This setting is used to individually activate or deactivate the scanner channels. A minimum of one channel must be active at all times. Press (+) to change status. These screens are only displayed if the Channel Scanner is "Installed" in the previous screen.

Note: The monitor will not allow all channels to be deactivated. Deactivating a channel while it is being scanned may cause a "Flow Loss" diagnostic, however the alarm should clear after approximately two minutes.

Dwell Threshold : This setting selects the percentage of an Alarm Level 1 concentration which will result in a 60 second extended sample time on the channel. Range is 30 to 70%. Press (+) to increase, (-) to decrease setting. Factory default is 70%. This screen is only displayed if the channel scanner is "Installed".

Operation

Auxiliary Input: This item selects whether a 4-20 mA auxiliary input is being used. Options are "Installed" and "Not Installed". Press (+) to change settings. Factory default is "Not Installed". (See "Auxiliary Input" section of this manual for more information.



Aux Input Alarm: This input determines if the Auxiliary Input will activate alarms on the monitor. Options are "Enabled" and "Disabled". If the alarm is enabled, the auxiliary input will alarm through the unit Level 3 alarm relay. If "Disabled" no alarms will be activated. Press (+) to change setting. This screen is displayed only if the Auxiliary Input is "Installed". (See "Auxiliary Input" section of this manual for more information.)

Auxiliary Alarm Level: Used to set the mA level from the auxiliary device which will result in a Level 3 alarm if the Auxiliary Alarm was enabled on the previous screen. This screen is displayed only if the Auxiliary Input is "Installed". (See "Auxiliary Input" section of this manual for more information).

Aux Input Alarm Direction: This setting determines if the Auxiliary Input Alarm is activated above or below the alarm mA setpoint.

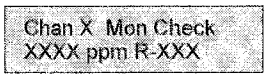
Audible Alarm for Aux: * Used to set the optional audible alarm to sound if an auxiliary input is in alarm. Options are "ON" or "OFF". Press (+) to change setting. The factory default is "OFF".

*Added to second CLD software version.

Analog Output Range: Used to set the range for the 4-20 mA current output and the 2-10v voltage output scaling factor. Press (+) to change the setting. The factory default is "0-1000 ppm".

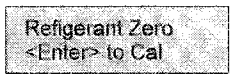
CALIBRATION Side Menu

Note: For a step-by-step calibration procedure, refer to the "Calibration " section of this manual.



The entry point into the Calibration Side Menu.

Note: If unit "Trouble" is detected during calibration, a "trouble" diagnostic will be displayed and the display will go back to the main menu "Trouble" screen.

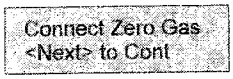


The field calibration password " – +– – ++" must be entered to proceed with calibration. Press <Enter> to proceed. Press <Previous> to back out of the calibration routine.

Current refrigerant concentration is displayed. Alarms are held. Wait approximately 5 seconds until mode changes from "Ready" to "Mon Check".

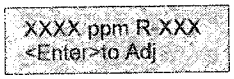
Note: There are two major side menus under Calibration, Refrigerant Zero and Refrigerant Span.

REFRIGERANT ZERO Side Menu

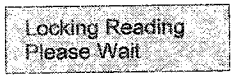


The entry point into the Refrigerant Zero Side Menu. This is used to verify the monitor Zero setting.

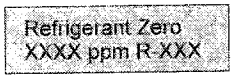
The "Starting Cal" screen is displayed for approximately 20 seconds while the module prepares for re-calibration. If unit has a 4 channel scanner, it will be locked on channel 1.



The "Unable to Cal" is displayed if the module will not accept recalibration data. (See Troubleshooting section of this manual.) Display reverts back to "Refrigerant Zero" Major Menu.

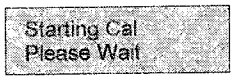


Directs the user to connect the Zero gas canister or the zero scrubber to the monitor sample port. Press <Next> to continue.

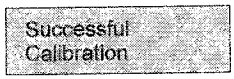


If a Zero gas canister is used, open regulator valve to begin gas flow. If using a Zero scrubber filter, disregard this step and press <Next>.

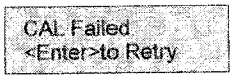
This screen displays the measured concentration based on the current instrument calibration.



Locks on to current reading and prepares for re-calibration.

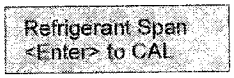


At this point the displayed zero can be adjusted to zero using the (+) and (-) keys. Press <Enter> when finished.

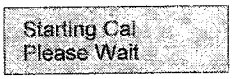


Note: Pressing <Cancel>at any point prior to this will abort calibration routine and the unit will revert back to previous calibration.

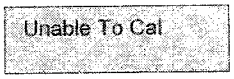
These screens display when the new values are being transmitted and stored in the monitor (approximately 20 seconds).



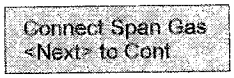
The "Successful Calibration" verifies that the new values were accepted and are now being used.



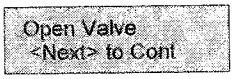
This screen appears if the new zero calibration values are outside the adjustment limits or the <Cancel> key has been pushed. Press <Enter> to retry or <Cancel> to revert back to previous values.



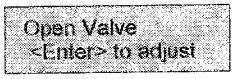
REFRIGERANT SPAN Side Menu



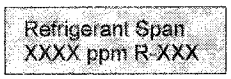
The entry point into the Refrigerant Span Side Menu.



The "Starting Cal" screen is displayed for approximately 20 seconds while the monitor prepares for re-calibration.

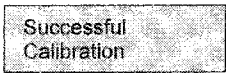


The "Unable to Cal" is displayed if the module will not accept recalibration data. (See the Trouble shooting section of this manual for possible causes.)

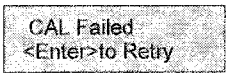


Directs the operator to connect the Refrigerant Span gas canister to the sample port.

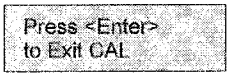
Instructs operator to open span gas regulator to allow gas to flow to instrument.



Displays the measured concentration based on current instrument calibration. Press <Enter>if reading does not match span gas concentration shown on outside of canister. If reading matches span gas concentration, press <Cancel> to abort calibration routine.



At this point the operator can increment (+) or decrement (-) the displayed value to the correct concentration as noted on the calibration gas canister. Press <Enter> when finished.



Displayed while monitor is being updated.

The "Successful Calibration" verifies that the new values were accepted and are now being used.

This screen appears if the new span calibration values are outside the adjustment limits or the <Cancel>key has been pushed. Press <Enter> to retry or <Cancel> to revert back to previous values.

After completing calibration, press <Next> key until above screen is displayed. Press <Enter> to exit calibration menu.

Remote Alarm Reset

Latched refrigerant alarms can be acknowledged (Reset) locally by pressing the <+> key on the clear language display while viewing the alarm message.

Latched refrigerant level alarms can also be remotely reset through a momentary contact opening.

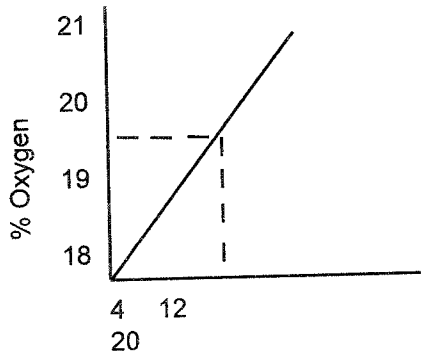
This capability can be used to determine if an alarm condition has cleared or still exists. If the refrigerant concentration is below the preset alarm ppm point, the alarm will reset and will not re-latch. If the concentration is above the alarm ppm point, the alarm will immediately re-latch.

The monitor ships with a jumper between terminals 1 and 2 of J16 on the monitor module. This jumper is removed and replaced with a normally closed switch if the remote reset feature is used.

To remotely reset an alarm, apply a momentary contact opening to terminals 1 (RST+) and 2 (RST-) on the J16 terminal strip. A switch with signal-level contacts, typically gold flashed, must be used. The maximum distance from the reset switch to the monitor using 18 AWG shielded wire is 300 feet.

Audible Alarm Output

A 12 VDC output from the module is provided as standard to power a piezo-electric audible alarm horn (150 mA non-inductive max. load). The audible horn is a field-installed option. A plugged hole is provided on the bottom of the monitor enclosure to mount the optional horn. The horn is connected to terminals 6 (+12V) and 7 (SPKR) on terminal block J17 of the module. The Audible Alarm Kit includes the required gasketing to retain the NEMA-4 enclosure rating.



The audible horn will sound whenever the selected Level 1, 2 or 3 alarm is active. The alarm configuration "Latched" or "Unlatched" will be the same as what has been set for the selected Level 1, 2 or 3 alarm. Pressing <+> from the "Alarm" screen will acknowledge a latched alarm and silence the audible alarm. The audible alarm is then reset when the refrigerant concentration falls below the preset alarm point.

The audible alarm can also be configured to sound if the monitor is displaying a TROUBLE (malfunction) diagnostic. If the audible alarm is active, it can be silenced by pressing <+> from the trouble screen or when the diagnostic clears.

Auxiliary Input

The module is capable of accepting an auxiliary 4-20 mA input from another source. This feature could be used to tie in a device such as a an oxygen monitor so it could alarm through the refrigerant monitor alarm system. Specifically, when the mA output from the auxiliary device is above/below the Auxiliary Alarm level setting, the Level 3 alarm relay on the monitor module will change state. When the auxiliary input option is used, the Level 3 alarm will activate when either the refrigerant concentration exceeds the Level 3 Alarm setting or the preset Auxiliary Input mA value is exceeded.

Figure 11
Auxiliary Alarm Example

Depending on the device used, it may be necessary to alarm when the input mA value is below the alarm steeping while other devices need to alarm above the alarm point. An example of alarming when the input falls below the level might be an oxygen monitor where the output is proportional to the % oxygen. As the available oxygen drops, so does the mA input. By contrast, a refrigerant monitor input that increases with concentration would need to be set up to alarm when the mA input goes above the setting.

The auxiliary input is enabled and the other set-up parameters are set-up through software in the "Settings" menu.

The optional audible alarm can be configured to sound if the auxiliary input exceeds the auxiliary alarm level. The horn can be silenced by pressing <+> from the alarm screen or when the auxiliary alarm input drops below the auxiliary alarm level.

To properly determine the auxiliary device alarm point, the scaling in relation to the 4-20 mA range of the device must be known. The chart below shows an example of an oxygen monitor in which an alarm was desired at 19.5% sensed oxygen level.

In the previous example, the "Auxiliary Alarm Level" would be set at 12.0 mA and the "Aux Alarm Direction" would be set to "Below".

Operation

Monitor Cross-Sensitivity

The Trane Refrigerant Monitor is factory calibrated specifically for the refrigerant of interest. With the large number of different chemicals and refrigerants in equipment rooms, it is very important that an air monitoring device be as resistant to cross-sensitivity as possible. The photo-acoustic technology used in this instrument is one of the most selective available; however, the instrument may respond, in varying degrees, to other chemicals that may be in the monitored area. Listed below are the instrument's sensitivity to 100 ppm of other commonly used refrigerants when calibrated for the specific refrigerant listed. These are typical values for reference only.

Example: A monitor calibrated for HCFC-123 will display 4 ppm when exposed to 100 ppm of HCFC-22.

Calibrated for HCFC-123

Refrigerant	Response
CFC-11	<1 PPM
HFC-134a	140 PPM
HCFC-22	4 PPM
CFC-113	80 PPM

Calibrated for CFC-11

Refrigerant	Reposnse
HCFC-123	3 PPM
HFC-134a	20 PPM
HCFC-22	30 PPM
CFC-113	25 PPM

Calibrated for HCFC-22

Refrigerant	Response
HFC-134a	25 PPM
CFC-11	16 PPM
HCFC-123	35 PPM
CFC-113	39 PPM

Calibrated for HFC-134a

Refrigerant	Response
HCFC-22	1 PPM
HCFC-123	8 PPM
CFC-11	2 PPM
CFC-113	17 PPM

Due to the large number of possible interferants other than refrigerants, it is impractical to list them. Direct any questions regarding specific interferants that are expected to be in the monitored area to your local Trane office.

Note: Cross-sensitivity data not verified during UL testing.

Calibration

Introduction

The monitor is factory calibrated for the specific refrigerant desired however, it is recommended that the calibration be checked regularly, at a minimum annually, and a log kept detailing any adjustments required. This Installation, Operation and Maintenance manual should be referenced to assist in operating the display and identifying components or connection points.

Material Required

1. Trane™ Calibration Kit containing:

- Zero Gas Scrubber
- Flow Regulator
- Interconnecting Tubing and Fittings
- Span Gas Scrubber
- Carrying Case

2. A canister of the specific refrigerant span gas is required.

This calibration check should be performed only by qualified personnel familiar with the instrument and its operation.

⚠ Warning!
During calibration, the monitor is not in service and any alarm conditions that may occur during the calibration sequence will not be recognized, possibly resulting in serious personal injury or death.

Preparing for Calibration

1. Ensure the area surrounding the monitor is free from any gas hazard. Operate permanent or portable ventilation as necessary.
2. Unit should be operating for at least 2 hours before a calibration check is attempted.
3. Access the calibration menu using the display located on the unit front panel.
4. Page through the display by pressing <Next> until you get to the "Calibration" main menu. Press <Enter> to begin calibration check routine.
5. Enter the Field Calibration password, " - + - - + + ". Press <Previous> if you wish to back out of the calibration routine.
6. The monitor will go into the Monitor Check Mode after 5 seconds and the refrigerant concentration based on the current unit calibration will be displayed. All new alarms will not be recognized.
7. Remove the gas sampling tube from the monitor sample inlet. Disconnect sample channel #1 if a scanner is installed.

Zero Calibration Check

1. The first routine is used to check the unit Zero calibration. Press <Next> to proceed to the Refrigerant Zero screen. Press <Enter> to begin Zero Calibration. The display will read "Starting Cal, Please Wait". If a channel scanner is installed, it will be locked onto channel #1. Refer to Figure 12 for connection information.

Note: Either a Zero Gas Scrubber or a canister of Zero gas can be used to check the zero setting on a Model RMWD monitor.

2. When the "Connect Zero Gas" screen is displayed, connect the Zero Scrubber or the Zero Gas Canister to the sample port on the monitor as shown

2. (Continued) in Figure 12. Use sample port #1 if a scanner is installed. Press <Next> to continue.

⚠ Caution:
Be sure Zero Scrubber is used and not Span Gas Scrubber.

Note: If a Zero Gas canister is used, connect as shown in Figure 13 except substitute Zero canister for Span Gas canister. The tee and a scrubber must be used whenever compressed gas is applied to the unit to avoid over pressurization of the pump circuit.

3. "Open Valve" will be displayed. If the Zero gas canister is used, open the regulator to allow gas to flow. If a scrubber is being used, disregard this step. Press <Next> to continue to Step 4.
4. The next screen will display the sample concentration based on the current unit calibration. After waiting at least three minutes, press <Enter> to adjust zero setting. If reading is zero, press <Cancel> twice to exit Zero calibration routine and move to Refrigerant Span routine.
5. If <Enter> was pressed to adjust, the unit will lock onto the reading. Use the (+) and (-) keys to adjust displayed reading to zero. Press <Enter> when finished. Monitor will now store the new Zero setting.
6. Either "Successful Calibration" or "Cal Failed" will be displayed. If calibration was successful, the display will proceed to the Span Calibration. If calibration failed, the unit will revert back to the previous zero value. Press <Enter> to repeat Zero Calibration. Shut off Zero Gas flow if canister is being used.

Note: If Calibration continues to fail, refer to the "Troubleshooting" section in this manual.

Refrigerant Span Calibration Check

1. At the "Refrigerant Span" screen, press <Enter> to Calibrate. The display will read "Starting Cal Please Wait". Refer to Figure 13 for connection information.
2. Connect the Span Gas canister to Sample Port #1 when the display prompts you to do so. Also, remove any caps on the span gas scrubber. Press <Next> to continue.
3. Open the regulator valve when instructed and press <Next> to continue.
4. After at least three minutes and the displayed value is stable, compare the displayed PPM value to what is listed on the calibration span gas canister. If the displayed value matches the span gas concentration, press <Cancel> twice to exit calibration mode. If the displayed value differs from the value on the canister, press (+) or (-) to change the displayed value to match the calibration gas value. Press <Enter> to continue. The display will read "Starting Cal".

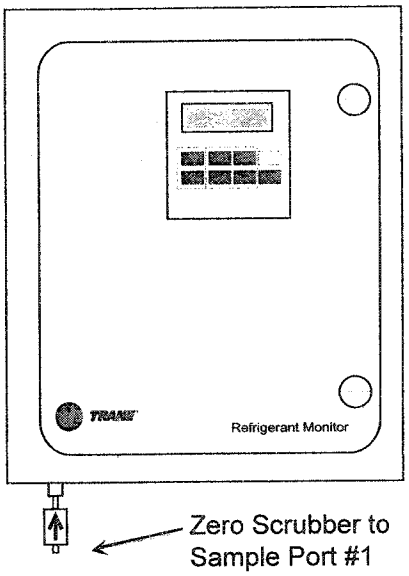
Calibration

5. Either "Successful Calibration" or "Cal Failed" will be displayed. If the calibration was successful, the new span values have been stored and will be used for all future readings. Press <Next> three times, then <Enter> to return the instrument to operation. If the Calibration failed, the monitor will revert back to the values previously stored. Press <Enter> to retry span calibration.

Note: If Calibration continues to fail, refer to the "Troubleshooting" section of this manual or consult the factory.

6. Disconnect the span gas canister, connect all sample lines that may have been removed and exit calibration routine. Unit is ready to be put back into service.
7. Log the date and note any adjustments made on a monitor calibration log.
8. Return all parts to the Calibration Kit carrying case.

Figure 12
Zero Calibration Check Connections



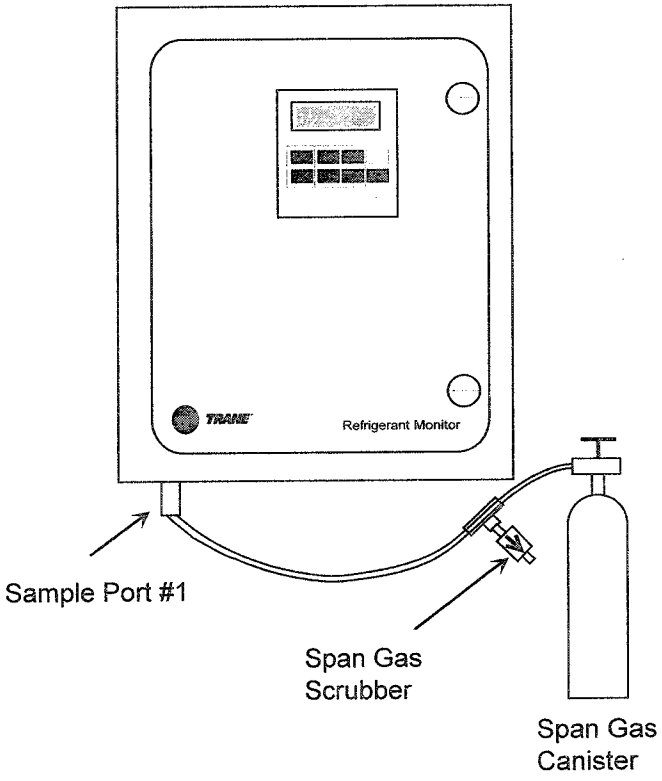


Figure 13
Calibration Check Connections Connections

Note: If Zero Gas is used, connect canister to Sample Port #1 using connect arrangement similar to what is shown in Figure 13, substituting the Zero canister for the Span Canister and the Zero Scrubber for Span Gas Scrubber.

Troubleshooting

Diagnostic	Possible Cause
Communication lost with module	Wires to module shorted, open, or reversed.
RAM loss	Loss of battery backed up RAM
IR source failure	Wire from IR source broken or disconnected
	Burned out IR source
Chopper failure	Motor failure
	Wire unplugged
	Photo pick up failure or unplugged
	Chopper physically obstructed
	Defective circuit board assembly
Temperature sensor failure	IR bench temperature sensor unplugged or failed
Bench flow loss *	Filter, tubing, sample line clogged, kinked or collapsed
	Optical bench pump failure
	Pressure switch failure or unplugged
	Pressure switch incorrectly connected to printed circuit board
	Exhaust line blocked
	Optical bench pump failure
Scanner flow loss	Filter, tubing, sample line clogged, kinked or collapsed
	Scanner pump failure
	Pressure switch failure or unplugged
	Exhaust line blocked
	Scanner pump failure
	Improper connection of scanner
Out of temperature range	Ambient temperature too low
	Optical bench heater malfunctioned or unplugged
	Temperature sensor failure or unplugged
	Heater unplugged or failure
	The transistor that controls the heater has failed
Refrigerant level too low	Monitor out of calibration
Refrigerant monitor failure	Any other trouble than listed diagnostic
Auxiliary input failure	Input is out of range, above 20 mA or below 4 mA
	Check wiring to auxiliary input connector
	Check output of 4-20 input device
	Input is installed but no device is connected
External reset failure	No external reset switch installed and jumper removed
	Jumper on connector has been grounded
	Check wiring to normally closed switch
	Check switch operation
	Operator depressing switch too long (60 seconds +)

* Note: 4 Channel Scanner Units—A bench flow loss diagnostic appears if any sample inlet is plugged when power is initially applied to the unit or after a power loss. Each sample inlet, even if unused during normal operation, must have a filter installed to avoid nuisance faults.

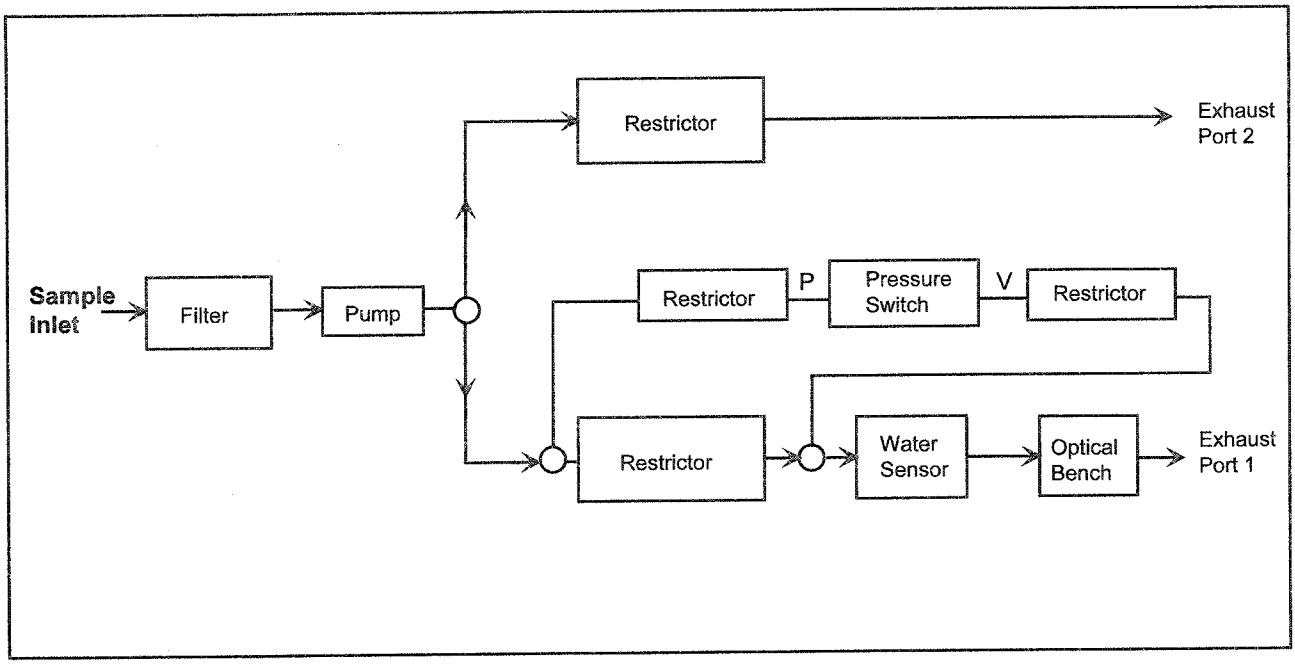
Figure 14
Single Channel Model



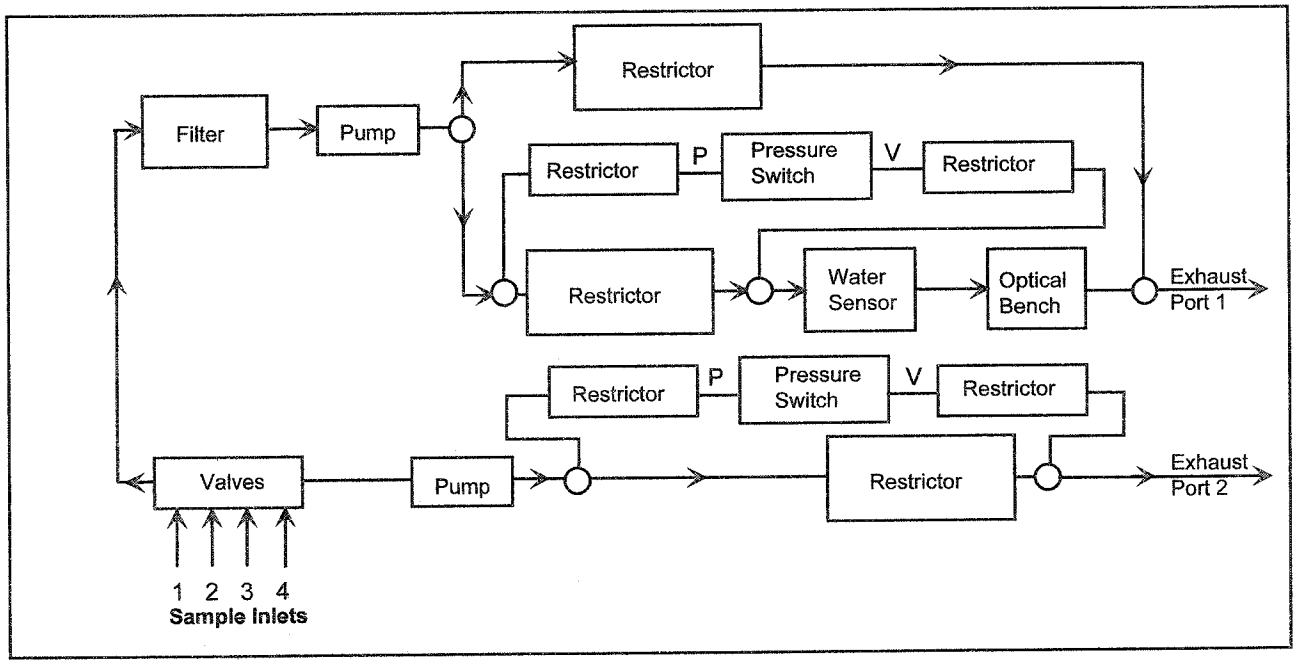


Figure 15
Unit with 4 Channel Scanner

Enclosure

Technical Specifications

Mechanical

Enclosure

NEMA-4 rated. Hinged door with 2 quarter-turn latches. Beige with black face plate.

Mounting

4 mounting tabs provided on back of enclosure.

Weight

Single channel unit = 42 lbs. operating, 45 lbs. shipping.
4-channel scanner unit= 45 lbs. operating, 49 lbs. shipping.

Sample Pumping Rate

0.75 LPM minimum with 150 feet of 1/8" ID sample tubing.

Electrical

Inputs

Power Input - The refrigerant monitor will operate from a source of AC power of 100 VAC to 240 VAC, 50 to 60 Hz. Power input not to exceed 80 watts in single channel operation.

Auxiliary Input - 4 to 20 mA Input referenced to ground. Input impedance is 200 (±4) Ω resistive.

Remote Reset - An input will be provided to remotely reset latched alarm relay(s). On activation, all latched alarms will be reset. Maximum distance from monitor to contacts is 300 feet using shielded 18 AWG twisted pair wire.

Outputs

Analog - Two analog outputs are provided to indicate refrigerant gas concentration. These outputs may be used independently and simultaneously.

Ranging for both outputs is common.

Ranges selectable by software:
0 to 100 PPM
0 to 1000 PPM

The resolution on each range is 1 PPM.

4 to 20 mA: Sourcing current to module ground. Load = 200 ohms maximum.

0 to 10 VDC: Sourcing referenced to module ground. Output current to 7 mA maximum.

Relays - Relay contact ratings are as follows:

Resistive load:
-7.2 Amps @120 VAC
-5.0 Amps @240 VAC

Inductive load:
-2.88 Amps Pilot Duty
-1/3 HP, 7.2 FLA, 43.2 LRA

Audible alarm output:
12 VDC, 100Ω load maximum

Gas Sensing Characteristics

Gas Sensitivity

Standard factory calibration for HCFC-123, CFC-11, HCFC-22 and HFC-134a. Special factory calibrations for other refrigerants are available.

Alarm levels

Alarm levels are software adjustable in steps of 1 PPM over the following ranges:

Alarm Levels:

HCFC-123	Low Limit	High Limit
Alarm Level #1	3 PPM	Lowest of 50 PPM or Alarm Level #2 -1
Alarm Level #2	Alarm Level #1 + 1	Alarm Level #3 - 1
Alarm Level #3	Alarm Level #2 + 1	1000 PPM

All other refrigerants	Low Limit	High Limit
Alarm Level #1	3 PPM	Alarm Level #2 -1
Alarm Level #2	Alarm Level #1 + 1	Alarm Level #3 - 1
Alarm Level #3	Alarm Level #2 + 1	1000 PPM

Technical Specifications

Factory Default Values Are:

Accuracy Rating

Refrigerant	Level 1	Level 2	Level 3
HCFC-123	50	150	500
CFC-11, HCFC-22, HFC-134a, CFC-12, CFC-113, CFC-114, CFC-500, CFC-502	50	150	1000
Ammonia	10	25	50

Note: These are the current recommended alarm level values at the time of printing. They can be easily adjusted as required.

Precision - Accuracy depends upon both precision and calibration standard accuracy. For negligible effect, calibration standard inaccuracy must be less than 1/10 precision inaccuracy.

0- 50 PPM = ± 1 PPM

51-1000 PPM= ± 10% of reading

Reference Operating Conditions:
Ambient Temperature =
23 ± 10°C
Atmospheric Pressure =
28.5 ± 2 in. Hg
Relative Humidity = 50 ± 20%
Line Voltage = 120 VAC

Calibration Standards:
Reproducibility - The reproducibility over a 12 month period will be within ± 1 PPM In the range 0 - 50 PPM under reference operating conditions.

Response Time

90% of a step change in 75 second maximum (at analyzer input). There is an additional transport time of 30 seconds with 150 foot of 1/8" tubing at a flow of 0.75 LPM. Additional scanner dwell time = 30 seconds per point. If a reading is observed greater than the threshold value, the scanner will dwell at that point for an additional 60 seconds.

Repeatability

Zero stability due to ambient, ±1 PPM with a maximum temperature change of 2.78°C per hour.

Linearity

0 to 100 PPM: linear

100 to 1000 PPM: ± 2% of full scale reading

Noise immunity

± 1 PPM with a zero gas filter attached.

Warmup Time

2 hours maximum (20 minutes typical)

Environmental

Temperature range

Operating: 0°C - 50°C
Temperature effect within this range is ± 0.3% of reading per °C.

Non operating: -10 to 60°C

Humidity

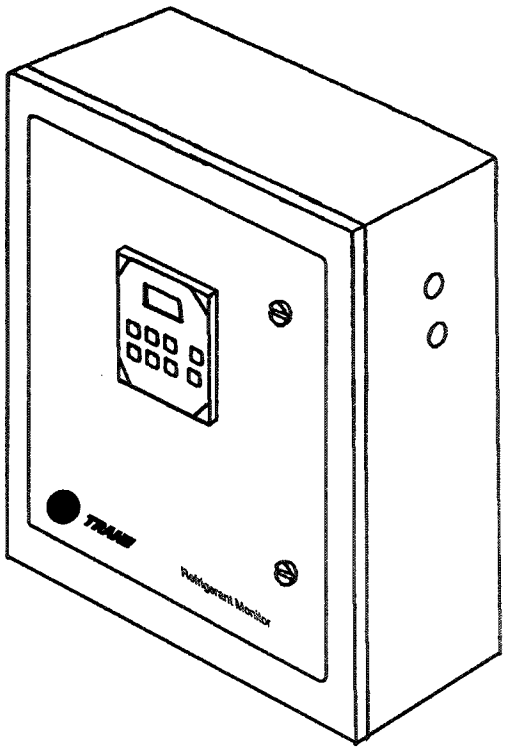
Operating and non operating; 5 to 95% R.H. Non condensing, over the operating temperature range.

Pressure

Operating: 10.2 PSIA to 15.66 PSIA

Non operating:
2.17 PSIA to 15.66 PSIA

Agency Listing



This refrigerant monitor is listed under the UL 2075 performance standard. UL has also tested and verified the monitor to CSA standard C22.2 #205. The ammonia unit has not been investigated by UL and is not covered under this listing.

Model Number

Unit Model Number

For service and replacement purposes, the Trane Model RMWD Refrigerant Monitor is assigned a multiple-character alphanumeric model number that precisely identifies each unit. The model number key is shown here.

Use of the model number will enable the owner/operator, installing contractor, and service technician to define the characteristics of any RMWD unit. Be sure to refer to the model number when ordering replacement parts or requesting service.

General Information

Literature Change History

RMWD-TSR-1 (May 1996)

Original issue of the trouble shooting manual pertaining to Trane™ Model RMWD Refrigerant Monitor design sequence "A0".

Introduction

This document provides troubleshooting and repair information for the Trane RMWD style Refrigerant Monitor. Included is a discussion of the internal diagnostic test the instrument processor performs on the flow system hardware during start-up in addition to performance under normal operating conditions. Finally, unit diagnostic messages are described and specific component tests are provided.

Unit Description

The Trane™ Model RMWD Refrigerant Monitor circulates room air through a sensing cell to provide a continuous indication of refrigerant vapor concentration. It is intended for indoor use in mechanical equipment rooms which house air conditioning or refrigeration equipment or in areas where bulk refrigerants are stored.

The monitor utilizes infrared photoacoustic sensing technology, allowing accurate measurement of refrigerant vapors with minimum interference from other chemicals in the vicinity. The instrument is compound-specific and factory calibrated for the specific refrigerant of interest. It is capable of measuring down to 1 parts-per-million (ppm) and displaying refrigerant concentrations from 0-1,000 ppm. The monitor can signal alarms at three different concentration levels. These alarms are factory set, but can be easily adjusted in the field. A unit "trouble" alarm indicates internal problems with the instrument. A level alarm or a trouble alarm condition will cause the display to flash with a message and activate a dry contact relay(s) which can be used to control external alarm lights or horns, start emergency ventilation, or signal a building management system.

The refrigerant level alarm relays can be configured as latching or non-latching. 0-10 VDC and 4-20 mA analog outputs are provided for connection to a data recorder or building management system. These analog outputs can be scaled as 0-100 ppm or 0-1000 ppm. The standard unit monitors one zone. The optional multi-channel scanner can be factory or field installed to monitor up to four zones.

General Information

Infrared Photoacoustics

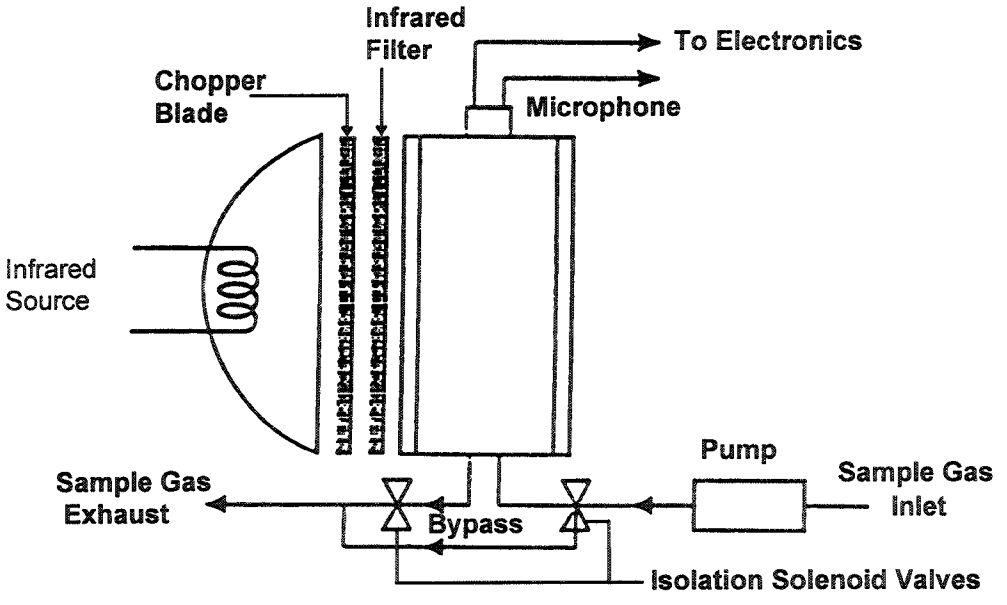
Increased industrialization together with a growing concern for human safety and the environment have stimulated the demand for sensitive and reliable methods of detecting trace amounts of pollutants and toxic gases. The advantages of infrared photoacoustic gas detection which the Trane RMWD refrigerant monitor uses include greater sensitivity, high immunity to interferents, fast response time and low maintenance.

The RMWD refrigerant monitor detects toxic gases by a process called infrared photoacoustic spectroscopy. The photoacoustic effect is the emission of sound by an enclosed sample on the absorption of chopped infrared light.

Portions of the Infrared Photoacoustics section reprinted with permission from Brüel and Kjær Instruments, Inc.

When a gas is irradiated with light, it absorbs some of the incident light energy, proportional to the concentration of the gas. The absorbed light energy is immediately released as heat and this causes the pressure to rise. When the incident light is modulated at a given frequency, the pressure increase is periodic at the modulation frequency. Pressure waves, or sound waves as they are commonly known, are easily measured with a microphone. They are audible if their frequency is between 20 Hz and 20 kHz.

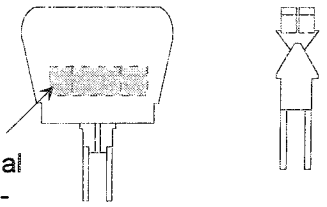
The intensity of the sound emitted depends on a number of factors; the nature and concentration of the substance and the intensity of the incident light.



The selectivity which can be achieved in spectroscopy is due to the fact that substances absorb light of specific wavelengths which are characteristic of that substance.

The sequence of events in this process are:

- gas sample is sealed in measurement chamber
- chamber is irradiated with pulsed, narrow-band light
- gas absorbs light proportional to its concentration and converts it to heat
- gas heats and cools as the light is chopped
- temperature fluctuations generate pressure waves,
- pressure waves are detected by microphone



The main parts of a photo-acoustic set-up (see Figure 1) are a chamber to contain the gas sample, a light source, a means of modulating the light (usually a chopper), a detector to measure the sound (usually a microphone) and a method of processing the signal. The signal is interpreted by the electrical components into a parts per million (ppm) display.

RMWD Style Refrigerant Monitor

Monitor Installation

- Securely mount vertically on wall away from vibration sources using four mounting tabs
- Monitor Installation, Operation and Maintenance manual, RMWD-IOM-1, or the latest revision, has detailed installation information
- Application engineering manual REF-AM-3, or the latest revision, Refrigeration System Equipment Room Design, has further recommendations regarding sampling locations to meet ASHRAE 15 guidelines

Wiring

- Monitor should have a dedicated power source to make sure it is always on even if other equipment is off
- Monitor will accept 100-240 volts a.c., 50 or 60 Hz
- Fuses (FUS 0927), jumper (PLU 0528) and fuse holder (HLD 0167 - black "key") ship with monitor in small box and are inserted in terminal strip, see examples at left for location.
- Monitor alarm contact ratings: Resistive: 7.2 amps at 120 volts a.c., 5.0 amps at 240 volts a.c.; Inductive: 2.88 amps pilot duty, 1/3 HP, 7.2 FLA, 43.2 LRA

Note: Monitor has a NEMA 4 rated enclosure. Use the plugged knockouts provided. Do not cut holes for wiring because shavings may short the electronics. Any added holes may compromise NEMA 4 integrity of the enclosure.

Trouble relay energizes during normal operation which closes normally open contacts. If monitor trouble occurs, relay is de-energized and contacts open

- Auxiliary input
  - 4-20 mA signal can come in to monitor from another device like an oxygen monitor - 18 AWG shielded wire is recommended, maximum of 250 feet (76 m)
  - level 3 alarm contacts change on excessive refrigerant concentration or mA signal
- 4-20 mA and 0-10 volt d.c. analog outputs
  - proportional to displayed refrigerant concentration
  - software selectable for 0-100 or 0-1000 ppm
  - 18 AWG shielded wire is recommended
  - 500 feet (152 m) max. length

Status LED's on main circuit board (see Figure 3)

- **Power:** green if normal
- **Alarm levels if refrigerant concentration exceeds setpoints:**
  Level 1 - amber
  Level 2 - red
  Level 3 - red
- **Ready:** green if normal
- **Trouble:** red if diagnostic appears

Filters

Change sample filters (ELM1144 - end of line, FLR1396 - inside monitor) regularly depending on the cleanliness of the equipment room. A flow loss condition at the monitor indicates a change may be required.

Figure 2 - Typical RMWD Monitor Major Component Locations

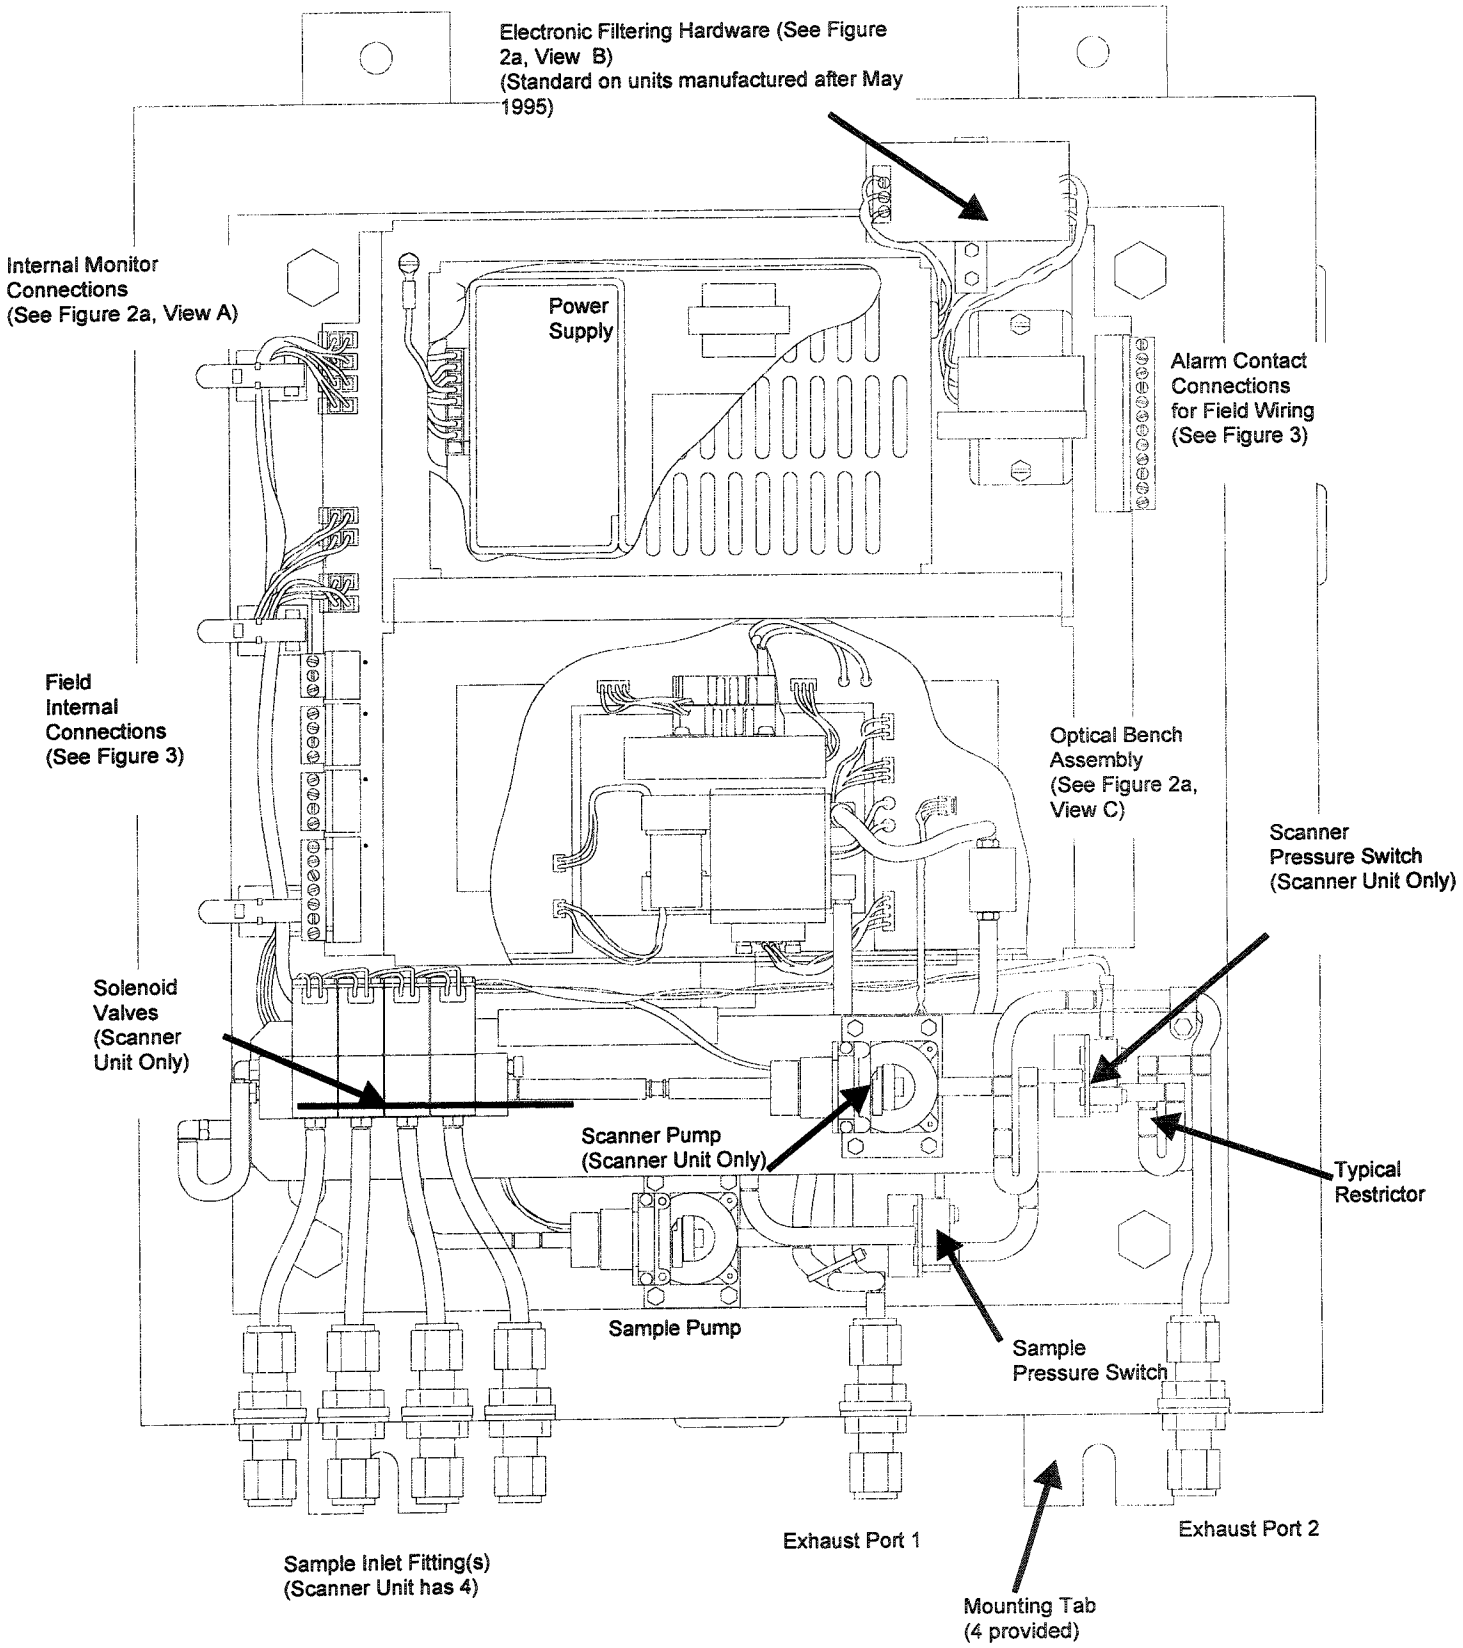

Figure 2 a - Typical RMWD Internal Wiring Connections

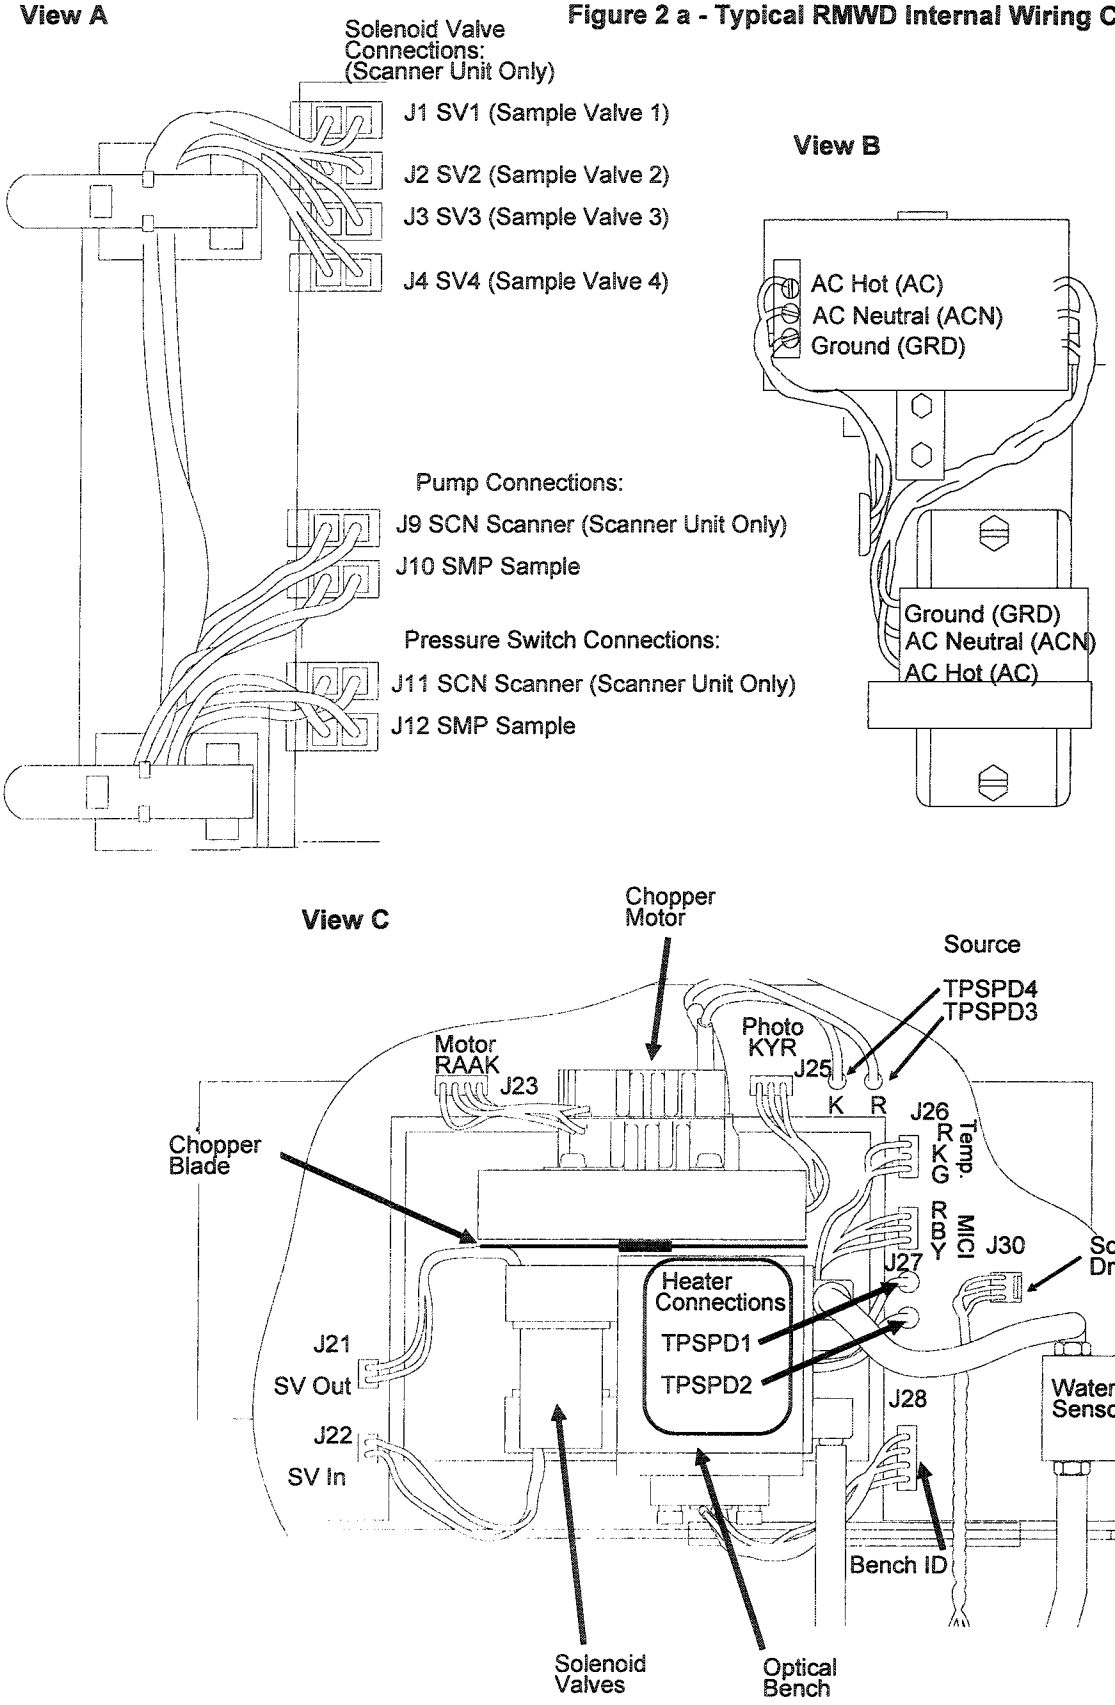

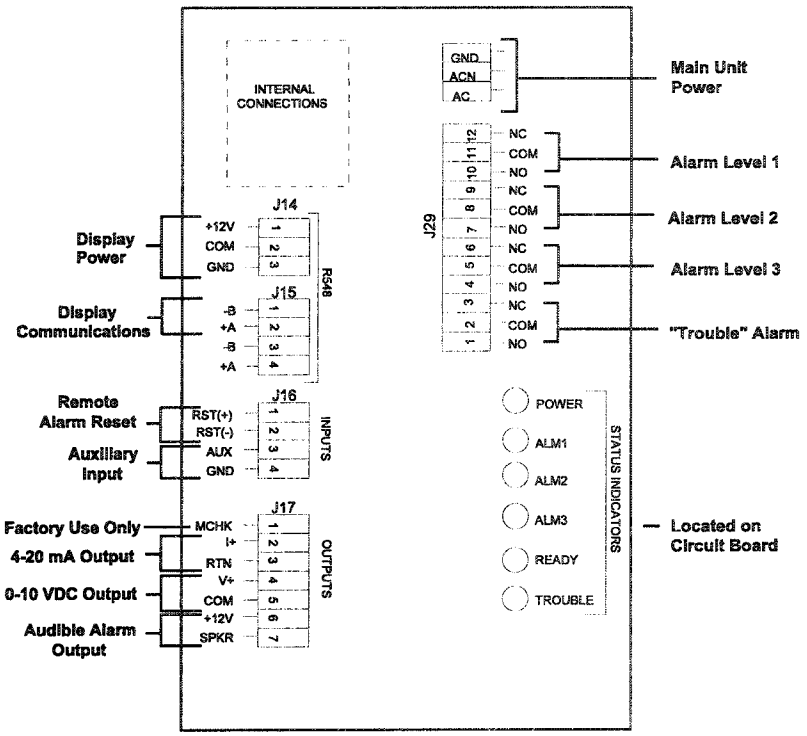

Figure 3

Remote Mounted Wiring

Unit Mounted/UCP2 Wiring

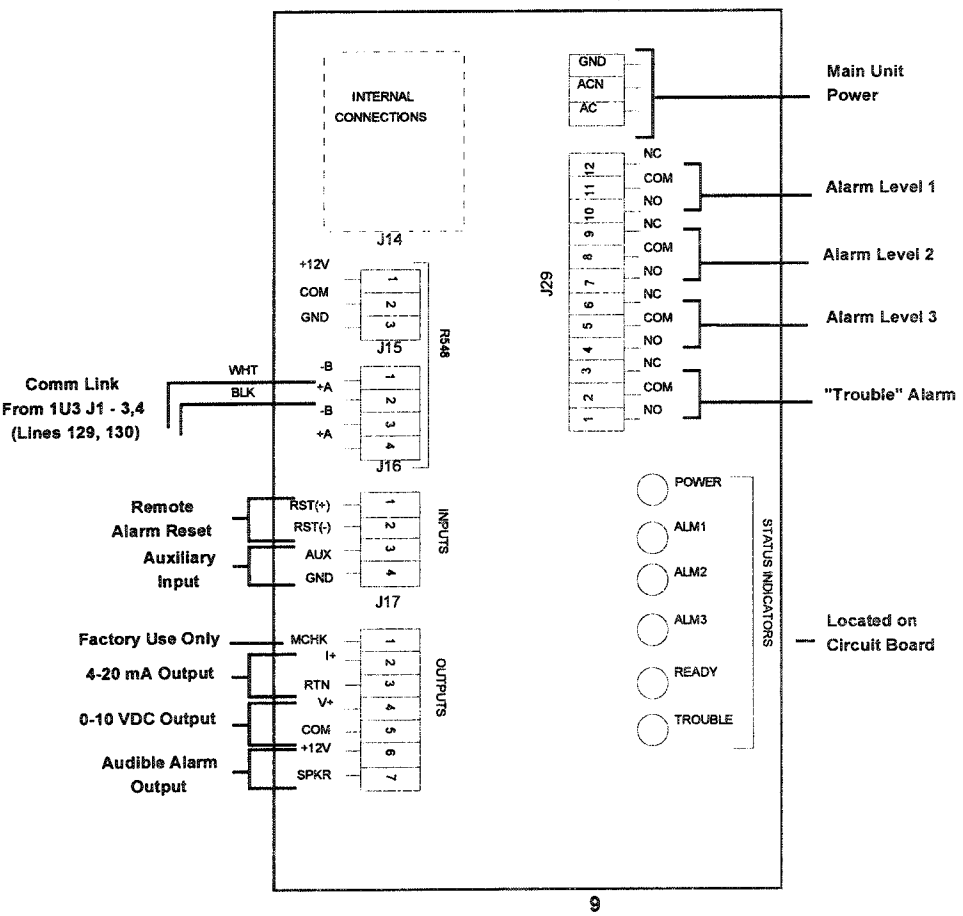

Figure 4 - UCP2 Schematic Wiring for Clear Language Display, Stepper and Circuit

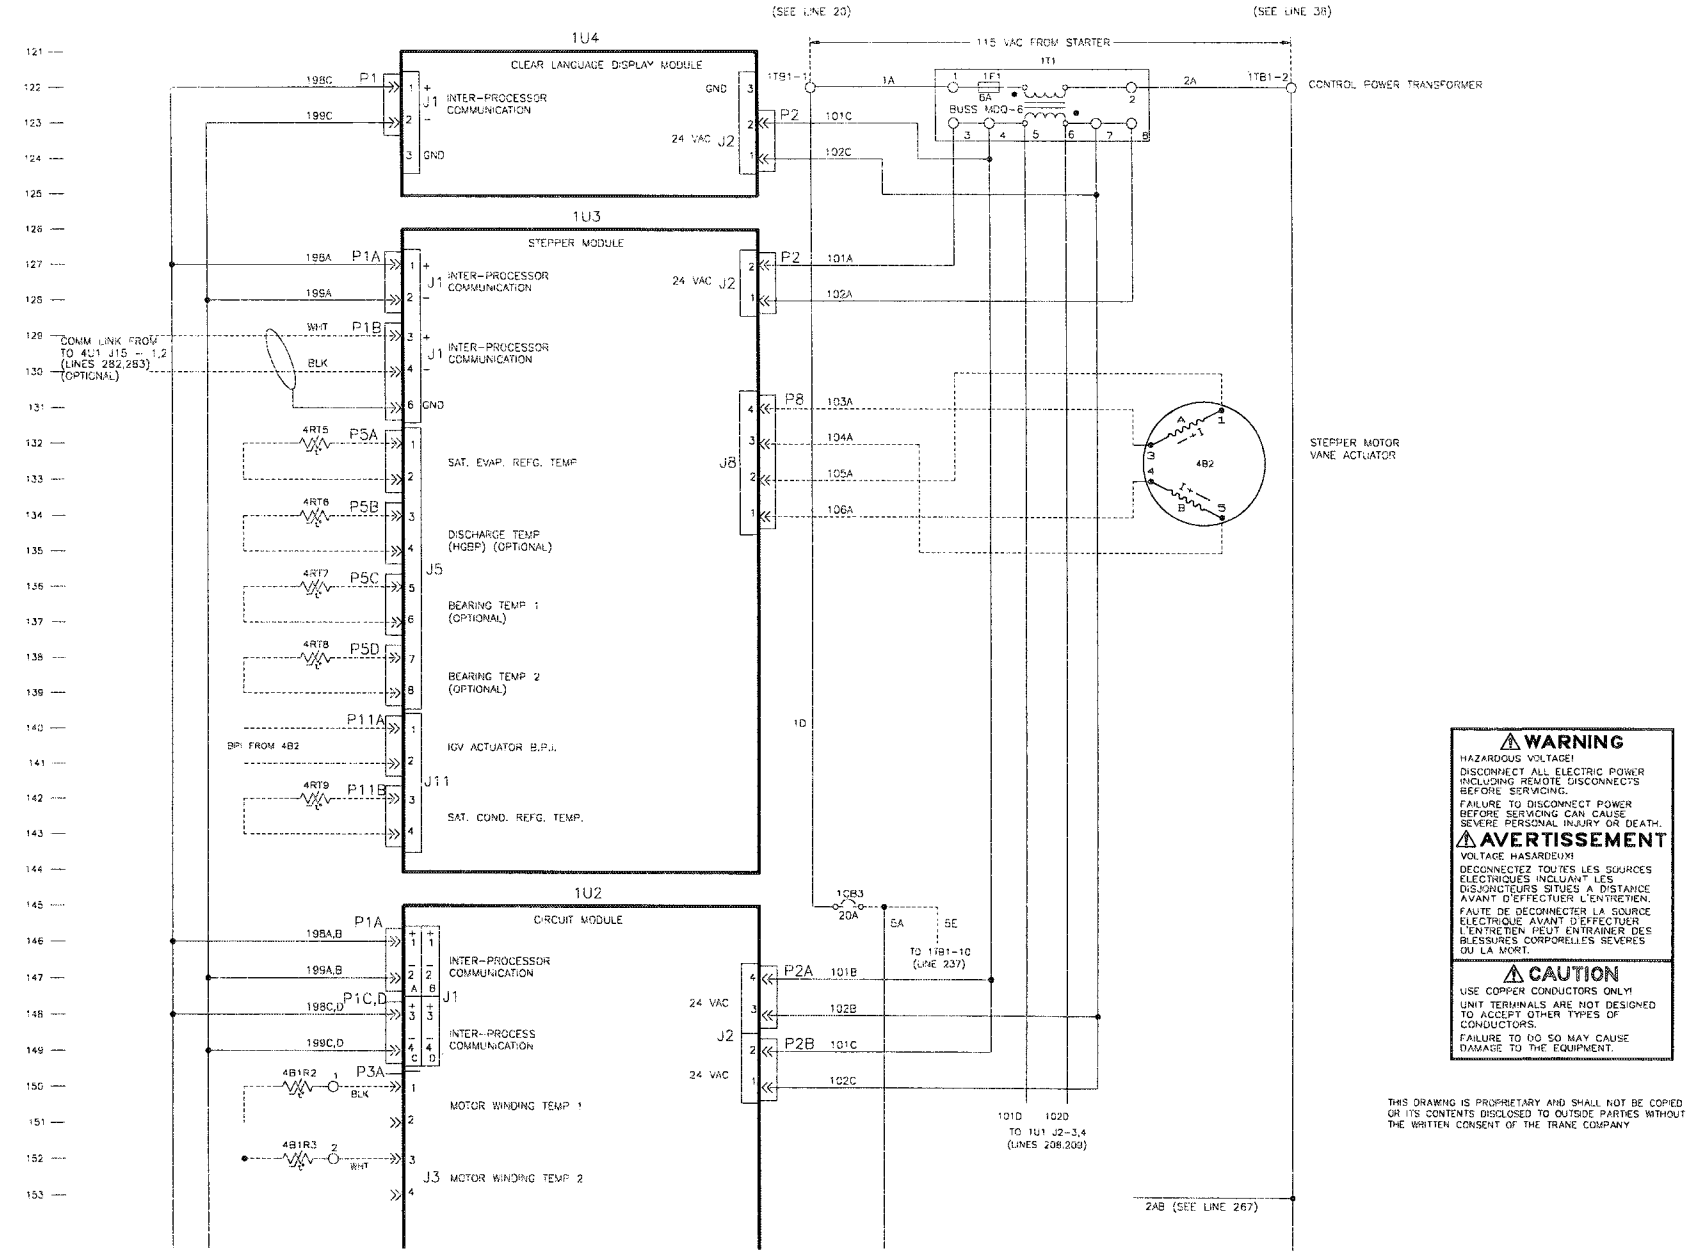

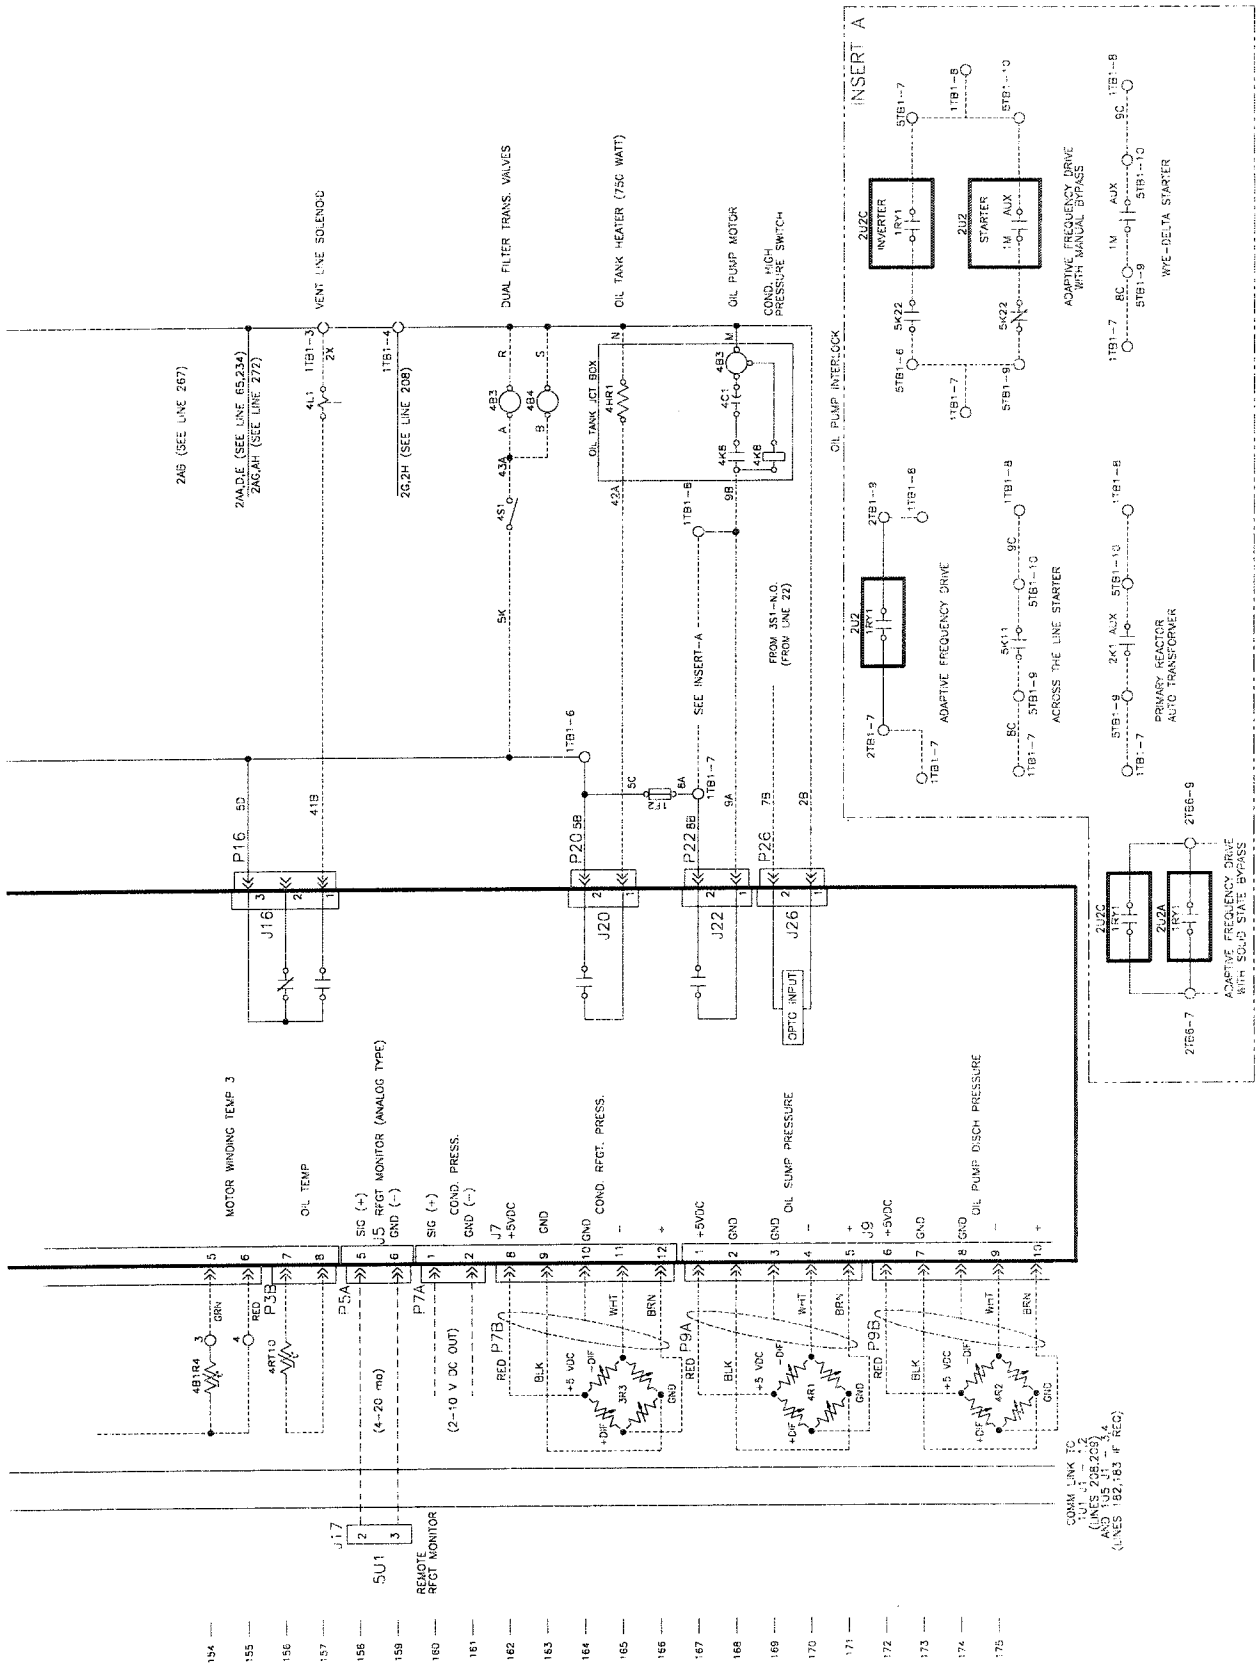

Figure 4 - UCP2 Schematic Wiring for Clear Language Display, Stepper and Circuit

Refrigerant Monitor / UCP2 Connections

Two options exist:

- **Analog**: Alarm setpoint changes, etc. are done from the monitor's keypad. The UCP2 will only display the current parts per million (ppm) and has no control over the monitor. The UCP2 must be configured for analog type refrigerant monitor to display the ppm readout. Run 18 AWG shielded, twisted wire to the following terminals. **Note**: the maximum distance is 500 feet (152 m).

UCP2 - 1U2 (Circuit) Module		Refrigerant Monitor
J5-5	To	J17-2
J5-6	To	J17-3

See Figure 4 for wiring details.

- **IPC**: All settings and control of the refrigerant monitor is done through the UCP2 keypad. **Note:** To meet UL requirements, a green light (KIT2990) must be present in the monitor's door to show that power is applied. The UCP2 must be configured for IPC which will allow the refrigerant monitor screens in UCP2 to become active. Run 18 AWG shielded, twisted wire to the following terminals - 500 feet (152 m) maximum.

UCP2 - 1U3 (Stepper) Module		Refrigerant Monitor
1U3 J1-3	To	J15-1
1U3 J1-4	To	J15-2
J1-6, Use for ground		

See Figure 4 for wiring details.

Note 1: See software issues for related refrigerant monitor and UCP2 compatibility.

Note 2: KIT 3032 adds a human interface at the monitor to a RMWD monitor which doesn't have one.

Note 3: Control is from UCP2 or human interface on the monitor, not both.

Tracer Connections

- If UCP2 exists:
  A UCP2 TCI Comm 4 module (to Summit) and a TCI Comm 3 module (to Tracer 100) will upload the ppm display from the refrigerant monitor if configured in UCP2 as an analog monitor. If the refrigerant monitor is configured and connected IPC to UCP2, the ppm and any monitor diagnostics are passed up to Tracer.
- No UCP2:
  Tracer 100 Series does not accommodate connecting the Refrigerant Monitor directly to the Tracer. It would need to be connected to a PCM or UPCM. Tracer Summit BCU's each have two (2) Universal Input points that can be configured to interface the Refrigerant Monitor analog and / or binary outputs.

What Tracer does with the information depends on the sequence of operation for the job, what points are to be set up for alarms and how the Tracer is programmed. Contact BASD for details.

Battery Backup - The micro processor has a battery backup and the computer chip is non-volatile so that settings and memory are not lost when power is off to the unit. The unit itself does not have a battery backup to continue monitoring during a power outage.

Run Test Monitor - Alarm contact relays can be tested by using the span gas from the calibration kit. Change the alarm contact setpoints below the concentration for the span gas and apply the span gas to the sample inlet. The contacts should change state.

Software Issues

A white label located in the top of the monitor enclosure shows the manufacturing date. The software version number for the human interface is displayed during warm-up. This information is also found in the Status Menu.

Design sequence A, Software version 1.0 - The first date codes in production were mid-August 1994. The optional audible alarm will sound on a level 3 alarm.

Design sequence A, Software version 2.0 - This started in production on March 2, 1995 and allows communication / programming from the UCP2. Therefore, the monitor could function without the clear language display. This version will support the optional monitor mounted audible alarm selectability for alarm levels 1, 2 or 3. The audible alarm can also be set to alarm for a monitor trouble condition. Note that this is independent of the three alarm levels. Refrigerant R-12 monitors are fully supported by software.

Design sequence A, Software version 2.0 - UL label applied starting April 1, 1995. At the same time additional electronic hardware was added to the bench circuit to minimize interference from radiated electrical noise such as radio pagers, etc.

Design sequence A, Software version 3.0 - All refrigerant monitors with a date code of June 20, 1995 or later have version 3 of refrigerant monitor software. This software will change the analog output so it doesn't go to 2.0 mA during monitor check. This situation caused nuisance diagnostics on the UCP2.

Version 2 software will allow the UCP2 to communicate directly with the refrigerant monitor via the IPC (inter-processor communication link). The UCP2 must have software released on February 17, 1995 or later, and the modules must have the extensions as shown below.

Description	CTV X-Code	RTHB X-Code
Chiller Module (required UCP2 module)	X13650450-08	X13650499-05
Clear Language Display Module (required UCP2 module)	X13650448-07	X13650448-07
TCI Comm4 Module (optional UCP2 module)	X13650457-05	x13650457-05
TCI Comm3 Module (optional UCP2 module)	X13650460-05	X13650460-05
TCI Printer Interface Module - (optional UCP2 module)	X13650458-05	X13650458-05

General Information

Monitor Cross-Sensitivity

The Trane Refrigerant Monitor is factory calibrated specifically for the refrigerant of interest. With the large number of different chemicals and refrigerants in equipment rooms, it is very important that an air monitoring device be as resistant to cross-sensitivity as possible. The photo-acoustic technology used in this instrument is one of the most selective available; however, the instrument may respond, in varying degrees, to other chemicals that may be in the monitored area. Listed below are the instrument's sensitivity to 100 ppm of other commonly used refrigerants when calibrated for the specific refrigerant listed. These are typical values for reference only.

Example: A monitor calibrated for HCFC-123 will display 4 ppm when exposed to 100 ppm of HCFC-22.

Calibrated for HCFC-123

Refrigerant	Response
CFC-11	<1 PPM
HFC-134a	140 PPM
HCFC-22	4 PPM
CFC-113	80 PPM

Calibrated for CFC-11

Refrigerant	Response
HCFC-123	3 PPM
HFC-134a	20 PPM
HCFC-22	30 PPM
CFC-113	25 PPM

Calibrated for HCFC-22

Refrigerant	Response
HFC-134a	25 PPM
CFC-11	16 PPM
HCFC-123	35 PPM
CFC-113	39 PPM

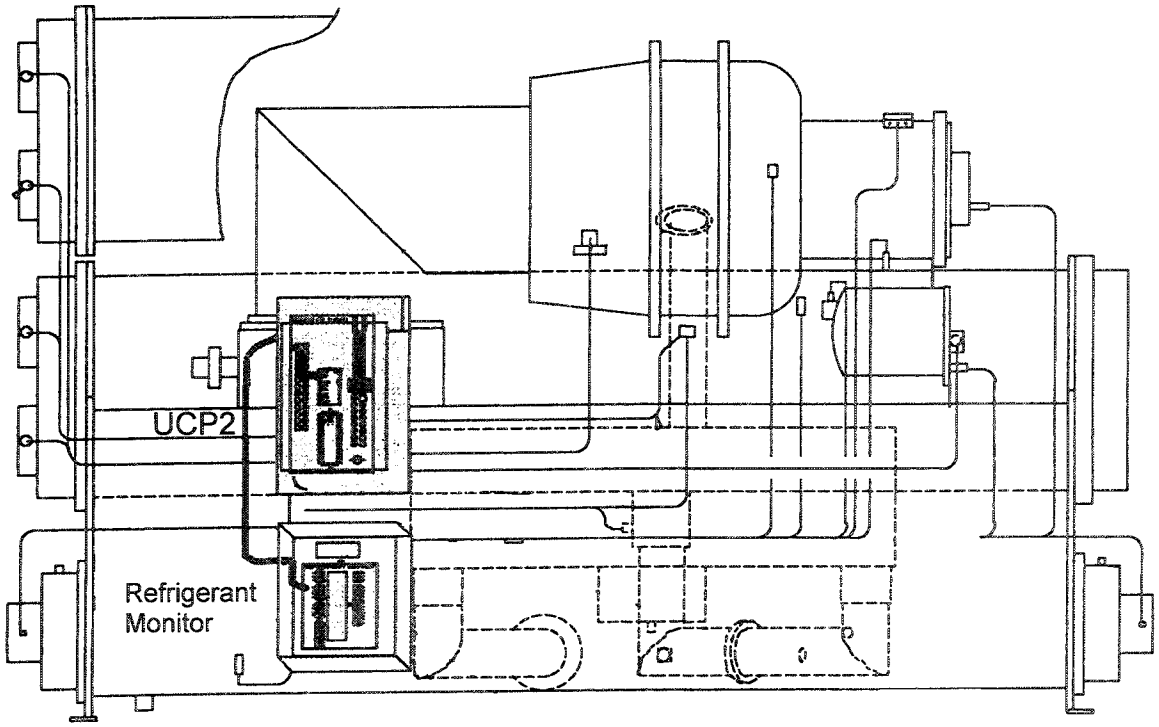
Calibrated for HFC-134a

Refrigerant	Response
HCFC-22	1 PPM
HCFC-123	8 PPM
CFC-11	2 PPM
CFC-113	17 PPM

Due to the large number of possible interferants other than refrigerants, it is impractical to list them. Direct any questions regarding specific interferants that are expected to be in the monitored area to your local Trane office.

Note: Cross-sensitivity data not verified during UL testing.

The optional Trane unit mounted refrigerant monitor is operationally identical to the remote mounted monitor, except for the clear language display. This has been replaced by a plain, painted front panel, with a green light to indicate power is present. The unit mounted monitor also has some additional stiffeners and hardware to eliminate the transmission of any vibration.



The menu screen "Refrigerant Monitor Type" at the UCP2 human interface allows the selection of two possible values:

- 01 - Analog Monitor
- 02 - IPC Monitor

When **IPC Monitor** is entered, the menu asks for a password prior to accessing the settings and then rotates through a series of screens to initiate the monitor. The password, UCP2 set-ups, inputs, calibration and diagnostic menus are found in the latest revision of CVHE-CLD-1 under the heading "Refrigerant Monitor Settings Group".

The unit mounted refrigerant monitor is designated 4U1 on Trane wiring diagrams. Although the Interprocessor Communication can go to any IPC connection, it was placed at the stepper module 1U3 since this was an open connection.

Figure 5 - Typical Unit Mounted Refrigerant Monitor

Monitor Control

RMWD refrigerant monitor control is from either the unit mounted CLD or the UCP2 (CVRB) clear language display but not both. One clear language display on the unit or UCP2 cannot be used to control more than one monitor.

Method for controlling two or more devices from a single monitor alarm contact:

The dry contacts in the refrigerant monitor can be used to control multiple devices such as lights, buzzers, exhaust fan contactors, etc. The Technical Specifications section of this manual lists the monitor contact ratings which should not be exceeded. The preferred method for powering multiple devices is shown in Figure 6 which shows a relay powered through the monitor's alarm contacts. The relay's contacts then power the other devices. This provides isolation so that sensitive components like the Trane tower light can be wired to the same circuit as an exhaust fan contactor.

Clear Language Display (CLD)

All setup, alarm, diagnostic, measured concentration and calibration information for the monitor is accessed through an eight button, two line, 16 character backlit clear language display (CLD) mounted in the unit front panel.

Items to check:

- The chip may have a terminal that appears to be in place, but is actually bent over on top of the socket, making occasional contact. Look under the chip.
- Touch the keypad to assure that the display has not been turned off. Try more than one key in case it is a keyboard problem. Check the keyboard connector on the CLD board.
- On the RMWD from the top pin in the main board to the bottom the voltages are as follows:
  - J 14 - 1, +12 vdc
  - J 14 - 2, Common - 0 vdc
  - J 14 - 3, Ground - 0 vdc
  - J 15 - 1, - B + 1.6 to GND
  - J 15 - 2, +A + 2.3 to GND
    Measured 0.7 to 0.8 from A to B
  - J 15 - 1, -B to + A, + 0.7 vdc

If the display is not lit, check the connection on the CLD board with the red and black wires which powers the display light.

R-12 "Undefined" Message
The R-12 monitors, version 1.0, were coded so there was no way to put R-12 onto the clear language display. A compromise was to use the word "undefined". Version 2.0 or later software fully supports R-12 monitors.

Figure 6 - RMWD Wiring for Controlling Two Devices from One Alarm Contact

	Alarm Level 3 = XXXX ppm R-XXX	The minimum refrigerant concentration necessary to trigger a Level 3 Refrigerant Alarm (press + to increment, - to decrement) **XXXX ppm** *
	**Audible Alarm For Rfgt = XXXXX	The refrigerant alarm level which causes the optional Audible Alarm to sound [Off, Alarm1, Alarm2, **Alarm3**]
	**Audible Alarm For Trouble = XXX	Select the optional Audible Alarm to sound for a Trouble condition [**Off**, On]
	Alarm Level 1 = XXXXX	Alarm Level 1 relay configuration [Latching, **Non-Latching**]
	Alarm Level 2 = XXXXX	Alarm Level 2 relay configuration [Latching, **Non-Latching**]
	Alarm Level 3 = XXXXX	Alarm Level 3 relay configuration [Latching, **Non-Latching**]
	Channel Scanner = XXXXX	Select the multi-channel scanner [**Installed**, **Not Installed**] **Default dependent on scanner installation** (only displayed during "Warm-up")
	Scanner Chan 1 = XXXXX	Select Channel 1 Status [**Active,** Inactive] (displayed if channel scanner is installed)
	Scanner Chan 2 = XXXXX	Select Channel 2 Status [Active, **Inactive**] (displayed if channel scanner is installed)
	Scanner Chan 3 = XXXXX	Select Channel 3 Status [Active, **Inactive**] (displayed if channel scanner is installed)
	Scanner Chan 4 = XXXXX	Select Channel 4 Status [Active, **Inactive**] (displayed if channel scanner is installed)
	Dwell Threshold = XX %	Select the percentage of Alarm Level 1 necessary to dwell on a channel for an additional 60 seconds 30 - **70%** (displayed if channel scanner is installed)
	Auxiliary Input = XXXXX	Select Auxiliary Input installation status [Installed, **Not Installed**]
	Aux Input Alarm = XXXXX	Select Auxiliary Input alarm status [**Enabled,** Disabled] (displayed if Auxiliary Input is Installed)
	Auxiliary Alarm Level = XX.X mA	Select the alarm condition level for the auxiliary input. (displayed if Auxiliary Input is Installed)

Bold = Factory Default
* See Factory Default Value Chart in Settings Side Menu

Start-Up Sequence

The start-up diagnostic test for a single point unit and the start up diagnostic test for a scanner unit are two different tests. A single point unit must be configured as a single point unit (Channel Scanner Not Installed) and a scanner must be configured as a scanner (Channel Scanner Installed). The display will confirm if the unit is configured as a scanner by showing a channel number with the instrument read-out. The instrument runs the diagnostic test prior to allowing the operator to reconfigure the unit. Installing or not installing a scanner is an option only when the unit has just been powered up and in warm-up mode. Changes in this Settings Menu, if necessary, must be made at this point. The operator must then wait a minimum of eight seconds, power off and restart the unit to check that the change was stored in memory.

During start up and while the unit is performing the flow diagnostic test, the sample inlet(s) and exhausts should not be blocked or the unit will fail this test. Put a sample filter on each used and unused channel, so that on initial power up or a power failure, the scanner sees all channels open.

A unit that has failed a start-up diagnostic test will continue to display a flow loss error even if the problem that caused the unit to generate this error is corrected. To correct the problem, the unit must be powered off, restarted and successfully pass the appropriate flow diagnostic test to eliminate the flow loss error display.

A unit that has generated a flow loss error during normal operation will respond to the correction of the problem that caused the error and the error display will clear. A scanner unit may however take one scanner cycle to finally clear the error message. Check the READY LED on the right side of the main board for instantaneous indication of the instrument's status.

A single point unit will only generate a Bench Flow Loss. A scanner unit generate either a Bench Flow Loss error or a Scan Flow Loss error. Bench Flow Loss will take precedence over Scan Flow Loss in a scanner unit with both faults.

The bench pressure switch actually changes state during the diagnostic test and normal operation. **Shorting the terminals of this switch will NOT resolve the bench flow loss**. It will cause the unit to fail the start up diagnostic test or fail during normal operation. The scan pressure switch is required to switch during start-up once and remain closed during normal operation. **Do not short either of the pressure switches.**

The pressure switches measure the differential pressure across the two orifice restrictors (see Figure 9). There is no flow through the switch.

Bench Flow Loss

⚠ Caution:
Use care when handling tubes and fittings. The fittings are rigid and easily broken.

Single Point Units

Disconnect all inlet and exhaust tubing outside the monitor enclosure. This will isolate the problem to within the monitor or in the external tubing and filter(s).

The bench solenoid valves open and close every 3.5 seconds. Check for bubble activity at EXHAUST Port 2 as shown in Figure 10. Low flow or no flow at this port is most likely caused by a defective pump or saturated inline particle filter.

Check for bubble activity at EXHAUST Port 1. Flow will start and stop depending on if bench solenoid valves are open or closed. If flow does not completely stop, one or both of the bench valves are defective or the inlet fitting to the optical bench may be loose.

Use a voltmeter to measure the logic input from the pressure switch (negative lead to chassis, positive lead to black wire of SMP PRSS connector on left of main board). Set the range of the volt-meter to 0.00 (range hold auto-ranging voltmeters) and monitor the logic level switch every 3.5 seconds during normal operation.

A pressure switch that is always open may be the result of a defective pressure switch, loose tubing connecting to pressure switch or a clogged restrictor in the tubing.

A pressure switch that is always closed may be the result of a loose fitting to the inlet of the optical bench in addition to the same causes for a switch always open.

If the Bench Flow Loss error is the result of the unit failing the start-up diagnostic test, restart the unit while monitoring the logic input of the bench pressure switch. The result should match the bench pressure switch logic input as shown in Table 1.

A pressure switch that is not switching fast enough to follow the test sequence is most likely the result of deterioration in pressure switch performance but may be one of the reasons stated previously.

The fittings on the inline filter are glued and any attempt to remove or change the direction of the fittings will break the seal and/or crack the filter housing. A cracked filter fitting will not generate a Bench Flow Loss error in a single point unit. However, it will cause sample dilution. Replace the entire filter assembly if a problem is suspected.

A leak in the brass union fittings for the sample inlet or exhausts will not generate a Bench Flow Loss error, however, these fittings should be changed if a leak is suspected.

Reconnect all tubing when done. Use an end of line filter on each input line. Limit the length of tubing on any one port to 150 ft. (45.7m) (total length of sample and exhaust lines). Do not combine exhaust lines.

Table 1 - Single Point Unit Start-Up Diagnostic Routine

	Duration (Sec)	Bench Inlet Valve	Bench Outlet Valve	Bench Pressure Switch
Start Up Test	12	Closed	Closed	Open
	1	Open	Open	Closed
	1	Open	Closed	Open
	1	Open	Open	Closed
	1	Closed	Open	Open
Cycle repeats like this during Normal Operation	3.5	Open	Open	Closed
	3.5	Closed	Closed	Open
	3.5	Open	Open	Closed
	3.5	Closed	Closed	Open

Bench Flow Loss

⚠ Caution:
Use care when handling tubes and fittings. The fittings are rigid and easily broken.

Scanner Units

Disconnect all inlet and exhaust tubing outside the monitor enclosure.

Check flow at EXHAUST port 1 (see Figure 10). The bench valves cycle on and off every 3.5 seconds.

No or low flow at this port is most likely caused by a defective sample pump or saturated particle filter. It may also be caused by a defective scanner valve. Allow the channel scanner to scan all four lines to determine if low flow is associated with one or all of the scanner lines.

If the flow does not vary slightly between two different levels every 3.5 seconds, this could indicate a defective bench valve or a loose inlet fitting to the optical bench.

Use a voltmeter to measure the logic input from the pressure switch (negative lead to chassis, positive lead to black wire of SMP PRSS connector on left of main board). Set the range of the voltmeter to 0.00 (range hold auto-ranging voltmeters) and monitor the logic level switching every 3.5 seconds during normal operation.

A pressure switch that is always open may be the result of a defective pressure switch, loose tubing connecting to pressure switch or a clogged restrictor in the tubing.

A pressure switch that is always closed may be the result of a loose fitting to the inlet of the optical bench in addition to the same causes for a switch always open.

If the Bench Flow Loss error is the result of the unit failing the start up diagnostic test, restart the unit while monitoring the logic input of the bench pressure switch. The result should match the bench pressure switch logic input as shown in Table 2.

Table 2 - Scanner Unit Start-Up Diagnostic Routine

	Duration (Sec)	Scan Valve 1	Scan Valve 2	Scan Valve 3	Scan Valve 4	Bench Inlet Valve	Bench Outlet Valve	Bench Pressure Switch	Scanner Pressure Switch
Start Up Test	12	Scan	Scan	Scan	Scan	Closed	Closed	Open	Closed
	1	Sample	Scan	Scan	Scan	Open	Open	Closed	Closed
	1	Sample	Scan	Scan	Scan	Open	Closed	Open	Closed
	1	Sample	Scan	Scan	Scan	Open	Open	Closed	Closed
	1	Sample	Scan	Scan	Scan	Closed	Open	Open	Closed
	1	Sample	Scan	Scan	Scan	Open	Open	Closed	Closed
	1	Scan	Scan	Scan	Scan	Open	Open	Open	Closed

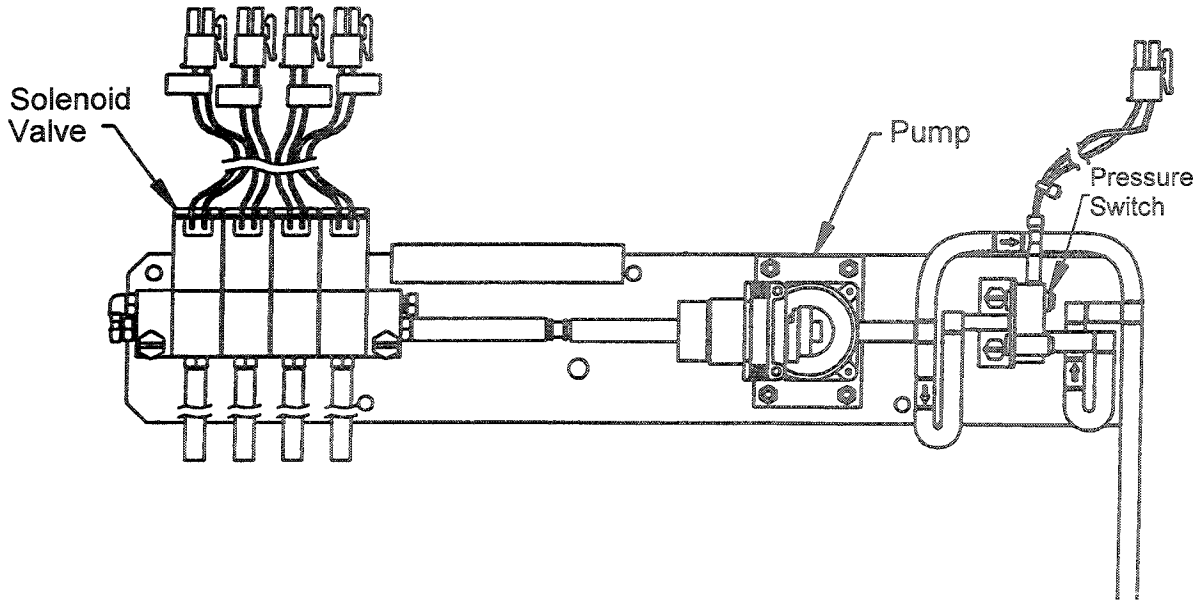
	1	Scan	Scan	Scan	Sample	Open	Open	Open	Closed
	1	Scan	Scan	Sample	Scan	Open	Open	Closed	Closed
	1	Scan	Scan	Scan	Scan	Open	Open	Open	Closed
	1	Scan	Scan	Scan	Sample	Open	Open	Closed	Closed
	1	Scan	Scan	Scan	Scan	Open	Open	Open	Closed
	1	Sample	Sample	Sample	Sample	Open	Open	Closed	Open
Cycle repeats like this during Normal Operation	3.5	Sample	Scan	Scan	Scan	Open	Open	Closed	Closed
	3.5	Sample	Scan	Scan	Scan	Closed	Closed	Open	Closed
	3.5	Sample	Scan	Scan	Scan	Open	Open	Closed	Closed
	3.5	Sample	Scan	Scan	Scan	Closed	Closed	Open	Closed

Bench Flow Loss

⚠ Caution:
Use care when handling tubes and fittings. The fittings are rigid and easily broken.

The scanner manifold valves allow flow to the scanner pump when not energized (normally open port) and will be noted as Scan in Table 2 to indicate that flow from this line is directed to the scanner pump. The scanner manifold valves will redirect flow to the sample pump when energized (normally closed port) and will be noted as Sample in Table 2 to indicate that flow from this line is directed to the sample pump.

A pressure switch that is not switching fast enough to follow the previous test sequence is most likely the result of deterioration in pressure switch performance but may be due to one of the reasons stated earlier.



The fittings on the inline filter are glued and any attempt to remove or change the direction of the fittings will break the seal and/or crack the filter housing. A cracked filter fitting will cause a scanner unit to fail a diagnostic start up test and generate a Bench Flow Loss error. Replace the entire filter assembly if a problem is suspected.

A leak in the scanner manifold valves or the fittings on that block will cause the unit to fail a start up diagnostic test and the generation of a flow fail error. A leak to the sample side will cause a bench flow loss error and a leak to the scanner side will cause a scanner flow loss error. Any leak in solenoids or fittings and tubing leading to the sample pump will cause a bench flow loss. If a problem is suspected with the scanner manifold/valves, the entire assembly should be replaced.

A leak in the brass union fittings for the sample inlet or exhausts will not generate a Bench Flow Loss error, however, these fittings should be changed if suspected of leaking.

Reconnect all tubing when done. Use an end of line filter on each input line. Limit the length of tubing on any one port to 150 ft. (45.7m) (total length of sample and exhaust lines). **Do not** combine exhaust lines.

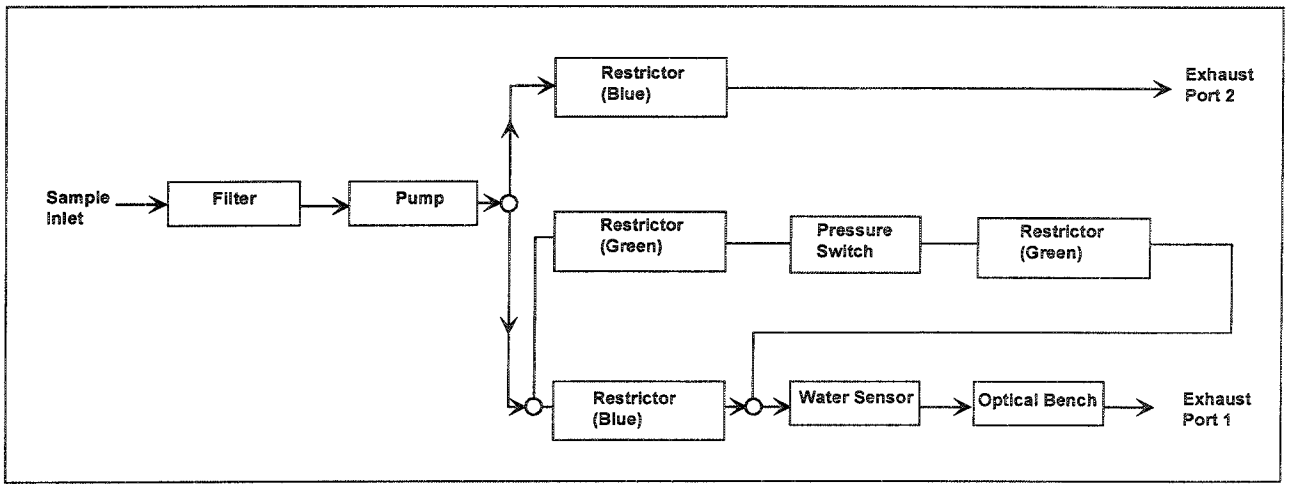
Figure 8 - Scanner Assembly

Scan Flow Loss

⚠ Caution:
Use care when handling tubes and fittings. The fittings are rigid and easily broken.

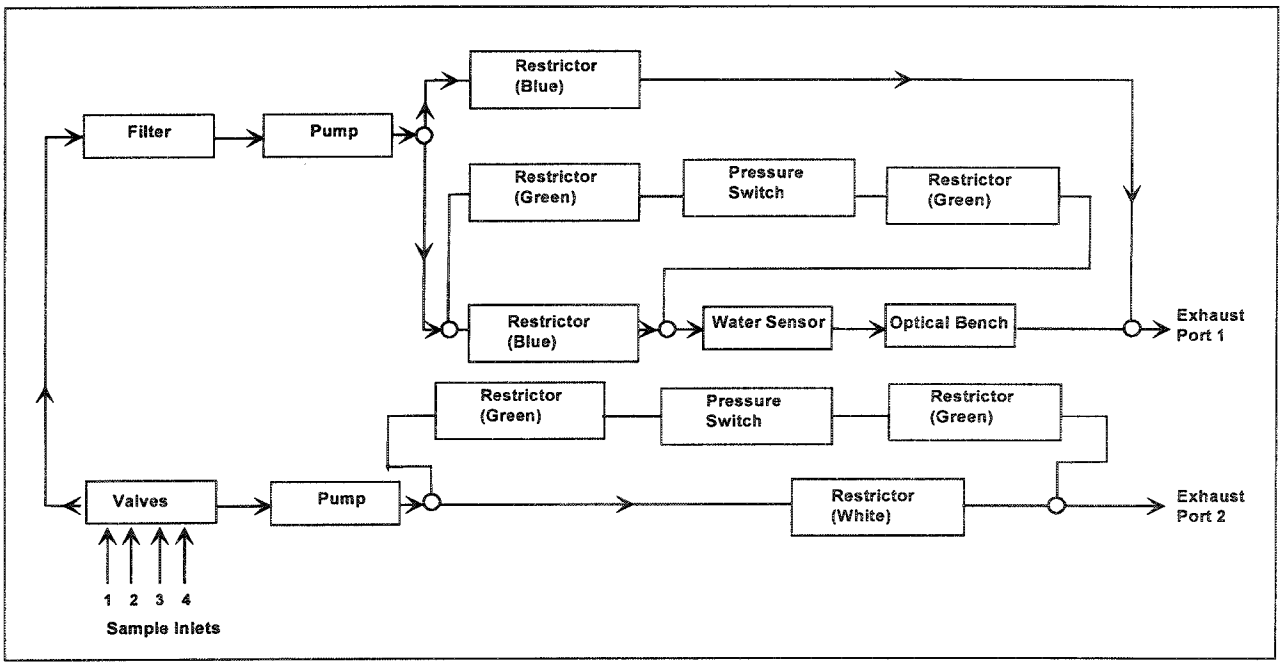
Scanner Unit

Disconnect all inlet and exhaust tubing outside the monitor enclosure.



During normal operation, the scan pressure switch is closed. Check flow at EXHAUST port 2 (see Figure 10). Low or no flow indicates a defective scanner pump. If the flow is sufficient, use a voltmeter to test the logic input of the scan pressure switch (negative lead to chassis, positive lead to black wire of SCN PRSS connector on left of main board). Set the range of the voltmeter to 0.00 (range hold auto-ranging voltmeters). This should remain **closed** during normal operation. If there is flow but the switch is open, the probable cause is a defective switch, loose tubing to the switch or clogged restrictor in the tubing leading to the pressure switch ports.

The scan flow switch is tested only once during the diagnostic test. It remains closed during normal operation. If the unit generates a Scan Flow Loss error as a result of failing the diagnostic test, monitor the output at EXHAUST port 2 (see Figure 10). Restart the unit and about 25 seconds into the diagnostic test, the flow should dip to zero for one second and the scanner pressure switch should open (check logic input of scanner pressure switch in Table 2). If the flow does not cease entirely for that one second, there is a leak in the scanner valve assembly and/or the fittings and tubing between that assembly and the scanner pump. If the flow does actually drop to zero but the pressure switch does not respond, then look for a defective pressure switch, loose tubing and/or clogged restrictor to the switch.



Reconnect all tubing when done. Use an end of line filter on each input line. Limit the length of tubing on any one port to 150 ft. (45.7m) (total length of sample and exhaust lines). Do not combine exhaust lines.

Instrument Flow Diagram

Figure 9 Single Channel Monitor

Monitor with 4 Channel Scanner

Notes:

1. Restrictor Orifice Diameter by Color Code:
   Green = 0.007"
   Blue = 0.020"
   White = 0.030"
2. Arrow on restrictor indicates flow direction

Module Diagnostic Messages

Display:	**Communication Lost With Module**
Description:	The clear language display (CLD), or UCP2 if no CLD is used, is not communicating with the monitor.
How does it affect unit operation:	Monitor will continue to operate in the READY mode. Alarm condition outputs will continue to be energized if ppm readings exceed setpoints. LED's on monitor will display correctly. This diagnostic does NOT cause the monitor to enter a Trouble Status condition. You can scroll through the CLD or UCP2 menu items and see the ppm readings for the data last collected before communication failure. The CLD may even read *READY* if that was the operating condition before the communication failure.
What causes the diagnostic:	The diagnostic is the result of a loss of communication with either the CLD or UCP2. In both cases the communication transfer is via wires connected to J15, terminals 1 and 2.
How to troubleshoot:	Check to be sure the wires are in place at the monitor and CLD, or UCP2. The connection points are J15, terminals 1 and 2. **Can not connect to both CUP2 and CLD.** If using twisted pair to the UCP2, be sure the cable shield is grounded at the UCP2. Check to be sure the connector and its screws are secure, at the monitor and CLD or UCP2. **Note:** Control is from UCP2 or Human Interface on the monitor but not both.
What components to test:	Clear Language Display Wiring - as described

Display:	**Trouble** (plus diagnostic message or channel data)
Description:	Malfunction of the monitor diagnosed by internal operational checks.
How does it affect unit operation:	Any diagnostic listed below causes the monitor to enter a *Trouble* Status condition. There are two levels of *Trouble*. Major, are those conditions that may result in inaccurate data collection. Minor, are those that are informational in nature but do NOT affect the accuracy of sample data measurements. A Major *Trouble* condition will result in turning On the red trouble LED, the Trouble relay switching, and the Clear Language Display (CLD) will flash when at the operating mode menu. Optional unit mounted alarm will sound if it was installed and if it is programmed. It can be quieted by pressing the + key (plus key). This optional alarm will NOT sound with Version 1.0 monitor software. A Minor *Trouble* condition will NOT turn on the red LED, sample measurements will continue, alarm conditions will be output. The CLD will flash trouble status but indicate *READY* mode, the green LED will indicate the same. Reset - If a Major diagnostic occurs during start-up, the unit must be turned OFF to reset after fixing the problem. Minor diagnostics will clear even if they occur during startup. If the diagnostic occurs during the Normal mode of operation then repair of the failure cause will reset the red LED and trouble relay, followed by the clearing of the CLD within 2 minutes. Refrigerant level alarms are disabled during Major *Trouble* diagnostic. Bench sampling and read-out continues during the *Trouble* condition
What causes the diagnostic:	Any of the following diagnostics put the monitor in this status condition: Major: RAM Loss, IR Source Fail, Chopper Fail, Temp Sensor Fail, Bench Flow Loss, Scan Flow Loss, Out Of Temp Rng, Rfgt Lvl to Low Minor: Aux Input Fail, Ext Reset Fail
How to troubleshoot:	See the individual diagnostics
What components to test:	See the individual diagnostics

Module Diagnostic Messages

Display:	RAM Loss
Description:	The monitor module has lost the data in its battery backed RAM.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. Monitor operation will be severely affected.
What causes the diagnostic:	The diagnostic occurs if the RAM information has been changed. *RAM loss* diagnostic occurs for one of two reasons: Could occur after programming the calibration coefficients into the memory through the factory setup menu. It could also occur in the event of RAM loss (possibly due to a battery failure on the main board).
How to troubleshoot:	Cycle power off, then back on to see if the message clears. After it clears a calibration should be performed to confirm accuracy. If calibration has deviated significantly, then one of the coefficients has probably changed and there would probably be other machine problems occurring. With the *RAM loss* condition, several of the menu items will be scrambled and not make sense.
What components to test:	Battery cannot be changed, monitor chassis assembly must be replaced.

Display:	IR Source Fail
Description:	The infra-red optical source has failed.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. The monitor operation will be severely affected. After power up, monitor will NOT cycle through start-up in its normal sequence. May display *Communication Lost With Module* on start-up. Sample reading may vary in the presence of refrigerant, but will NOT be accurate. Will reset without cycling power, even when problem occurs on start-up.
What causes the diagnostic:	Failure of the bench source light.
How to troubleshoot:	Cycle power off, then back on to see if the message clears. Check the resistance of the light source, wires located at the top of the bench near the motor. Label on the board is "Source". Resistance should be about 5 ohms across the light. If the resistance is significantly higher, i.e. 1K ohms, then the light has failed. Check the power at the Source terminals, one of the two terminals should read nominally 5.0 Vdc to ground.
What components to test:	Check unit circuit board wiring to source, near top of bench. Light cannot be changed, monitor chassis assembly must be replaced.

Display:	Chopper Fail
Description:	The optical Bench photo interrupter has failed.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. The monitor will display ppm but accuracy is affected. Will reset without cycling power, even when problem occurs on start-up.
What causes the diagnostic:	When the chopper blade stops or slows this diagnostic occurs
How to troubleshoot:	Chopper blade is fragile. When turned by hand, it is normally very resistant to rotation. It does NOT spin freely. Check wiring to the chopper motor. Listen for a bent chopper blade that might be rubbing
What components to test:	None Chopper motor, bench and printed circuit board must all be replaced as an assembly.

Module Diagnostic Messages

Display:	Temp Sensor Fail
Description:	The bench temperature sensor has failed.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. When viewing the Status Menu, the bench temperature will be blank. The monitor will display ppm but accuracy is affected because the temperature sensor determines how much heat to add to the bench. Will reset without cycling power, even when problem occurs on start-up.
What causes the diagnostic:	Failure of the bench temperature sensor, located on the upper right of the bench.
How to troubleshoot:	Check the wiring to the sensor, located at the upper right corner of the bench assembly, terminal labeled "Temp"
What components to test:	Check the resistance of the temperature sensor, after unplugging from the board: Red to Black = 7.5 Meg Ohms Red to Green = 7.5 Meg Ohms Black to Green = 40 K Ohms From top to bottom: Red, Black, Green

Display:	Scan Flow Loss
Description:	Flow loss through the bypass circuit of the scanner.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* Status condition. Bench sampling and read-out continue during the trouble condition, but accuracy could be affected due to flow problem.
What causes the diagnostic:	The diagnostic is the direct result of the incorrect signal being received from the scanner pressure switch. The scanner pressure switch simply reacts to the flow through the scanner bypass circuit by measuring the pressure drop across a restrictor in the hose. The switch makes and breaks as the flow changes. Pressure switch set-points are non-adjustable. There is an adjustment screw, but adjustment is NOT recommended. The switch contacts are normally open, and close above a pressure of 1.0 +/- 0.2 (0.8 to 1.2) inches water column. They will open again as the pressure drops below 0.5 inches water column. Normal scanner flow involves the scanner pump supplying a constant supply of sample air, plus the switching of the four scanner sequencer valves. Normal operation results in a constant flow to the exhaust port from three of the four inlets, bypassing the bench. During the start-up scanner flow sequence is not the same. Refer to the table representing the start-up sequence. You will find a one second period just before normal operation begins where all four scanner sequencer valves are directing flow to the bench which result in no flow at the scanner pressure switch. Therefore, simply jumpering the switch results in a scanner flow loss if the machine goes through startup.
How to troubleshoot:	Check components involved. Using voltmeter confirm 5.0 vdc to ground on black wire at the switch. With voltmeter on red wire and ground note cycling of switch during the one second cycle at startup. Then it should remain closed throughout the normal operation. Programming - If the monitor programming is set for a single channel with a scanner installed or vice-versa *Bench Flow Loss* will be indicated.
What components to test:	Wiring - verify that the pressure switch is connected to SCN PRSS terminal Leaks - especially on scanner units where the diagnostic has occurred on start-up. Pressure switch; Pump; Hoses and Restrictors; Filters Four Channel Sequencer valves - four channel scanner units only

Module Diagnostic Messages

Display:	Out of Temp Rng
Description:	The refrigerant monitor is out of the temperature range where it can measure refrigerant.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. If heater is disconnected or not working, the monitor will continuously stay in warm-up. The monitor will display ppm but accuracy is affected. Will reset without cycling power, even when problem occurs on start-up.
How to troubleshoot:	Troubleshoot the same as *Temp Sensor Fail*
What components to test:	None

Display:	Rfgt Lvl Too Low
Description:	The displayed refrigerant level is less that -4 ppm
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. The monitor will display ppm but accuracy should be questioned. Will reset without cycling power, even when problem occurs on start-up
What causes the diagnostic:	When monitor displays a level less than -4 ppm
How to troubleshoot:	Vibration: Fluctuating readings from -200 to 0 have been observed. Remove the monitor from its location to verify vibration caused the diagnostic. Other vibration sources should also be investigated. Electrical radiated noise: Disconnect outputs and use an extension cord power supply from an alternate source to see if the noise source can be isolated. Look for intercoms, walkie talkies, switchgear, etc.

Display:	Rfgt Mon Fail
Description:	Severe problem with monitor.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. The monitor will display ppm but accuracy is affected. Will reset without cycling power, even when problem occurs on start-up.
What components to test:	None

Display:	Aux Input Fail
Description:	Auxiliary Input is not functioning.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Minor *Trouble* status condition. The monitor will display ppm. Will reset without cycling power, even when problem occurs on start-up.
How to troubleshoot:	Uninstall Auxiliary input if one doesn't exist.
What components to test:	Check Auxiliary input wires.

Module Diagnostic Messages

Display:	Bench Flow Loss
Description:	Flow loss to the optical bench.
How does it affect unit operation:	This diagnostic causes the monitor to enter a *Trouble* Status condition. Bench sampling and read-out continue during the trouble condition, but accuracy could be affected due to flow problem. If Scan Flow Loss is also detected it will not be displayed until this condition has cleared.
What causes the diagnostic:	The diagnostic is the direct result of the incorrect signal being received from the bench pressure switch. The bench pressure switch simply reacts to the sample flow through the bench by measuring the pressure drop across a restrictor in the hose. The switch makes and breaks as the flow cycles. Pressure switch set-points are non-adjustable. There is an adjustment screw, but adjustment is NOT recommended. The switch contacts are normally open, and close above a pressure of 1.0 +/- 0.2 (0.8 to 1.2) inches water column. They will open again as the pressure drops below 0.5 inches water column. Normal bench flow involves the bench pump supplying a constant supply of sample air, plus the bench inlet and outlet solenoids opening and closing. Normal operation results in a constant flow to the exhaust port, bypassing the bench, plus a 3.5 second flow, and 3.5 seconds no flow through the bench itself. During the start-up bench flow sequence is not the same. Also, this sequence varies for a scanner or single channel monitor. Refer to Table 1 for single point units and Table 2 for scanner units start-up sequence for both units.
How to troubleshoot:	Check components involved. Using voltmeter confirm 5.0 vdc to ground on black wire at the switch. With voltmeter on red wire and ground note cycling of switch in 3.5 second intervals, open - closed - open... At the same time as you are watching the switch action, using a glass of water watch for the flow - no flow - flow cycling from the hose leaving the bench by observing the bubble activity. On single circuit machines this can be checked at exhaust port one. Four channel units require disassembling the hose at exhaust port one to separate the bench hose. Programming - If the monitor programming is set for a single channel with a scanner installed or vice-versa *Bench Flow Loss* will be indicated. Refer to the Bench Flow Loss section of this guide.
What components to test:	Wiring - verify that the pressure switch is connected to SMP terminal Leaks - especially on scanner units where the diagnostic has occurred on start-up. Pay particular attention to the hose from the four sequencer valves to the bench pump. Pressure switch; Pump; Hoses and Restrictors; Filters Four Channel Sequencer valves - four channel scanner units only

Display:	Ext Reset Fail
Description:	The external reset switch has failed or the jumper is missing.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Minor *Trouble* Status condition,. All latching alarms will act as non-latching. Bench sampling, readout, and alarms continue during this trouble condition. The internal red LED labeled trouble is NOT turned on because the monitor remains in the *READY* mode.
What causes the diagnostic:	The diagnostic is the direct result of the incorrect signal being received from the INPUT terminals. The correct signal is provided by a normally closed contact or jumper wire.
How to troubleshoot:	Check to be sure the jumper wire is in place if no external reset switch has been installed. The connection points are J16, terminals 1 and 2. Check to be sure the connector and its screws are secure. If an external switch is installed, using voltmeter confirm that the resistance across these terminals is zero.
What components to test:	Wiring - check as above External reset switch (normally closed switch), not provided by Trane

Quick Problem Checks

A. Bench flow loss - Check installation to be sure all lines are open at the bottom of the panel. In this order:

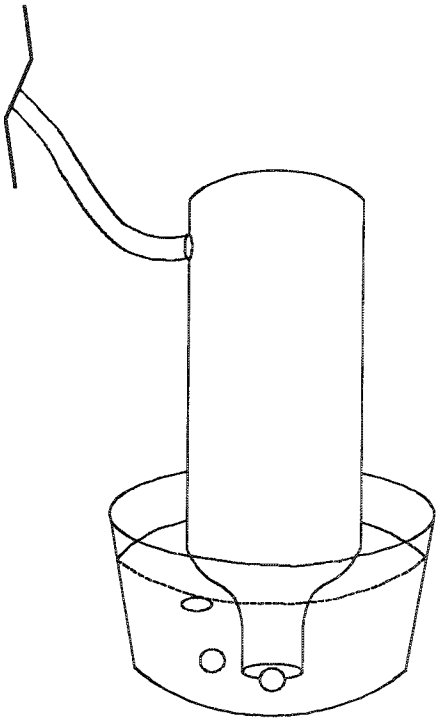
1. Inspect switches and tubing for kinks and cracks.

2a. Bench pressure switch will open and close during normal operation. 0 and 5 volts d.c. (switching) will be seen on a voltmeter by placing leads on the terminals of the pressure switch.

2b. Scanner pressure switch (scanner unit only) must be closed all the time.

3. Are the restrictors installed in the right direction? Arrow indicates flow. See Figure 9 for details.

4. After switches and tubing are checked, look at the pump. Rotate to insure the crank is not rubbing anywhere.



5. Remove cover from bench and listen for solenoid activity. Should be switching Open / Close during a 7 second cycle.

6. Using a glass of water, observe the bubble activity at the exhaust ports (see Figure 10). Port 1 should be cycling on / off, Port 2 should be nearly constant. (Single point monitor only.)

7. Is the monitor programmed properly, check if scanner is installed, or not. Then re-start.

Notes: Bench Flow Loss display does not clear the display immediately, but it does clear itself after two minutes. If in doubt as to whether or not the condition has cleared, observe the LED trouble light on the circuit board. It will turn off immediately after the problem has cleared.

Figure 10 - Measuring bubble activity, see step 6.

Quick Problem Checks

If a bench flow loss condition occurs during start-up (warm-up) it will be necessary to power-down and restart the monitor to clear the diagnostic.

Bench flow loss will occur on a four channel monitor programmed for single channel operation because the four scanner channels are all blocking airflow to the bench circuit. To avoid this problem, program properly or remove the bench circuit inlet tube from the left side of the four solenoids.

Check bench flow problems by measuring flow through the bench circuit. During the 3.5 second cycle, flow can be grossly checked with use of a bottle cap (approximately 1-1⁄8 inch diameter), or a soda bottle (approximately 3/4 inch diameter). The following bubble rates per 3.5 second cycle can be expected:

	Flow Loss	Normal Flow
Bottle Cap	2	6
Bottle	4	8

See Figure 10.

B. Refrigerant level too low - If the output is erratic and bounces from a low reading to a normal reading, suspect problems resulting from either vibration or radiated electrical noise. See **Module Diagnostic Messages** for further information.

C. Refrigerant Conversion - The monitor can not be converted from one refrigerant to another in the field - it must be sent back to the factory for recalibration.

D. Diagnostic Conditions - Any diagnostic condition causes a "Trouble Status" condition on the monitor. The Trouble relay closes and the front display flashes when at the Operating Mode menu. Optional unit mounted alarm will sound if it is installed and programmed. Pressing the "+" key will quiet the alarm. Refrigerant level alarms are disabled. Bench sampling and readout continue during the trouble condition.

Table 3 - Diagnostic Relay Conditions

Condition	Normally Open Contacts	Normally Closed Contacts
Off	Open	Closed
On - Ready	Closed	Open
Trouble	Open	Closed

Calibration Procedure

Introduction

This section details the recommended field calibration check procedure for the Trane Model RMWD refrigerant monitor. The monitor is factory calibrated for the specific refrigerant desired however, it is recommended that the calibration be checked annually at a minimum, and a log kept detailing any adjustments required. The appropriate Installation, Operation and Maintenance manuals for this instrument should be referenced to assist in operating the display and identifying components or connection points.

General Information

- Kit TOL 0170 includes:
  - regulator
  - span gas scrubber (FLR 1404)
  - zero scrubber (FLR 1403)
  - connecting tubing and fittings
  - carrying case and instructions (calibration gas **is not** included)
- Calibration gas -
  - R-11: TOL 0171
  - R-22: TOL 0172
  - R-123: TOL 0173
  - R-134A: TOL 0174
  - zero gas: TOL 0175

The RMWD test regulator releases just over 2.0 liters per minute. A 100 liter bottle would last about 50 minutes.

The used calibration gas canisters and the various filters are not considered hazardous waste due to the small concentration of refrigerant. If a large number of canisters or filters were being dumped, this might be an issue and require further investigation. Local codes apply.

Calibration Procedure

Material Required

1. Trane Calibration Kit containing:
   - Zero Gas Scrubber
   - Flow Regulator
   - Interconnecting Tubing and Fittings
   - Span Gas Scrubber
   - Carrying Case
2. A canister of the specific refrigerant span gas

Ths calibration check should be performed only by qualified personnel familiar with the instrument and its operation.

⚠ Warning!
During the calibration procedure, the monitor is not in service and any alarms that may occur during the calibration sequence will not be recognized. This could create a hazardous condition.

Preparing for Calibration

1. Ensure the area surrounding the monitor is free from any gas hazard. Operate permanent or portable ventilation as necessary.
2. Access the calibration menu using the display located on the unit front panel. See the Installation, Operation and Maintenance manual for details on the use of the monitor's various menus.
3. Page through the display by pressing <Next> until you get to the "Calibration" main menu. Press <Enter> to begin calibration check routine.
4. Enter the Field Calibration password, " - + - - + + ".
5. The monitor will go into the Monitor Check Mode and the refrigerant concentration based on the current unit calibration will be displayed. All new alarms will not be recognized.
6. Remove the gas sampling tube from the monitor sample inlet. Disconnect sample channel #1 if a scanner is installed.

Zero Calibration Check

1. The first routine is used to check the unit Zero calibration. Press <Next> to proceed to the Refrigerant Zero screen. Press <Enter> to begin Zero Calibration. The display will read "Starting Cal, Please Wait". If a channel scanner is installed, it will be locked onto channel #1. Refer to Figure 11 for connection information.

Note: Either a Zero Gas Scrubber or a canister of Zero gas can be used to check the zero setting on a Model RMWD monitor.

2. When the "Connect Zero Gas" screen is displayed, connect the Zero Gas Scrubber or the Zero Gas Canister to the (continued) sample port on the monitor as shown in Figure 11. Use sample port #1 if a scanner is installed. Press <Next> to continue.

⚠ Caution:
Be sure Zero Scrubber is used and not Span Gas Scrubber.

Note: If a Zero Gas canister is used, connect as shown in Figure 11 except substitute Zero canister for Span Gas canister. A Span Gas scrubber must be used whenever pressure gas is applied to the unit to avoid over pressurization.

Calibration Procedure

3. "Open Valve" will be displayed. If the Zero gas canister is used, open the regulator to allow gas to flow. If a scrubber is being used, disregard this step. Press <Next> to continue to Step 4.
4. The next screen will display the sample concentration based on the current unit calibration. After waiting at least three minutes, press <Enter> to adjust zero setting. If reading is zero, press <Cancel> twice to exit Zero calibration routine and move to Refrigerant Span routine.
5. If <Enter> was pressed to adjust, the unit will lock onto the reading. Use the (+) and (-) keys to adjust displayed reading to zero. Press <Enter> when finished. Monitor will store new Zero setting.
6. Either "Successful Calibration" or "Cal Failed" will be displayed. If calibration was successful, the display will proceed to the Span Calibration. If calibration failed, the unit will revert back to the previous zero value. Press <Enter> to repeat Zero Calibration. Shut off Zero Gas flow if canister is being used.

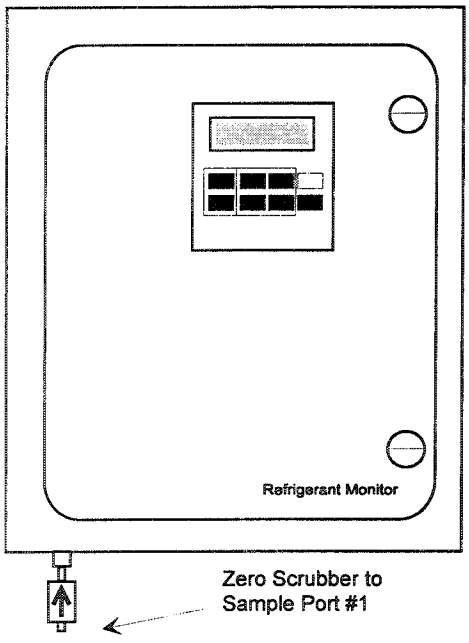
Refrigerant Span Calibration Check

1. At the "Refrigerant Span" screen, press <Enter> to Calibrate. The display will read "Starting Cal Please Wait". Refer to Figure 12 for connection information.
2. Connect the Span Gas canister to Sample Port #1 when the display prompts you to do so. Also, remove any caps on the span gas scrubber. Press <Next> to continue.
3. Open the regulator valve when instructed and press <Next> to continue.
4. After at least three minutes and the displayed value is stable, compare the displayed PPM value to what is listed on the calibration span gas canister. If the displayed value differs from the value on the canister, press (+) or (-) to change the displayed value to match to match the calibration gas value. Press <Enter> to continue. The display will read "Starting Cal".

Calibration Procedure

5. Either "Successful Calibration" or "Cal Failed" will be displayed. If the calibration was successful, the new span values have been stored and will be used for all future readings. Press <Next> three times then <Enter> to return the instrument to operation. If the Calibration failed, the monitor will revert back to the values previously stored. Press <Enter> to retry span calibration.
6. Disconnect the span gas canister and connect all sample lines that may have been removed. Unit is ready to be put back into service.
7. Log the date and note any adjustments made on a monitor calibration log.
8. Return all parts to the Calibration Kit carrying case.

Figure 11 - Zero Calibaration Check Connections



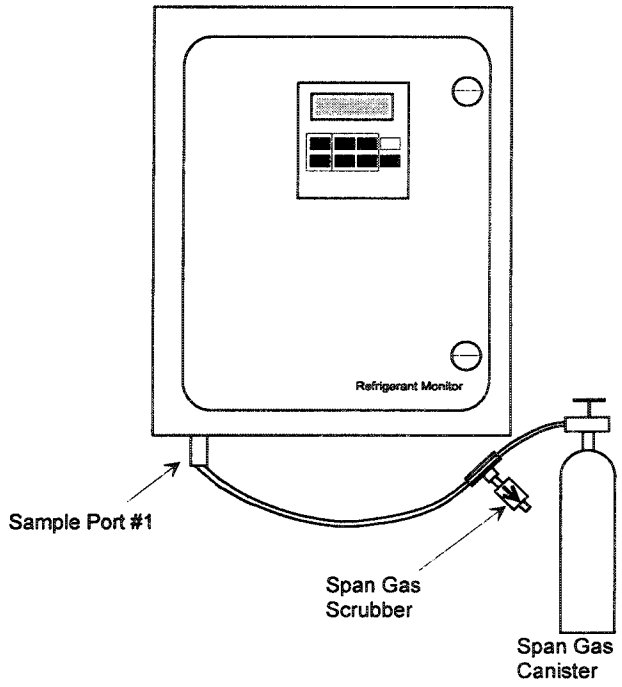


Figure 12 - Span Calibration Check Connections

Note: If Zero Gas is used, connect canister to Sample Port #1 using connect arrangement similar to what is shown in Figure (Span), substituting the Zero Canister for the Span Canister and the Zero Scrubber for Span Gas Scrubber.

Pressure Switch Checkout

Testing Procedure

Equipment

- Pressure Gauge 0 - 3 inches H_20 range
- Pressure Source
- Ohm Meter
- Tubing Harness shown below

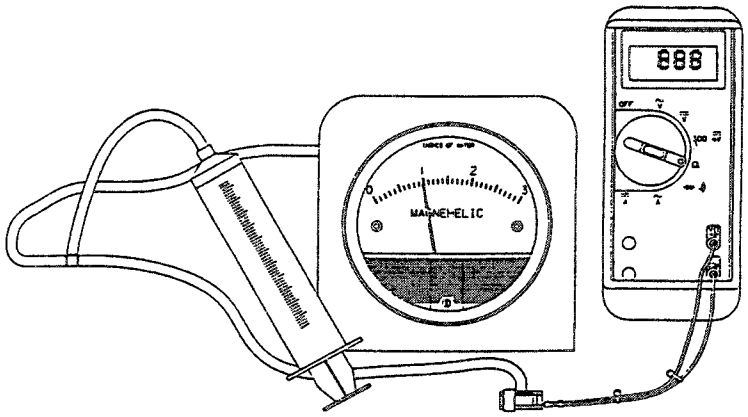
Setup

See Figure 13

Procedure

1. Connect tubing to high pressure port of switch.
2. Use syringe to vary pressure in range of 0 - 3.0 inches H_20 four times.
3. Return pressure to zero.
4. Gradually apply pressure until ohm meter indicates closure of switch.
5. Note pressure that is required to generate closure. Pressure must be > 0.8 inches H_20 open and < 1.2 inches H_20 closed.
6. Increase pressure to 2.0 inches H_20.
   Note: Contact resistance at 2 inches H_20 is <= 50 ohms.
7. Reject a switch which does not meet specifications in steps 5 and 6.

Figure 13 - Pressure Switch Testing Equipment



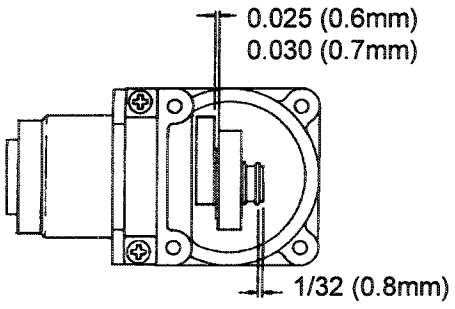


Figure 14 - Pump clearances

Technical Specifications

Mechanical

Enclosure

NEMA-4 rated. Hinged door with 2 quarter-turn latches. Beige with black face plate.

Mounting

4 mounting tabs provided on back of enclosure.

Weight

Single channel unit = 42 lbs. operating, 45 lbs. shipping. 4-channel scanner unit= 45 lbs. operating, 49 lbs. shipping.

Sample Pumping Rate

0.75 LPM minimum with 150 feet of 1/8" ID sample tubing.

Electrical

Inputs

Power Input - The refrigerant monitor will operate from a source of AC power of 100 VAC to 240 VAC, 50 to 60 Hz. Power input not to exceed 80 watts in single channel operation.

Auxiliary Input - 4 to 20 mA Input referenced to ground. Input impedance is 200 (±4) Ω resistive.

Remote Reset - An input will be provided to remotely reset latched alarm relay(s). On activation, all latched alarms will be reset. Maximum distance from monitor to contacts is 300 feet using shielded 18 AWG twisted pair wire.

Outputs

Analog - Two analog outputs are provided to indicate refrigerant gas concentration. These outputs may be used independently and simultaneously.

Ranging for both outputs is common.

Ranges selectable by software:
0 to 100 PPM
0 to 1000 PPM

The resolution on each range is 1 PPM.

4 to 20 mA: Sourcing current to module ground. Load = 200 ohms maximum.

0 to 10 VDC: Sourcing referenced to module ground. Output current to 7 mA maximum.

Relays - Relay contact ratings are as follows:

Resistive load:
-7.2 Amps @120 VAC
-5.0 Amps @240 VAC

Inductive load:
-2.88 Amps Pilot Duty
-1/3 HP, 7.2 FLA, 43.2 LRA

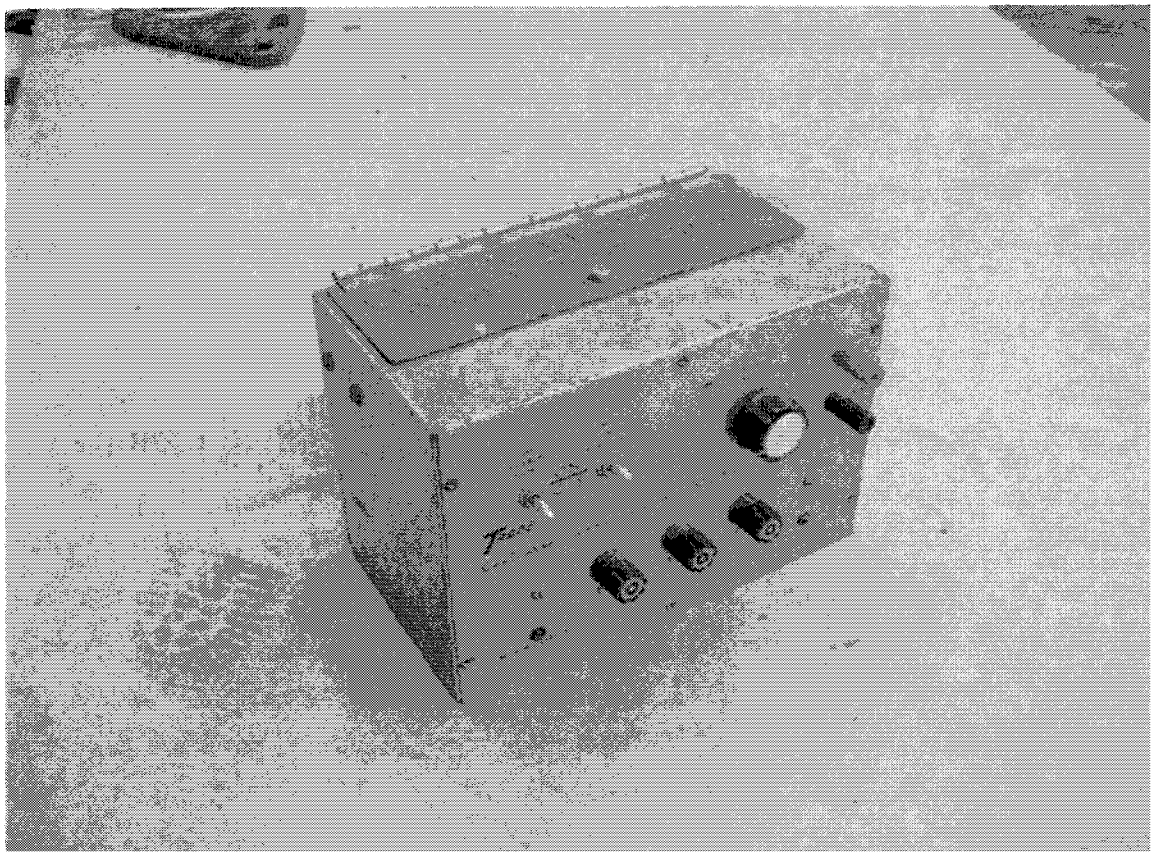
Audible alarm output:
12 VDC, 100Ω load maximum

Gas Sensing Characteristics

Gas Sensitivity

Standard factory calibration for HCFC-123, CFC-11, HCFC-22 and HFC-134a. Special factory calibrations for other refrigerants are available.

Alarm levels



Alarm levels are software adjustable in steps of 1 PPM over the following ranges:

Alarm Levels:

HCFC-123	Low Limit	High Limit
Alarm Level #1	3 PPM	Lowest of 30 PPM or Alarm Level #2 -1
Alarm Level #2	Alarm Level #1 + 1	Alarm Level #3 - 1
Alarm Level #3	Alarm Level #2 +1	1000 PPM

All other refrigerants	Low Limit	High Limit
Alarm Level #1	3 PPM	Alarm Level #2 -1
Alarm Level #2	Alarm Level #1 + 1	Alarm Level #3 - 1
Alarm Level #3	Alarm Level #2 +1	1000 PPM

TOL-90
CTV Solid State
Overload Tester
Instruction Manual

INTRODUCTION

The TOL-90 Solid State Overload Tester:

- Simulates any level of motor current from zero to ten times the rated load amps(RLA).
- Simulates the operation of the 1M motor contactor auxiliary.
- Gives visual indication of "overload" trip due to either excessive locked rotor current or motor running current.
- Gives visual indication of distribution fault trip.

The motor current is simulated by placing a variable DC test voltage across the B1-B2 terminals of the SSOL, in place of the current calibrator. This test voltage is referred to as the "current signal." NOTE: A DIGITAL VOLTMETER IS REQUIRED TO READ THIS TEST VOLTAGE. The magnitude of this "current signal" is such that 100 percent RLA = 1.00 VDC and is directly proportional to motor current draw(See FIG. 1). The source for this voltage is the +15 VDC power supply in the SSOL. The ON-OFF switch(SW1) is a means of turning off the current signal.

The 1M contactor auxiliary is simulated by a manually operated toggle switch(SW2).

The "Overload" and "Distribution Fault" trip indicators are powered by the same SSOL outputs that trip their respective circuit breakers. An overload is indicated by a steady glowing light. A distribution fault is indicated by a flashing light due to the pulsed output from the SSOL.

RECOMMENDED TEST EQUIPMENT

1. Digital Voltmeter - (Required)
2. Clamp-on Ammeter
3. Timer or Clock with second hand

Refer to Service Bulletin CTV-SB-22A for additional information regarding the SSOL.

CTV SOLID STATE OVERLOAD TEST FORM

To Aid in Recording System Data and Test Results ..... Page 12

OPERATING INSTRUCTIONS

Prior to testing, fill in the General Information Section on the test form (page 12) as completely as possible. The following tests correspond to the bottom half of the test form.

CAUTION: WHEN PERFORMING THE FOLLOWING TESTS, DO NOT SHORT THE OUTPUT TERMINALS E1-E2, F1-F2, or F3-F4 TOGETHER AS DAMAGE TO THE SSOL COULD RESULT.

PRELIMINARY MEASUREMENTS

Note: Measurements A, B, and C can be made only if the system is in operation.

A. If possible, measure and record motor running current using a clamp-on ammeter.

B. At the same time that the motor running current is measured(above), measure and record the DC voltage across the "current calibrator" resistor at terminals B1 and B2 on the SSOL, using a digital voltmeter.

C. Divide measurement "A" by measurement "B" to obtain a multiplier in AMPS/VDC. This multiplier should equal the motor RLA if the current transformers and current calibrators are selected properly. This multiplier can be used to obtain the actual current values corresponding to the DC voltage readings obtained in the Functional Tests(part II)by taking(DC voltage from test form) x (multiplier) = actual motor current.

D. Measure and record the voltage between terminals XX1 and X2 on the SSOL. This is a nominal 115 VAC and is required for the operation of the SSOL.

E. Measure and record the voltage between the +15 terminal on the "swing out" board and B2. NOTE: If the SSOL is not equipped with a swing-out board, the +15 output can be measured between the cathode(designated by a silver stripe) of DIODE D19 located on the main printed circuit board and terminal B2. This voltage should be between +14.25 VDC and +15.75 VDC. If this voltage is out of tolerance, the SSOL will probably fail the Functional Tests and require replacement.

F. Measure and record the voltage between the -15 terminal on the "swing out" board and B2. NOTE: If the SSOL is not equipped with a swing out board, the -15 output can be measured between the anode(end opposite of the silver stripe) of DIODE D18 located on the main printed circuit board and terminal B2. This voltage should be between -14.25 VDC and -15.75 VDC. If this voltage is out of tolerance, the SSOL will probably fail the Functional Tests and require replacement.

FIGURE 1

FUNCTION	NOMINAL CURRENT LEVEL (% of RLA)	VOLTAGE ACROSS CURRENT CALIBRATOR (B1 - B2)
Maximum Locked Rotor Trip Setting	1070%	10.70 VDC
Typical Locked Rotor Amps(LRA)	250%	2.50 VDC
Motor Overload Trip Level	107%	1.07 VDC*
Motor Rated Load Amps(RLA)	100%	1.00 VDC
Motor Starter Transition Level	85%	0.85 VDC*
Distribution Fault Trip Level	20%	0.20 VDC*
Motor De-energized	0%	0.00 VDC

* Actual measured test voltage may vary slightly from values indicated. Refer to the corresponding test instructions for details.

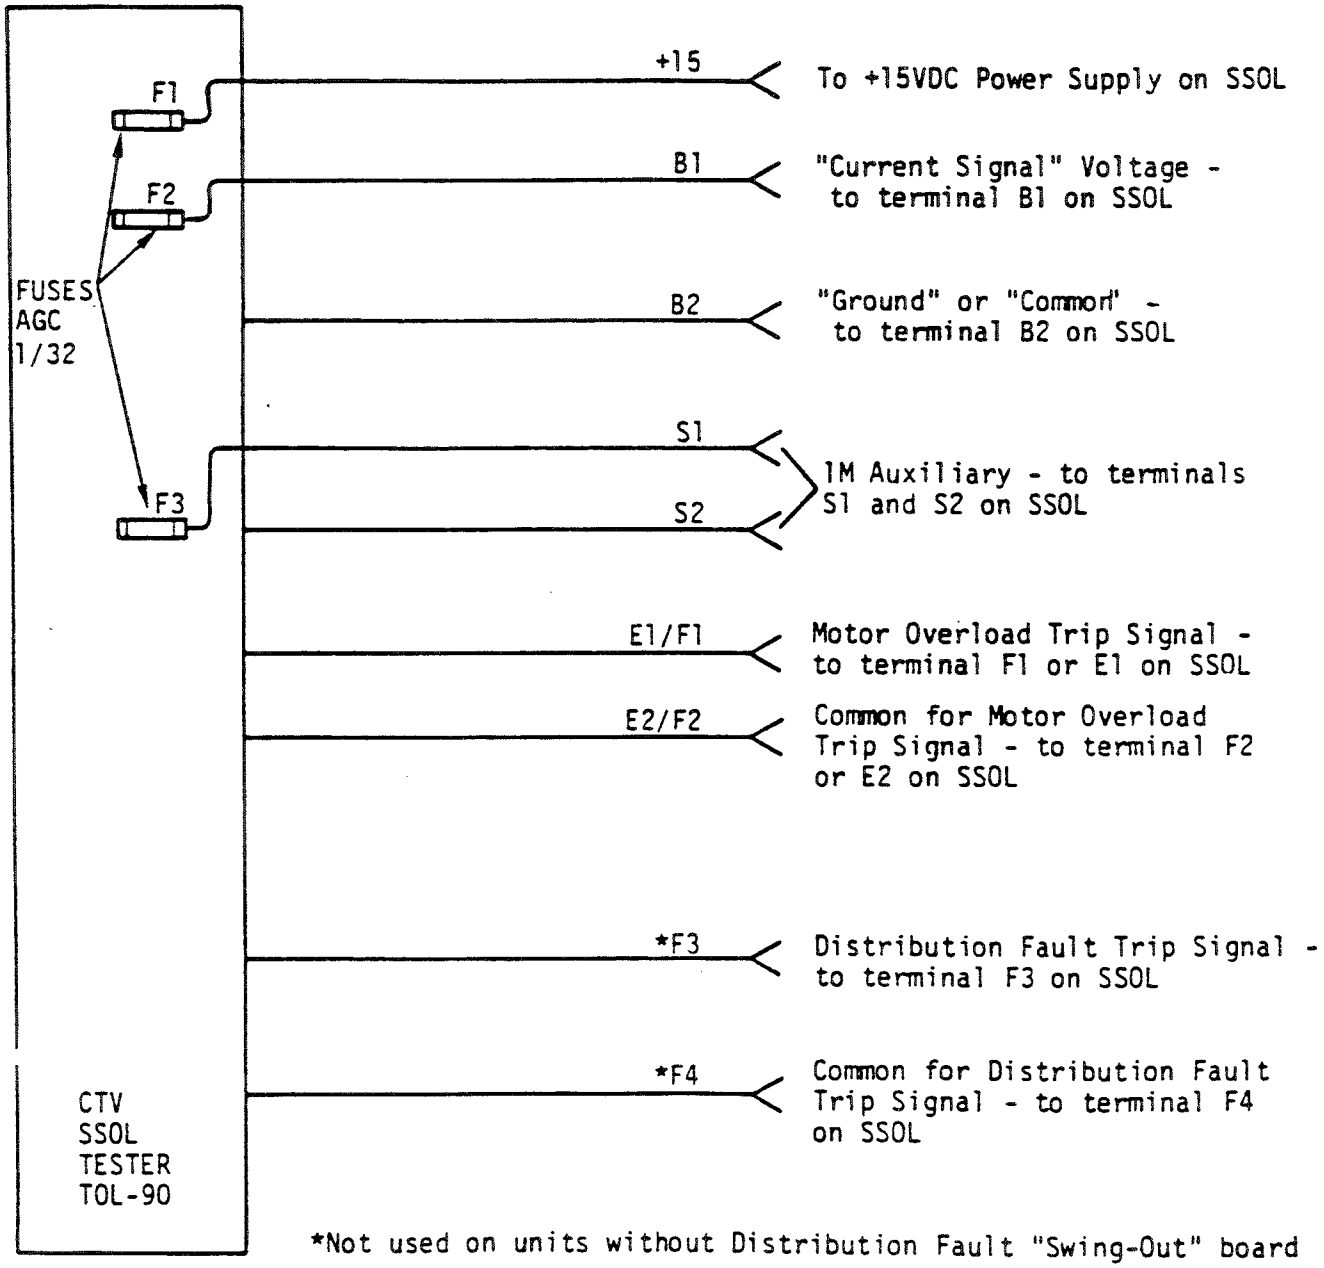
FUNCTIONAL TESTS

SET UP

1. Disconnect the wires from terminals S1 and D1 on the SSOL.

   WARNING: THESE WIRES MUST BE DISCONNECTED TO PREVENT THE COMPRESSOR MOTOR FROM STARTING DURING THE TEST SEQUENCE.

2. Make sure that the safety trip indicators on the control panel and starter are tripped to prevent accidental startup.



3. Remove the current calibrator resistor from terminals B1 and B2 on the SSOL.

4. Connect the leads from the TOL-90 to the matching terminals on the SSOL and on the "swing out" board(refer to Figure 2). It may be necessary to loosen the terminal screws on the SSOL. NOTE: If the SSOL is not equipped with a "swing out" distribution fault board, leave leads F3 and F4 unconnected while connecting lead +15 to the cathode(designated by a silver strip) of Diode D19 on the main printed circuit board.

5. Connect the positive(+) lead of a digital voltmeter to the test point on the TOL-90 labeled B1 and the negative(-) lead to the test point laveled B2. Set the voltmeter on the 20 VDC scale.

6. Energize the SSOL by applying 115 VAC at terminals XX1 and X2.

FIG. 2 - TOL-90 CTV SSOL TESTER HOOKUP DIAGRAM

*Not used on units without Distribution Fault "Swing-Out" board

FUNCTIONAL TESTS

A. Acceleration Time Limit(60 HZ)

1. Set the frequency adjustment switch on the SSOL to 60 Hz.

2. Set DVM on 20 VDC scale.

3. Turn SW2 OFF.

4. Turn SW1 ON.

5. Turn "current signal adjust" knob until DVM reads approximately 2.0 VDC.

6. Set maximum acceleration time switch on SSOL to desired setting.

7. Turn SW2 on. The "motor overload" LED should light after the time set in step 6 has elapsed.

8. Record the actual time observed(test form part II).

B. Acceleration Time Limit(50 Hz)

1. Set the frequency adjustment switch on the SSOL to 50 Hz.

2. Repeat steps 2 through 8 from test "A".

3. Return frequency adjustment switch to its normal position.

C. Locked Rotor Trip Level

1. Set the maximum acceleration time limit switch on the SSOL to maximum setting(all switches on). This should allow 63 seconds to perform this test prior to a "motor overload" indication due to the acceleration time limit.

2. Turn SW2 OFF.

3. Set DVM on 20 VDC scale.

4. Turn SW1 ON.

5. Adjust the "current signal" until the DVM reads approximately 1.5 VDC or greater.

6. Turn SW2 ON.(The acceleration time limit is now in effect.)

7. Increase the "current signal" until the "motor overload" LED lights. This indicates that the locked rotor trip level has been exceeded. If the acceleration time limit is exceeded in this step, it can be reset by turning SW2 OFF and then ON again.

8. Record the trip level DC voltage obtained in step 7. Multiplying this value by 100 will give the percentage of RLA. For example, a reading of 6.50 VDC corresponds to 650% of RLA. This should be roughly equivalent to the setting of the LRA set potentiometer on the SSOL.

FUNCTIONAL TESTS(con't)

D. Transition Level

1. Turn SW2 OFF.

2. Turn SW1 ON.

3. Adjust the "current signal" until the DVM reads approximately 1.20 VDC.

4. Turn SW2 ON.

5. Slowly reduce the "current signal". Listen and watch for the transition relay on the SSOL to pull in and note the DVM reading.

6. Record the reading on the test form. The SSOL should be set to transition at 85% of RLA. Due to the nature of the "current signal" during actual operation and the SSOL circuit design, the corresponding test voltage you should read is approximately .80 VDC $\pm$ .07 VDC.

E. Motor Overload Trip Level

1. Turn SW2 OFF.

2. Turn SW1 ON.

3. Adjust the "current signal" until the DVM reads approximately 0.60 VDC.

4. Turn SW2 ON. The transition relay on the SSOL should pull in after approximately one second.

5. Increase the "current signal". Note the DVM reading when the "motor overload" indicator lights.

6. Record the DVM reading noted in step 5. The SSOL should be set to trip at 107% of RLA. Due to the nature of the "current signal" during actual operation and the SSOL circuit design, the corresponding test voltage you should read is approximately 1.13 VDC $\pm$ .05 VDC.

F. Motor Overload Trip Level with 10% Jumper Removed

1. Remove the 10% jumper from terminals J1 and J2 on the SSOL.

2. Repeat steps 1 through 5 from test E.

3. Record the value obtained. It should be approximately 10% less than the value obtained in test E(1.02 VDC $\pm$ .05 VDC).

4. Reconnect the jumper to terminals J1 and J2 on the SSOL.

FUNCTIONAL TESTS(con't)

G. Distribution Fault Trip Level

1. Turn SW2 OFF.

2. Turn SW1 ON.

3. Adjust the "current signal" to approximately 0.50 VDC.

4. Turn SW2 ON. The transition relay on the SSOL should pull in after approximately one second.

5. Adjust the "current signal" slowly downward. Note the DVM reading when the "distribution fault" indicator lights.

6. Record the DVM reading noted in step 5. The SSOL should be set to trip at approximately 20% of RLA. Due to the nature of the "current signal" during actual operation and the SSOL circuit design, the corresponding test voltage you should read is approximately 0.18 VDC $\pm$ .05 VDC.

H. Load Proportional DC Voltage Signal

1. Turn SW1 ON.

2. Adjust the "current signal" until the DVM reads as close as possible to 1.000 VDC.

3. Remove the (+) voltmeter lead from the test point B1 and measure the voltage at terminal V1 on the SSOL. This voltage should read -8.25 VDC $\pm$ .20 VDC.

4. Recheck the "current signal" voltage at test point B1 to verify that it is still as close as possible to 1.000 VDC. If it is not, readjust the "current signal" and repeat step 3.

5. Record the final DVM reading obtained in Step 3.

DRY RUNNING A STARTER USING THE TOL-90

With the motor leads disconnected for the purpose of dry-running the starter, the TOL-90 can be used to simulate different current conditions in the motor. The "current signal" can be adjusted to verify starter transition as well as the operation of the motor overload and distribution fault circuit breakers.

WARNING: FAILURE TO DISCONNECT POWER BEFORE SERVICING COULD RESULT IN PERSONAL INJURY OR DEATH FROM ELECTRICAL SHOCK.

1. After the power to the starter has been disconnected, disconnect the motor leads and properly isolate them. These leads could be energized while dry running the starter.

2. DO NOT disconnect any control wiring from the SSOL. If any wiring was disconnected for prior tests, reconnect it before proceeding.

3. Remove the current calibrator resistor from terminals B1 and B2 on the SSOL.

4. Connect leads +15, B1 and B2 of the TOL-90 to the SSOL. F1, F2, F3 and F4 may be connected if visual indication of motor overload and distribution fault is desired.

5. Connect a DVM to the B1(+) and B2(-) test points on the TOL-90.

TEST PROCEDURES

1. Close the disconnect or circuit breaker to apply power to the starter and SSOL.

2. Turn SW1 ON.

3. Adjust the "current signal" to approximately 1.50 VDC or to a value corresponding to the calculated LRA(See Figure 1).

4. Provide a start signal to the starter.

5. Reduce the "current signal" to approximately 0.70 VDC and verify that transition occurs.

6. Increase the "current signal" to approximately 1.25 VDC and verify that the motor overload circuit breaker trips.

7. Repeat steps 1 through 5.

8. Turn SW1 OFF and verify that the distribution fault circuit breaker trips.

9. De-energize the starter and the SSOL.

10. Remove the TOL-90 and reconnect the current calibrator resistor to terminals B1 and B2 on the SSOL.

CLEAN-UP CHECKLIST

1. Set frequency adjustment switch on SSOL to desired setting(50/60 Hz).
2. Set maximum acceleration time switch on SSOL to desired setting.
3. Reconnect the current calibrator resistor to terminals B1 and B2 on the SSOL.
4. Reconnect the wires to terminals S1 and D1 on the SSOL.
5. Reconnect the "10% jumper" to terminals J1 and J2 on the SSOL, if required.

OPERATION

The Trane Motor Starter Protection System was developed to make it possible for the owners of existing Trane CenTraVacs® to upgrade their CenTraVac starters to obtain the protection, safety, and reliability available from the current state-of-the-art in starter design. CenTraVac starters equipped with the MSPS provide improved protection to the motor, and to the starter itself, from the harmful effects of disturbances in incoming electrical power, and from possible malfunctions of the CenTraVac starter or controls.

The Motor Starter Protection System provides protection against occurrances that cannot be detected or corrected by earlier starters. Also, it provides more positive, accurate, and faster response to other occurrances that were protected against in the original equipment. Equipped with the MSPS, an existing Trane CenTraVac is afforded all of the protection available in the latest models of Trane equipment.

The Motor Starter Protection System provides the following benefits:

A. Protection against momentary interruptions to incoming power (distribution fault). Interruptions can cause serious equipment damage, and could not be detected in previous types of starters.
B. Provides accurate and repeatable overload protection at rated load current. Overloads previously provided have been shown to lack repeatability, and failed to provide adequate protection.
C. Provides accurate overload protection at locked rotor current during equipment startup.
D. Provides positive initiation of disconnect if the motor requires excessive time to accelerate to full speed.
E. Provides initiation of positive disconnect if the starter requires excessive time to make transition from start to run modes.
F. Provides positive protection against low line voltage.
G. Provides inherent protection against several possible malfunctions in the starter control circuit.

A. Distribution Fault Circuit Breaker Operation

A distribution fault is defined as a loss of line voltage for less than 60 electrical cycles. This type of short duration power interruption can be damaging to many types of induction motor driven equipment.

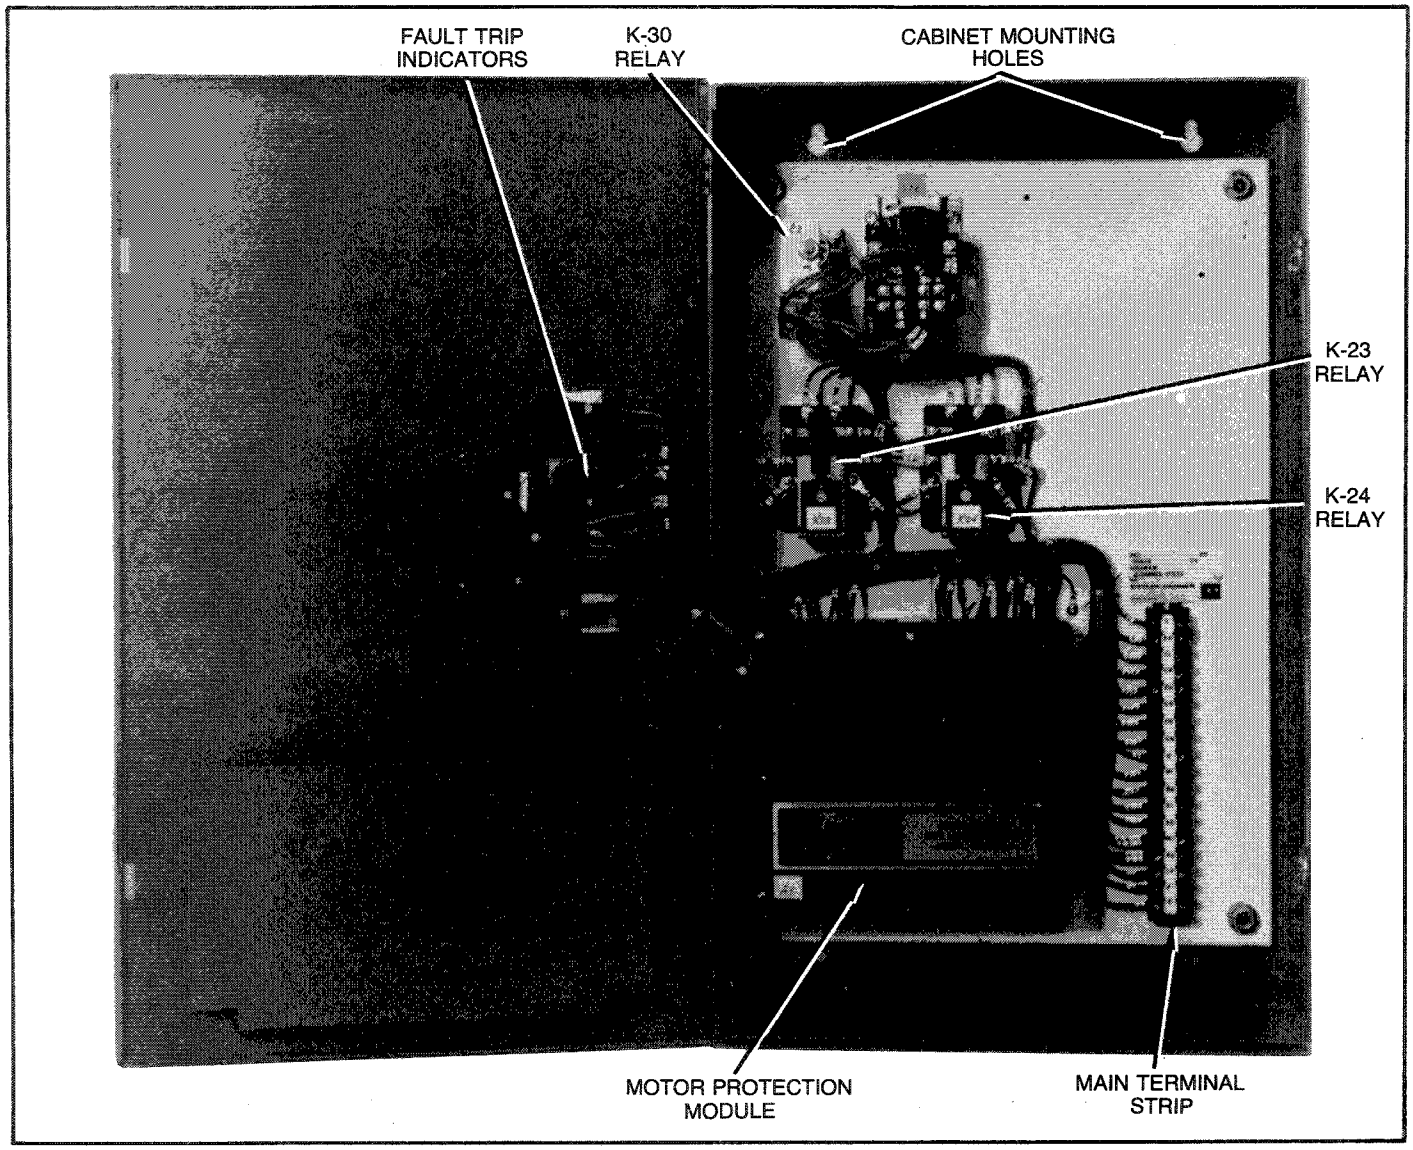

FIGURE 1 - Motor Starter Protection System Cabinet

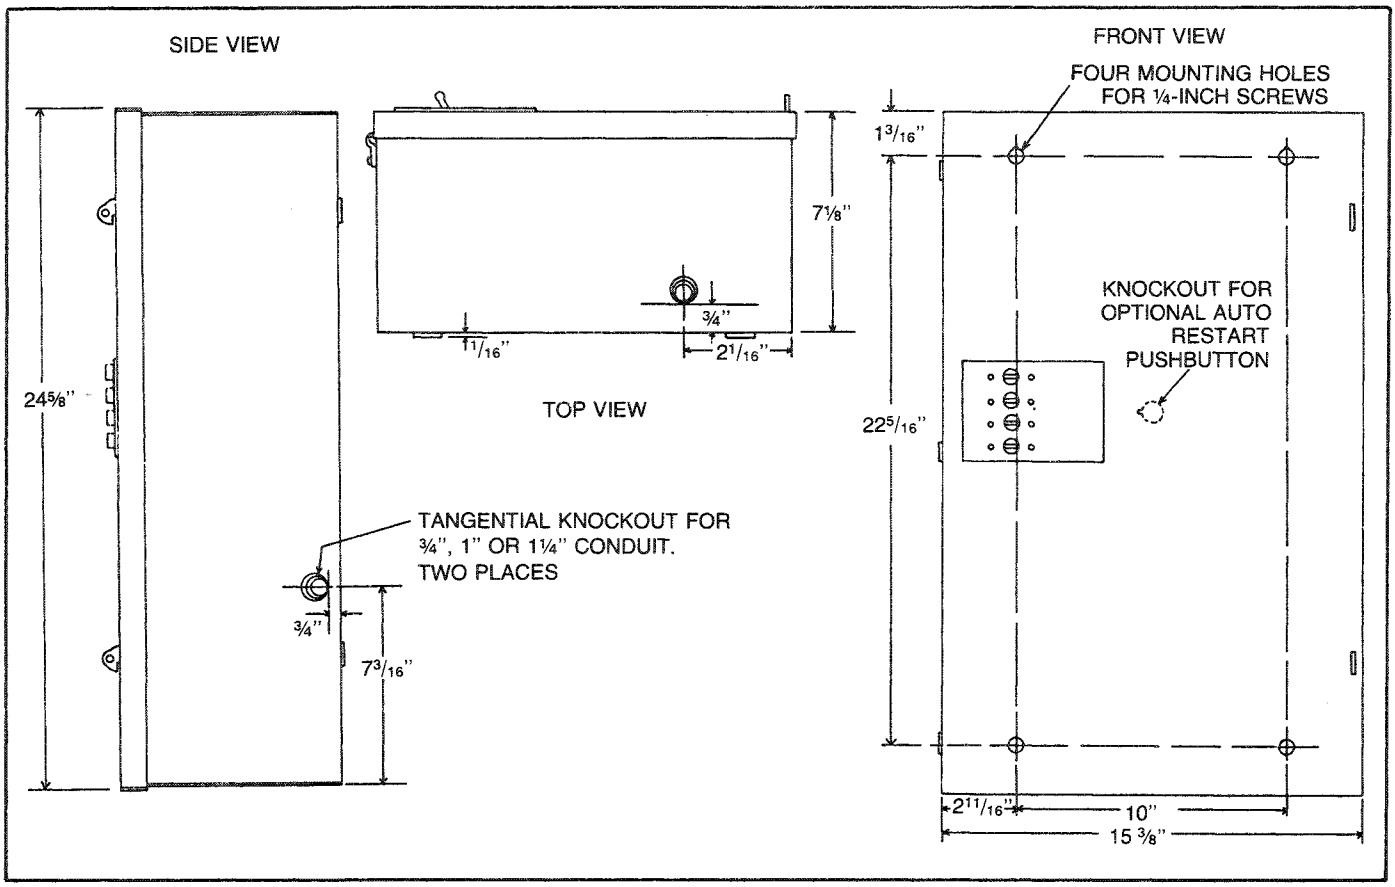

FIGURE 2 - Motor Starter Protection System Cabinet Dimensions

The damage occurs because an induction motor acts as a generator for several seconds after power is disconnected. The voltage generated by the motor can hold in control relays and starter contactors when a voltage loss occurs. The period of time the contactors are held in is approximately 60 electrical cycles or 1 second for a water cooled CenTraVac.

If line voltage is reestablished during the period of time the contactors are being held in by the motor generated voltage, and the two voltages are out of phase, motor torques may occur which are 6 to 10 times normal running torques. These torques occur as the motor is pulled into phase and may be in either the forward or reverse direction. These high torques cause severe overloading of the impeller hub area, with resultant upsetting of the impeller keyway and in severe cases cracking or destruction of the impellers.

The Motor Starter Protection System detects a distribution fault by monitoring two things; current draw and the M1 contactor. The tripping of the Distribution Fault Circuit Breaker is initiated based on the fact that, in normal operation, only during the occurances of an actual distribution fault is it found that the motor current draw is less than 20% of RLA and the M1 contactor is energized at the same time. An induction motor will normally always draw over 20% of RLA, even when completely unloaded; and whenever the M1 contactor is energized the motor is running. The only exceptions to the last statement occur during a distribution fault or during a starter dry run.

The distribution fault lockout is initiated when the motor current drops below 20% of RLA with the M1 contactor energized.

The Motor Starter Protection System senses this set of conditions to be a voltage loss for the reasons explained in the previous two paragraphs. Tripping of the Distribution Fault Circuit Breaker operation is completed within 6 electrical cycles (1/10 of a second) of the time when the voltage loss occurs.

B. Current Overload Protection

Operation of a CenTraVac motor over full load current causes the motor to overheat, thereby reducing its life. The MSPS senses the highest current on any of the three phases during equipment operation and will quickly disconnect the motor if unacceptable current draw exists. The solid state overload employed in the MSPS to protect motors from current overloads are much more accurate and reliable than electrical-mechanical devices previously employed.

C. Protection From Starting Current Overloads

Magnetic overload relays previously employed prevent tripping during starting in-rush by employing a time delay to bypass the overload device during equipment startup and acceleration. MSPS monitors current draw continuously, and will disconnect the motor if current requirements during startup and acceleration are excessive.

D. Motor Acceleration and Initiation of Transition

The MSPS initiates transition by sensing a decrease in starting in-rush current. Transition to the run mode takes place only after the motor is up to speed and the in-rush current has decreased to acceptable levels. Transition is based on what is actually occurring, and is not based strictly on time as with ex-

isting starters. However, if time to accelerate is excessive, or if the time to make transition is too long, the Motor Starter Protection System will disconnect the starter immediately. With an MSPS, the motor is not permitted to continue to attempt to reach operating speed for long time periods if it is unable to do so. Also, transition resistors will not be subjected to overload because transition has occurred while current is still at unacceptably high levels.

E. Under Voltage of Control Voltage Detection

Under voltage in the control circuit can cause various control relays to trip. This can give false indications as to why the CenTraVac chiller shut down. The MSPS detects undervoltage and trips the starter circuit breaker located in the fault trip indicator module.

F. Protection From Circuit Malfunction

Malfunctions, such as loose wires or fluttering controls which result in interrupted control signals in the starter control circuit, can cause the same effects as momentary power interruptions. An interrupted control signal will cause the MSPS to trip the starter circuit breaker which in turn de-energizes the starters.

Typically, only one pilot relay is used in starters to initiate the starter sequence. For added safety, the MSPS has dual pilot relays, which monitor each other. If one pilot relay has welded contacts or a burned out coil, the MSPS will trip the starter circuit breaker which in turn de-energizes the starter.

SHIPMENT

The shipping carton contains the Motor Starter Protection System Cabinet. There are three calibration resistors enclosed in a paper envelope inside the cabinet. Wiring diagrams may also be shipped in the carton or separately. All components are inspected before leaving the factory. Claims for damage should be filed with the carrier. Figure 1 illustrates the cabinet.

INSTALLATION

This section describes the procedure for installation of the Motor Starter Protection System (MSPS) kit in essentially all star-delta, closed transition starters, auto-transformer, and cross the line starters. A typical installation and connection drawing, which is also included in each kit, is shown on Page . This section also directs the installer as to components which must be removed from the starter and the MSPS components which are added.

NOTE: *Open transition starters must be converted to closed transition before attempting to install the Motor Starter Protection System.*

WARNING: OPEN MAIN STARTER DISCONNECT SWITCH BEFORE PERFORMING ANY OPERATIONS. FAILURE TO DO SO MAY RESULT IN SERIOUS PERSONAL INJURY OR DEATH CAUSED BY ELECTRIC SHOCK.

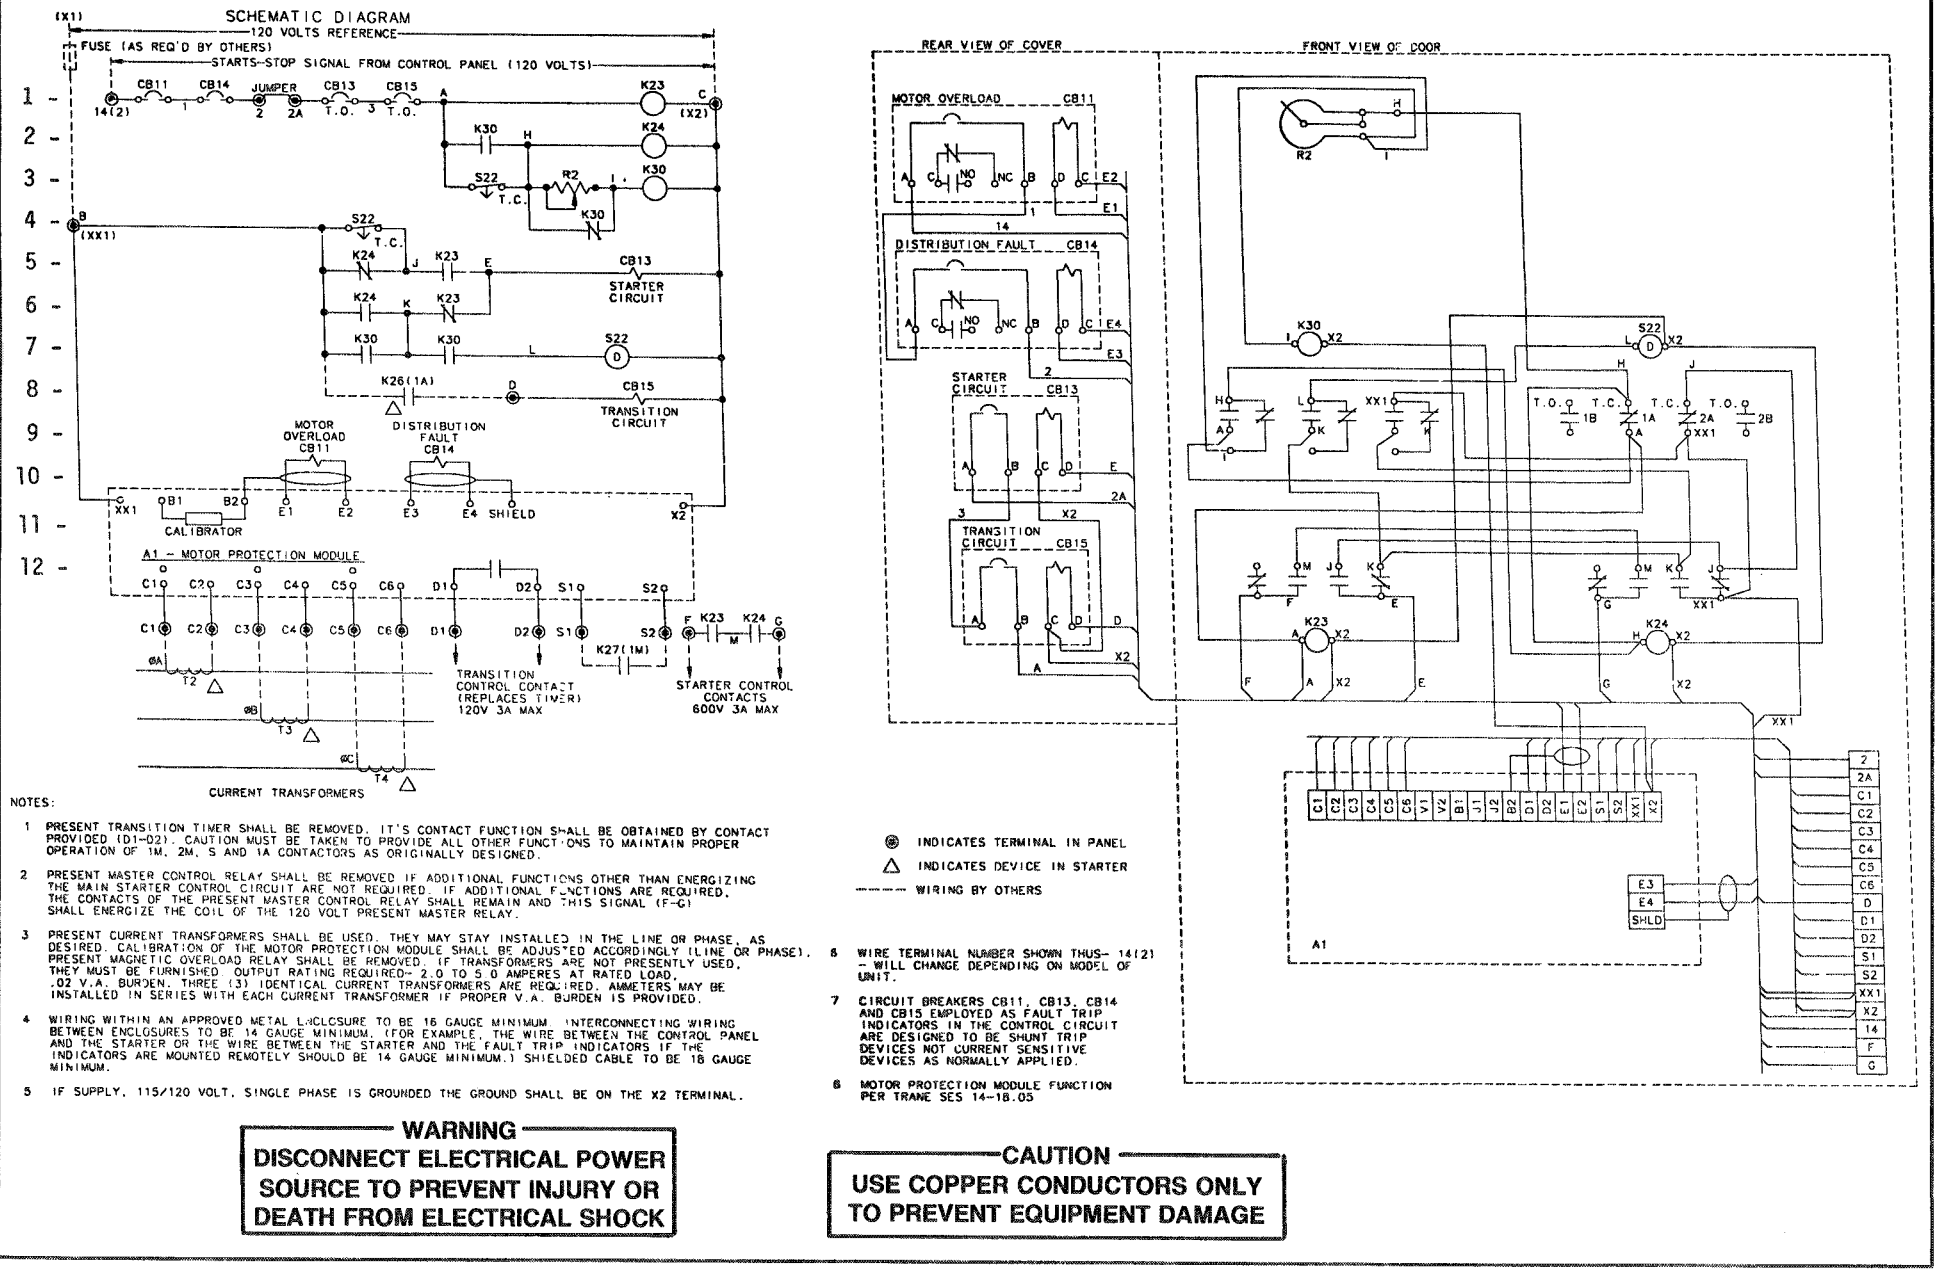
Components Removed from Existing Starter

Components required to perform certain electrical functions in the existing starter are to be removed and replaced by the improved components of the MSPS. The components involved are:

1. Current overloads. These are removed because the sensing and trip functions of the current overloads are provided by the MSPS.
2. The transition timer is removed. The initiation of transition is provided by the MSPS. If the existing transition timer had provided other functions for the control of the 1M, 2M, S or 1A contactors, then add relays to provide the additional functions.
3. The existing master control relay is removed because the function of energizing the main starter control circuit is provided by the MSPS. If the existing master control relay had provided other functions, then add relays to provide the additional functions.

Components Added

Components to be added are:



Three identical current transformers with an output rating of 2.0 to 5.0 amps at compressor motor rated load and 0.02 V.A. burden. The function of the current transformers is to sense the current in each phase on the load side of the starter.

Cabinet Location and Installation

The cabinet should be located near the chiller starter to minimize length of interconnecting wiring. The cabinet can be fastened to a wall using appropriate anchors, or it can be secured to a free-standing frame constructed of steel angle stock. Figure 2 provides dimensions of the cabinet and the location of mounting holes in the back of the cabinet. The cabinet weighs approximately 45 pounds and this must be considered when mounting the cabinet to a wall or constructing a free-standing frame.

WIRING

Refer to Figure 3 or the diagram shipped with the unit for wiring instructions, including recommended wire sizes. Figure 3 is typical only and provides general information for Star-Delta, closed transition applications. Be sure to use the diagram for the specific job application.

NOTES:

1 PRESENT TRANSITION TIMER SHALL BE REMOVED. IT'S CONTACT FUNCTION SHALL BE OBTAINED BY CONTACT PROVIDED (D1-D2). CAUTION MUST BE TAKEN TO PROVIDE ALL OTHER FUNCTIONS TO MAINTAIN PROPER OPERATION OF 1M, 2M, S AND 1A CONTACTORS AS ORIGINALLY DESIGNED.

2 PRESENT MASTER CONTROL RELAY SHALL BE REMOVED IF ADDITIONAL FUNCTIONS OTHER THAN ENERGIZING THE MAIN STARTER CONTROL CIRCUIT ARE NOT REQUIRED. IF ADDITIONAL FUNCTIONS ARE REQUIRED, THE CONTACTS OF THE PRESENT MASTER CONTROL RELAY SHALL REMAIN AND THIS SIGNAL (F-G) SHALL ENERGIZE THE COIL OF THE 120 VOLT PRESENT MASTER RELAY.

3 PRESENT CURRENT TRANSFORMERS SHALL BE USED. THEY MAY STAY INSTALLED IN THE LINE OR PHASE, AS DESIRED. CALIBRATION OF THE MOTOR PROTECTION MODULE SHALL BE ADJUSTED ACCORDINGLY (LINE OR PHASE). PRESENT MAGNETIC OVERLOAD RELAY SHALL BE REMOVED. IF TRANSFORMERS ARE NOT PRESENTLY USED, THEY MUST BE FURNISHED. OUTPUT RATING REQUIRED- 2.0 TO 5.0 AMPERES AT RATED LOAD, .02 V.A. BURDEN. THREE (3) IDENTICAL CURRENT TRANSFORMERS ARE REQUIRED. AMMETERS MAY BE INSTALLED IN SERIES WITH EACH CURRENT TRANSFORMER IF PROPER V.A. BURDEN IS PROVIDED.

4 WIRING WITHIN AN APPROVED METAL ENCLOSURE TO BE 16 GAUGE MINIMUM. INTERCONNECTING WIRING BETWEEN ENCLOSURES TO BE 14 GAUGE MINIMUM. (FOR EXAMPLE, THE WIRE BETWEEN THE CONTROL PANEL AND THE STARTER OR THE WIRE BETWEEN THE STARTER AND THE FAULT TRIP INDICATORS IF THE INDICATORS ARE MOUNTED REMOTELY SHOULD BE 14 GAUGE MINIMUM.) SHIELDED CABLE TO BE 18 GAUGE MINIMUM.

5 IF SUPPLY, 115/120 VOLT, SINGLE PHASE IS GROUNDED THE GROUND SHALL BE ON THE X2 TERMINAL.

⊛ INDICATES TERMINAL IN PANEL

6 WIRE TERMINAL NUMBER SHOWN THUS- 14(2) - WILL CHANGE DEPENDING ON MODEL OF UNIT.

7 CIRCUIT BREAKERS CB11, CB13, CB14 AND CB15 EMPLOYED AS FAULT TRIP INDICATORS IN THE CONTROL CIRCUIT ARE DESIGNED TO BE SHUNT TRIP DEVICES NOT CURRENT SENSITIVE DEVICES AS NORMALLY APPLIED.

8 MOTOR PROTECTION MODULE FUNCTION PER TRANE SES 14-18.05

WARNING

DISCONNECT ELECTRICAL POWER SOURCE TO PREVENT INJURY OR DEATH FROM ELECTRICAL SHOCK

CAUTION

USE COPPER CONDUCTORS ONLY TO PREVENT EQUIPMENT DAMAGE

FIGURE 3 - Typical Wiring, Motor Starter Protection System, Star-Delta, Closed Transition Application

CALIBRATION

This section covers procedures for calibrating and preparing the MSPS for operation. The adjustments to be made are:

Line Frequency Adjustment
Overload Calibration
Locked Rotor Current Lockout
Low Voltage Lockout
Maximum Acceleration Time
High Voltage Compensation

Adjustment Procedures

WARNING: BEFORE WORKING ON THE MSPS OR ANY ELECTRICAL EQUIPMENT DISCONNECT ALL ELECTRIC POWER TO THE EQUIPMENT. FAILURE TO DO SO MAY RESULT IN SERIOUS PERSONAL INJURY OR DEATH BY ELECTRIC SHOCK.

NOTE: *On units equipped with the Distribution Fault function a small circuit board mounted inside the Motor Protection Module must be tilted out to perform calibration. This is done by gently pulling on the two black tabs located on the top of the circuit board and tilting it down on its hinges.*

I. Line Frequency Adjustment
The MSPS can operate on either 50 or 60 Hertz electrical systems. The line frequency is set as follows:
A. The line frequency of the jobsite must first be determined (60 Hertz for all U.S. installations).
B. The frequency switch (see Figures 4 and 5) should then be set to the position which corresponds to the installation frequency.
C. Write in the setting made on the Motor Protection Module Nameplate.

II. Compressor Motor Overload Setting
The overload is set by adjusting the resistance of the current calibrator within the Motor Protection Module (MPM). The MPM is designed so that with the current calibrator correctly set the overload will trip at 107% of the motor rated load current. The use of a 107% trip point prevents nuisance full load trips and yet protects the compressor motor from potentially damaging overloads.

The correct procedure for setting the overload is as follows:
A. Determine the Rated Load Amperage (RLA) and the current transformer ratio for the unit. Where the actual jobsite voltage is equal to, or lower than, the specified voltage

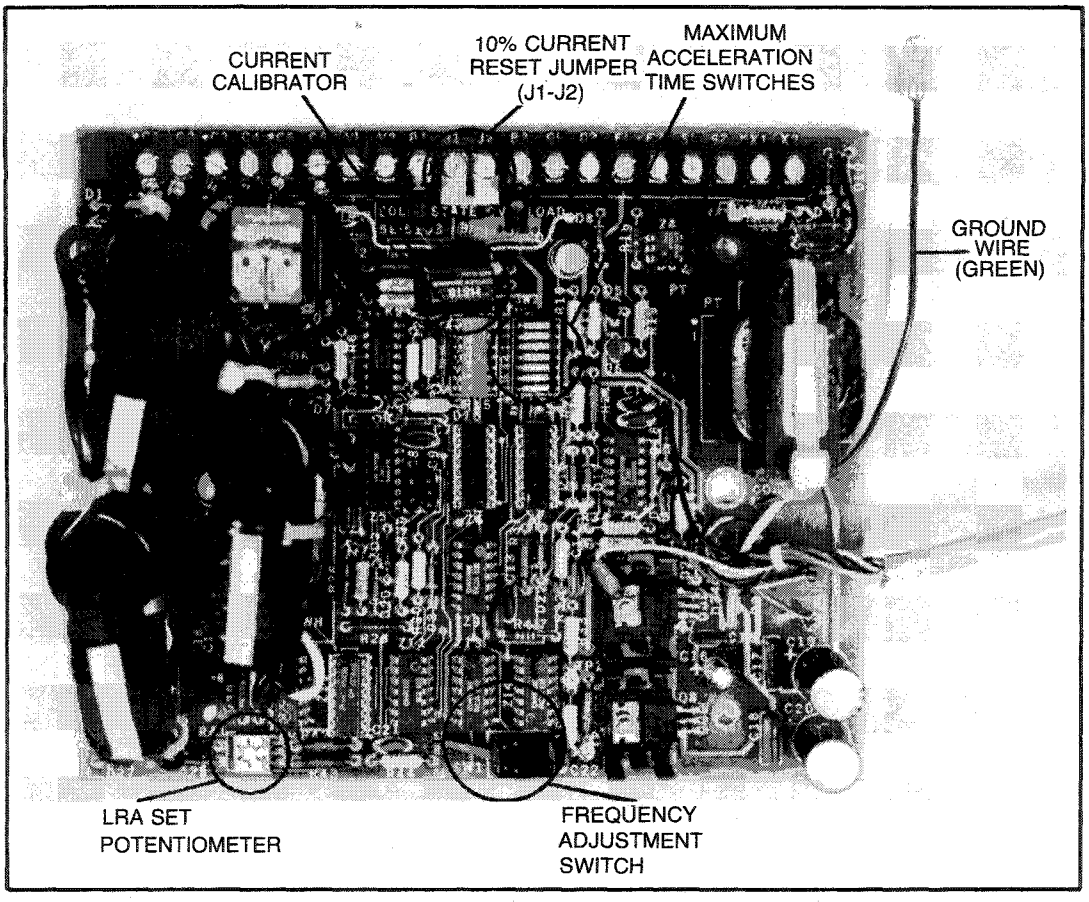

FIGURE 4 - Motor Protection Module

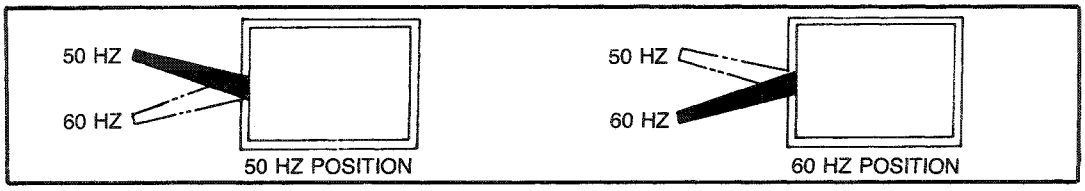

FIGURE 5 - Frequency Switch

TABLE 1 - Current Calibrator Selection Table

I_{SEC} Ampere Rating		Number on Current Calibrator	Potentiometer Adjustment Resistance (Ohms)	I_{SEC} Ampere Rating		Number on Current Calibrator	Potentiometer Adjustment Resistance (Ohms)
Min.	Max.			Min.	Max.		
2.01	2.05	H816	185	3.51	3.55	H817	106
2.06	2.10	H816	180	3.56	3.60	H817	105
2.11	2.15	H816	176	3.61	3.65	H817	103
2.16	2.20	H816	172	3.66	3.70	H818	102
2.21	2.25	H816	168	3.71	3.75	H818	101
2.26	2.30	H816	165	3.76	3.80	H818	99.2
2.31	2.35	H816	161	3.81	3.85	H818	97.9
2.36	2.40	H816	158	3.86	3.90	H818	96.6

3.16	3.20	H817	118	4.66	4.70	H818	79.9
3.21	3.25	H817	116	4.71	4.75	H818	79.1
3.26	3.30	H817	114	4.76	4.80	H818	78.2
3.31	3.35	H817	113	4.81	4.85	H818	77.4
3.36	3.40	H817	111	4.86	4.90	H818	76.6
3.41	3.45	H817	109	4.91	4.95	H818	75.8
3.46	3.50	H817	108	4.96	5.00	H818	75.1

rating shown on the unit nameplate, the overload setting can be established based on the nameplate RLA. When the actual voltage is higher than the specified voltage, refer to "High Voltage Compensation" found on Page 9.

NOTE: *If the unit is equipped with power factor correction capacitors which are connected on the load side of the overload current transformers, the RLA shown on the unit nameplate will have to be recalculated for the purpose of setting the overload. To determine the adjusted RLA, the machine should be run to full load and amperage readings taken on the load and line sides of the capacitor terminal points. The nameplate RLA should be multiplied by the ratio of the current on the line side of the capacitors to current on the load side of the capacitors. This gives the adjusted RLA used to set the current calibrator. (See the example below).*

$$\text{Adjusted RLA} = \text{Nameplate RLA} \times \frac{\text{Line Side Current}}{\text{Load Side Current}}$$

Example:
Motor Rating (RLA) = 100 amps
Current on line side of capacitors = 84 amps
Current on load side of capacitors = 92 amps

$$\text{Adjusted RLA} = 100 \text{ amps} \times \frac{84 \text{ amps}}{92 \text{ amps}} = 91 \text{ amps}$$

NOTE: *If the power factor capacitors are connected on the line side of the current transformers for the MPM, or if the capacitor leads are run through the current transformers with the motor leads, the RLA does not need to be adjusted. The motor nameplate RLA should be used to set the current calibrator in this case.*

B. Once the correct RLA has been determined, the rated load secondary current (I/sec) at full load is dependent upon the location of the current transformers. The correct methods to determine I/sec are discussed below:

1. Current Transformer Monitoring Line Current
   If the current transformers are located so that they monitor line current, the value of the I/sec is determined by dividing the current transformer ratio into the RLA (See the equation example below.)

   I/sec = RLA ÷ (CT ratio)

   Example:
   RLA = 91 amps
   CT ratio = $\frac{100}{5}$

   I/sec = $91 \div \frac{(100)}{5}$

   I/sec = 4.55

2. Current Transformers Monitoring Phase Current
   If the current transformers are located in a star delta starter in such a way that they monitor phase current, the value of I/sec is determined by dividing the current transformer ratio into the RLA and multiply this quantity by 0.58. (See the equation example below)

   I/sec = (RLA ÷ CT Ratio) x 0.58

   Example:
   RLA = 91 amps
   CT Ratio = $\frac{100}{5}$

   I/sec = $(91) \div \frac{(100)}{5} \times 0.58 = 2.64$

C. With the l/sec value obtained, use Table 1 to determine the correct calibrator and its setting. For the preceeding example in which the line current is being monitored (l/sec = 4.55) the correct current calibrator would be H818. The correct calibrator setting would be 82.6 ohms. With the calibrator setting adjusted in this manner, the overload trip point would be 107% of the nameplate RLA.

D. To set the current calibrator it must be removed from the module. Using a digital ohmmeter (3-1/2 place accuracy minimum) set the resistance of the calibrator to the value taken from Table 1.

E. Replace current calibrator in module. Write the calibrator number and setting on the MPM nameplate.

III. Locked Rotor Current Lockout Adjustment

The MPM protects the compressor motor from excessive locked rotor current draw during startup. The correct procedure for setting the LRA trip point is as follows:

A. The LRA trip point is dependent upon the setting of the current calibrator which must first be set correctly.

B. The LRA trip point is set using the LRA potentiometer. (See Figures 4, 6 and 7.)

C. To determine the correct setting of the LRA potentiometer, the percent ratio of the compressor motor locked rotor amperage to full load amperage must be determined. This is computed using the following equation:

$$\frac{\text{Nameplate LRA}}{\text{Nameplate RLA}} \times \%\ \text{In-rush Current} = \%\ \text{Ratio}$$

EXAMPLE:
Star Delta Starter (Normal In-Rush Current = 33%)
Nameplate RLA = 100 amps
Nameplate LRA = 600 amps

$$\frac{600\ \text{amps}}{100\ \text{amps}} \times 33\% = 198\ \text{amps}$$

NOTE: The above example is for a Star-Delta type starter. It should be noted that normal "in-rush" current is dependent upon the type of starter being used. Table 2 lists the different starter type characteristics.

D. To set the LRA potentiometer insert a screwdriver in the adjusting slot and turn the potentiometer to the full counter-clockwise (CCW) stop. This establishes a percent ratio setting of 70. From this point the potentiometer should be rotated clockwise so the end of the potentiometer slot that was pointing towards the 70% position is aligned with the desired setting, as shown in Figure 6.

NOTE: *The range of adjustment of the LRA potentiometer is 70 to 1070 percent of RLA.*

E. Write the percent ratio setting (example 198%) on the nameplate of the MPM.

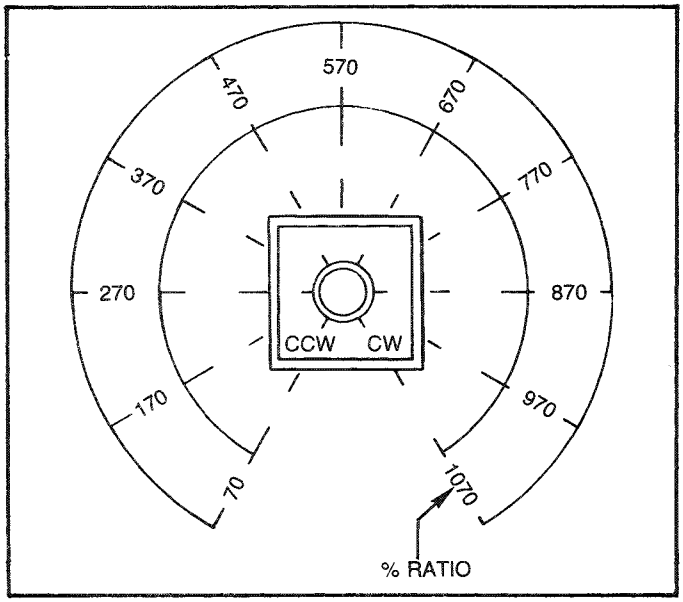

FIGURE 6 - LRA Potentiometer

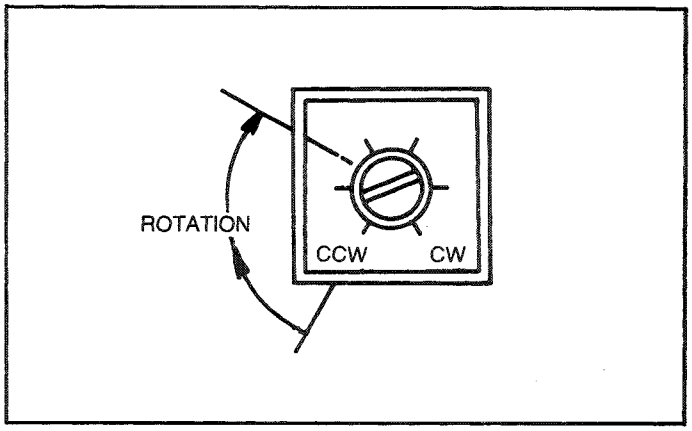

FIGURE 7 - Sample LRA Setting

IV. Maximum Acceleration Time Adjustment

The MPM limits the maximum acceleration time the motor can undergo by tripping the "Motor Overload" circuit breaker, locking the machine off, whenever the MPM does not transition in the time period set on the LRA time adjustment. (See Figure 8). This prevents the motor from drawing LRA for an excessive priod of time and overheating. The maximum acceleration time is set as follows:

A. Determine the desired maximum acceleration time (between 1 and 63 seconds) for the unit. Current production CenTraVacs utilizing Star-Delta type starters have the maximum acceleration time set at 12 seconds. This setting may vary depending on the type of unit, type of starter, and jobsite conditions. The setting should be based on the typical acceleration time for the particular unit and jobsite conditions.

B. Once the desired value is known, the combination of switches on the LRA time adjustment which adds to this value should be switched to the on position (see Figure 8).

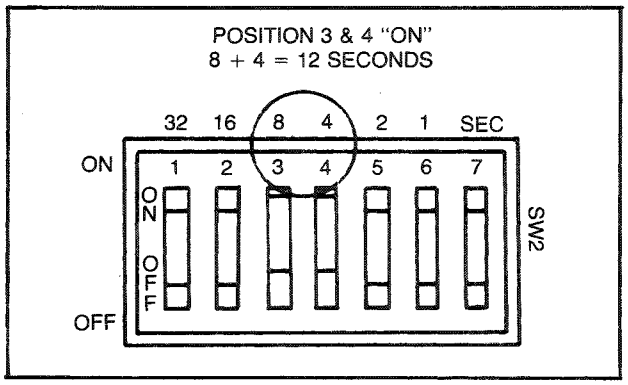

FIGURE 8 - Maximum Acceleration Time Switch

TABLE 2 - Starter Electrical Characteristics

Type of Starter	Starting Characteristics - % of Rated Value			
	% Tap	Motor Voltage	Motor Current	Motor Torque
Full Voltage Type				
Magnetic - X-Line	n/a	100	100	100
Reduced Voltage Types				
Auto-Transformer	80	80	80	64
	65	65	65	42
	50	50	50	25
Primary Reactor	80	80	80	64
	65	65	65	42
	50	50	50	25
Reduced - Inrush Types				
Star-Delta	n/a	100	33	33
Open or Closed Transition	n/a	100	33	33

NOTE: *If none of the switches are in the on position the unit will not start. The MPM allows no acceleration time in this situation and the "Motor Overload" circuit breaker will trip immediately upon attempted startup.*

C. Write the LRA time adjustment setting on the MPM nameplate.

V. High Voltage Compensation:
The RLA shown on the unit nameplate is based on original design conditions and the nominal voltage ordered. The actual jobsite voltage quite often varies from the nominal. Higher than nominal line voltage permits the motor to produce higher than rated horsepower without motor current draw in excess of nameplate. To prevent overloading of the motor due to higher than rated voltage, the MPM should be recalibrated. This can be done in one of two ways:

A. By removal of the 10% current reset jumper from Terminals J1-J2 in the MPM (see Figure 4), the module is automatically recalibrated so that approximately 90% of the motor nameplate current rating is the new "rated" current for the application. The MPM should be setup normally, the removal of the jumper recalibrates all functions of the MPM.

B. The MPM can also be recalibrated to compensate for high voltage by resetting the current calibrator. The proper value is determined by multiplying the I/sec value by the ratio of the rated voltage to the actual line voltage. (See the equation.)

$$\text{New I/sec} = \text{I/sec} \times \frac{\text{rated voltage}}{\text{actual line voltage}}$$

Example:
Original I/sec = 4.55
Rated Voltage - 460 volts
Actual line voltage = 485 volts

$$\text{New I/sec} = 4.55 \times \frac{460 \text{ volts}}{485 \text{ volts}} = 4.32$$

The new I/sec value is then used to enter Table 1 and determine a new current calibrator setting. The calibrator should be reset to this value. This will recalibrate all other MPM functions, compensating for the high voltage condition.

TABLE 3 - Typical Louis Allis RVX Motor Characteristics

Frame Size 1760 - 455 HP - 60 Hertz			
Voltage	Amperage		
		Locked Rotor	
	Full Load	Star	Delta
440	529	845	2660
460	510	880	2780
480	498	920	2900

NOTE: *When the MPM overload current setting is recalibrated in either of the above ways the locked Rotor Current Lockout Adjustment should also be reset. This is because unlike Rated Load Amps which is reduced with higher voltage, Locked Rotor Current increases with an increase in voltage. This is illustrated in Table 3 which is based on a Louis Allis type RVX motor. It may be seen that for a 455 horsepower motor, as the voltage increases by 9.1% (from 440 to 480 volts) the RLA decreases by 6.2% (from 529 to 498 amps) and the LRA (star) increases by 8.9% (from 845 to 920 amps). The LRA current trip point should be set higher by the same percentage that the overload current is set down. When the 10% current reset jumper is removed, the percent ratio of locked rotor is rated load amperage should be increased 10% over its original setting. When the current calibrator is recalibrated downward by the ratio of rated voltage to actual voltage, the ratio of the locked rotor to rated load amperage should be set upward by the ratio of actual voltage to rated voltage.*

Any recalibration of the module, such as removal of the J1-J2 jumper, or recalibration of the current calibrator should be noted on the MPM module cover along with the reason for recalibration.

VI. Low Voltage Lockout Calibration
The Motor Starter Protection System incorporates an adjustment which allows selection of the minimum operating control voltage. If the unit experiences a control voltage below the setting of the low voltage lockout, the Starter Protection System locks the machine off through the "Starter Fault" circuit breaker. The low voltage lockout adjustment is made on

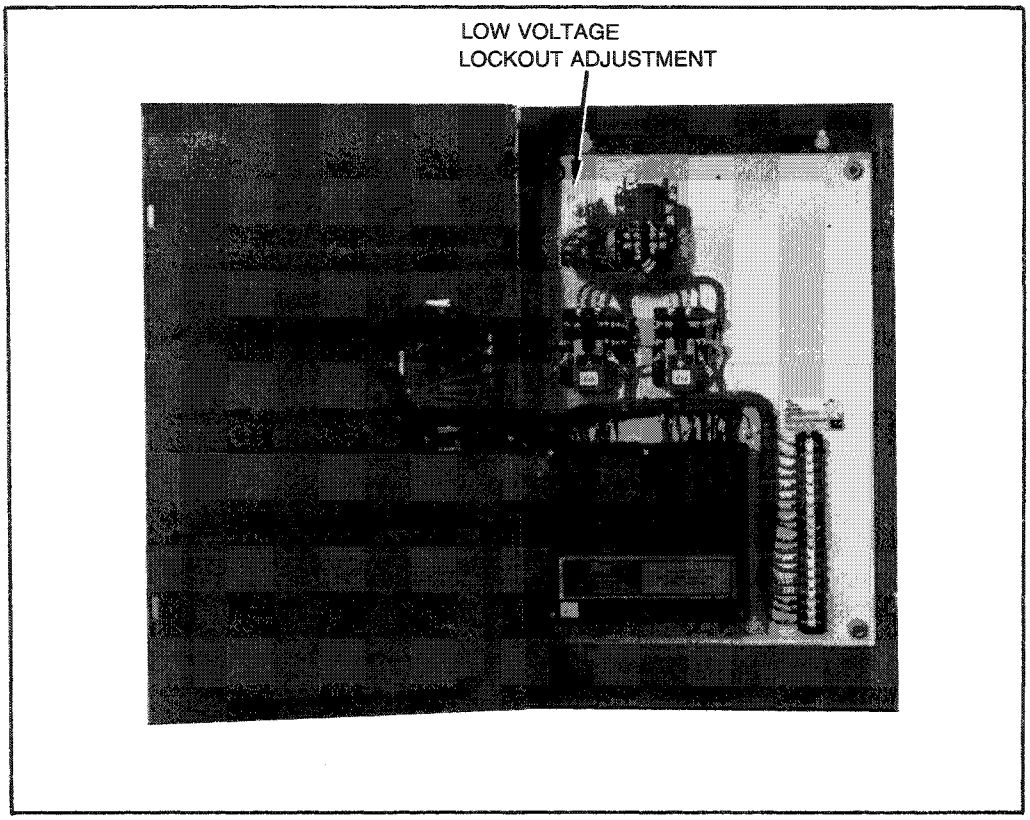

FIGURE 9 - Low Voltage Lockout Adjustment Location

the slotted potentiometer located on the upper left side of the cabinet. See Figure 9. Use the following procedure:

A. Turning the low voltage potentiometer full counter-clockwise provides a trip point of 80 volts ± 10%.
B. Turning the low voltage potentiometer full clockwise provides a trip point of 108 volt ± 10%.
C. The desired nominal trip point voltage can be adjusted to any voltage between these extremes by adjusting the low voltage potentiometer accordingly. The percentage change of the low voltage setting varies linearly with the percentage rotation of the potentiometer. This is expressed by:

(DESIRED VOLTAGE-80) ÷ 28 x 100% = PERCENT ROTATION

For Example:
Desired Lockout voltage is 94 volts.
(94-80) ÷ 28 x 100% = 21%
Turn the potentiometer 21% of the way from full counter-clockwise to full clockwise.

DRY RUN OF STARTERS EQUIPPED WITH MOTOR STARTER PROTECTION SYSTEM

CAUTION: Power will be "ON" for this test. Use extreme caution so as not to contact the starter. Contact may result in serious personal injury or death caused by electric shock.

Starters equipped with the Motor-Starter Protection system may be "dry-run" just as starters not similarly equipped. There are two differences which must be noted:

1. Before the dry run, the distribution fault circuit breaker must be disconnected. This may be accomplished by simply removing a wire from the distribution fault circuit breaker. If this is not done the starter will not sequence but will lockout on distribution fault instantaneously upon initiation of the start sequence.

   It should be noted that this provides a simple check for proper operation of the distribution fault function of the motor protection module. The distribution fault circuit breaker should trip instantly if it is left connected during a starter dry run.
2. The second difference which should be noted is that immediately upon energization of the dry run, the starter will go through transition. This happens because the MPM initiates transition on the basis of motor current draw. During a normal startup the CenTraVac, compressor inlet vanes are closed which allows the motor current to drop from LRA to a value below RLA. When the motor current drops from LRA to 85% of RLA during start, the MPM initiates transition. During a dry run there is no current draw so the MPM immediately initiates transition.

MOTOR STARTER PROTECTION SYSTEM TYPICAL SEQUENCE OF OPERATION

See Figure 3 for typical wiring.

Upon a call for a start from the unit control panel power to terminal 14 (line 1) in the fault trip indicator module (A13) power flows through the fault trip indicator contacts (line 1). Power flows on to energize pilot relay K23 (line 1). It also flows through the S22 timer NC contact (line 3) to energize pilot relay K24 (line 2). Power also feeds through the K30 relay NC contact (line 4) to energize the K30 relay.

The K30 NC contacts (line 4) open leaving the K30 relay (line 3) to be held energized through the low control voltage potentiometer R2 (line 3). The K30 NO contacts (line 2) close holding pilot relay K24 (line 2) energized and power to the low control voltage potentiometer R2 (line 3). Two sets of K30 NO contacts (line 7) close energizing the S22 timer (line 7).

Both pilot relays K23 and K24 are now energized. The K23 NO contacts (line 5) which are wired in series with the K24 NO contacts (line 7) both close allowing power to flow between terminal F (line 5) and terminal G (line 7) causing the starter contactors to begin the unit start sequence.

A set of NO auxiliary contacts (line 12) on the main starter contactor close causing the Motor Protection Module A1 to begin to monitor locked rotor current draw and begin timing the motor acceleration time.

The K23 and K24, NO and NC, self monitoring contacts (lines 5 and 6) switch preventing the "Starter Circuit" fault indicator CB13 (line 5) from tripping.

The S22 timer NC contact (line 3) opens requiring that power be held to pilot relay K24 (line 2) and the potentiometer R2 (line 3) through the relay K30 contact (line 2).

An S22 timer NC contact (line 4) opens to remove power from terminal J (line 5), this prevents the "Starter Circuit" fault indicator (line 5) from tripping.

If the starter is a reduced voltage or current type (e.g. Star-Delta or Auto transformer) which requires transition to occur, this is initiated by the Motor Protection Module A1 when motor current drops below 80 percent of unitrated load current draw, indicating the motor is up to full running speed. It initiates transition by closing a set of contacts giving a transition signal (line 12).

If the unit does not complete transition once intiated, that is, one of the transition contactors (the transition resistor contactor on a Star-Delta type starter indicated by a set of K26 1A NO contact, line 8) remains closed too long, the "Transition Circuit" fault indicator will trip shutting down the machine.

Upon completion of transition the Motor Protection Module A1 monitors the rated load current of the unit to prevent overloads.

CENTRAVAC MOTOR STARTER PROTECTION SYSTEM SEQUENCE OF OPERATION FOR EACH FAULT CONDITION

See Figure 3 for typical wiring.

Following are the descriptions of the conditions which will cause each fault trip indicator to trip when the Motor Protection System is operating correctly.

Motor Overload CB-11 — There are three faults which will cause the Motor Protection Module (MPM) to trip the "Motor Overload" fault indicator. They include:

1. Current draw in excess of rated load amperes. If at any time after the point when the MPM calls for transition to occur, the unit current draw exceeds 107% of the rated load amperes the MPM is calibrated for, the MPM will send a signal to trip the "Motor Overload" fault indicator.
2. Current draw in excess of normal locked rotor amperes. If at any time during the time between the point when the motor is first energized and the point when the (MPM) calls for transition to occur the unit current draw exceeds the value set on the LRA potentiometer in the MPM, the MPM will send a signal to trip the "Motor Overload" fault indicator.
3. Excessive acceleration time. If the unit current draw does not drop to below 80% of rated load amperes following energization of the starter, indicating that the motor never reached full speed in the time set on the maximum acceleration time switches in the MPM, the MPM will send a signal to trip the "Motor Overload" fault indicator.

Distribution Fault CB-14 — The MPM will trip the "Distribution Fault" fault indicator whenever there is a loss of line voltage to the unit when it is running. It is impossible to sense the actual loss of line voltage because as soon as the voltage loss occurs, the compressor motor begins to act as a generator and will produce enough power to support all control functions for approximately 60 cycles.

For this reason, voltage loss is sensed is by monitoring current draw. The fact that makes this possible is that even when completely unloaded an induction motor draws at least 15% - 20% of its rated load amperes. On this basis, the Motor Protection Module monitors the main starter contactor to determine if the unit is running and the current draw of the unit to determine if it is drawing less than 15% of its rated load amperes. The main contact must be monitored so the MPM knows when the current is below 15% because of a normal shutdown. If the contactor is closed and the current is below 15% of rated load amperes the MPM will send a signal to trip the "Distribution Fault" fault indicator.

Starter Circuit — CB-13. There are six faults which will cause the "Starter Circuit" fault indicator to trip. They include:

1. Intermittent control voltage or a fluttering flow switch (see Figure 3). The sequence of operation to protect against this is as follows: The unit is operating in a normal manner and

control power flickers at terminal 14 (line 1). Upon loss of power pilot relays K23 (line 1) and K24 (line 2), relay K30 (line 3) and timer S22 (line 7) will drop out. If control power returns to terminal 14 (line 1) in less than 10 seconds pilot relay K23 (line 1) will pull in. Relay K30 and pilot relay K24 will not be able to pull in because the S22 timer contact (line 3) is timed too close, it takes 10 seconds to close following a control power loss. The pilot relay K23 NO contact (line 5) will close and because the pilot relay K24 NC contact (line 5) does not open power will be applied to trip the "Starter Circuit" fault indicator CB13 (line 5) locking the machine off until manually reset. The S22 timer uses a 10 second timing period because if control power has been off for this period of time, the standard control panel will have locked the unit off and will not allow a restart until it has gone through a post lube & prelube period which eliminates any danger of compressor or starter damage because of rapid recycling.

2. Low Control Voltage — the sequence of operation to protect against this is as follows: The unit is operating in a normal manner and the control voltage drops to the trip level set with the Low Control Voltage Protection potentiometer R2. At this point, the low control voltage protection relay K30 drops out. The K30 relay NO contact (line 2) opens de-energizing pilot relay K24 (line 2). Both pilot relay K24 NO contacts (line 7) open dropping out the starter and sending power to "Starter Circuit" CB13 (line 7) fault indicator causing it to trip.

3. Pilot Relay Failure — The sequence of operation to protect against pilot relay failure, either failure to pull in or drop out, is as follows: The unit calls for a start and the pilot relay K23 (line 1) pulls in correctly, but the pilot relay K24 (line 2) does not pull in; this could be for any reason, burned out coil, loose wire, etc. The pilot relay K23 NO contact (line 5) closes but the pilot relay L24 NC contact (line 5) will not open. This will send power to the "Starter Circuit" CB13 (line 7) fault indicator causing it to trip. The other pilot failure mode would be if one of the relays would not drop out i.e., it was welded in. This is protected against as follows: The fact that a pilot relay is welded in will be caught on the next unit shutdown. Assume for this example that the pilot relay K24 will not drop out. When the unit shuts down the pilot relay K23 NC contact (line 6) will close. The pilot relay K24 NO contact will remain in the closed position. This will send power to the "Starter Circuit" CB13 (line 7) fault indicator causing it to trip.

4. Intermittant Control Voltage Protection Timer (S22) Failure. The timer could fail in two modes, either contacts open or contacts closed. If the Timer S22 fails with contacts open, upon a call for a start the pilot relay K23 (line 1) will be energized. The pilot relay K24 (line 2) will not be energized because the Timer S22 NC contact (line 3) is open and holding pilot relay K24 out. The pilot relay K23 NO contact (line 5) closes and pilot relay K24 NC contact (line 5) will remain closed. This will send power to the "Starter Circuit" CB13 fault indicator (line 5) causing it to trip.

   If the timer S22 fails with contacts closed upon a call for a start the pilot relays K23-K24 will pull in normally. The Timer S22 NC contact (line 4) will not open, this will send power through the pilot relay K23 contacts (line 5) causing it to trip.

5. Low Control Voltage Protection Control Relay (K30) Failure. The relay K30 could fail in two modes, either contacts open or contacts closed. If the relay K30 fails with the contacts open upon a call for a start, the pilot relay K23 (line 1) will be energized. The relay K30 contacts (line 7) will not close and so the timer S22 (line 7) will not be energized. The Timer S22 NC contact (line 4) will not open, this will send power through the pilot relay K23 contacts (line 5) and to the "Starter Circuit" CB13 fault indicator (line 5) causing it to trip.

   If the relay K30 fails with the contacts closed, when the unit shuts down, the relay K30 NO contacts (line 7) will not open. This will allow power to flow through the pilot relay K23 NC contacts (line 6) to the "Starter Circuit" CB13 fault indicator (line 5) causing it to trip.

6. Low Control Voltage Protection Potentiometer (R2) Failure. If the low voltage potentiometer (R2) (line 3) fails, it will fail open. If the unit is running in a normal manner when the low voltage potentiometer (R2) fails this will cause the relay K30 (line 3) to drop out. The relay K30 NO contacts (line 2) open dropping the pilot relay K24 (line 2). The pilot relay K24 NC contacts (line 5) close sending power through the pilot relay K23 NO contact (line 5) which will remain closed, to the "Starter Circuit" CB13 fault indicator (line 5) causing it to trip.

Transition Circuit CB 15 — The "Transition Circuit" CB15 fault indicator (line 8) will be tripped whenever the transition contactor auxiliary K26 (line 8) remains closed for a period of time longer than that allowed by the "Transition Circuit" CB15 fault indicator (1.5 seconds). This indicates that the unit did not complete transition properly.

TROUBLE ANALYSIS

The charts on the following pages provide trouble analysis sequences for the Motor Starter Protection System. Problem symptoms are listed across the top of the chart and possible causes are listed in the left hand column. Recommended solutions are in the right hand column. The numbers in the columns under the problem symptoms indicate possible causes and solutions for those symptoms. The numbering indicates most likely through least likely causes of the problem; 1 being most likely, 2 being second most likely, etc.

CHART 1 - Nuisance Trip Trouble Analysis

Symptom/ Possible Cause	Motor Overload Trips	Distribution Fault Trips	Starter Fault Trips	Transition Fault Trips	Recommended Action
Incorrect Current Calibrator Adjustment or Installation	3				Determine Proper setting recalibrate and install
Incorrect LRA Trip Point Setting	4				Determine Proper setting and recalibrate LRA trip setting.
High Voltage Recalibration Jumper Removed	7				Determine if jumper should be removed to compensate for high voltage.
Excessive Running Motor Current Draw	1				Check for faulty compressor motor
Excessive LRA Motor Current Draw	2				Check for faulty compressor motor
Frequency Selector Switch Incorrectly Set	5				Check selector setting
Motor Acceleration Time to Long	8				Contact The Trane Co. Tech. Ser., La Crosse, WI
Low Voltage to Unit			3**		Contact Power Company
Motor Current Drops Below 20% RLA		5			Contact The Trane Co., Tech. Ser., La Crosse, WI
Distribution Fault (complete voltage loss) Occurs For Over 1½ Cycles	11 (Only on units not equipped DF)	1			Contact Power Company
Current Transformers Incorrectly Wired (dot polority incorrect)	9	2			Rewire Current Transformer
Faulty Circuit Breaker - CB11	10				Replace circuit breaker
1M (K27) Auxiliary Contactor Hanging In		4			Replace contactor
Flow Switch or Similar Safety Device Fluttering			1**		Check water flows, check for air in systems, check for correct installation
Loose Control Circuit Wiring			2**		Check continuity of circuits to locate - tighten wiring
Low Voltage Trip Misadjusted			4**		Readjust trip to desired value.
Chattering 2M (K28) Auxiliary or Main Contactor		3			Replace contactor
S-22 Timer Defective			7**		Replace contactor
Defective Circuit Breaker CB-13			8		Replace circuit breaker
Locked Rotor Trip Time Set Incorrectly	6				Contact The Trane Co., Tech. Ser., La Crosse, WI
Defective Circuit Breaker CB-15				2**	Replace circuit breaker.
Transition Resistor Hanging In (K-26)			9*	1**	Replace contactor.
Welded Pilot Relay Contacts (K23-K24)			5		Replace contactor.
Defective Pilot Relay Coils (K23-K24)			6		Replace contactor coils.
Defective MPM Module	12	6			Replace module.

* Air cooled and unit mounted starters only

** MSPS retrofit kit only

CHART 2 - Trouble Analysis, System and Solid State Fails to Function

Symptom/ Possible Cause	Motor Overload Will Not Trip	Distribution Fault Will Not Trip	Starter Fault Will Not Trip	Transition Fault Will Not Trip	Starter Will Not Transition	Incorrect V1-V2 Control Voltage	Recommended Action
Verify 120 volts Across XX1 and X2	1	1	1	1	1	1	Check Power Supply Wiring
Verify Correct Wiring & Closure on S1-S2 (K-27)	2	2					Check continuity of circuits to locate correct wiring or replace contactor as required.
Incorrect Current Calibrator Adjustment	3	3			2	2	Determine proper setting and recalibrate LRA trip setting.
Current Transformer Incorrectly Wired or Defective	4				3	3	Check continuity of circuits to locate correct wiring.
Faulty Circuit Breaker CB11	5						Replace circuit breaker.
Low Voltage Trip Misadjusted			2				Determine desired setting and recalibrate low voltage set potentiometer
Defective Circuit Breaker CB13			5	2*			Replace circuit breaker
Defective Circuit Breaker CB14		4					Replace circuit breaker
Defective Circuit Breaker CB15				3**			Replace circuit breaker
Incorrect Wiring on V1-V2 Terminals						4	Check continuity of circuits to locate - correct wiring.
Auxiliary Contactor on K-26 Defective			4				Check continuity of circuits to locate - replace contactor.
Auxiliary Contactor on K-23 and K-24 Defective			3				Check continuity of circuits to locate - replace contactor.
Defective MPM Module	6	5					Replace module.

* Air cooled and unit mounted starters only
**MSPS retrofit kit only

INSTALLATION INSTRUCTIONS FOR ADDITION OF AUTO RESTART PANEL TO MOTOR STARTER PROTECTION SYSTEM (OPTIONAL)

See Figure 10.

1. Mount the auto restart panel in the upper right hand of the Motor Starter Protection System cabinet. There are two screw holes provided in the back panel.
2. Remove the plug in the door and install the pilot light and pushbutton station. This will indicate that a line switch shut-down and automatic restart has occurred.
3. Run two wires from the pilot light to Terminals 2 and 3 on the auto restart panel.
4. Connect one short wire from the pushbutton to the ground side of the indicating light and run a second wire back to Terminal 9 on the auto restart panel.
5. Remove the jumpers between 2 and 2A on the Motor Starter Protection System cabinet main terminal strip. Connect wires 6 and 7 from the auto restart panel to Terminals 2 and 2A, respectively, of the MSPS main terminal strip.
6. Disconnect the existing shielded wires E3 and E4 from CB14 on the MSPS cabinet door and reconnect E4 to Terminal 8 on the auto restart panel. Thoroughly insulate E3 with tape and tuck it away as it is no longer required.
7. CB14 is now inoperative.
8. Connect the 115 VAC terminal (No. 1) on the auto restart panel to XX1 on the MSPS main terminal strip.
9. Connect the grounded terminal (No. 2) on the auto restart panel to X2 on the MSPS main terminal strip.
10. Run wires from Terminals 4 and 5 on the auto restart panel to the appropriate connections in the chiller control panel.

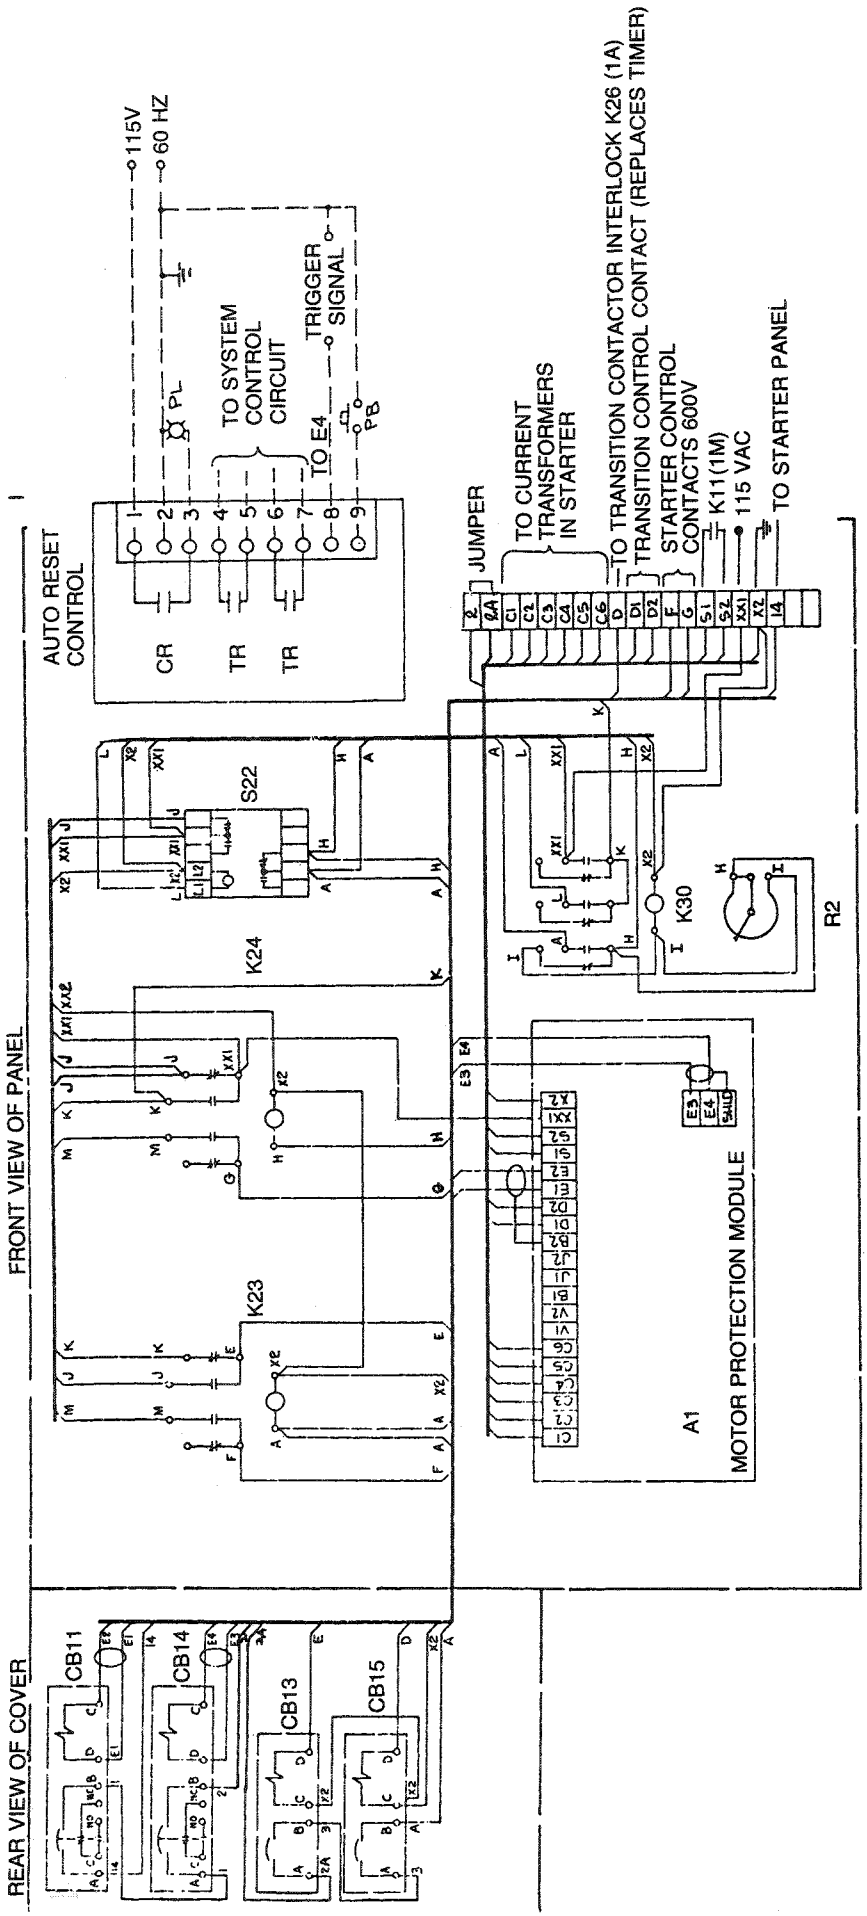

FIGURE 10 - Auto Restart Panel Wiring

MOTOR STARTER PROTECTION SYSTEM TYPICAL SEQUENCE OF OPERATION

(See drawing 2305-1604 or page 5 of MPCA-10M-1)

Upon a call for a start from the unit control panel power to terminal 14 (line 1) in the fault trip indicator module (A13) power flows through the fault trip indicator contacts (line 1). Power flows on to energize pilot relay K23 (line 1). It also flows through the S22 timer NC contact (line 3) to energize pilot relay K24 (line 2). Power also feeds through the K30 relay NC contact (line 4) to energize the K30 relay.

The K30 NC contacts (line 4) open leaving the K30 relay (line 3) to be held energized through the low control voltage potentiometer R2 (line 3). The K30 NO contacts (line 2) close holding pilot relay K24 (line 2) energized and power to the low control voltage potentiometer R2 (line 3). Two sets of K30 NO contacts (line 7) close energizing the S22 timer (line 7).

Both pilot relays K23 and K24 are now energized. The K23 NO contacts (line 6) which are wired in series with the K24 NO contacts (line 7) both close allowing power to flow between terminal F (line 5) and terminal G (line 7) causing the starter contactors to begin the unit start sequence.

A set of NO auxiliary contacts (line 12) on the main starter contactor close causing the Motor Protection Module A1 to begin to monitor locked rotor current draw and begin timing the motor acceleration time.

The K23 and K24, NO and NC, self monitoring contacts (lines 5 and 6) switch preventing the "Starter Circuit" fault indicator CB13 (line 5) from tripping.

The S22 timer NC contact (line 3) opens requiring that power be held to pilot relay K24 (line2) and the potentiometer R2 (line 3) through the relay K30 contact (line 2).

An S22 timer NC contact (line 4) opens to remove power from terminal J (line 5), this prevents the "Starter Circuit" fault indicator (line 5) from tripping.

If the starter is a reduced voltage or current type (eg. Star-Delta or Auto transformer) which requires transition to occur this is initiated by the Motor Protection Module A1 when motor current drops below 80 percent of unitrated load current draw, indicating the motor is up to full running speed. It initiates transition by closing a set of contacts giving a transition signal (lines 10 and 11).

If the unit does not complete transition once initiated, that is one of the transition contactors (the transition resistor contactor on a Star-Delta type starter) indicated by a set of K26 (1A NO contact (line 8) remains closed too long, the "Transition Circuit" fault indicator will trip shutting down the machine.

Upon completion of transition the Motor Protection Module A1 monitors the rated load current of the unit to prevent overloads.

CenTraVac Motor Starter Protection System Sequence of Operation for Each Fault Condition

(See Drawing 2305-1604 or MPCA-IOM-1 page 5)

Following are the descriptions of the conditions which will cause each fault trip indicator to trip when the Motor Protection System is operating correctly.

Motor Overload CB-11 – There are three faults which will cause the Motor Protection Module (MPM) to trip the "Motor Overload" fault indicator. They include:

1. Current draw in excess of rated load amperes. If at any time after the point when the MPM calls for transition to occur the unit current draw exceeds 107% of the rated load amperes the MPM is calibrated for, the MPM will send a signal to trip the "Motor Overload" fault indicator..
2. Current draw in excess of normal lock rotor amperes. If at any time during the time between the point when the motor is first energized and the point when the (MPM) calls for transition to occur the unit current draw exceeds the value set on the LRA potentiometer in the MPM, the MPM will send a signal to trip the "Motor Overload" fault indicator.
3. Excessive acceleration time – If the unit current draw does not drop to below 80% of rated load amperes following energization of the starter, indicating that the motor never reached full speed in the time set on the maximum acceleration time switches in the MPM, the MPM will send a signal to trip the Motor Overload" fault indicator.

Distribution Fault CB-14 – The MPM will trip the "Distribution Fault" fault indicator whenever there is a loss of line voltage to the unit when it is running. It is impossible to sense the actual loss of line voltage because as soon as the voltage loss occurs, the compressor motor begins to act as a generator and will product enough power to support all control functions for approximately 60 cycles.

For this reason the way the voltage loss is sensed is by monitoring current draw. The fact that makes this possible is that even when completely unloaded an induction motor draws at least 15% - 20% of its rated load amperes. On this basis, the Motor Protection Module monitors the main starter contactor to determine if the unit is running and the current draw of the unit to determine if it is drawing less than 15% of its rated load amperes. The main contact must be monitored so the MPM knows when the current is below 15% because of normal shutdown. If the contactor is closed and the current is below 15% of rated load amperes the MPM will send a signal to trip the "Distribution Fault" fault indicator.

Starter Circuit – CB-13. There are five faults which will cause the "Starter Circuit" fault indicator to trip. They include:

1. Intermittent control voltage or a fluttering flow switch (see Drawing 2305-1604 or page 5 of MPCA-IOM-1) The sequence of operation to protect against this is as follows: The unit is operating in a normal manner and control power flickers at terminal 14 (line 1) . Upon loss of power pilot relays K23 (line1) and K24 (line 2), relay K30 (line3) and timer S22 (line 7) will drop out. If control power returns to terminal 14 (line 1) in less than 10 seconds pilot relay K23 (line 1) will pull in. Relay K30 and pilot relay K24 will not be able to pull in because the S22 timer contact (line 3) is timed too close, it takes 10 seconds to close following a control power loss. The pilot relay K23 NO contact (line 5) will close and because the pilot relay K24 NC contact (line 5) does not open power will be applied to trip the "Starter Circuit" fault indicator CB13 (line 5) locking the machine off until manually reset. The S22 timer uses a 10 second timing period because if control power has been off for this period of time, the standard control panel will have locked the unit off and will not allow a restart until it has gone through a post lube & prelube period which eliminates any danger of compressor or starter damage because of rapid recycling.
2. Low Control Voltage – the sequence of operation to protect against this is as follows: The unit is operating in a normal manner and the control voltage drops to the trip level set with the Low Control Voltage Protection potentimeter R2. At this point, the low control voltage protection relay K30 drops out. The K30 relay NO contact (line 2) opens deenergizing pilot relay K24 (line 2). Both pilot relay K24 NO contacts (line 7) open dropping out the starter and sending power to "Starter Circuit" CB13 (line7) fault indicator causing it to trip.
3. Pilot Relay Failure – The sequence of operation to protect against pilot relay failure, either failure to pull in or drop out, is as follows: The unit calls for a start and the pilot relay K23

(line 1) pulls in correctly, but the pilot relay K24 (line 2) does not pull in; this could be for any reason, burned out coil, loose wire, etc. The pilot relay K23 NO contact (line 5) closes but the pilot relay L24 NC contact (line 5) will not open. This will send power to the "Starter Circuit" CB13 (line 7) fault indicator causing it to trip. The other pilot failure mode would be if one of the relays would not drop out i.e., it was welded in. This is protected against as follows: The fact that a pilot relay is welded in will be caught on the next unit shutdown. Assume for this example that the pilot relay K24 will not drop out. When the unit shuts down the pilot relay K23 NC contact (line 6) will close. The pilot relay K24 NO contact will hang in the closed position. This will send power to the "Starter Circuit" CB13 (line 7) fault indicator causing it to trip.

4. Interminent Control Voltage Protection Timer (S22) Failure. The timer could fail in two modes, either contacts open or contacts closed. If the Timer S22 fails with contacts open, upon a call for a start the pilot relay K23 (line 1) will be energized. The pilot relay K24 (line 2) will not be energized because the Timer S22 NC contact (line 3) is open and holding pilot relay K24 out. The pilot relay K23 NO contact (line 5) closes and pilot relay K24 NC contact (line 5) will remain closed. This will send power to the "Starter Circuit" CB13 fault indicator (line 5) causing it to trip.n

   If the timer S22 fails with contacts closed upon a call for a start the pilot relays K23-K24 will pull in normally. The Timer S22 NC contact (line 4) will not open, this will send power through the pilot relay K23 contacts (line 5) causing it to trip.

5. Low Control Voltage Protection Control Relay (K30) Failure
   The relay K30 could fail in two modes, either contacts open or contacts closed. If the relay K30 fails with the contacts open upon a call for a start, the pilot relay K23 (line 1) will be energized. The relay K30 contacts (line 7) will not close and so the timer S22 (line 7) will not be energized. The Timer S22 NO contact (line 4) will not open, this will send power through the pilot relay K23 contacts (line 5) and to the "Starter Circuit" CB13 fault indicator (line 5) causing it to trip.

If the relay K30 fails with the contacts closed, when the unit shuts down, the relay K30 NO contacts (line 7) will not open. This will allow power to flow through the pilot relay K23 NC contacts (line 6) to the "Starter Circuit" CB13 fault indicator (line 5) causing it to trip.

6. Low Control Voltage Protection Potentiometer (R2) Failure

If the low voltage pot. (R2) (line 3) fails, it will fail open. If the unit is running in a normal manner when the low voltage potentiometer R2 fails this will cause the relay K30 (line 3) to drop out. The relay K30 NO contacts (line 2) open dropping the pilot relay K24 (line 2). The pilot relay K24 NC contacts (line 5) close sending power through the pilot relay K23 NO contact (line 5) which will remain closed, to the "Starter Circuit" CB13 fault indicator (line 5) causing it to trip.

Transition Circuit CB 15 – The "Transition Circuit" CB15 fault indicator (line 8) will be tripped whenever the transition contactor auxiliary K26 (line 8) remains closed for a period of time longer than that allowed by the "Transition Circuit" CB15 fault indicator (1.5 seconds). This indicates that the unit did not complete transition properly.

A1 - Motor Protection Module

This module contains the electronic circuitry to monitor the following and protect against the following faults.

1. Running motor overload
2. Locked rotor motor overload
3. Excessive acceleration time
4. Distribution fault

It also initiates transition based on motor current draw when the motor is up to speed.

See Service Bulletin CTV-SB-22A for detailed information on operation and calibration.

A12 - Starter Protection Module

This module contains the following components.

1. The pilot relays(K23 and K24)
2. The low control voltage protection control relay(K30)
3. The low control voltage protection potentiometer(R2)
4. The interminent control voltage protection timer(S22)

It provides protection against the following faults.

1. Interminent control voltage/flow switch flutter
2. Low control voltage
3. Pilot relay malfunction
4. S22 timer failure(fail safe)

A13 - Fault Trip Indicator Module

This module contains the four manual reset circuit breakers which lock the machine out in the event of a fault occurrence signal from the

Motor Protection Module or Starter Protection Module. These circuit breakers include:

1. Motor overload(CB11)
2. Starter circuit(CB13)
3. Distribution fault(CB14)
4. Transition circuit(CB15)

Motor Protection Retrofit Component Description

*CB11 - Motor Overload Fault Indicator

This is an instantaneous trip manual reset fault trip circuit breaker which is tripped by the Motor Protection Module(A1) in the event of a motor overload. See the description covering the Motor Protection Module for faults included under the description "Motor Overload."

*CB13 - Starter Circuit Fault Indicator

This is a time to trip manual reset fault trip circuit breaker which is tripped in the event of:

1. A pilot relay malfunction(burn out or weld in)
2. An occurrence of intermintent control voltage or fluttering flow switch
3. Low control voltage
4. S22 timer failure
5. K30 relay failure

The breaker trips after a period of approximately 1.5 seconds of power to the circuit breaker coil.

*CB14 - Distribution Fault Indicator

This is an instantaneous trip manual reset fault trip circuit breaker which is tripped by the Motor Protection Module(A1) in the event of a distribution fault. See the description covering the Motor Protection

Module for faults included under the description "Distribution Fault."

*CB15 - Transition Circuit Fault Indicator

This is a time to trip manual reset fault trip circuit breaker which trips in the event of the transition resistor contactor or contact auxiliary staying in too long. This breaker trips after a period of approximately 1.5 seconds of power to the circuit breaker coil.

NOTE: All fault indicator circuit breakers are designed to be shunt trip devices not current sensitive devices as normally applied.

K23-K24 Pilot Relays

These relays are used to energize the main contactor of the starter when a start is called for. They also are wired in such a way that if either one malfunctions the "Starter Circuit" (CB13) fault indicator will trip. The contact rating of these relays is 600 volts at 3 amperes maximum.

K30 - Low Control Voltage Protection Relay

This is a control relay which is used in combination with the R2 Potentiometer to provide protection against low control voltage.

R2 - Low Control Voltage Protection Potentiometer

This is a potentiometer which is used in combination with the K30 relay to provide an adjustable low voltage trip point. It is wired in series with the coil of the K30 relay and operates by dropping a set voltage prior to the K30 coil. This causes the K30 to drop out at some set voltage and trip the "Starter Circuit"(CB13) fault indicator. The rating of this variable resistor is 3.5 K at 3.25 watts.

S22 - Interminent Control Voltage Protection Timer

This is a solid state timer with two normally closed, instant open, time to close contacts.

When the timer is energized, its contacts open instantly and remain open as long as it is energized. When the timer is de-energized, its contacts remain open for 10 seconds and then close.

This timer is not adjustable.

T2 - T3 - T4 Current Transformers

These are three current transformers which feed a current signal to the Motor Protection Module to tell it what load the machine is operating at.

They must provide a 2.0 to 5.0 amp signal at unit rated load at a 0.02 V.A. burden.

MOTOR OVERLOAD TROUBLE ANALYSIS CHART

SYMPTOM						
	MOTOR OVERLOAD TRIPS					
POSSIBLE CAUSE	At the Instant of First Contactor Hit	During Acceleration Before Transition	Transistion	After Transition	At Power Up of Control Circuit	
Incorrect LRA Trip Point Setting	1					Determine Proper Setting and Recalibrate
LRA TRIP Time Set Incorrectly	2	2			1*	+Determine Proper Setting and Recalibrate
Incorrect Current Calibrator Adjustment or Installation	3		1	1		Determine Proper Setting and Recalibrate
Current Transformers Incorrectly Wired (Dot Polarity Incorrect)	4	3	2			Rewire Current Transformers
Excessive Running Motor Current Draw	5	5		2**		Check Current Load Limiting Circuitry and Calibration
Faulty Circuit Breaker CB11	6	6	4	3		Replace Circuit Breaker
Defective MPM Module	7	7	6	5	2	Confirm Failure-Replace MPM
Frequency Selector Switch Incorrectly Set		4				Check Selector Setting
Motor Acceleration Time Too Long		+1				Contact La Crosse Service
MPM Module Sensitivity High			5			See Service Bulletin CTV-SB-65
Refrigerant Carryover Occurring When Machine is Up to Speed			3	4		Determine the Cause of Carryover - Correct

MOTOR OVERLOAD TROUBLE ANALYSIS CHART

* The Motor Overload Circuit Breaker will trip instantly at initial control circuit power up if all LRA Trip Time Switches are in the OFF position.

** If the LLR allows any overshoot to occur the unit may experience momentay overloads causing the Circuit Breaker to trip. If the LLR cannot be adjusted to prevent this overshoot a variable orifice restrictor(RSR-1)may be installed in the 2016 lbs main air supply line before the pilot positioner. This should be adjusted to slow the vane stroke as necessary to prevent overshoot.

\+ See Charts below for nominal settings. On units which start with high evaporator temperatures these times may have to be extened to prevent nuisance trip outs.

TYPICAL MAXIMUM ACCELERATION TIME SETTINGS
FOR CVHA AND CVHB DESIGN MACHINES

STARTER TYPE	RECOMMENDED MAXIMUM ACCELERATION TIME SETTINGS
Star-Delta	12 Seconds
Auto-Transformer	8 Seconds
Across-The-Line	4 Seconds

TYPICAL MAXIMUM ACCELERATION TIME SETTINGS
FOR CVHE DESIGN MACHINES

2/25/83
SUPERSEDES CTV-SB-22A
DATED 10/5/81

SUBJECT: CENTRAVAC SOLID STATE MOTOR PROTECTION MODULE - OPERATION, CALIBRATION AND TROUBLESHOOTING

INTRODUCTION:

The purpose of this Service Bulletin is to discuss the operating characteristics of the Trane Motor Protection Module (MPM) and to outline the correct procedures for calibration and troubleshooting. The module is presently supplied on all Air Cooled CenTraVacs and Water Cooled CenTraVacs equipped with the new Trane Unit-Mounted Starter. In addition, it is also part of the new Motor Starter Protection System (MSPS) Retrofit Kit marketed by Service Products. This Bulletin also discusses the operation, calibration and troubleshooting procedure for the Motor Starter Protection System Retrofit Kit.

DISCUSSION:

Motor Protection Module (MPM) Features:

Listed below are the operational functions and features of the Motor Protection Module:

1. To provide precise compressor motor overload protection.
2. To protect against excessive locked rotor (in-rush) current draw.
3. To limit the length of time that in-rush current may be drawn.
4. To protect the unit from damage which can be caused by an electrical distribution fault.
   NOTE: A distribution fault is defined as a complete loss of line voltage for a period of less than 60 cycles.
5. The module initiates starter transition when the compressor reaches full speed.
6. To provide a DC voltage signal which is proportional to load.
7. It can be adjustable to compensate for high line voltage.
8. It is adjustable for 50 or 60 Hertz operation.

Motor - Starter Protection System (MSPS) Features:

The Motor Starter Protection System Retrofit Kit consists of three modules. One is the Motor Protection Module previously discussed, another houses the fault indicator circuit breakers and the third contains the Starter Protection System. The features and functions of the starter protection system are listed below:

1. To protect against the effects of pilot relay contact welding.
2. To protect against the effects of the loose control wiring.
3. To protect against the effects of intermittent control voltage (ie., fluttering flow switches, etc.)
4. It incorporates an adjustable undervoltage lock out for the control circuit.
5. The circuits are wired to protect the transition Resistor against excessive operating time.

CALIBRATION PROCEDURES (MOTOR PROTECTION MODULE)

CAUTION: WHENEVER WORKING ON THE MPM, AS WITH ANY ELECTRICAL EQUIPMENT, STOP THE MOTOR AND DISCONNECT ALL POWER TO THE UNIT. FAILURE TO DO SO MAY RESULT IN ACCIDENTAL SHOCK OR DEATH BY ELECTROCUTION. PREVENT PERSONAL INJURY BY ALWAYS DISCONNECTING ELECTRICAL POWER BEFORE WORKING ON ELECTRICAL EQUIPMENT.

NOTE: On units equipped with the Distribution Fault function, a small circuit board mounted in the center of the MPM must be tilted outward to perform MPM calibration. This is done by gently pulling on the two black tabs, located on the top of the circuit board, and tilting it down on its hinges.

I. Line Frequency Adjustment:

The MPM can operate on either 50 or 60 Hertz electrical systems. The line frequency is set as follows:

A. The installation line frequency must first be determined. (60 Hertz for all U.S. installations.)
B. The frequency switch (see Figure 1) should then be set to the position which corresponds to the installation frequency (see Figure 2).
C. Write in the setting made on the MPM nameplate (see Figure 3).

II. Compressor Motor Overload Setup:

The overload is set by adjusting the resistance of the current calibrator. The MPM is designed so that with the current calibrator correctly set, the overload will trip at 107% of the motor rated load current. The use of a 107% trip point prevents nuisance full load trip outs while still protecting the compressor motor from potentially damaging overloads.

The correct procedure for setting the current calibrator is as follows:

A. Determine the Rated Load Current (RLA) and the current transformer ratio for the unit. Where the actual jobsite voltage is equal to or lower than the specified voltage rating shown on the unit nameplate, the current calibrator setting can be established based on the nameplate RLA.

When the actual voltage is higher than the specified voltage, see Section V (High Voltage Compensation).

FIGURE 3 - MOTOR PROTECTION MODULE NAMEPLATE

If the unit is equipped with power factor correction capacitors which are connected on the load side of the overload current transformers, the RLA shown on the unit nameplate will have to be recalculated for the purpose of setting the overloads. On CenTraVacs shipped with factory installed power factor capacitors, the adjusted RLA should be shown on the electronic overload cover and the overload set accordingly. To determine the adjusted RLA on other units, the machine should be run to full load and amperage readings taken on the load and line sides of the capacitor terminal points. The nameplate RLA should be multiplied by the ratio of the current on the line side of the capacitors to current on the load side of the capacitors. This gives the adjusted RLA to be used to set the current calibrator. (See equation and example below.)

$$\text{Adjusted RLA} = \text{Nameplate RLA} \times \frac{\text{line side current}}{\text{load side current}}$$

Example: Motor Rating (RLA) = 100 amps
Current on line side of capacitors = 84 amps
Current on load side of capacitors = 92 amps

$$\text{Adjusted RLA} = 100 \text{ amps} \times \frac{84 \text{ amps}}{92 \text{ amps}} = 91 \text{ amps}$$

If the power factor capacitors are connected on the line side of the MPM current transformers or if the capacitor leads are run through the current transformers with the motor leads (Figure 4) the RLA must not be adjusted.

The motor nameplate RLA should be used to set the current calibrator in this case.

Refer to Engineering Bulletin EB-CTV-44 for additional information and recommendations concerning field addition of power factor correction capacitors.

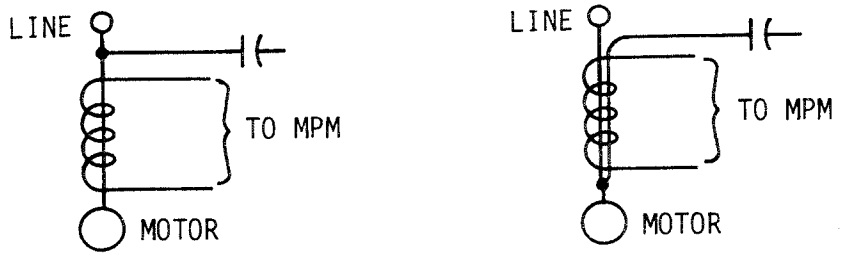

FIGURE 4 - Current Transformers

B. Once the correct RLA has been determined, the rated load secondary current (I_{sec}) from the current transformer can be determined. The value of I_{sec} at full load is dependent upon the location of the current transformers. The correct methods to determine I_{sec} are discussed below:

1. Current Transformer Monitoring Line Current
   If the current transformers are located to monitor line current, the value of the I_{sec} is determined by dividing the current transformer ratio into the RLA. (See the equation and example below.)

$$I_{sec} = RLA \div (CT\ ratio)$$

Example RLA = 91 amps

$$CT\ ratio = \frac{100}{5}$$

$$I_{sec} = \left(91 \div \frac{100}{5}\right)$$

$$I_{sec} = 4.55$$

2. Current Transformers Monitoring Phase Current
   If the current transformers are located in a star-delta starter in such a way that they monitor phase current, the value of I_{sec} is determined by dividing the current transformer ratio into the RLA and multipling this quantity by 0.58. (See the equation and example below.)

$$I_{sec} = RLA \div CT\ Ratio) \times 0.58$$

Example: RLA = 91 amps

$$CT\ Ratio = \frac{100}{5}$$

$$I_{sec} = (91 \div \frac{100}{5} \times 0.58$$

$$I_{sec} = 2.64$$

NOTE: When donut-type current transformers are used, the wires passed through them are sometimes wrapped around and passed through more than once. When this is done, the CT ratio is effectively divided by the number of times the wire passes through the CT. This means a 200/5 CT with the wire passed through it twice should be treated as a 100/5 CT.

C. With the I_{sec} value found above, use Table 1 to determine the correct current calibrator and its setting. For the above example in which the line current is being monitored (I_{sec} = 4.55), the correct current calibrator would be H818. The correct calibrator setting would be 82.6 ohms. With the calibrator setting adjusted in this manner, the overload trip point would be 107% of the nameplate RLA.

D. To set the current calibrator, it must be removed from the module. Using a digital ohmmeter (3-1/2 digit accuracy minimum) set the resistance of the calibrator to the value taken from Table 1.

E. Replace the current calibrator in the module. Write the calibrator number and setting on the MPM nameplate.

NOTE: With the current calibrator set correctly and the unit operating at full load, a DC voltage of approximately 8.25 VDC should exist across terminals V1-V2 in the MPM.

III. Locked Rotor Current Lockout Adjustment

The MPM protects the compressor motor from excessive LRA current draw during start-up. It does this by tripping the motor overload circuit breaker any time the set LRA is exceeded. The correct procedure for setting the LRA trip point is as follows:

A. The LRA current trip point setting is dependent upon the type of starter being used with the CenTraVac compressor motor.

B. The LRA current trip point is set using the LRA set potentiometer (Figure 1).

C. The correct setting position for the LRA set potentiometer as applied to different types of starters are shown in Figure 5.

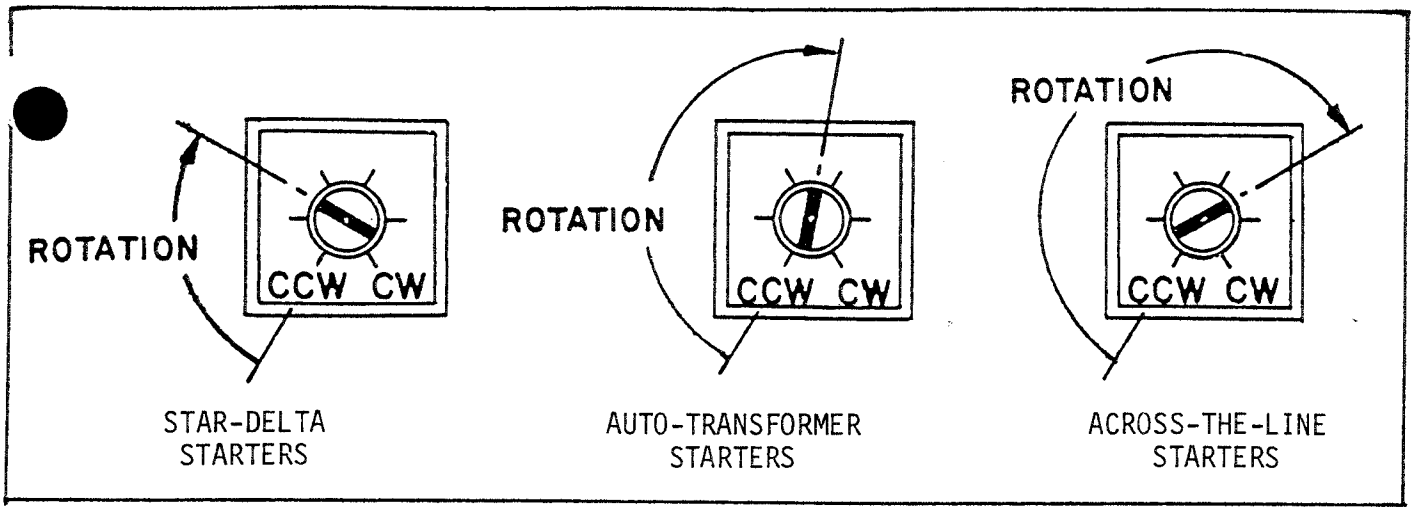

FIGURE 5 - LRA SET POTENTIOMETER POSITIONS FOR DIFFERENT TYPE STARTERS

D. To set the LRA set potentiometer, insert a screw driver in the adjusting slot and turn potentiometer to the fully counter-clockwise (CCW) stop. This establishes a reference position. From this point, the potentiometer should be rotated clockwise to the position, shown in Figure 5, which corresponds to the compressor motor starter being used.

E. As can be seen by the calibration markings on the LRA set potentiometer, this is a rough setting only. If it is found that the "motor overload" circuit breaker trips <u>immediately</u> (1 sec) upon energization of the starter, the LRA current trip point may have to be set higher. Doing this will not harm the operation of the MPM or the compressor motor.

F. Write the nameplate LRA and the nameplate RLA on the MPM nameplate. See Figure 3.

G. Calculate the "RATIO ___%" using the formula below. Write this on the nameplate. See Figure 3.

$$\text{Ratio \%} = \frac{\text{Motor LRA*}}{\text{Motor RLA}} \times 100\%$$

Example: Motor RLA - 100 AMPS

Motor LRA = 200 AMPS

$$\frac{200 \text{ AMPS}}{100 \text{ AMPS}} \times 100\% = \text{Ratio } 200\%$$

* Locked rotor amperes (LRA) is the reduced value obtained depending on the method of starting. See Table 2.

TABLE 2 STARTING CHARACTERISTICS FOR VARIOUS TYPES OF MOTOR STARTERS

TYPE OF STARTER	% TAP	STARTING CHARACTERISTICS - % OF RATED VALUE		
		MOTOR VOLTAGE	MOTOR LRA CURRENT	MOTOR TORQUE

Reduced - Inrush Types				
Star-Delta	n/a	100	33	33
Open or Closed Transition	n/a	100	33	33

IV. Maximum Acceleration Time Set

The MPM limits the maximum acceleration time the motor can undergo by tripping the "Motor Overload" circuit breaker, locking the machine off whenever the machine does not transition in the time period set on the acceleration time adjustment (Figure 1). This prevents the motor from drawing LRA for an excessive period of time and overheating the motor. The maximum acceleration time is set as follows:

A. Determine the desired maximum acceleration time (between 1 and 63 seconds) for the unit. Table 3 gives recommended settings for typical units. This setting may vary, depending on the type of unit, type of starter and jobsite conditions. It should be set, based on the typical acceleration time for the particular unit and jobsite conditions.

TABLE 3 - TYPICAL MAXIMUM ACCELERATION TIME SETTINGS

STARTER TYPE	RECOMMENDED MAXIMUM ACCELERATION TIME SETTINGS
Star-Delta	12 Seconds
Auto-Transformer	8 Seconds
Across-The-Line	4 Seconds

B. Once the desired value is known, the combination of switches on the LRA time adjustment which adds to this value should be switched to the "ON" position (see Figure 6).

NOTE: If none of the switches are in the "ON" position, the unit will not start. The MPM allows no acceleration time in this situation and the "Motor Overload" circuit breaker will trip immediately upon attempted start-up.

12 SECONDS = 8 + 4
TURN ON SWITCHES 3 & 4

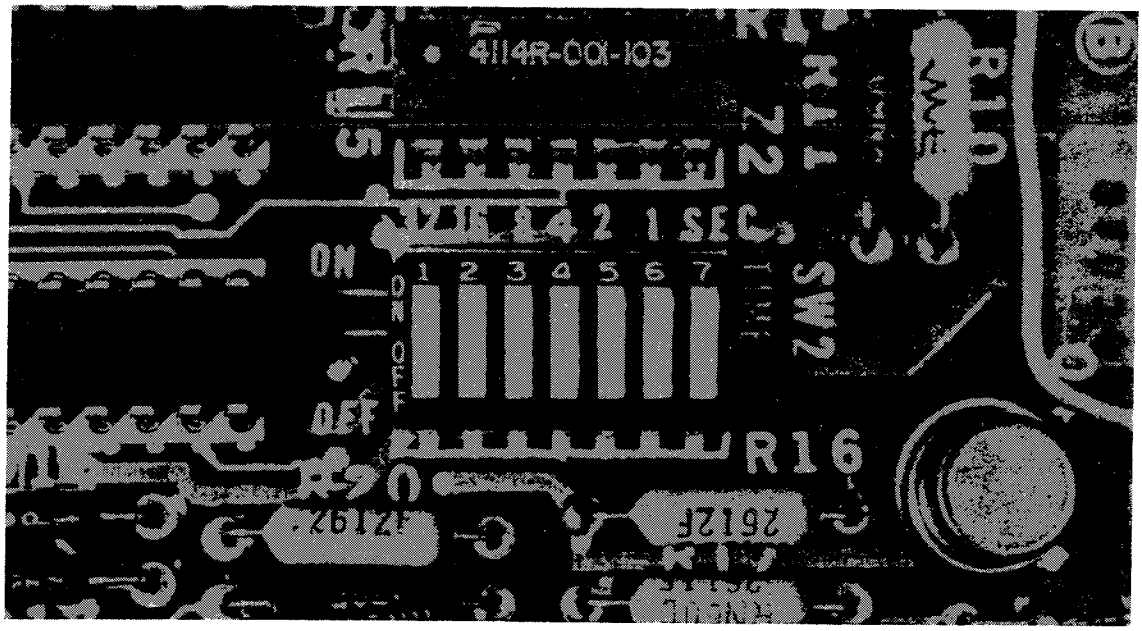

FIGURE 6 - MAXIMUM ACCELERATION TIME SWITCH

C. Write the LRA time adjustment setting on the MPM nameplate. See Figure 3.

V. High Voltage Compensation:

The RLA shown on the unit nameplate is based on original design conditions and the nominal voltage ordered. The actual jobsite voltage quite often varies from the nominal. Higher than nominal line voltage permits the motor to produce higher than rated horsepower without motor current draw in excess of nameplate. To prevent overloading of the motor due to higher than rated voltage, the MPM should be recalibrated. This can be done in either of two ways:

A. By removal of 10% current reset jumper from terminals J1 - J2 in the MPM (see Figure 1), the module is automatically recalibrated so that approximately 90% of the motor nameplate current rating is the new "rated" current for the application. The MPM should be setup normally, as removal of the jumper recalibrates all functions of the MPM.

B. The MPM can also be recalibrated to compensate for high voltage by resetting the current calibrator. The proper value is determined by multiplying the I_{sec} value, determined in the Compressor Motor Overload Setup section of this Service Bulletin, by the ratio of the rated voltage to the actual line voltage. (see the equation and example below.)

$$\text{New } I_{sec} = I_{sec} \times \frac{\text{rated voltage}}{\text{actual line voltage}}$$

Example: Original $I_{sec} = 4.55$
Rated Voltage = 460 volts
Actual line voltage = 485 volts

$$\text{New } I_{sec} = 4.55 \times \frac{460 \text{ volts}}{485 \text{ volts}} = 4.32$$

The new I_{sec} value is then used to enter Table 1 and determine a new current calibrator setting. The calibrator should be reset to this value. This will recalibrate all other MPM functions, compensating for the high voltage condition.

C. Whenever the MPM is recalibrated for high voltage, the LRA Potentiometer should be turned up one space higher than indicated on Figure 4 to prevent nuisance tripouts at start-up. The reason for this is that higher than nameplate LRA current draw would occur. This must be compensated for by turning up the LRA Potentiometer.

Any calibration of the module, such as removal of the J1 - J2 jumper or recalibration of the current calibrator should be noted on the MPM module cover along with the reason for recalibration.

NOTE: When any recalibration of the motor overload is performed on a water-cooled CenTraVac equipped with a pneumatic LLR, the LLR must be recalibrated just as the overload. If this is not done, nuisance overload tripouts will occur.

VI. CVAC Load Limiting Control Calibration

On CVAC's, the MPM controls the load limiting of the motor through a load proportional DC voltage which it sends to the vane control module. If the MPM has been calibrated correctly, the vane control module should start load limiting at 98% of RLA. The load proportional DC voltage can be measured across terminals V1 - V2 of the MPM. At rated load, this voltage will be -8.25 VDC. This voltage varies linearly with the machine running amperage.

Example: 100% RLA = (-)8.25 VDC
98% RLA = (-)8.25 x .98 = (-)8.09 VDC

VII. Vane Control Module Load Limit Calibration

A. The current calibrator must be correctly set before the control module load limiting can be calibrated.

B. The unit should then be started.

C. The voltage across terminals V1 - V2, in the control module, should be measured while the machine is being loaded. The control module current limiting calibrator should be set so the machine begins load limiting when the V1-V2 voltage reaches (-)8.09 volts DC. This corresponds to a machine load of 98% of FLA.

D. Manually unload and load the machine, rechecking to make sure load limiting begins at a V1-V2 signal voltage of (-)8.09 volts DC. The unload - load lights can be used to verify proper limiting as well as visually observing the damper motor.

E. The load limiting of the control module is now set correctly.

VIII. Dry Running Starters Equipped with the Motor Protection Module

Starters equipped with the Motor Protection Module can be dry run at startup in the same manner as starters not so equipped. There are two differences which should be noted.

A. Before the starter can be dry run, the Distribution Fault circuit Breaker must be disconnected. This can be done by simply removing a wire from the Distribution Fault Circuit Breaker. If this is not done, the starter will not sequence, but will lockout on distribution fault instantly upon initiation of the start.

   This occurs because the distribution fault trip is initiated when the motor current drops below 20% of RLA with the M1 contactor energized. See the "Distribution Fault Trip Operation" section of this Bulletin for the reasoning behind this. The only time the above circumstances can occur, is during an actual distribution fault or a starter dry run.

B. The other difference which will be noticed, is that immediately upon energization of the dry run, the starter will go through transition.

   This happens because the MPM initiates transition on the basis of motor current draw. During a normal startup, the vanes are closed which allows the motor current to drop from LRA to a value below RLA. When the motor current drops from LRA to 80% of RLA during start, the MPM initiates transition. During a dry run, there is no current draw, so the MPM, immediately (1 sec) initiates transition.

IX. Distribution Fault Circuit Breaker Operation

A distribution fault is defined as a loss of line voltage for less than 60 electrical cycles. This type of short duration power interruption can be damaging to many types of induction motor driven equipment.

The damage occurs because an induction motor acts as a generator for several seconds after power is disconnected. The voltage generated by the motor can hold in control relays and starter contactors when a voltage loss occurs. The period of time the contactors are held in, is approximately 60 electrical cycles or 1 second for a Water Cooled CenTraVac, and 20 cycles or 1/3 second, for an Air Cooled CenTraVac.

If line voltage is re-established during the period of time the contactors are being held in by the motor generated voltage, and the two voltages are out of phase, motor torques may occur which are 6 to 10 times normal running torques. These torques occur as the motor is pulled into phase and may be in either the forward or reverse direction. These high torques cause severe overloading of the impeller hub area, with resultant upsetting of the impeller keyway and in severe cases cracking or destruction of the impellers.

The Motor Protection Module detects a distribution fault by monitoring current draw and the M1 contactor. The tripping of the Distribution Fault Circuit Breaker is initiated based on the fact that, in normal operation, only during the occurrances of an actual distribution fault is it found that the motor current draw is less than 20% of RLA and the M1 contactor is energized at the same time. An induction motor will normally always draw over 20% of RLA, even when completely unloaded; and whenever the M1 contactor is energized, the motor is running. The only exceptions occur during a distribution fault or during a starter dry run.

The distribution fault lockout is initiated when the motor current drops below 20% of RLA with the M1 contactor energized. The motor Protection Module senses this set of conditions to be a voltage loss for the reasons explained in the previous two paragraphs. Tripping of the Distribution Fault Circuit Breaker is completed within 6 electrical cycles (1/10 of a second) of the time when the voltage loss occurs.

It should be noted that this provides a way to check for the proper operation of the distribution fault function of the Motor Protection Module. The Distribution Fault Circuit Breaker should trip instantly if it is left connected during a starter dry run.

CALIBRATION PROCEDURE (MOTOR STARTER PROTECTION RETROFIT KIT ONLY)

I. Low Voltage Lockout Calibration

The Motor-Starter Protection System Retrofit Kit incorporates an adjustment which allows the minimum operating control voltage to be set. If the unit experiences a control voltage below the setting of the low voltage lockout, the Starter Protection Module (SPM) locks the machine out with the "Starter Fault" circuit breaker. The low voltage lockout adjustment is on the outside of the Starter Protection Module. It is a slotted potentiometer type adjustment located on the side of the SPM module. (See Figure 7.) It can be set using the following guides:

A. Turning the low voltage set potentiometer fully counter-clockwise gives a trip point of 80 volts ± 10%.
B. Turning the low voltage set potentiometer fully clockwise gives a trip point of 108 volts ± 10%.
C. The nominal trip voltage can be adjusted to any value between these extremes by adjusting the low voltage set potentiometer. See the following equation:

(Desired Voltage - 80) ÷ 28 x 100% = Percent rotation
Amount of potentiometer rotation required

Example: Desired lockout voltage = 94 volts
(94 - 80) ÷ 28 x 100% = 50%

Turn the potentiometer 50% of the way from fully CCW to fully CW.

NOTE: A good nominal setting is 94 volts, or 50% rotation.

II. Start Circuit Protection

A "Starter Circuit" tripout will occur whenever the control circuit power to the starter is momentarily interrupted. Such interruptions could include a fluttering flow switch, loose wiring or a defective control. There is no calibration which can be performed on this circuit.

III. Transition Circuit Protection

A "Transition Circuit" tripout will occur if the transition resistors remain in the circuit for over one and a half seconds. This protects the resistors from conditions which will cause rapid burnout. There is no calibration which can be performed on this circuit.

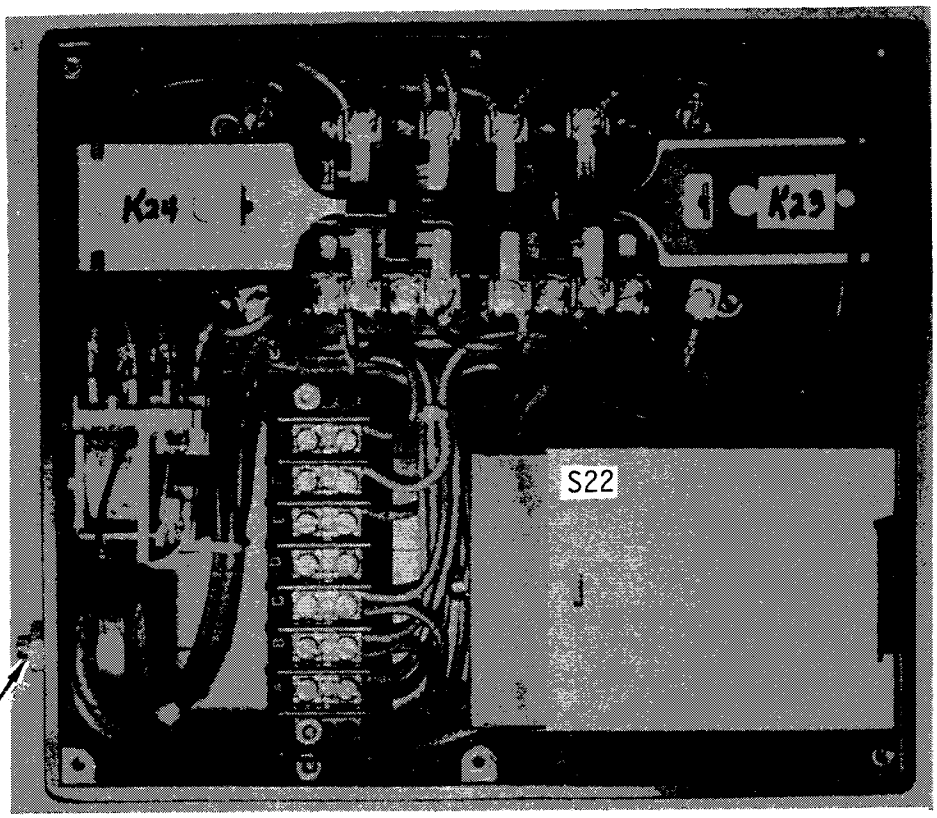

FIGURE 7 - STARTER PROTECTION MODULE

TROUBLESHOOTING MPM/MPS

The wiring diagrams on the following pages give typical wiring schemes for the Motor Protection Module and Motor Starter Protection System Retrofit Kit. Figure 8 shows the wiring of the MPM by description of the terminal board stud's interconnections. Figure 9 is a typical wiring diagram of a Unit Mounted Starter equipped with a MPM. Figure 10 is a typical wiring diagram of the Motor Starter Protection Retrofit Kit.

The charts on the following pages give troubleshooting sequences for the Motor Protection Modules. Problem symptoms are listed across the top of the chart, possible causes in the left hand columns and recommended solutions in the right hand column. The numbers in the columns under the problem symptoms indicate possible causes and solutions for those symptoms. The numbering indicates the probability of the corresponding cause/solution being the one which is causing the problem; 1 being the most likely, 2 the second most likely, and so on.

TROUBLESHOOTING NUISANCE TRIPPING

SYMPTOM/ POSSIBLE CAUSE	MOTOR OVERLOAD TRIPS	DISTRIBUTION FAULT TRIPS	STARTER FAULT TRIPS	TRANSITION FAULT TRIPS	RECOMMENDED ACTION
Incorrect Current Calibrator Adjustment or Installation	3				Determine proper setting, re-calibrate and install.
Incorrect LRA Trip Point Setting	4				Determine proper setting and re-calibrate LRA trip setting.
High Voltage Re-calibration Jumper Removed	7				Determine if jumper should be removed to compensate for high voltage.
Excessive Running Motor Current Draw	1				Check for faulty compressor motor.
Excessive LRA Motor Motor Current Draw	2				Check for faulty compressor motor.
Frequency Selector Switch Incorrectly Set	5				Check selector setting.
Motor Acceleration Time to Long	8				Contact La Crosse Service
Low Voltage To Unit			3**		Contact Power Company
Motor Current Drops Below 20% RLA		5			Contact La Crosse Service
Distribution Fault (complete voltage loss) Occurs For Over 1-1/2 Cycles.		1			Contact Power Company
Current Transformers Incorrectly Wired (dot polority incorrect)	9	2			Rewire Current transformers
Faulty Circuit Breaker - CB11	10				Replace circuit breaker.
1M (K27) Auxiliary Contactor Hanging In		4			Replace contactor.
Flow Switch or Similar Safety Device Fluttering			1**		Check water flows, check for air in system, check for correct instal-lation.
Loose Control Circuit Wiring			2**		Check continuity of circuits to locate-tighten wiring
Low Voltage Trip 1 Misadjusted			4**		Readjust trip to desired value.

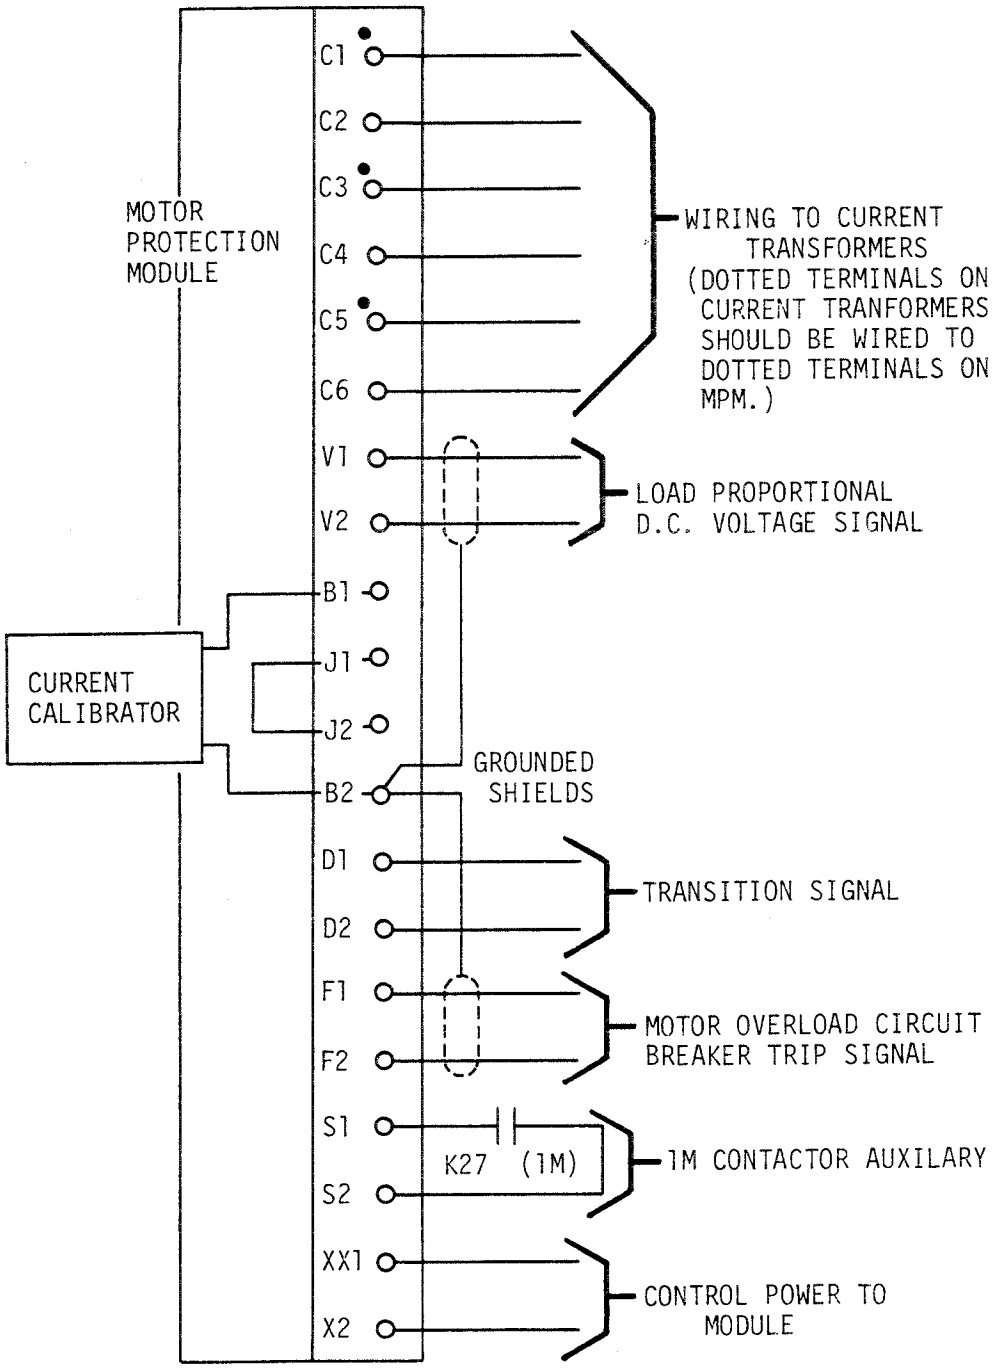

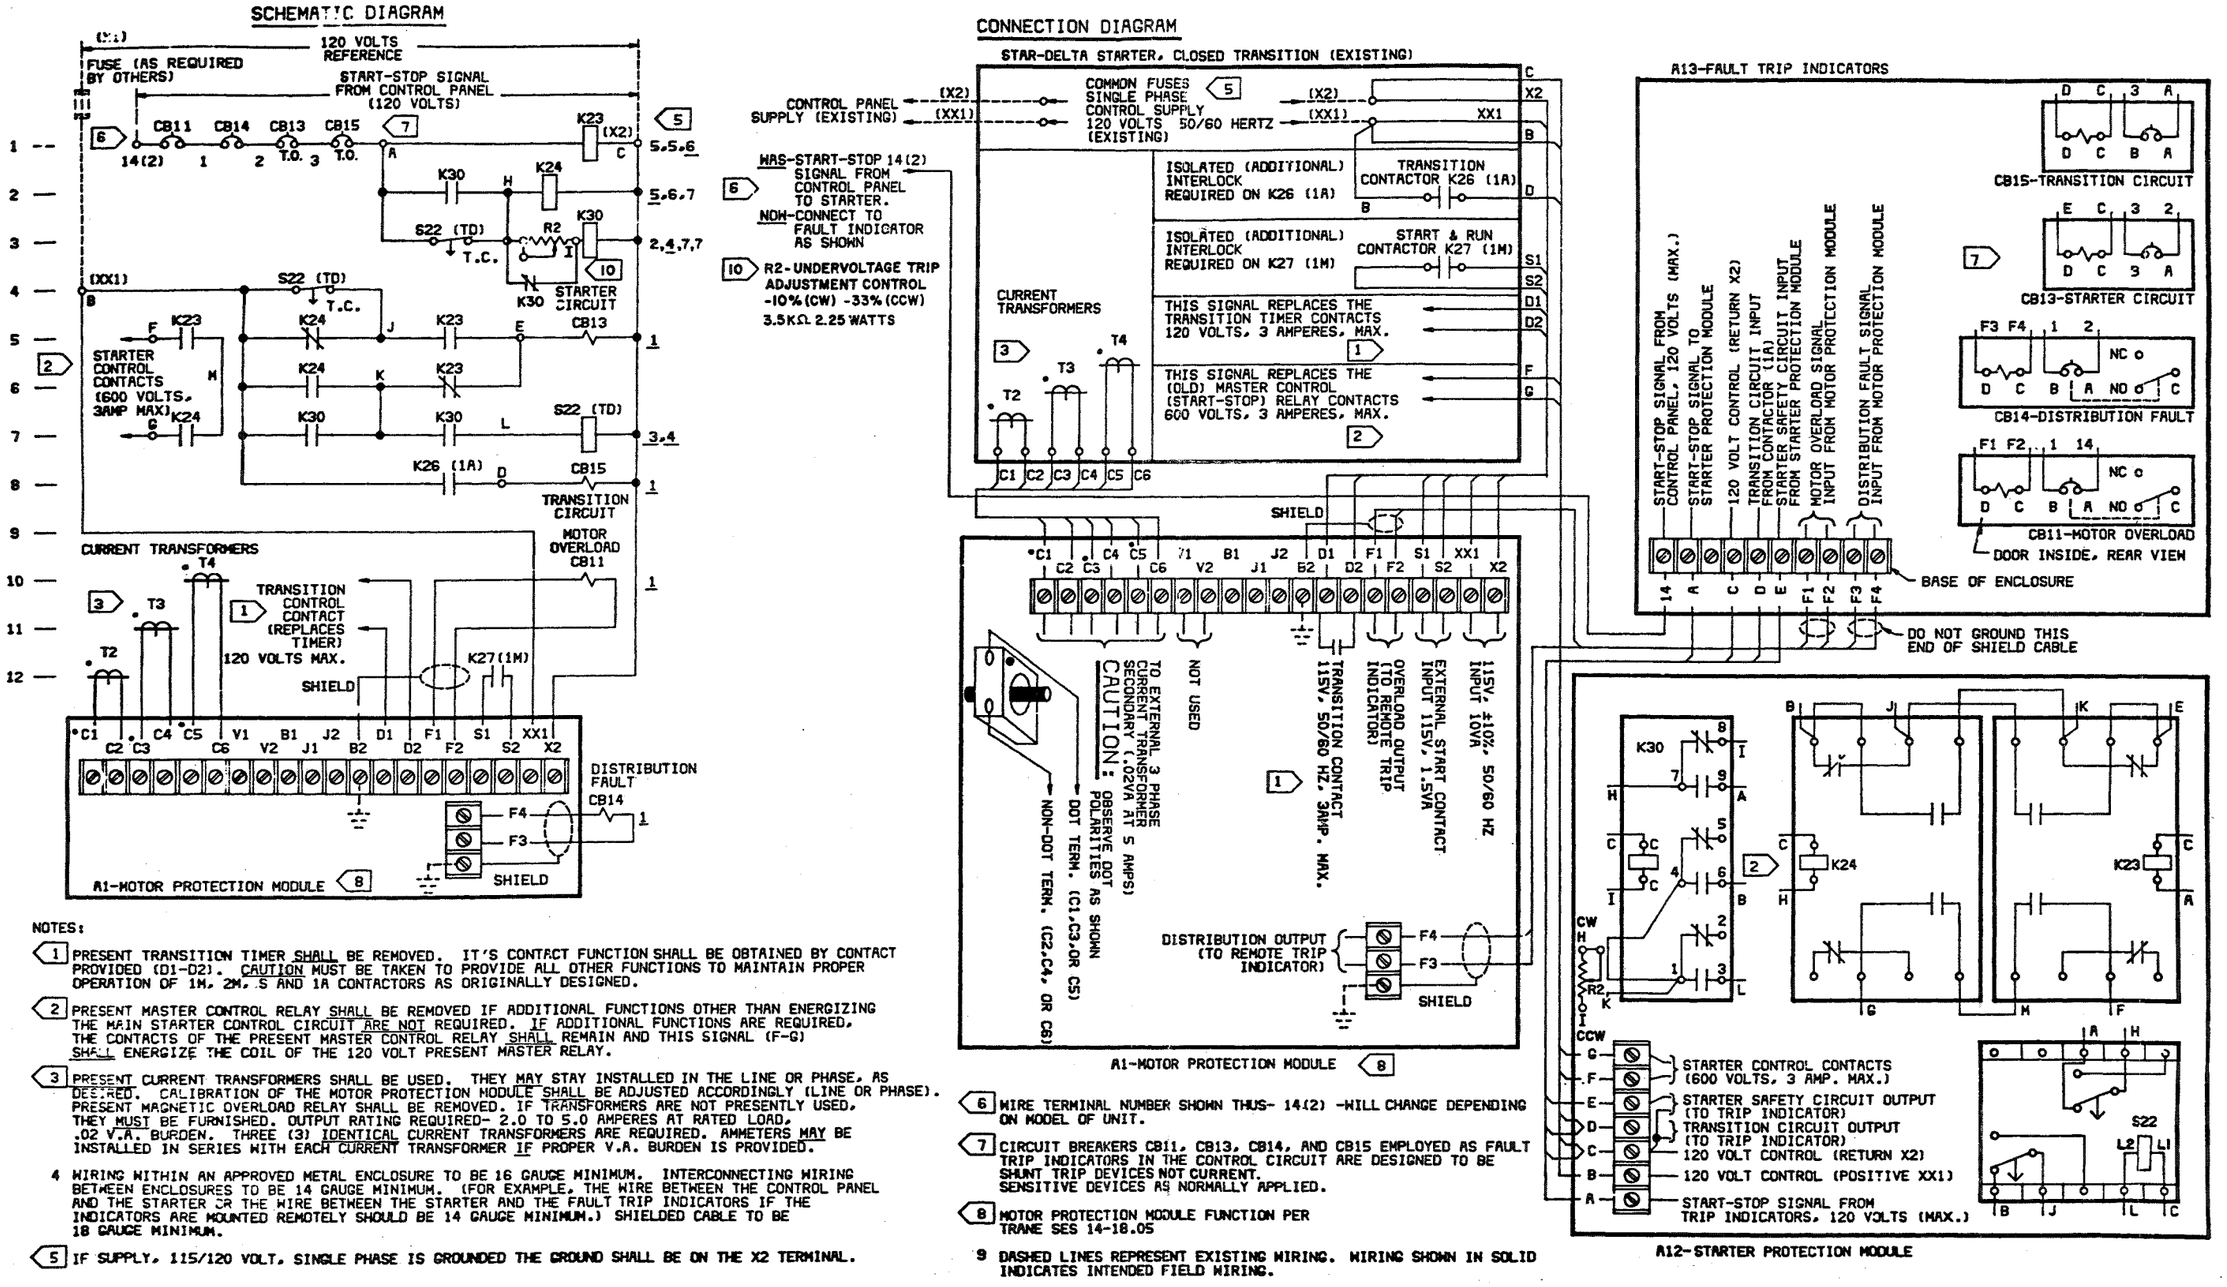

FIGURE 8 - MOTOR PROTECTION MODULE INTERCONNECTIONS

NOTES:

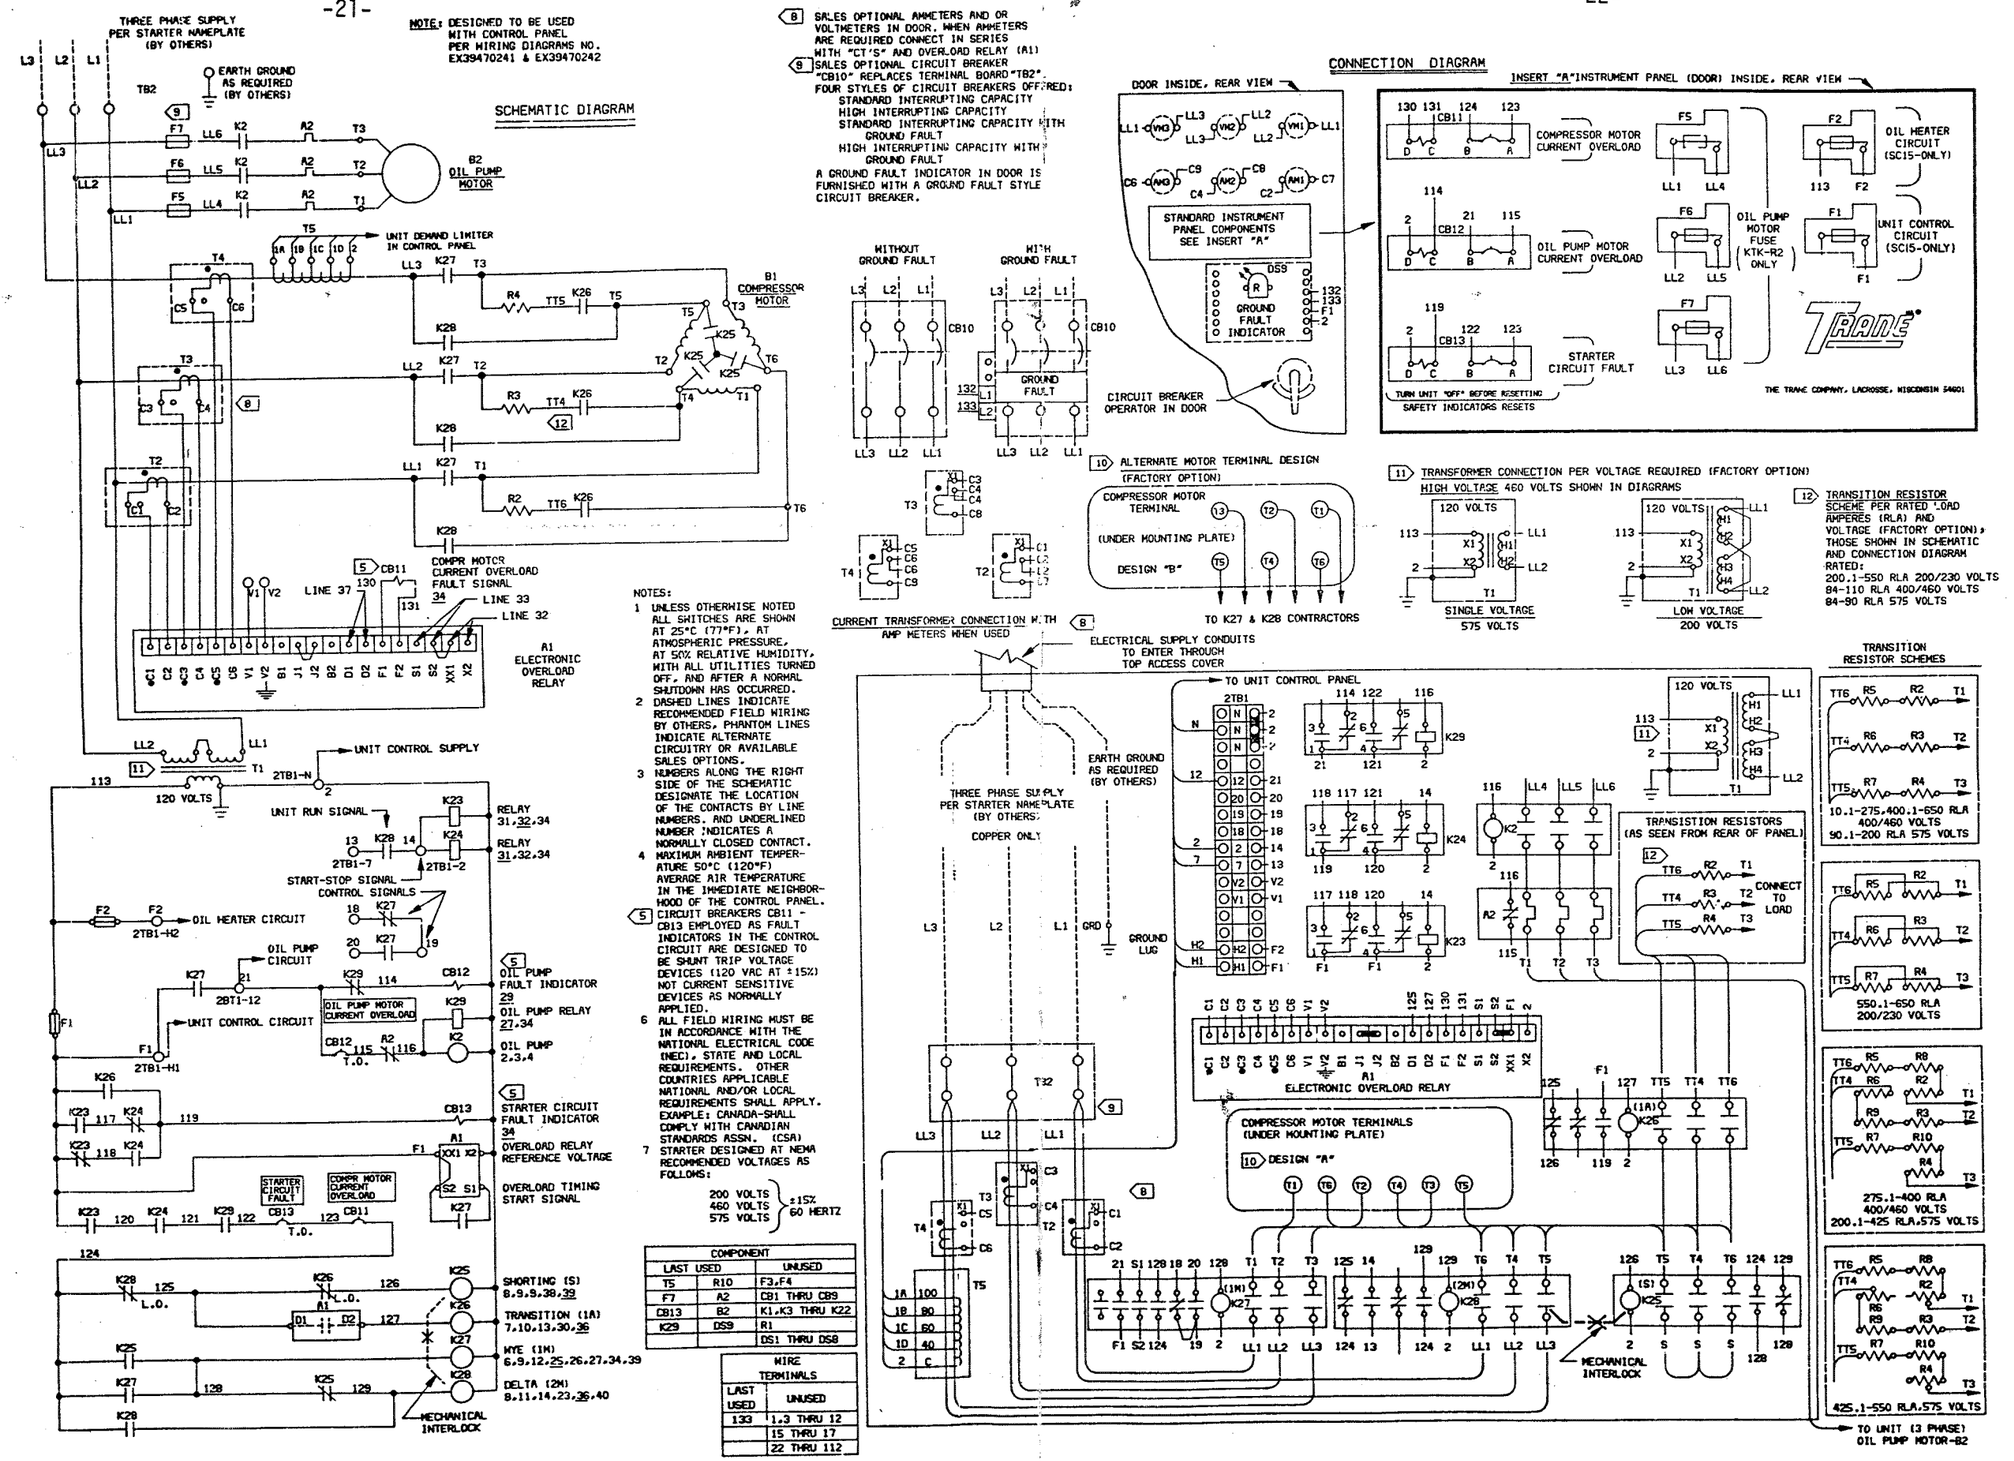
1. PRESENT TRANSITION TIMER SHALL BE REMOVED. IT'S CONTACT FUNCTION SHALL BE OBTAINED BY CONTACT PROVIDED (D1-D2). CAUTION MUST BE TAKEN TO PROVIDE ALL OTHER FUNCTIONS TO MAINTAIN PROPER OPERATION OF 1M, 2M, S AND 1A CONTACTORS AS ORIGINALLY DESIGNED.

2. PRESENT MASTER CONTROL RELAY SHALL BE REMOVED IF ADDITIONAL FUNCTIONS OTHER THAN ENERGIZING THE MAIN STARTER CONTROL CIRCUIT ARE NOT REQUIRED. IF ADDITIONAL FUNCTIONS ARE REQUIRED, THE CONTACTS OF THE PRESENT MASTER CONTROL RELAY SHALL REMAIN AND THIS SIGNAL (F-G) SHALL ENERGIZE THE COIL OF THE 120 VOLT PRESENT MASTER RELAY.

3. PRESENT CURRENT TRANSFORMERS SHALL BE USED. THEY MAY STAY INSTALLED IN THE LINE OR PHASE, AS DESIRED. CALIBRATION OF THE MOTOR PROTECTION MODULE SHALL BE ADJUSTED ACCORDINGLY (LINE OR PHASE). PRESENT MAGNETIC OVERLOAD RELAY SHALL BE REMOVED. IF TRANSFORMERS ARE NOT PRESENTLY USED, THEY MUST BE FURNISHED. OUTPUT RATING REQUIRED- 2.0 TO 5.0 AMPERES AT RATED LOAD, .02 V.A. BURDEN. THREE (3) IDENTICAL CURRENT TRANSFORMERS ARE REQUIRED. AMMETERS MAY BE INSTALLED IN SERIES WITH EACH CURRENT TRANSFORMER IF PROPER V.A. BURDEN IS PROVIDED.

4. WIRING WITHIN AN APPROVED METAL ENCLOSURE TO BE 16 GAUGE MINIMUM. INTERCONNECTING WIRING BETWEEN ENCLOSURES TO BE 14 GAUGE MINIMUM. (FOR EXAMPLE, THE WIRE BETWEEN THE CONTROL PANEL AND THE STARTER OR THE WIRE BETWEEN THE STARTER AND THE FAULT TRIP INDICATORS IF THE INDICATORS ARE MOUNTED REMOTELY SHOULD BE 14 GAUGE MINIMUM.) SHIELDED CABLE TO BE 18 GAUGE MINIMUM.

5. IF SUPPLY, 115/120 VOLT, SINGLE PHASE IS GROUNDED THE GROUND SHALL BE ON THE X2 TERMINAL.



6. WIRE TERMINAL NUMBER SHOWN THUS- 14(2) -WILL CHANGE DEPENDING ON MODEL OF UNIT.

7. CIRCUIT BREAKERS CB11, CB13, CB14, AND CB15 EMPLOYED AS FAULT TRIP INDICATORS IN THE CONTROL CIRCUIT ARE DESIGNED TO BE SHUNT TRIP DEVICES NOT CURRENT SENSITIVE DEVICES AS NORMALLY APPLIED.

8. MOTOR PROTECTION MODULE FUNCTION PER TRANE SES 14-18.05

9. DASHED LINES REPRESENT EXISTING WIRING. WIRING SHOWN IN SOLID INDICATES INTENDED FIELD WIRING.

SUBJECT: CENTRAVAC SOLID-STATE OVERLOAD NUISANCE TRIPOUT

INTRODUCTION:

The purpose of this Service Bulletin is to discuss nuisance tripouts of the solid-state overload (Motor Protection Module) used on CVHA/CVHB CenTraVacs. Module modification may be required to prevent nuisance motor overload tripouts at starter transition. This bulletin applies only to CVHA and CVHB low voltage machines shipped prior to July 1982. Units shipped after July 1982 have SSOLs which have been modified to prevent nuisance tripouts.

Other CenTraVacs which have the motor protection module system field installed may also be affected.

DISCUSSION:

Some CVHA and CVHB CenTraVacs have exhibited a nuisance motor overload trip which may occur at transition on star/delta starters. This is caused by high transient currents produced during transition. These transient currents do not occur on all units. The occurrence is dependent upon the speed of starter operation (contact closure during transition), motor construction (manufacture of stator) and unit load at start-up.

A starter which transitions slowly (takes a relatively long time for the contactors to complete transition once it has been initiated) may allow the motor to slip out of phase with incoming power. The resulting slip then can produce a transient current as the starter connects to delta. Because of this, older style units on which motor/starter protection retrofit kits are being installed, may also be susceptible to these nuisance tripouts.

The original manufacturing tolerances inherent in stator windings also influence the transition transient currents. Therefore, even with two identical motors it is possible that one may experience nuisance tripout and the other may not. It is not possible to predict which machines may experience nuisance tripouts until the unit is actually operating under field conditions.

A heavy evaporator load at start, (warm evaporator water) will typically cause longer acceleration times. High starting load causes transient currents which are higher and of longer duration. Therefore, a unit which starts normally with cool evaporator water, may experience a nuisance tripout under an extremely hot start condition.

Overload Identification:

As stated in the Introduction section of this Bulletin, units shipped after July 1982 are equipped with SSOLs which have been modified.

Before proceeding to the corrective action section of this bulletin, the overload module should be inspected to determine if it is the earlier version. Examine the terminal strip as shown in Figure 1. When looking into the SSOL with the terminal strip toward the top, as it is mounted in the starter, the fifth and sixth terminals from the right in an unmodified SSOL are labeled F1 and F2. Terminals 5 and 6 in a modified SSOL are labeled E1 and E2. The upper two screw terminals on the swing out of an unmodified SSOL circuit board are labeled F3 and F4. The modified SSOL terminals are labeled E3 and E4 (see Figure 2).

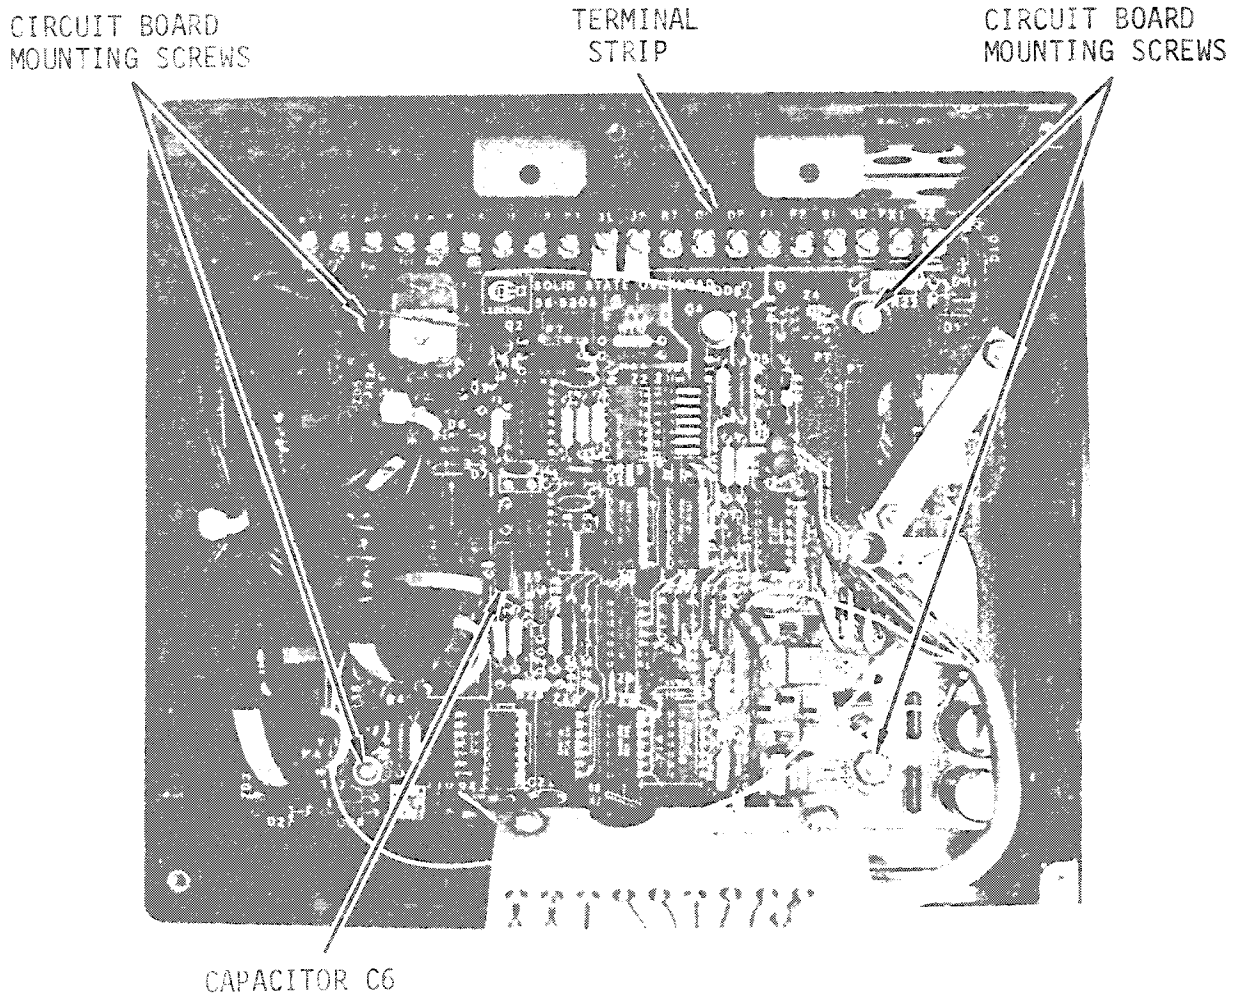

FIGURE 1 - Solid State Overload Circuit Board

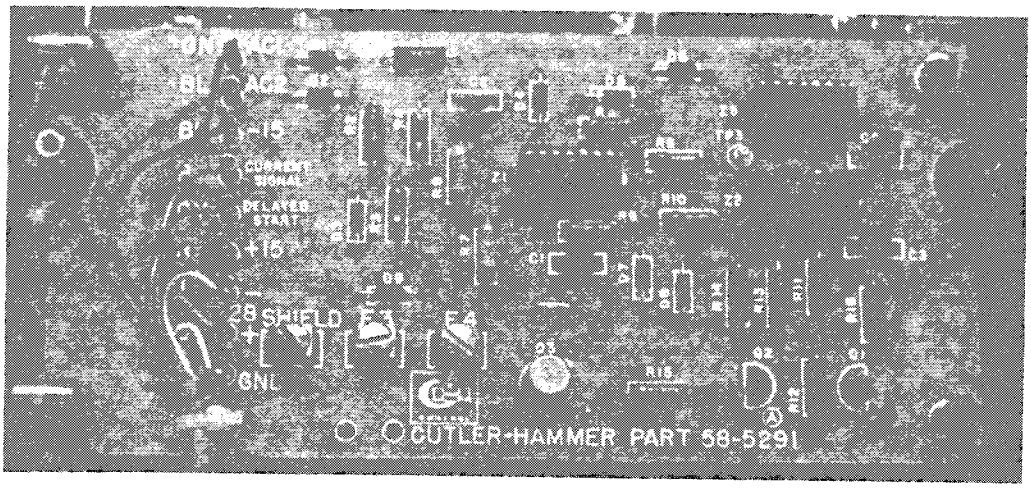

FIGURE 2 - Solid State Overload Swing Out Circuit Board

Any SSOL without the swing out circuit board is an unmodified model.

The modified SSOL has the changes described in this bulletin incorporated into its circuitry. Therefore, the modification described here is not applicable to a modified SSOL.

Tripout Diagnosis:

Proper identification of the exact time of the tripout occurrence is very important. The corrective action described in this bulletin applies only to tripouts which occur precisely as the contactors finish transition from start to delta. The motor will accelerate normally, transition will occur as the current drops to 80% of RLA as normal, but as soon as the contactors can be heard transitioning the "Motor Overload" fault trip indictor on the starter door will trip. If the nuisance tripout does not occur precisely at transition as described, the following corrective action does not apply.

CORRECTIVE ACTION:

Corrective action involves replacement of the C6 capacitor on the main circuit board in the SSOL. The C6 capacitor originally supplied on all SSOL's provides approximately an 8 cycle delay after transition before the module begins to sense running current. The addition of a larger capacitor increases the delay time preventing nuisance tripouts. The C6 capacitor that needs to be replaced is shown in Figure 1. This designation is written on the circuit board next to the capacitor. The capacitor has a flat rectangular shape and is orange in color.

For replacement, a 40 to 70 mf (micro farad) electrolytic capacitor rated between 35 and 50 volts should be used. Such capacitors are available at most electronic supply stores.

To remove the old capacitor, it will be necessary to remove the main circuit board. It is held in place by four screws located near the corners of the circuit board. See Figure 1. The board is held in place with electrical isolating washers and star lockwashers. Care must be taken to note the location of these parts while the board is being removed, so that they are replaced correctly.

Once the circuit board has been removed, the capacitor can be desoldered and removed.

NOTE: A soldering pencil of no larger than 35 watts should used when soldering electronic components. Higher power soldering irons may overheat the components causing failure.

Excess solder will often be left in the mounting holes when the old capacitor is removed. This may make installation of the new capacitor difficult. The excess solder may be removed with a desoldering tool or "solder sucker". This is a tool which sucks melted solder from the soldered joints. This tool is available at most electronic supply stores.

Once the old capacitor has been removed, the new one may be installed. The original capacitor was a non-polarized type while the new one is polarized and must be installed correctly.

NOTE: The new capacitor must be installed with the correct polarity to prevent failure of the SSOL.

The correct polarization of the capacitor is with the positive (+) end toward the terminal strip.

Insert the new capacitor into the circuit board and solder in place. Be careful not to use too much solder. Excess solder can cause a short circuit on the circuit board. Clip the excess wire off the capacitor leads. Bolt the circuit board back into the black box. Be careful to reinstall all spacers and insulators in the correct position. Carefully reinstall the SSOL in the starter making sure it is wired correctly.

NOTE: The F1-F2 terminals of the unmodified SSOL are <u>not</u> 115 VAC power inputs. XX1-X2 are the 115 VAC power inputs. The control voltage wiring in the starter, which is used to power the SSOL, may be labeled F1 and F2. These wires do not go to F1 and F2 in the SSOL, they go to XX1 and X2. The F1 and F2 terminals of the SSOL should be wired to the "Motor Overload" fault trip indicator. Follow the unit wiring diagram when reinstalling the module.

PARTS ORDERING INFORMATION:

All parts should be purchased locally.

NEW PRODUCTION:

CenTraVac starters (direct ship and unit mounted) shipped after July 1982, are equipped with the modified SSOL which eliminates the nuisance tripout.

SUBJECT: INSTALLATION OF THE DISTRIBUTION FAULT AUTOMATIC RESET OPTION USED ON CENTRIFUGAL UNITS

INTRODUCTION:

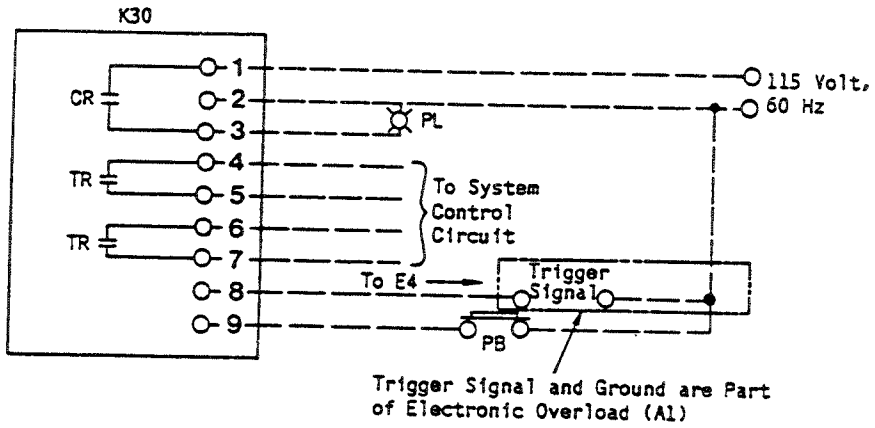
This service bulletin provides instructions for installing a distribution fault automatic reset option on centrifugal units that use the Cutler Hammer solid state overload. This option is designed to automatically restart the unit after line power has been restored following a power loss.

Also discussed is a possible nuisance condition with the timing relationship between the Model CVHE oil pump, the anti-recycle timer, and the distribution fault timing.

DISCUSSION:

This section explains the function of the standard distribution fault option and the need for automatic reset.

A distribution fault is defined as a loss of three-phase line voltage due to a distribution system failure. When a power failure occurs during unit operation, the solid state overload senses the immediate drop in line current while the starter remains energized. The overload responds by tripping the distribution fault breaker to stop unit operation. The breaker must be manually reset to restart the unit. Since some buildings require continuous cooling, it is not practical to manually reset the breaker every time the power is interrupted. To eliminate the manual reset, an automatic reset module can be installed to restart the unit within two minutes after the main supply power is restored.



Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Manual Reset Operation

As soon as line voltage is lost, a trigger voltage generated by the solid state overload (A1) is applied to Terminal 8 of the reset control. This 28 VDC signal causes the normally closed TR contacts (Terminals 4 to 5 and 6 to 7 of K30) to open. When these contacts open, the unit shuts down. Two minutes after the trigger voltage has disappeared and line voltage has been restored, the TR contacts will reclose, allowing restart of the unit, provided the 30-minute anti-recycle timer has timed out.

Simultaneously with the generation of the trigger signal, the CR contacts will close, applying power to Terminal 3 which activates a pilot light. This CR is a latching relay which means that the pilot light will remain energized as long as the 115 volt supply power is on. Closure of the push button contacts will reset this CR circuit and extinguish the pilot light. The push button may have to remain depressed for two or three seconds to allow the capacitor in the latching circuit to completely discharge. See Figure 1.

Figure 1
Automatic Reset Control
Wiring Connections

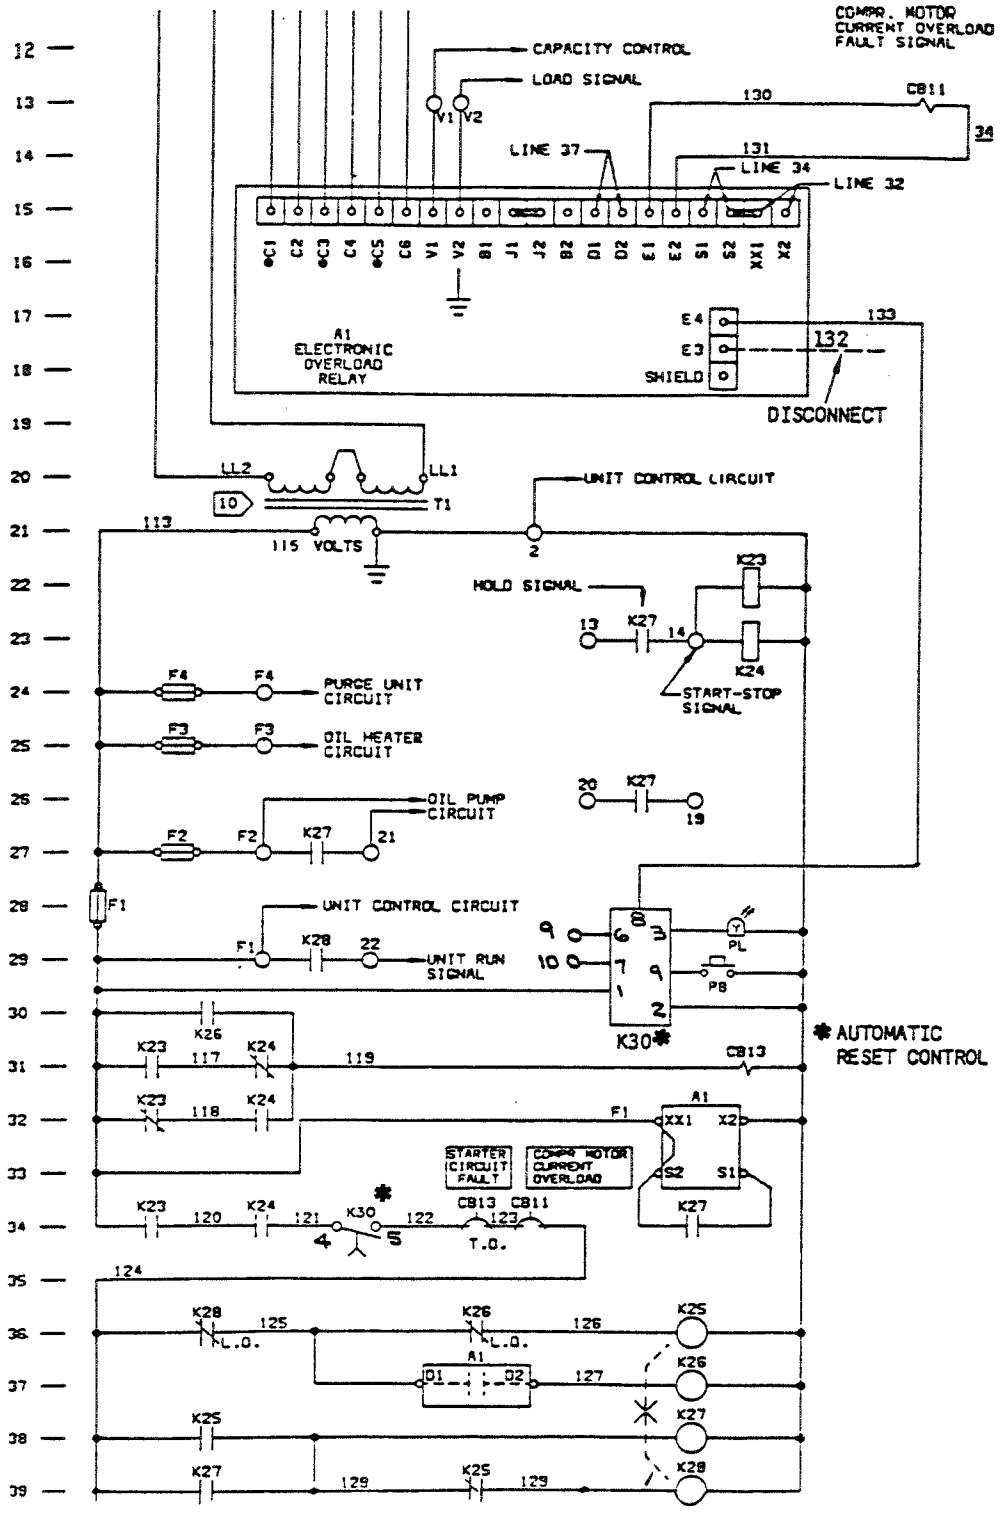
AUTOMATIC RESET INSTALLATION:

To install the automatic reset option, use the following procedure:

CVHE Control System

1. Remove the jumper from Terminals 9 and 10 of the unit control panel.

2. Connect the leads from Terminals 6 and 7 of the automatic reset control (K30) to Terminals 9 and 10. See Figure 2.



3. Disconnect wires 121, 122, 132 and 133 from the distribution fault circuit breaker (CB15) which is mounted on the starter panel door.

4. Remove CB15 from the starter panel door.

Figure 2
Typical Starter
Schematic Diagram

5. Mount the automatic reset control (K30) in an easily accessible location inside of the starter panel.

   To install the automatic reset control, two 3/16-inch diameter holes must be drilled as shown in Figure 3. Mount the control using two #8-32 screws with washers and nuts.

6. The push button pilot light assembly (PB/PL) should be mounted in the location that was occupied by CB15. A hole must be cut in the panel as shown in Figure 4. A ring is provided for mounting the assembly to the starter panel door.

   Figure 5 illustrates the push button pilot light assembly and Figure 6 shows the wiring connections for the assembly.

7. Wire the automatic reset control according to the schematic diagrams shown in Figures 2 and 7. Wires 121 and 133 that were removed from CB15 can be reused. Connect wire 121 to K30 (Terminal 4), wire 122 to K30 (Terminal 5) and wire 133 to K30 (Terminal 8). Additional 16 gauge wire may be required. Remove or insulate wire 132.

WARNING
DISCONNECT ELECTRICAL POWER SOURCE TO PREVENT INJURY OR DEATH FROM ELECTRICAL SHOCK

CAUTION
Use copper conductors only to prevent equipment damage

"A" and "B" Design Motor/Starter Protection System (MSPS)

1. Mount the automatic reset control (K30) in the upper right-hand corner of the MSPS. The mounting holes are pre-drilled on the "B" design MSPS.

2. Remove the knockout in the MSPS panel door and install the pilot light and push button switch. When the installation is complete, this light will indicate that automatic reset has occurred.

3. Run the two wires from the pilot light to terminals 2 and 3 of the automatic reset control.

4. Run one wire from the push button to the ground side of the pilot light. Run a second wire from the push button to terminal 9 on the automatic reset control.

5. Remove the jumper between terminals 2 and 2A on the MSPS. Run wires from terminals 2 and 2A to terminals 6 and 7 respectively on K30.

6. Disconnect the shielded wires E3 and E4 from the distribution fault circuit breaker (CB14). Reconnect wire E4 to terminal 8 of the automatic reset control (K30). Wire E3 is not needed, so it should be well insulated and tucked out of the way.

7. Run a 120 volt wire from terminal XX1 of the MSPS to terminal 1 of the automatic reset control.

8. Connect terminal 2 of the automatic reset control to terminal X2 of the MSPS.

Terminals 4 and 5 of the automatic reset control are not used. Refer to Figure 1 for wiring details.

Nuisance Tripping of the Low Oil Pressure Fault Indicator

Nuisance tripping of the low oil pressure fault indicator can occur due to improper timing between the automatic reset control, the anti-recycle timer and the oil pump timer of Model CVHE units. This condition can occur when unit attempts to restart after a distribution fault has occurred. The automatic restart control allows for a two minute delay after power has been restored, during which time the oil pump timer is in the post-lube timing cycle. If the anti-recycle timer has timed out, it will begin its normal timing cycle after the two minute lockout cycle of the automatic reset control. In some cases, the post-lube timing cycle of the oil pump timer is completed before the anti-recycle timer can initiate a restart. As the oil pump timer recycles, it interrupts the low oil fault indicator.

To insure that the automatic reset control does not interfere with the timing of the oil pump, the timing of the automatic reset control should be changed from two minutes to thirty seconds, which allows the start signal to be received before the oil pump timer has timed out.

To change the timing of the automatic reset control (Figure 8) to thirty seconds, remove the four cover screws and lift out the panel. The control components are located on the back side of the panel. Remove the resistor shown in Figure 9 and replace it with a 1/2-watt, 120K ohm resistor.

Literature Changes:

Added clarification that this bulletin only applies to "Version 1" and "Version 2" of the Cutler-Hammer SSOL.

Subject: CUTLER-HAMMER SOLID-STATE OVERLOAD (SSOL) UPGRADE

Introduction:

This service bulletin outlines several recommended changes and additions to "Version 1" and "Version 2" of the Cutler-Hammer solid-state overload ("SSOL"; Trane part no. RLY-765). Built from 1981 through December 1986, the affected SSOLs were used in CVHE, CVHB, CVAC and MSPS retrofit kit applications.

Note: By March 1st, 1987, 4 different versions of the Cutler-Hammer SSOL (electrically designated as "A1") will be available in the field. However, **only "Version 1" and "Version 2" are affected by the upgrade described in this bulletin since these improvements are completed by the factory on "Version 3" and "Version 4" of the SSOL!** To distinguish one version of the SSOL from another, look for the following identifying characteristics:

a. "Version 1". The original—and most familiar—version of the Cutler-Hammer SSOL was introduced in 1981 and manufactured until September 1986.

b. "Version 2". Built from September 1986 through December 1986, this variation of the SSOL is most readily identified by the "REV A" that appears on the front cover of the module. It can also be distinguished from Version 1 by comparing the p.c. board assemblies: Version 2 does not include the 50/60-Hz frequency adjustment switch, and all of the IC chips are soldered into place.

c. "Version 3". Identified by a "REV B" on the module's front cover, this SSOL variation is scheduled for production from January 1987 until March 1987, and includes these modifications: removal of the locked rotor potentiometer; a different transformer; removal of the J1-J2 jumper; and factory installation of the "new style" transition relay, MOV, capacitor and surge suppressor described in this bulletin.

d. "Version 4." Scheduled for initial production in March 1987, Version 4 of the SSOL will be known as the "AG-5". In addition to all of the modifications described for Version 3, the AG-5 includes a redesigned p.c. board. You will also notice that the terminal strip and acceleration time DIP switches are relocated to the outside of the SSOL module.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Discussion:

Testing and evaluation of "Versions 1 and 2" of the Cutler-Hammer solid-state overload module revealed areas where improvements can be made to increase reliability. The following sections discuss each of these areas in detail.

1. Intermittent Transition

The plug-in style transition relay originally provided in the overload module was an American Zettler Model AZ420-70-4HUS, while an AMF Potter-Brumfield Model R10-E1-X2 replacement relay was used for La Crosse service stock. Both of these relays have contacts made from a cadmium-oxide/silver-type material.

Cycle testing has shown that intermittent closures occasionally occur as a result of cadmium build-up between the surfaces of the relay contacts. A material specification change was made that requires the use of all-silver contacts in the transition relay.

2. Nuisance Tripping Due to Current Imbalance

The SSOL module senses the 3 current phases of the motor and converts them to a proportional DC voltage output at Terminals V1-V2. The resulting VDC signal is then used by the capacity control module to current-limit the chiller. When a significant amount of current imbalance exists in the system, the Cutler-Hammer SSOL may trip on the highest of the 3 current legs while the capacity control module is trying to current-limit based on the average. This type of nuisance trip only occurs when the unit's running load current is near 100%.

Installation of a capacitor wired in parallel with the current calibrator (Terminals B1-B2) in the SSOL will eliminate these nuisance trips.

3. Electrical Component Failures Due to Voltage Transients

High voltage spikes in the 120 VAC control circuit can cause SSOL module failure. This particular problem was discussed in Service Bulletin CVHE-SB-12A, which recommended field installation of a surge suppression device (metal oxide varistor, or "MOV") in the control circuit to protect the 120 VAC input portion of the overload module.

Further inspection of failed overload modules also verified that voltage transients can be introduced into the low voltage circuit (V1-V2) and cause the failure of operational amplifier Z1. This type of failure is usually the result of improper wiring in the V1-V2 circuit between the SSOL in the starter panel and the capacity control module in the chiller control panel. Remember that interconnecting wiring for V1-V2 must be 18 AWG, shielded wire. When properly installed, the shielding is only grounded at the starter panel.

Caution: Voltage from external sources may be induced into the V1-V2 circuit and damage the SSOL module if the wiring is improperly grounded.

Transient voltage suppression can be obtained with the addition of a bipolar surge suppressor---or "TRANS ZORB"---across the SSOL's V1-V2 terminals. The addition of this device is not only recommended for all installations without proper shielding, but can also be added to any installation with shielded wire for increased voltage-transient protection.

Note: Shielded cable was not used in some Trane-built, unit-mounted starters manufactured between January 1985 and January 1986. Be sure to review all succeeding installations of Model CVHE and CVHB units with free-standing starters to verify that the V1-V2 wiring conforms to the specifications outlined in this bulletin.

4. Electrostatic Discharge (ESD)

Because of the "metal oxide semiconductor" (MOS) component technology used in the construction of the SSOL module, the electronic components on the p.c. board are susceptible to damage caused by electrostatic---or "static" ---discharge. Static discharges are most often transmitted by a person touching the SSOL's electronic components or the p.c. board itself.

To prevent electrostatic discharges, always wear static control wrist straps (i.e., 3M Model 2071 wrist straps, or equivalent) whenever working inside the overload module.

Corrective Action:

When service is required on a unit with "Version 1" or "Version 2" of a Cutler-Hammer SSOL, be sure to complete the modifications described below.

1. Intermittent Transition. Install a new transition relay (RLY-849) in place of the existing relay.

After February 1st, 1986, all relays ordered from La Crosse service stock are the new style. The model number of the new-style transition relay is R10-E1-Y2 (Potter-Brumfield). ("Y2" indicates that the relay contact material is all silver, rather than cadmium-oxide/silver.) Be sure to check your office stock of RLY-849 to ensure that all relays are the new style.

2. Nuisance Tripping Due to Current Imbalance. Install an electrolytic capacitor (22 to 26 MFD, rated for 25 to 100 VDC) across SSOL Terminals B1-B2; Trane part no. CPT-335 is recommended for this application.

Wire this capacitor in parallel with the existing current calibrator in the SSOL module. Since CPT-335 is nonpolarized, it can be installed without regard to the polarity of Terminals B1-B2. However, if a locally-supplied capacitor is used, be sure to install it so that the positive (+) side is on Terminal B1 and the negative (-) side is on Terminal B2.

3. Electrical Component Failures Due to Voltage Transients. Install a metal oxide varistor---Trane part no. SPS-11---in the unit control panel if one is not already there; refer to Service Bulletin CVHE-SB-12A for installation details.

Then, wire a "TRANS ZORB"---Trane part no. SPS-14---between SSOL Terminals V1-V2 to protect the Z1 output operational amplifier in the low voltage circuit.

4. Electrostatic Discharge. Whenever the cover of the SSOL module is removed for service, static discharge must be avoided! Wear static-control wrist straps to eliminate any possibility of electrostatic discharge.

For further information on this product or other Trane products, refer to the "Trane Service Literature Catalog", ordering number IDX-IOM-1. This catalog contains listings and prices for all service literature sold by Trane. The catalog may be ordered by sending a $20.00 check to: The Trane Company, Service Literature Sales, 3600 Pammel Creek Road, La Crosse, WI 54601.

SUBJECT: NUISANCE "DISTRIBUTION FAULT" TRIPS FOLLOWING UNIT SHUTDOWN

INTRODUCTION:

Centrifugal units equipped with Cutler-Hammer solid-state overloads (SSOLs) may experience nuisance "distribution fault" trips when the starter de-energizes during the normal shutdown sequence. This service bulletin explains why these nuisance trips occur, and what can be done to prevent them.

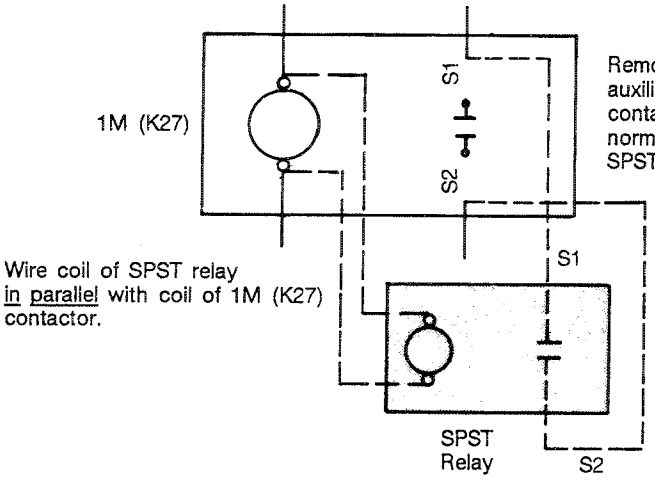
DISCUSSION:

To better understand why nuisance "distribution fault" trips occur, let's first review what a distribution fault is. "Distribution fault" is defined as the total loss of line voltage for a period lasting less than 60 electrical cycles. In this situation, the compressor motor remains on-line and acts as a generator; often, the motor is capable of generating enough voltage to allow the control circuit to remain energized for up to 1 second (i.e., 60 electrical cycles).

By contrast, during a normal shutdown (i.e., when the ON/OFF switch is adjusted to the OFF position), the compressor motor is instantly disconnected from the line. This simultaneously de-energizes the control circuit, dropping out all of its relays and contactors--and effectively eliminating the likelihood of a distribution fault trip.

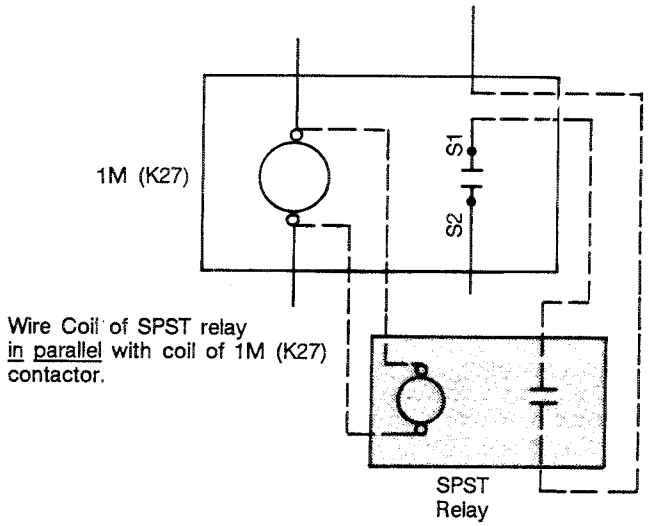
When a unit is protected by the Cutler-Hammer SSOL motor/starter protection system, existence of a distribution fault condition is detected within 1-1/2 electrical cycles; within 6 electrical cycles, the motor is off-line. SSOL recognition of a distribution fault is based on the status of the S1-S2 circuit (auxiliary on 1M) and motor amp draw: If the S1-S2 circuit remains closed while line current is less than 15% of RLA, a distribution fault exists.

In star-delta starter applications, this situation can occur if the 2M (K28) contactor opens, interrupting current to the motor, while a sluggish 1M (K27) contactor--or unresponsive auxiliary 1M contacts in the S1-S2 circuit--remains closed. As a result, the SSOL interprets what should be a normal, scheduled shutdown (i.e., one initiated with the unit ON/OFF switch) as a distribution fault, and trips the distribution fault indicator.



Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

CORRECTIVE ACTION:



Starter vendors interface their auxiliary contacts with the main contactor in a variety of ways. Depending on the method used, some auxiliary contacts can be adjusted to improve their responsiveness, while others are more easily changed out. In all situations where nuisance distribution fault trips are a problem, however, be sure to determine whether the presence of debris or corrosion is responsible for the sluggish reaction of the 1M (K27) contactor (or auxiliary contacts).

In the event that the 1M (K27) contactor is found to be in good condition--and neither adjustment nor replacement of the auxiliary contactor contacts eliminates the nuisance trip problem, wire a single-pole, single-throw relay into the distribution fault circuit. The addition of this relay ensures that the S1-S2 circuit opens as soon as the coil of the 1M (K27) contactor is de-energized (even though the auxiliary 1M contacts may still respond slowly).

Examples A and B illustrate two alternative methods for adding the SPST relay to the distribution fault circuit.

Subject: CUTLER-HAMMER SOLID-STATE OVERLOAD (SSOL; "A1") OPERATION, CALIBRATION AND TROUBLESHOOTING

Introduction:

This service bulletin describes the operation of the Cutler-Hammer solid-state overload module (electrically designated as "A1"), as well as appropriate procedures for SSOL calibration and trouble analysis. This module is provided in all current-production starter panels built to Trane specifications for CVHE and CVHB CenTraVacs (excluding those designed for use with the microcomputer-based UCP695 chiller control system).

It is important to note that by March 1st, 1987 4 different versions of the Cutler-Hammer solid-state overload (electrically designated as "A1") will be available in the field. Identifying characteristics that will enable you to distinguish one version from another are described below.

[ ] **"Version 1".** The original---and most familiar---version of the Cutler-Hammer SSOL was introduced in 1981 and manufactured until September 1986.

[ ] **"Version 2."** Built from September 1986 through December 1986, this variation of the SSOL is most readily identified by the "REV A" that appears on the front cover of the module. It can also be distinguished from Version 1 by comparing the printed circuit (p.c.) board assemblies: Version 2 does not include the 50/60-Hertz frequency adjustment switch, and all of the IC chips are soldered into place.

[ ] **"Version 3."** Identified by a "REV B" on the module's front cover, this SSOL variation is scheduled for production from January 1987 until March 1987, and includes these factory modifications:

a. removal of the locked rotor potentiometer;
b. a different transformer;
c. removal of the J1-J2 jumper;
d. a transition relay (RLY-849) with all-silver contacts; and,
e. factory-installation a metal oxide varistor (SPS-11), an electrolytic capacitor (CPT-335), and a TRANS ZORB surge suppressor (SPS-14). (Because these components are now installed at the factory, service bulletin CTV-SB-75---which describes field installation of these components---is not applicable.)

[ ] **"Version 4."** Scheduled for initial production in March 1987, Version 4 of the SSOL will be known as the "AG-5". In addition to all of the modifications described for Version 3, the AG-5 also includes these changes:

a. a redesigned p.c. board; and,
b. relocation of the terminal strip and acceleration time DIP switch to the outside of the SSOL module.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Discussion:

Following is a list of the SSOL's operational functions and features:

1. provides precise compressor motor overload protection;
2. protects against excessive locked rotor (inrush) current draw;
3. limits the length of time that inrush current is drawn;
4. protects the chiller from damage that could be caused by an electrical distribution fault;
5. initiates starter transition when compressor motor current drops to 85% of RLA;
6. provides a DC voltage signal that is proportional to the load;
7. can be adjusted to compensate for high line voltage; and,
8. can be adjusted for either 50- or 60-Hertz operation.

SSOL Calibration Procedure

WARNING: To prevent injury or death due to electrical shock, lock unit disconnect switch open before servicing SSOL module (A1).

The adjustments and calibration procedures itemized below---and detailed on the following pages of this bulletin---must be completed before the chiller is started. Remember to use a grounding strap whenever working on a SSOL module!

1. Adjust line frequency (SSOL Version 1 only).
2. Calibrate the motor overload resistor.
3. Adjust locked rotor current (SSOL Versions 1 and 2 only).
4. Set the maximum motor acceleration time.
5. Adjust for high-voltage compensation.

If the unit is equipped with the distribution fault function, the small circuit board mounted in the center of the SSOL must be tilted outward to calibrate the module. To move this circuit board out of the way, gently pull on the 2 black tabs located at the top of the board, and tilt it down on its hinges.

Note: To verify that the existing---or new---SSOL is operational, use Trane service tool TOL-90 to perform a functional checkout of the module. TOL-90 is available from Trane ServiceFirst, and is provided with operating instructions (TOL-OM-1). If you are using TOL-90 to test the module's integrity while it is still mounted in the starter panel:

a. remove the high voltage power supply from the starter panel;
b. connect a separate 115 VAC source to power up the SSOL; and,
c. disconnect the fuses on the primary side of the transformer.

Line Frequency Adjustment (SSOL Version 1 Only)

"Version 1" of the Cutler-Hammer SSOL module can be adapted to operate in either 50- or 60-Hertz electrical systems. To select the appropriate line frequency for a specific application:

1. Determine the line frequency of the installation. (Remember that all U.S. installations are 60 Hz.)

2. Position the SSOL's frequency adjustment switch at the appropriate setting. Refer to Figure 1 for the location of this switch on the SSOL's p.c. board; Figure 2 indicates the appropriate switch position for both 50 Hz and 60 Hz settings.

3. Check the appropriate box on the SSOL's nameplate (Figure 3) to record the line frequency switch setting selected in Step 2.

Note: Versions 2, 3 and 4 of the SSOL can also be used in 50-cycle applications. Though a specific line frequency adjustment is not necessary for any of these SSOL versions, the maximum acceleration time setting must be readjusted by multiplying the 60 Hz maximum acceleration time setting by "5/6". (For instance, if the maximum acceleration time setting is 30 seconds for a 60 Hz application, the corresponding 50 Hz setting is "30 x 5/6", or 25 seconds.)

Compressor Motor Overload Setup (SSOL Verions 1, 2, 3 and 4)

Compressor motor overload calibration is accomplished by adjusting the resistance of the current calibrator (shown in Figure 1). When the current calibrator is adjusted properly, the SSOL will trip at 107% of the compressor motor's RLA value. (This particular "trip" point prevents nuisance full-load lockouts, while still protecting the compressor motor from potentially damaging overloads.)

Follow the instructions outlined below to correctly set the SSOL's current calibrator:

1. Determine the chiller's RLA value and current transformer ratio; be sure to consider the conditions described below when arriving at these values:

a. If the job site voltage is equal to---or lower than---the specified voltage rating stamped on the chiller nameplate, base the current calibrator setting on the nameplate RLA value. However, if the actual voltage is higher than the specified voltage, refer to the instructions provided under "High Voltage Compensation" later in this bulletin.

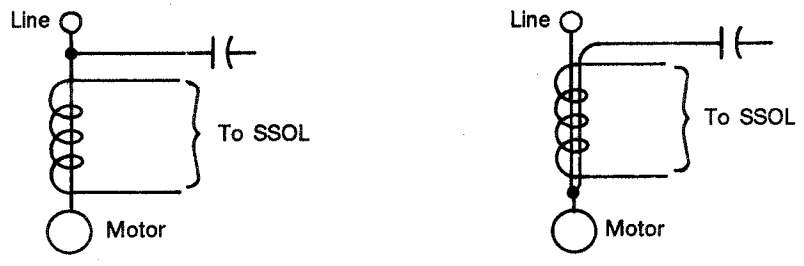
b. If the chiller is equipped with power factor correction capacitors (PFCCs) that are connected to the load side of the overload current transformers, the RLA value shown on the unit nameplate must be recalculated in order to correctly set the current calibrator.

This "adjusted" RLA value is already calculated for those units with factory-installed PFCCs, and it is marked on the cover of the solid-state overload (SSOL).

To determine the "adjusted" RLA value for other units, run the unit at full load; then take amperage readings on the load and line sides of the capacitor terminal points. Multiply the line-to-load-side ratio of these amp readings by the nameplate RLA to arrive at an "adjusted" RLA value.

Example

100 amps = Motor Rating (RLA Value) from Nameplate
84 amps = Line-Side Current Reading
92 amps = Load-Side Current Reading



$$\text{Nameplate RLA} \times \frac{\text{Line-Side Current}}{\text{Load-Side Current}} = \text{"Adjusted" RLA}$$

$$100 \text{ amps} \times \frac{84 \text{ amps}}{92 \text{ amps}} = 91.3, \text{ or } 91 \text{ amps}$$

If the PFCCs are connected on the line side of the SSOL current transformers---or if the capacitor leads are run through the current transformers with the motor leads (Figure 4), do not recalculate compressor RLA; use the RLA value stamped on the chiller nameplate to establish the current calibrator setting.

Note: For additional information and recommendations regarding field additions of power factor correction capacitors, refer to Trane Engineering Bulletin EB-CTV-44. Remember, too, that the PFCCs must be installed on Leads T1, T2 and T3---not on Leads T4, T5 and T6!

Figure 4
Current Transformers

2. Once the appropriate RLA value is determined (Step 1), calculate the rated load secondary current ("Isec") using 1 of the two methods described below. Notice that the calculation method selected---and the resulting Isec value---are dependent on the location of the current transformers (CTs).

a. CTs Monitoring Line Current. If the CTs are located to monitor line current, determine the Isec value by dividing the appropriate RLA value by the CT ratio.

Example
RLA Value = 91 amps
CT Ratio = 100:5 (or 20)

$$\frac{\text{RLA}}{\text{CT Ratio}} = \text{Isec}$$

$$\frac{91 \text{ amps}}{20} = 4.55$$

b. CTs Monitoring Phase Current. If the CTs in a wye-delta starter are positioned to monitor phase current, the Isec value is calculated by dividing the appropriate RLA value by the CT ratio, and then multiplying the result by 0.58.

Example
RLA Value = 91 amps
CT Ratio = 100:5 (or 20)

$$\frac{\text{RLA}}{\text{CT Ratio}} \times 0.58 = \text{Isec}$$

$$\frac{91 \text{ amps}}{20} \times 0.58 = 2.639, \text{ or } 2.64$$

Note: Where donut-type CTs are used, the wires routed through them are sometimes wrapped around and passed through the CTs more than once; this alters the "actual" CT ratio. To determine the CT ratio in this situation, divide the CT ratio by the number of times that the wire passes through the CT; in other words, the "actual" ratio for a 200:5 CT with a wire passed through it twice is 100:5.

3. Using Table 1 and the rated load secondary current ("Isec") value calculated in Step 2, determine the appropriate current calibrator and its potentiometer setting.

For example, if the "Isec" value is 4.55, the correct current calibrator is H818 and the potentiometer should be adjusted to 82.6 ohms; this adjustment will result in an overload trip point that is 107% of the nameplate RLA.

4. To adjust the current calibrator to the setting determined in Step 3, remove it from the SSOL module. Use a digital ohmmeter with a minimum accuracy of 3-1/2 places to obtain the desired resistance setting.

5. Return the current calibrator to the SSOL module. Be sure to record the calibrator number and setting on the SSOL nameplate.

Locked Rotor Current Lockout Adjustment (SSOL Versions 1 and 2 Only)

The SSOL is designed to protect the compressor motor from excessive LRA current draw during start-up by tripping the motor overload circuit breaker any time the set LRA is exceeded. Remember that the LRA current trip point value depends on the type of starter used with the CenTraVac compressor motor. It is set with the "LRA Setpoint" potentiometer found near the lower right-hand corner of the SSOL p.c. board. (See Figure 1.)

To properly set the LRA setpoint potentiometer:

1. Insert a screwdriver in the potentiometer adjusting slot; then turn the pot to the fully-counterclockwise (CCW) stop to establish a reference point.

2. Refer to Figure 5; then rotate the pot clockwise (CW) to the position that corresponds to the type of compressor motor starter used.

Note: The LRA setpoint pot positions illustrated in Figure 5 represent approximate settings for various starter types. To calculate a specific potentiometer setting, see Step 5.

Figure 5
LRA Setpoint Potentiometer Settings for Various Starter Types

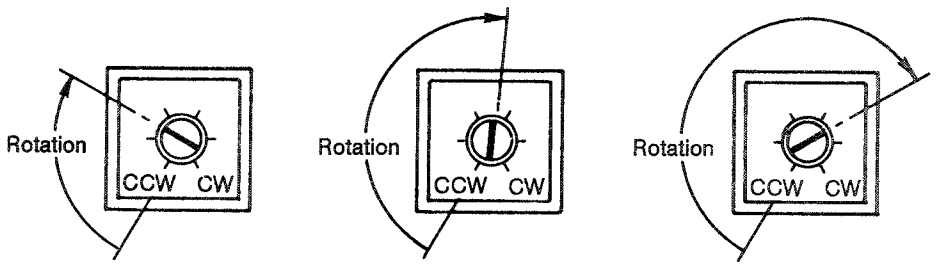


Table 1
Current Calibrator Settings

I.D. No. on Current Calibrator	Isec Ampere Rating		Current Calibrator "Pot" Setting (Resistance)	I.D. No. on Current Calibrator	Isec Ampere Rating		Current Calibrator "Pot" Setting (Resistance)
	Minimum	Maximum			Minimum	Maximum	
H816	2.01	2.05	185.0 ohms	H818	3.66	3.70	102.0 ohms
	2.06	2.10	180.0 ohms		3.71	3.75	101.0 ohms
	2.11	2.15	176.0 ohms		3.76	3.80	99.2 ohms
	2.16	2.20	172.0 ohms		3.81	3.85	97.9 ohms
	2.21	2.25	168.0 ohms		3.86	3.90	96.6 ohms
	2.26	2.30	165.0 ohms		3.91	3.95	95.4 ohms
	2.31	2.35	161.0 ohms		3.96	4.00	94.2 ohms
	2.36	2.40	158.0 ohms		4.01	4.05	93.0 ohms

H817	2.51	2.55	148.0 ohms		4.16	4.20	89.6 ohms
	2.56	2.60	146.0 ohms		4.21	4.25	88.5 ohms
	2.61	2.65	143.0 ohms		4.26	4.30	87.5 ohms
	2.66	2.70	140.0 ohms		4.31	4.35	86.5 ohms
	2.71	2.75	138.0 ohms		4.36	4.40	85.5 ohms
	2.76	2.80	135.0 ohms		4.41	4.45	84.5 ohms
	2.81	2.85	133.0 ohms		4.46	4.50	83.5 ohms
	2.86	2.90	130.0 ohms		4.51	4.55	82.6 ohms
	2.91	2.95	128.0 ohms		4.56	4.60	81.7 ohms
	2.96	3.00	126.0 ohms		4.61	4.65	80.8 ohms
	3.01	3.05	124.0 ohms		4.66	4.70	79.9 ohms
	3.06	3.10	122.0 ohms		4.71	4.75	79.1 ohms
	3.11	3.15	120.0 ohms		4.76	4.80	78.2 ohms
	3.16	3.20	118.0 ohms		4.81	4.85	77.4 ohms
	3.21	3.25	116.0 ohms		4.86	4.90	76.6 ohms
	3.26	3.30	114.0 ohms		4.91	4.95	75.8 ohms
	3.31	3.35	113.0 ohms		4.96	5.00	75.1 ohms
	3.36	3.40	111.0 ohms				
	3.41	3.45	109.0 ohms				
	3.46	3.50	108.0 ohms				
	3.51	3.55	106.0 ohms				
	3.56	3.60	105.0 ohms				
	3.61	3.65	103.0 ohms				

3. Initiate the chiller start sequence. If the motor overload circuit breaker trips as soon as (within 1 second) the starter energizes, the LRA current trip point may need to be set higher. (This will not harm the operation of the SSOL module or the compressor motor.)

4. Record the LRA and RLA values from the chiller nameplate on the SSOL's nameplate.

5. Use the following procedure to calculate the "RATIO _____%" value; then record this value on the SSOL nameplate.

$$\text{Ratio \%} = \frac{\text{Motor LRA*}}{\text{Motor RLA}} \times 100\% ,$$

*where LRA (locked rotor amperes) is the reduced value determined by starter type. See Table 2.

Example

Motor LRA = 200 amps
Motor RLA = 100 amps

$$\text{Ratio \%} = \frac{200 \text{ amps}}{100 \text{ amps}} \times 100\% = 200\%$$

Maximum Acceleration Time Setup (SSOL Versions 1, 2, 3 and 4)

Designed to limit the time allowed for transition to occur, the SSOL trips—and shuts down the unit—whenever the compressor motor fails to transition within the time period established with maximum acceleration time switches (Figure 1). This prevents the motor from drawing LRA for an excessive period of time which, in turn, prevents the motor from overheating.

To set the maximum acceleration time switches properly:

1. Determine the appropriate maximum acceleration time—between 1 and 63 seconds—for the unit; refer to Table 3 for typical settings by starter type.

Keep in mind that the type of unit and starter, as well as job site conditions, will determine how much the actual maximum acceleration time setting varies from the typical settings shown in Table 3.

2. Locate the maximum acceleration time DIP switches on the SSOL p.c. board; refer to Figures 1 and 6. Notice that each DIP switch represents a specific number of seconds (e.g., DIP switch no. 1 is 32 seconds, no. 2 is 16 seconds, etc.). Determine what DIP switch "seconds" values can be added to yield the maximum acceleration time found in Step 1; then flip these DIP switches to the ON position. (For instance, if the desired maximum acceleration time setting is 27 seconds, flip DIP switch nos. 2, 3, 5 and 6 to ON.)

Note: If none of the DIP switches is set at ON, the unit will not start. (The SSOL will not allow any time for motor acceleration in this situation, so the motor overload circuit breaker trips as soon as a start-up is attempted.)

3. Record the maximum acceleration time setting on the SSOL nameplate.

For 50 Hz Applications w/SSOL Versions 2, 3 or 4. When determining the appropriate maximum acceleration time, remember to compensate for the difference in line frequency. Multiply the appropriate 60 Hz maximum acceleration time by "5/6" to arrive at the proper setting for 50 Hz applications. (For instance, if the maximum acceleration time setting is 30 seconds for a 60 Hz application, the corresponding 50 Hz setting is "30 x 5/6", or 25 seconds.)

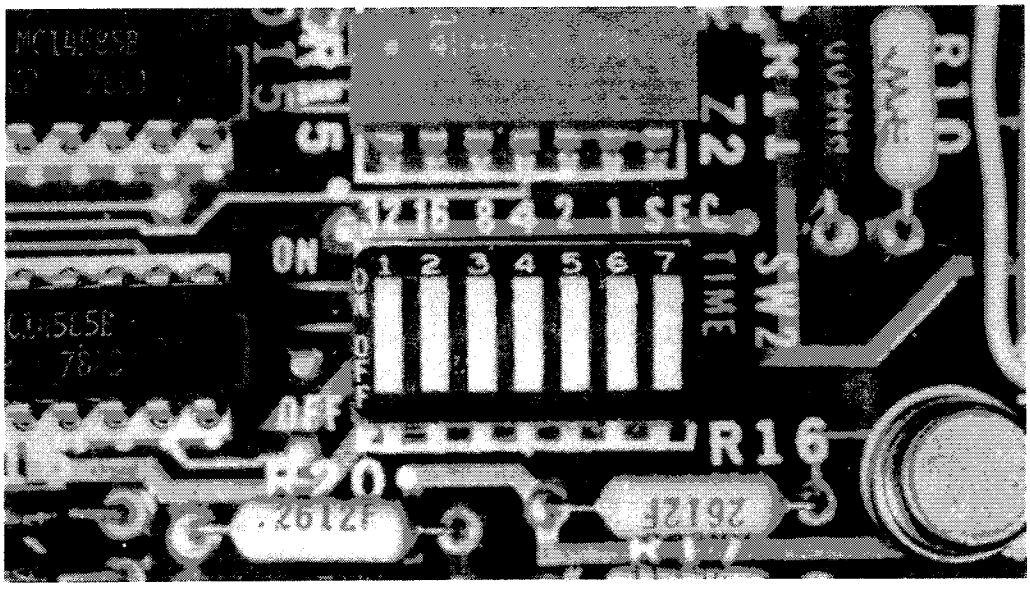

Table 2
Starting Characteristics of Various Types of Motor Starters

Starter Type	Starting Characteristics--- % of Rated Value			
	% Tap	Motor Voltage	Motor LRA	Motor Torque
Full-Voltage Type				
Magnetic, Across-the-Line	n/a	100%	100%	100%
Reduced Voltage Types				
Auto-Transformer	80%	80%	64%	64%
	65%	65%	42%	42%
	50%	50%	25%	25%
Primary Reactor	80%	80%	80%	64%
	65%	65%	65%	42%
	50%	50%	50%	25%
Reduced Inrush Types				
Wye-Delta	n/a	100%	33%	33%
Open- or Closed-Transition	n/a	100%	33%	33%

Table 3
Typical Maximum Acceleration Time Settings

Starter Type	Recommended Max. Acceleration Time Setting
Wye-Delta	27 seconds
Auto-Transformer	16 seconds
Across-the-Line	6 seconds

Figure 6
Maximum Acceleration Time DIP Switches

Example
12 seconds = 8 seconds + 4 seconds; therefore, flip DIP switch nos. 3 and 4 to ON.

High-Voltage Compensation Adjustment (SSOL Versions 1, 2, 3 and 4)

While the RLA value shown in the chiller nameplate represents the design nominal voltage, actual job-site voltage often varies from this value. Therefore, it is possible that a higher-than-nominal line voltage condition will cause the motor to generate excessive horsepower without exceeding the current draw shown on the nameplate.

To prevent motor overloading resulting from higher-than-rated voltage, recalibrate the SSOL module in 1 of 2 ways:

[ ] SSOL Versions 1 and 2 Only. Remove the 10% current reset jumper from Terminals J1-J2 in the SSOL (Figure 1); removal of this jumper automatically recalibrates the SSOL so that approximately 90% of the motor nameplate current rating is the new "rated" current for that application.

Note: SSOL setup does not change if the J1-J2 jumper is removed since all SSOL functions are automatically recalibrated.

[ ] SSOL Versions 1 thru 4. Reset the current calibrator. To arrive at a new current calibrator setting, multiply the Isec. value (calculated in "Compressor Motor Overload Setup") by the ratio of the rated line voltage to the actual line voltage.

$$\text{"New" Isec} = \text{Original Isec} \times \frac{\text{Rated Line Voltage}}{\text{Actual Line Voltage}}$$

Example

Original Isec = 4.55
Rated Line Voltage = 460V
Actual Line Voltage = 485V

$$\text{"New" Isec} = 4.55 \times \frac{460V}{485V} = 4.32$$

Using the "new" Isec value, the current calibrator number and Table 1, determine appropriate potentiometer setting; then readjust the pot to this value. (Remember that readjusting the current calibrator not only compensates for the high-voltage condition, but also recalibrates all other SSOL functions.)

* * * * * * *

Note: Whenever the SSOL is recalibrated for high voltage---whether by removing the J1-J2 jumper or by readusting the current calibrator, turn the LRA potentiometer 1 dial setting higher than that indicated in Figure 5 to prevent nuisance "trips" at start-up (since higher-than-nameplate LRA current draw will occur). Also, be sure to record the method---and reason for---high -voltage compensation on the cover of the SSOL module!

Dry-Running Starters w/SSOL Modules

Starter panels equipped with the SSOL module can be dry-run at start-up in the same manner as starters without the SSOL. However, 2 important differences must be noted:

1. The distribution-fault circuit breaker must be disconnected before the starter can be dry run. To disconnect the distribution-fault circuit breaker, simply remove a wire from it. If the breaker is not disconnected, the starter will not sequence, and the SSOL module will lock out on distribution fault as soon as the start sequence begins. (Lockout occurs because the distribution fault trip is initiated when motor current drops below 15% of the RLA with the M1 contactor energized; see "Distribution-Fault Circuit Breaker Operation". This situation will only occur during an actual distribution fault or during a starter dry-run.)

2. The starter will transition as soon as the dry-run is initiated. This immediate transition occurs because the SSOL initiates transition on the basis of motor current draw. During a normal start-up, motor current draw falls from the LRA value to one that is below the RLA because the inlet vanes are closed; when motor current draw falls to 85% of RLA during the start sequence, the SSOL initiates transition.

However, during a dry run, there is no current draw so the SSOL initiates transition immediately (within 1 second).

Note: The starter dry-run procedure is a good way to test the SSOL's distribution fault function; if it is working properly, the distribution-fault circuit breaker will trip as soon as the start sequence is initiated (provided that the breaker was not disconnected).

Operation of the Distribution-Fault Circuit Breaker

"Distribution fault" is defined as the total loss of line voltage for a period lasting less than 60 electrical cycles. This type of short-duration power interruption can be damaging to many types of induction-motor-driven equipment since an induction motor acts as a generator for several seconds after power is disconnected. The voltage generated by a water-cooled CenTraVac motor, for instance, is often sufficient to "hold in" control relays and starter contactors for approximately 60 electrical cycles---or 1 second---when a voltage-loss occurs.

If line voltage is re-established while the contactors are held in by motor-generated voltage---and the two voltages are out of phase, motor torques that are 6 to 10 times greater than the normal running torques can occur. These torques occur as the motor is pulled into phase and may be in either direction (forward or reverse). Such excessive torques severely overload the impeller hub area and may, in turn, upset the impeller keyway or---in severe cases---crack or destroy the impellers.

SSOL modules detect a distribution fault by monitoring current draw and the status of the M1 contactor. The distribution-fault circuit breaker is designed to trip when motor current draw is less than 15% of RLA while the M1 contactor is energized. The SSOL detects the existence of a distribution fault within 1-1/2 electrical cycles, and---within 6 cycles (1/10 of a second) ---trips the distribution-fault circuit breaker to take the compressor motor off line.

Normally, this situation will only occur during an actual distribution fault (or during a starter dry run) since: (a) an induction motor will typically draw more than 15% of RLA---even when completely unloaded, and (b) when the M1 contactor is energized, the motor is running.

Troubleshooting the SSOL

Note: The information presented in the following troubleshooting chart is only applicable for the SSOL; use of this chart alone will not verify the integrity of other starter panel components.

SSOL Troubleshooting Chart

Symptom	Recommended Action
Distribution-fault circuit breaker trips . . .	
1. while the chiller is running.	1. If this fault becomes a nuisance problem, use TOL-90 and the checkout procedures described in TOL-OM-1 to verify that the SSOL is functioning properly. If the results of this checkout indicate that the SSOL is defective, replace it.
2. during the start sequence, at the point when transition should occur.	2. Check for: a. installation of power-factor correction capacitors (PFCCs) on the start contactor (K27, or "1M"). If the PFCCs were incorrectly wired to the run contactor (K28, or "2M") instead of K27, the PFCCs will be placed in parallel at start-up, and the change in capacitance could drive the available current down to 15% of RLA. b. bouncing contacts---especially the auxiliary contacts on the starter contactors.
3. when the starter de-energizes during the normal chiller shutdown sequence.	3. This symptom is usually <u>not</u> the result of a SSOL problem; see service bulletin CTV-SB-76 for corrective action. However, if the suggestions described in CTV-SB-76 do not eliminate this problem, replace the SSOL.
Motor-current-overload circuit breaker trips . . .	
1. at start-up.	1. Check the: a. locked rotor setpoint potentiometer to make sure that it isn't turned too low. To properly set this pot, follow the instructions under "Locked Rotor Current Lockout Adjustment" in this bulletin. **Note:** The locked rotor setpoint pot is <u>only</u> found on Versions 1 and 2 of the SSOL. b. acceleration time setting. See "Maximum Acceleration Time Setup" in this bulletin. c. SSOL with TOL-90 and the instructions provided in TOL-OM-1. If this check indicates that the SSOL is defective, replace it.
2. at transition.	2. Check the SSOL module's terminal strip; <u>if Terminals 5 and 6 are labeled "F1" and "F2"</u>, complete the corrective action described in service bulletin CTV-SB-65.

(Continued on next page . . . . .)

SSOL Troubleshooting Chart (concluded)

Symptom	Recommended Action
Motor-current-overload circuit breaker trips . . . (continued)	
3. immediately after chiller loads up.	3. Check the: a. polarity of the V1-V2 wires connected to the capacity control module in the chiller control panel. b. voltage at V1-V2 in the SSOL. If the voltage measured at V1---with respect to V2---is positive, replace the SSOL.
4. at a value less than 100% of RLA.	4. Check: a. the balance of the 3-phase current. It may be necessary to add the electrolytic capacitor (CPT-335) described in CTV-SB-75. **Note:** The check just described in 4a is only applicable for SSOL Versions 1 and 2. b. for phase loss or phase reversal at the SSOL. To do this, connect the positive (+) lead of an oscilloscope to SSOL Terminal B1 and the negative (-) lead to Terminal B2. The oscilloscope should display a normal sine wave, as shown in Figure 7. If 1 phase is missing, the sine wave will appear as shown in Figure 8; Figure 9 shows the the type of sine wave produced if 1 phase is reversed.
Chiller does not transition.	1. Check for closure of the auxiliary K27 contacts in the SSOL's S1-S2 circuit. 2. Use TOL-90 to perform the "transition level" functional test described in TOL-OM-1. If test results verify that the transition relay on the SSOL is "pulling in", use an ohmmeter to check for closure of the transition relay contacts. If these contacts fail to close, replace the SSOL's transition relay (RLY-849).
Chiller transitions as soon as the start sequence is initiated.	1. Check the 3-phase current signals with an oscilloscope; see Item 4b under "Recommended Action" above. 2. Use TOL-90 and the checkout procedures described in TOL-OM-1 to check SSOL operation. If test results indicate that the SSOL is defective, replace it.

SUBJECT: CVHE/CVHB MOTOR OVERLOAD MODULE PROTECTION

INTRODUCTION:

This service bulletin discusses the addition of a surge suppressor across the power supply of CVHE and CVHB solid state motor overload modules. The addition of the suppressor is recommended to provide protection from high voltage spikes which can lead to module failures.

DISCUSSION:

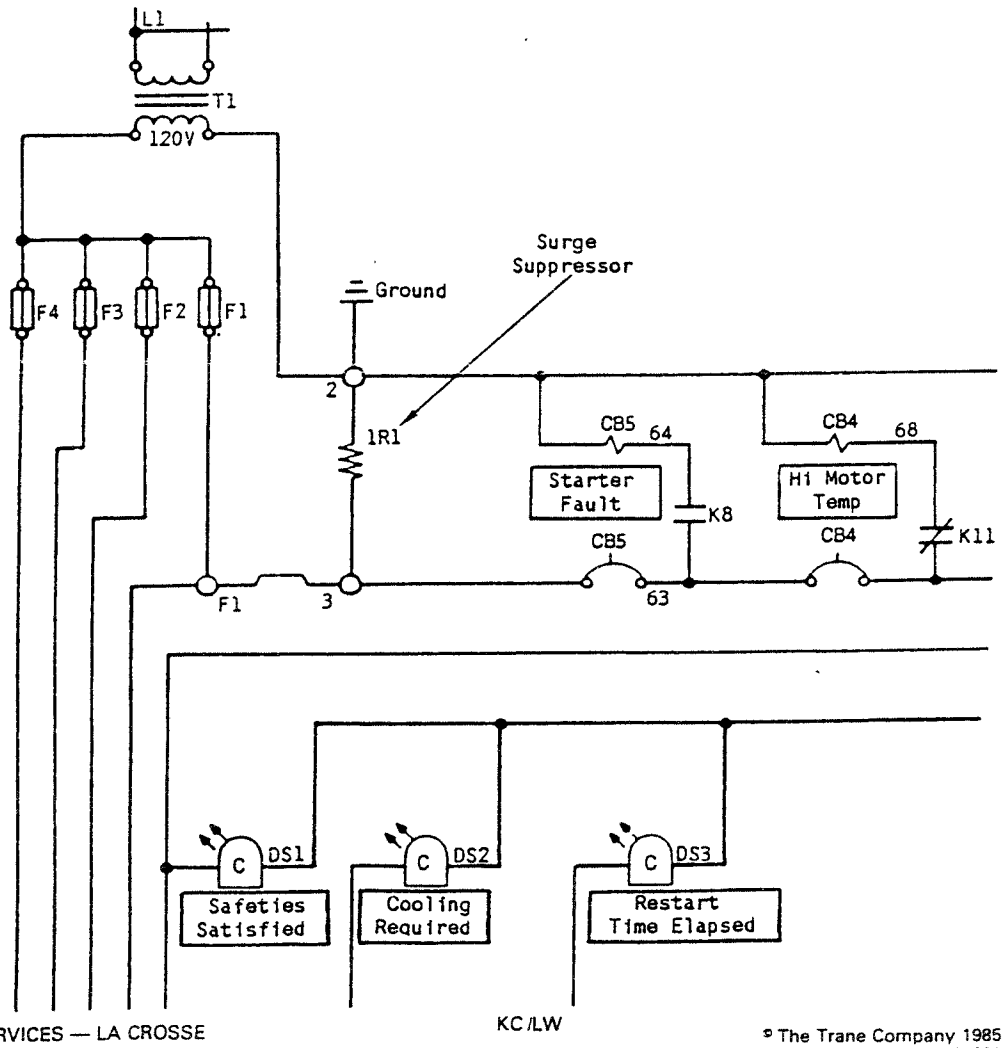
A number of Cutler-Hammer overload modules (Trane part number RLY-765) that have been returned as failed, appear to have been exposed to a high voltage condition. This high voltage could have been caused by inadvertent application of 110 volts through the low voltage side of the module or through transient line voltage spikes which can enter the module through its power supply. The module can be protected from these voltage spikes by the addition of a surge suppression device that connects to the module power supply. These devices are generally referred to as MOV's (metal oxide varistors).

CORRECTIVE ACTION:

Surge suppressors should be installed on all CVHE and CVHB units with solid state overload modules at unit start-up. Units which are being retrofitted to add the new solid state motor protection module should also have the suppressor added. Units that are already started should have the surge suppressor added on an opportunity basis such as a service call or annual maintenance.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Install a surge suppressor in the unit control panel across terminals 2 and 3 as shown in Figure 1. The suppressor (MOV) should have the following values:



- Maximum RMS volts -150
- Maximum energy rating - 80 joules
- Average power dissipation - 1 watt
- Peak pulse amps - 6,500

A surge suppressor can only protect against high voltage surges that do not exceed its design rating. Voltage surges in excess of this rating will cause the suppressor to fail. A failed surge suppressor is evident due to its almost total physical destruction. Failure of the suppressor will not interfere with the operation of the unit control system. Periodic inspection of the suppressor should be included with other normal maintenance procedures.

PARTS ORDERING INFORMATION:

The part number for the surge suppressor is SPS-11.

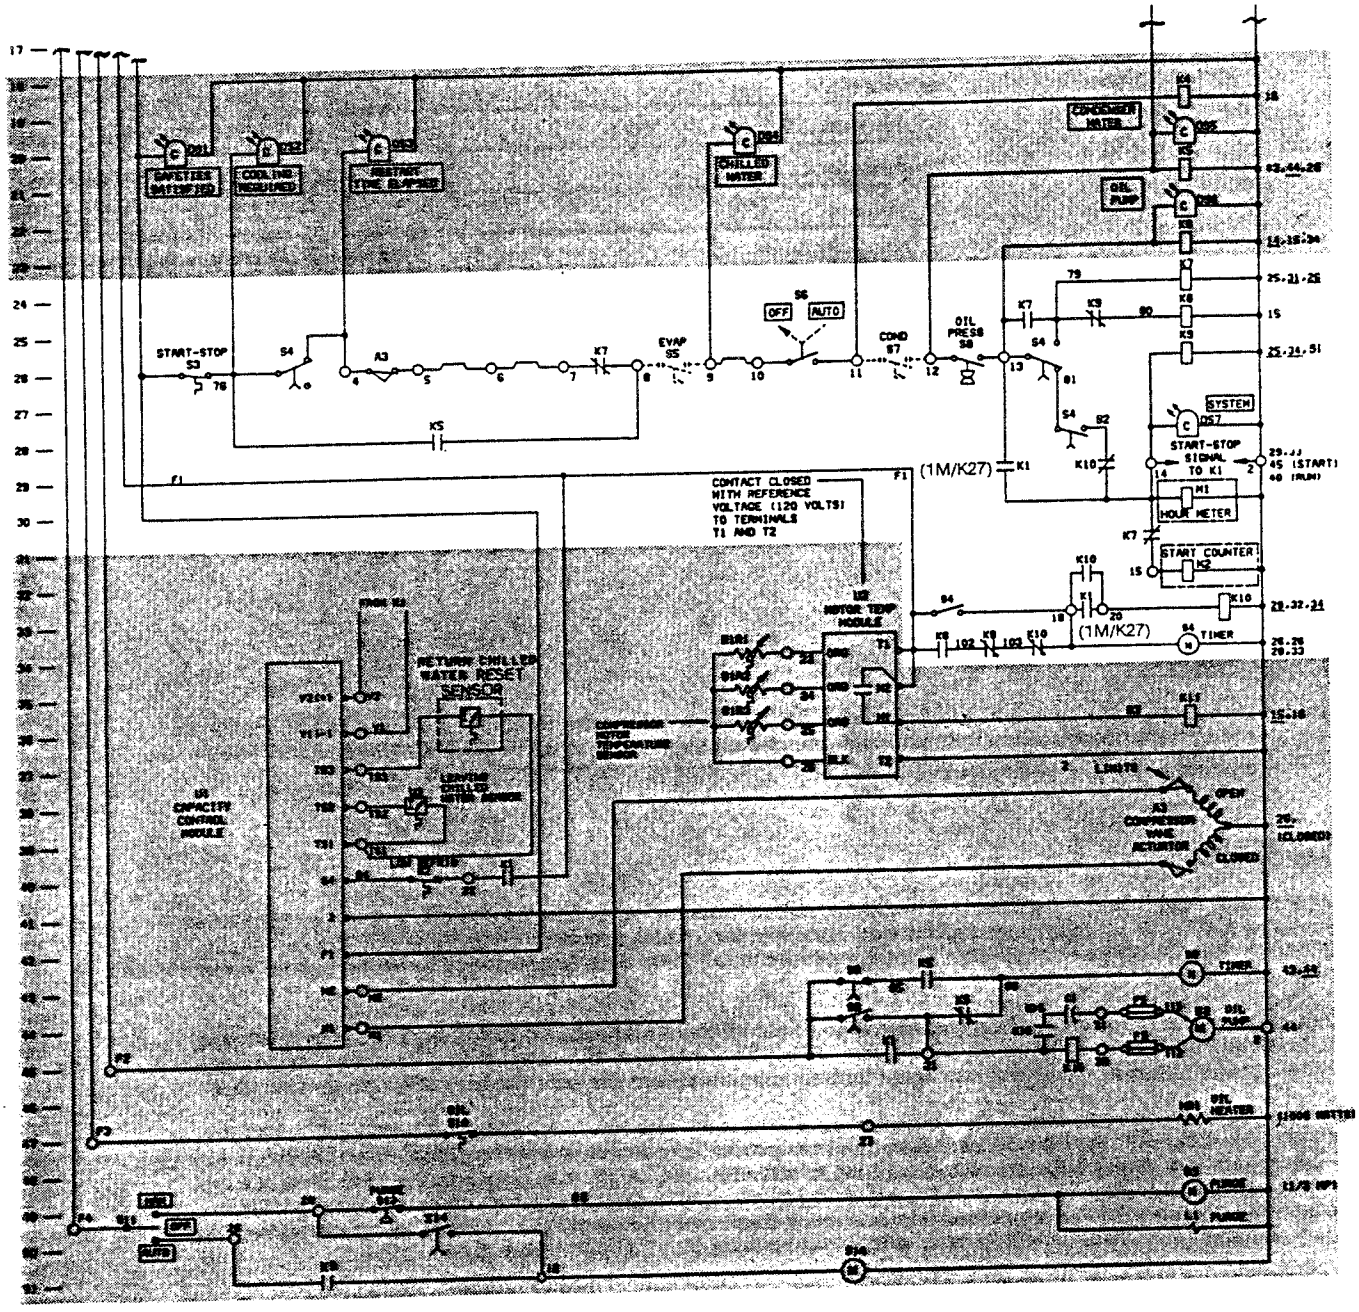
SUBJECT: "STARTER-FAULT" BREAKER/K10 RELAY RACE (CVHEs OF "A" THRU "J" DESIGNS)

INTRODUCTION:

Nuisance tripping of the unit control panel's "starter-fault" circuit breaker may occur in CVHEs of "A" through "J" design as a result of a "relay race" between the K10 relay and the auxiliary contacts on the 1M (K27) contactor. This service bulletin discusses why these nuisance trips occur, as well as what can be done to prevent them.

DISCUSSION:



Ordinarily, a normal "start" signal from Terminal 14 of the unit control panel energizes the 1M (K27) contactor which, in turn, closes 2 sets of normally-open auxiliary contacts. (Refer to the typical electrical schematic in Figure 1.) The auxiliary contacts located between Wires 13 and 14 (Lines 26 and 29) close first, followed by those located between Wires 19 and 20 (Line 33).

Notice that closure of the auxiliary contacts between Wires 13 and 14 establishes a "holding" circuit for the "start" signal before the contacts between Wires 19 and 20 can close. This sequence of events assures that the "start" signal is not interrupted when the K10 relay energizes and opens its normally-closed contacts between Wires 82 and 14 (Line 29).

Let's look at what would happen if the contact closure sequence were reversed. Once the inhibit circuit (Line 26) is satisfied (i.e., evaporator and condenser water flows are proven, and oil pressure is established), a "start" signal is sent to the starter panel through the normally-closed set of K10 contacts. If the K10 relay energizes (via closure of the auxiliary contacts between Wires 19 and 20) before the "holding" circuit is established, the starter energizes–but only momentarily. As soon as the normally-closed K10 contacts between Wires 82 and 14 open, the starter panel drops out of the circuit, and the unit control panel's "starter fault" circuit breaker trips 15 to 20 seconds later.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

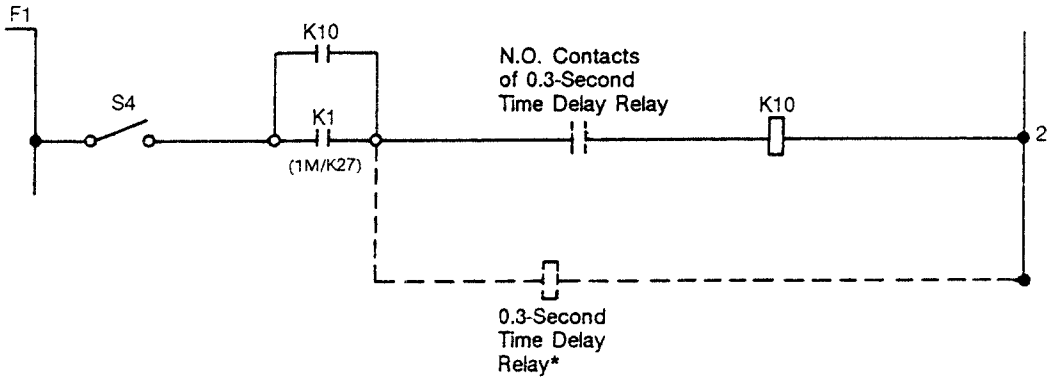
CORRECTIVE ACTION:

Following are 2 solutions designed to eliminate nuisance "starter fault" circuit breaker trips caused by a "relay race" between the K10 relay and the 1M (K27) contactor:

1. Establish the correct wiring sequence for Wires 13 and 14, and Wires 19 and 20.

Ensure that Wires 13 and 14 are connected to a set of normally-open, auxiliary contacts on the 1M (K27) contactor; contacts selected for this purpose should be located as close to the auxiliary-contact actuator as possible (i.e., the auxiliary switch located nearest the starter back panel). Then, connect Wires 19 and 20 to a set of normally-open auxiliary contacts located farther out on the auxiliary contact stack.

This wiring arrangement encourages establishment of the "holding" circuit before the normally-closed contacts of the K10 relay can open.



Note: The corrective action recommended above will successfully eliminate nuisance "starter fault" circuit breaker trips in most instances. However, if adjustments to the wiring sequence of Wires 13-14 and Wires 19-20 do not prevent this type of nuisance trip from recurring, it may be necessary to install a time delay relay. See Item 2 below for instructions.

2. Add a 0.3-second time delay relay to the K10 relay circuit.

Connect the normally-open contacts of 0.3-second time delay relay in series with the K10 relay; make sure that the contacts of the time delay relay are installed upstream of the K10 relay coil. Figure 2 illustrates this wiring arrangement.

The addition of this relay postpones the energizing of the K10 relay by 0.3 seconds, thereby assuring that the start signal "holding" circuit is established before the normally-closed K10 contacts open.

Figure 2
Addition of a 0.3-Second Time Delay Relay to the K10 Relay Circuit

*The 0.3-second time delay relay typically used for this purpose is RLY-872.

For further information on this product or other Trane products, refer to the "Trane Service Literature Catalog", ordering number IDX-IOM-1. This catalog contains listings and prices for all service literature sold by Trane. The catalog may be ordered by sending a $20.00 check to: The Trane Company, Service Literature Sales, 3600 Pammel Creek Road, La Crosse, WI 54601.

INTRODUCTION

This manual explains how to properly use TOL-91 to check the operating condition of the Trane AGM or Honeywell 901-D capacity control module in the field or at the shop. Be sure to follow these instructions carefully to ensure an accurate diagnosis of the control module's condition, and to avoid damaging either the module or the tester. Illustrations of the AGM capacity control module and TOL-91 are provided in Figures 1 and 2.

NOTE: While the copy and illustrations in this manual relate specifically to the AGM capacity control module used on CVHE and CVHB units, the same test procedure can be used to test the Honeywell 901-D module used on CVAC units. Any differences between the test procedures for these two types of modules are explained in the instructions.

CONTROL PANEL SIDE

BACK OF CONTROL MODULE

FIGURE 1 - Trane AGM Electronic Capacity Control Module (CVHE/CVHB Units)

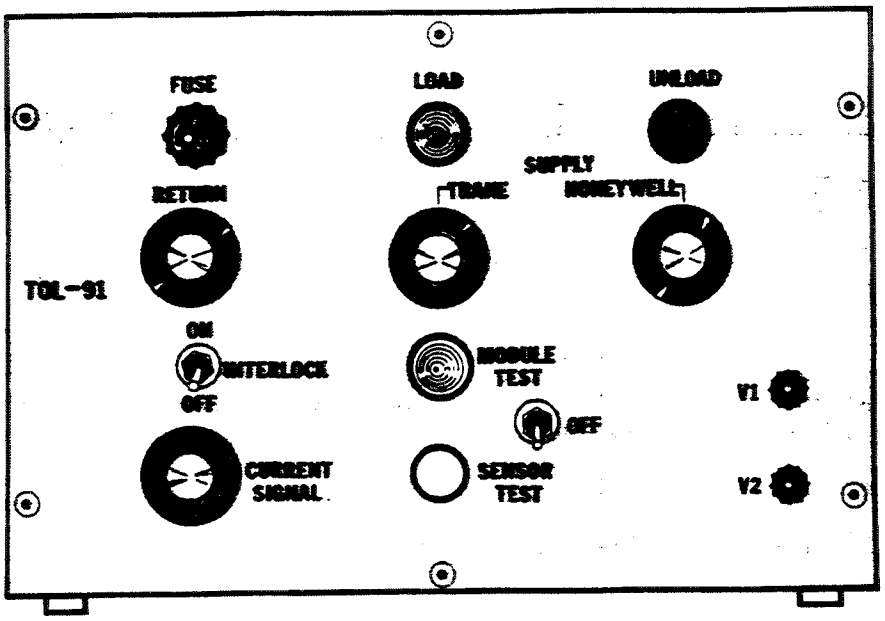

FIGURE 2 - TOL-91 (Capacity Control Module Tester)

SETUP FOR CAPACITY CONTROL MODULE CHECKOUT

WARNING: OPEN AND LOCK UNIT DISCONNECT TO PREVENT INJURY OR DEATH DUE TO ELECTRICAL SHOCK OR CONTACT WITH MOVING PARTS.

NOTE: Whenever TOL-91 is used to test capacity control modules in the field, be sure to disconnect all electrical wiring to the module before connecting the control module tester.

Connect the leads of the TOL-91 wiring harness to the proper terminals on the capacity control module. Notice that the terminal designations on the Trane AGM and Honeywell 901-D capacity control modules are different; the connection arrangement on each module is shown in Table 1.

TABLE 1 - Capacity Control Module Connection Arrangements

AGM CAPACITY CONTROL MODULE	HONEYWELL 901-D CAPACITY CONTROL MODULE
V2	R1
V1	R2
TS3	X2
TS2	XX1
TS1	M1
84	M2
2	V2
F1	V1
M2	TS1
M1	HTS2

To accomodate the differences in terminal designations, each of the TOL-91 wiring harness leads is marked with dual terminal identification numbers. These numbers represent the corresponding terminals on the AGM and Honeywell 901-D control modules. Once the harness is attached to the control module, **doublecheck each connection to ensure that TOL-91 is properly wired.**

NOTE: The TOL-91 wiring harness does not contain a wire for Terminal R2 of the Honeywell 901-D capacity control module since Terminals R2 and X2 are jumpered together.

TOL-91 Setup

Adjust the TOL-91 controls to the positions described below; refer to Figure 2 for the locations of these controls.

1. Current Signal Knob = Twelve O'Clock Position
2. Supply Knobs = Twelve O'Clock Position
3. Return Knob = Twelve O'Clock Position
4. Interlock Switch = ON Position
5. Module/Sensor Test = OFF Position

To read DC voltage signals for each of the test positions in this checkout procedure, adjust a digital voltmeter to the low DC voltage scale and attach the meter leads to Terminal Posts V1 and V2 on TOL-91.

Trane Capacity Control Module Setup (AGM)

1. Check the position of the dip switches located on the back of the control module. At least one of the dip switches of each component program (i.e., reset ratio, deadband, and load delay) should be positioned at ON. (The back of the control module is illustrated in Figure 3.)

   Use of these dip switches will enable the operator to check deadband, reset and load delay time. (Additional selections may be made, provided that all three of these functions--deadband, reset and load delay--are in the test circuit. Dip switch positions for alternate functions may be found in the CVHE Service Guide (HCTV-SG-2), Section 7.12.)

2. Before beginning any of the test procedures described in the following section, set the current limit control (labelled % CURRENT) on the Trane capacity control module to 100 percent. Then, adjust the module/sensor test switch on the TOL-91 to the MODULE TEST position.

3. Increase the current signal from TOL-91 until the amber current control light on the unit control panel illuminates. At this point, the digital voltmeter should register 8.25 VDC.

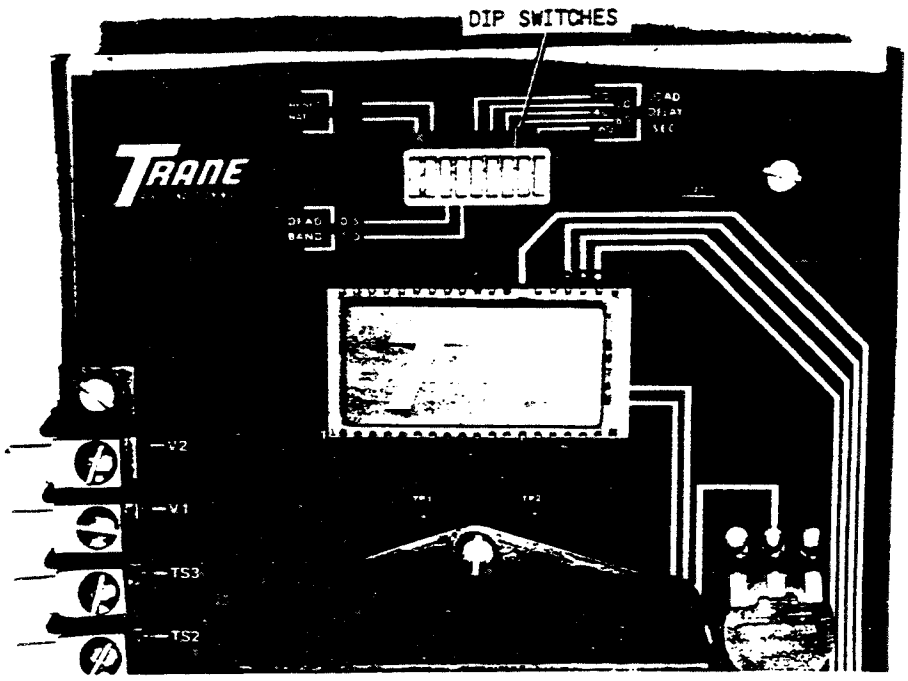

FIGURE 3 - Dip Switches (Back of Trane AGM Capacity Control Module)

CAPACITY CONTROL MODULE CHECKOUT PROCEDURE

To initiate the control module checkout procedure, a load signal must be sent to the capacity control module. To accomplish this on either a Trane AGM or Honeywell 901-D module, adjust the module/sensor test switch (on the TOL-91) to the MODULE TEST position. Then, rotate the load supply knob to the right of the twelve o'clock position.

NOTE: When testing the Trane AGM capacity control module, any of the adjustments made with the supply or return knobs of TOL-91 will be followed by a four to six-second pause to allow for the simulated temperature signal change.

NOTE: Be sure to adjust the Honeywell 901-D capacity control module to current limit at 8.25 VDC when functioning at full load. In addition, the temperature control knob must be positioned at 45 degrees.

1. Load Limit

Adjust the % CURRENT knob on the control module to 80 percent; then increase the current signal on TOL-91 until the amber current control light on the control panel illuminates. This light indicates that the current limit has been reached.

NOTE: On Honeywell 901-D control modules only, any increase in current beyond the current limit setpoint will result in a continuous unload signal.

2. **Load Limit and Unload 103 Percent (Trane AGM Control Modules Only)**

   Once the load limit is established (Step 1), slowly rotate the TOL-91 current signal knob until the pulsing, red UNLOAD light (on TOL-91) illuminates; this indicates an "over current" of 103 percent. (At this time, a constant red UNLOAD light also illuminates on the control module.)

   If functioning properly, the capacity control module should emit unload pulses at 0.25-second intervals until the chiller load is reduced to 100 percent.

3. **Load Limit and Unload 105 Percent (Trane AGM Control Modules Only)**

   Continue to rotate the TOL-91 signal knob until the UNLOAD lights on the TOL-91 and the control module indicate a continuous unload signal to a current level of 95 percent.

4. **Temperature Control**

   a. Readjust the current signal knob on TOL-91 to produce a load (i.e., green) signal on the capacity control module.

   b. Position the temperature control knob on the control module to the 45-degree setting.

   c. Slowly rotate the TOL-91 supply knob (i.e., "Trane" when testing the Trane AGM capacity control module, or "Honeywell" when testing the Honeywell 901-D capacity control module) to the left until an unload (i.e., red) signal is displayed both on the capacity control module and the TOL-91.

      With finer adjustment of the TOL-91 supply knob, a deadband or null condition can be obtained.

5. **Interlock**

   Turn the TOL-91 interlock from ON to OFF. Notice that an immediate and continuous unload (i.e., red) signal appears on the Trane AGM capacity control module, while a current limit with a continuous unload (i.e., red) signal appears on the Honeywell 901-D capacity control module.

   This signal indicates either that the inlet vanes are closing because of a low refrigerant temperature, or that the starter is being de-energized.

   Return the interlock switch to the ON position before proceeding to Step 6.

6. **Function Switch**

   Rotate the function switch on the capacity control module and note the action of the mode indicator lights. When the function switch is positioned at:

   a. LOAD, the green indicator light should illuminate.

   b. HOLD, none of the indicator lights should illuminate.

c. UNLOAD, the red indicator light should illuminate.

d. AUTO, the mode signal will respond to the simulated chilled water or current input signal.

7. **Load Limit in Any Function**

With the % CURRENT knob on the control module still set at 80 percent, adjust the control module function switch to any function position. Then, increase the current signal from TOL-91 and verify that the current limit and unload (i.e., red) indicator lights illuminate.

8. **Reset (Trane AGM Capacity Control Module Only)**

Set the temperature control knob on the capacity control module at 45 degrees, and adjust the TOL-91 "Trane" supply knob until a deadband or null condition exists. Then, simulate a decrease in return water temperature by turning the TOL-91 return signal knob to the left; the UNLOAD (i.e., red) light should illuminate.

Illumination of the UNLOAD light indicates automatic reset when the return water falls within the prescribed range of the reset sensor (i.e., as determined by the setting of the control point knob on the capacity control module).

Readjust the TOL-91 return knob to its original position before proceeding to Step 9.

9. **Sensor Test (Trane AGM Capacity Control Module Only)**

NOTE: A digital volt-ohmmeter (VOM) and jumper wire are required to conduct this test.

a. Adjust TOL-91 to the sensor test mode.

b. Connect the sensor and VOM in series using the two leads (with alligator clips) provided on TOL-91. See Figure 4.

c. Set the VOM for DC voltage and the low microamp (2 ma) range.

d. Convert the reading obtained from the VOM to water temperature using the data provided in Table 2.

NOTE: Readings from the VOM are equivalent to the Kelvin temperature scale.

CAPACITY CONTROL MODULE MOD0182 INSTALLATION INSTRUCTIONS

General

The Trane MOD0182 Capacity Control Module (CCM), has been designed to replace the pre-micro CVHE/CVHB/CVAC modules CNT0852, CNT0875 and CNT0876.

Some applications require different control algorithms to provide accurate and stable temperature control at system start-up. To accommodate these system differences, the MOD0182 Capacity Control Module can be configured for two different control sequences.

Installation/Wiring

The mounting and wiring terminal locations for the new module are very similar to the previous modules. However, there are additional terminals associated with a start-stop function, chilled water reset, remote demand limit and % RLA output that were not originally provided on the previous modules. Use of these and the necessary wiring instructions are explained in the **Added Features** section. The information below provides installation and mounting instructions that must be followed closely.

A plastic parts bag is provided with each new module. This bag contains the following parts:

- This manual, 2764-0009-05-00
- Three #8-32 x .375 SEM machine screws
- An options label, 6400-0661-01
- A short ground strap assembly
- A long ground strap assembly
- Two #10-32 x .500 machine screw
- Four #10 star washers
- Two #10 nut
- Two 2000 Ohm 20 watt resistors
- Three knobs
- A mounting template, 6400-0670-01

1. Mounting

a. The new module requires three mounting holes, two of the existing ones used for the original control and a third one to be added. Align the two large holes on the provided mounting template, 6400-0670-01 with the two existing holes used to mount the original control. The holes in the template are large enough to secure them with screws. A hole with a black circle around it is provided where the third mounting hole is to be located. Use a 1/4 inch drill bit.

b. Secure the new module to the door with the three provided #8-32 X .375 SEM machine screws. Do not use the existing thread forming screws used to mount the original control. They will damage the new module. The screws should not be over .375 inches long so as to not damage internal components. Also the star washer SEM is provided to insure electrical continuity through the paint.

c. On the provided Options label, 6400-0661-01, peel off the "40 to 100" label and place over the "% Current" area. Align using the top and side notches.

d. On the provided Options label, peel off the appropriate label to be applied over the "Control Point" area. Labels differ depending on whether the chiller is standard or extended temperature range and whether english or metric units are desired. Align using the bottom and side notches.

e. Install the three provided knobs. The knobs on the existing control will not work.

2. Connection Of The Ground Straps

a. Strip the insulation off the short ground strap and install on TB11-8.

Form 1-15.140(894)
Supercedes 1-15.140(693)

©American Standard Inc. 1994

2. Connection Of The Ground Straps (continued)

b. Route the short ground strap over to the #10-32 machine screw used to secure the front panel graphics to the door. This screw is located next to the door hinge midway between the top and bottom edges. If this screw is not in place, use one of the provided #10-32 screw sets and drill a hole. The two star washers are to be placed in contact with the door surface to allow conduction through the paint.

c. Remove the nut on this #10-32 screw leaving the star washer in place.

d. Install the ring quick connect terminal from both the short and long ground straps. Secure with the existing nut.

e. Run the long ground strap along the existing wiring harness into the panel.

f. Secure the ring terminal on this side of the long ground strap to the panel wall via the supplied #10 machine screw, star washers and nut. The two star washers are to be placed in contact with the panel wall to allow conduction through the paint.

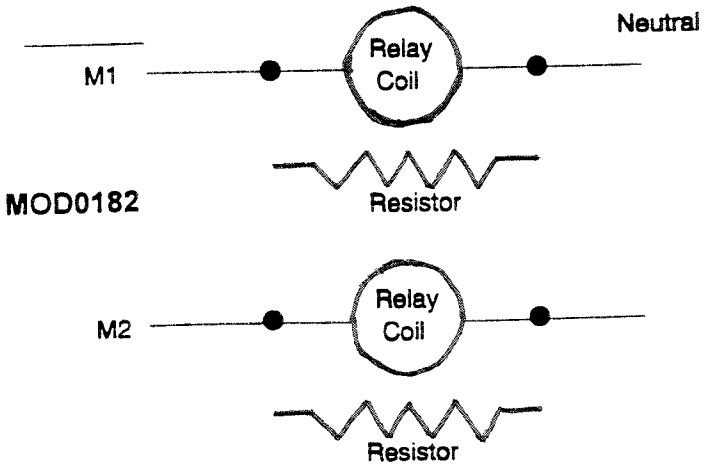
g. Secure both the long and short ground straps to the existing wiring harness to prevent binding when the panel door is closed.

3. CCM Temperature Sensors

The leaving and/or return chilled water sensors presently used on the pre-micro CVHE/CVAC modules CNT0852, CNT0875 and CNT0876 will not work with the new module. New sensors must be ordered when ordering the new module.

There are different sensors required depending on the desired options.

a. If neither the chilled water reset feature or the added feature of start differential (explained later) is desired, then only the CCM leaving chilled water sensor, SEN0132 needs to be ordered.



b. If either or both the chilled water reset feature and/or the added feature of start differential is desired, then a matched pair of the leaving chilled water sensor and return chilled water sensor needs to be ordered. Quantity one SEN0205 consists of this matched pair. Notice that since both sensors come with the matched pair, the SEN0132 sensor need not be ordered.

Both the SEN0132 and SEN0205 sensors fit in the existing wells. They, however, do fit loosely so a suitable quantity of thermal mastic heat paste is needed to secure the sensor.

4. Use on Air-Cooled Chillers

The actuators on air-cooled chillers are operated by 24 VAC relays. The triacs in the CCM module output 115 VAC. For this reason, 115 volt relays must be installed in the actuator circuit. To provide sufficient load on the module triacs when using the relays, a 2000 ohm, 20 watt resistor (included) **must** be installed in parallel with the coils of each relay. Because the resistors run warm, they should be mounted at least 4" from other components.

Figure 1

Control Set-Up

A. Control Range Adjustment

The modules normal control range is 35° F - 55° F. Extended range from 20° F - 70° F is available by setting the dip switch SW2-7 to the on position. For normal range switch, SW2-7 should be in the off position.

B. Dead Band

The module dead band can be set as follows:

Switch Position SW2-5	Switch Position SW2-6	Dead Band
Off	Off	±0.25° F
On	Off	±0.50° F
Off	On	±1.00° F
On	On	±1.50° F

C. Reset Ratio Schedule

The reset control process provided in the CCM uses the active control point, design delta temperature setting and the return chilled water temperature to determine the absolute amount of reset required. A return (entering) chilled water sensor must be installed in the system in order to use this feature. See the section on Installation/Wiring.

Switch Position SW2-3	Switch Position SW2-4	Reset Ratio	Deg. of Control Point Reset for Every 1° F Drop in Return Chilled Water Temp.
Off	Off	Infinite	0.0° F
On	Off	2.0	0.5° F
Off	On	1.0	1.0° F
On	On	0.5	2.0° F

The reset ratio is the Degs. F drop in the return chilled water temperature needed to cause a 1° F reset upward of the leaving chiller water temperature. See section D to determine how to set the design delta temperature when using the modules chilled water reset capabilities. If a remote analog input signal is to be used to control chilled water reset see Paragraph C in Added Features Section.

D. System Design Delta Temperature

When using a chilled water reset sensor, you must indicate to the module the system design chilled water temperature differential. Example: Unit design specification calls for 55° F entering chilled water and 45° F leaving chilled water. In this example, the design delta temperature is 10° F. Choose the setting closest to your system design specifications.

Switch Position SW3-7	Switch Position SW3-8	Design Delta Temperature
Off	Off	5° F
On	Off	10° F
Off	On	15° F
On	On	20° F

E. Load Delay

These switches control the off delay time between load and unload pulses.

E. Load Delay (continued)

Switch Position SW3-4	Switch Position SW3-5	Switch Position SW3-6	Load Delay
Off	Off	Off	10 Secs.
On	Off	Off	20 Secs.
Off	On	Off	30 Secs.
On	On	Off	40 Secs.
Off	Off	On	50 Secs.
On	Off	On	60 Secs.
Off	On	On	70 Secs.
On	On	On	80 Secs.

F. Current Control Setting

When using this module to replace CNT0852, CNT0875 or CNT0876 which obtain a chiller current level input signal from the Cutler-Hammer solid state overload (0 to -10 VDC), the switches SW1-1 through SW1-6 must be configured as follows. This corresponds to 8.25 VDC at full load.

SW1 Position					
1	2	3	4	5	6
On	On	Off	On	Off	On

G. System Start-Up Temperature Control

For operation in a typical comfort cooling, single chiller application, SW3-9 should be placed in the "On" position. The control will limit loading and control the leaving chilled water temperature to 5 degrees above the active setpoint for the first 15 minutes of operation to avoid overshoot during system pull down. After 15 minutes the control will allow further loading to bring the leaving chilled water to the active setpoint. Note: The 15 minute timing sequence begins when power is applied to pin 84.

With SW3-9 in the "Off" position, the unit will immediately control to the active setpoint upon start-up.

SW3-9	Operation
ON	Controls to 5° F above active setpoint for first 15 min. of operation.
OFF	Controls immediately to active setpoint.

Added Features

A. Start Differential

This module has a start/stop differential feature that will open and close a circuit between terminals TB11-6 and TB11-7 on the module, and that can be wired into the existing control scheme. In order to use the start-up/stop differential feature a return (entering) chilled water sensor must be used. See the section on Installation/Wiring. This feature allows you to set the chiller starting point based on the chilled water setpoint. Example: You may choose to set the chiller to start when the actual chilled water temperature gets to 7° F above the current module setpoint of 45° F. In this case, the chiller will start when the entering chilled water temperature rises to 52° F. The chiller offpoint is fixed at 1° below setpoint. Once the leaving chiller water temperature in the example above drops to 44° (1° F below setpoint), the chiller will stop after a time delay period. This period of delay will vary and shorten if the return chilled water temperature continues to drop below the 1° F off setting. The differential to start and the chiller off point will vary as the setpoint is changed. To select the differential to start, set switches SW3-1 through SW3-3 as follows:

A. Start Differential (continued)

Switch Position SW3-1	Switch Position SW3-2	Switch Position SW3-3	Differential To Start
Off	Off	Off	2 ° F
On	Off	Off	3 ° F
Off	On	Off	4 ° F
On	On	Off	5 ° F
Off	Off	On	6 ° F
On	Off	On	7 ° F
Off	On	On	8 ° F
On	On	On	10 ° F

B. Remote Demand Limit

The original CNT0852, CNT0875 and CNT0876 required an interface module to accept a remote 0-10 VDC or 4-20 mA input signal for current demand limiting. The new module will accept these signals directly at terminals TB12-1 and TB12-2 (See Figure 1). To select a voltage or current input, set the dip switch SW2-1 as follows:

SW2-1	Remote Signal
Off	Voltage Source
On	Current Source

When using a voltage source signal, the relationship to demand limit is shown below.

VDC	Load
0.0- 2.0	100%
2.0-10.0	115-(7.5 X VDC)
0.0-12.0	40%

Example: 5.0 VDC = 115-(7.5 X 5.0) or 77.5% maximum current

When using a current source signal, the relationship to demand limit is shown below.

mA	Load
0.0- 4.0	100%
4.0-20.0	115-(3.75 X mA)
20.0-24.0	40%

Example: 10mA = 115-(3.75 X 10.0) or 77.5% maximum current

The maximum voltage allowed from the remote device is 18 VDC. The maximum current allowed is 36 mA DC.

IMPORTANT: When no remote device is connected, the switch SW2-1 should be **ON**.

CAUTION: The 4-20mA input of this module conforms to ANSI standard for 4-20mA transmitters #ANSI-MC12.1-1975. TB12 PIN2 marked "input-" for both the 0-10 and 4-20mA transmitters is at ground potential. Review of individual 4-20mA transmitters attached to this input is strongly recommended to prevent damage to this module or the 4-20mA transmitter driving this module. When the CCM is used with a non-isolated transmitter, an isolating transmitter may be required such as Trane PLU0172 and TDR0271. Contact Trane customer service for further clarification.

C. Remote Chilled Water Reset

The original CNT0852, CNT0875 and CNT0876 modules required an interface module CNT0902 to accept a remote 0-10 VDC or 4-20 mA input signal for chilled water reset. To allow a remote input signal to take priority for control of chilled water reset switches SW2-3 and SW2-4 must both be in the OFF position. The new module will then accept these inputs directly at terminals TB12-3 and TB12-4 (see Figure 2). To select a voltage or current input set the dip switch SW2-2 as follows:

SW2-2	Remote Signal
Off	Voltage Source
On	Current Source

When using a **voltage source**, the relationship to chilled water reset is shown below.

VDC	Reset
0.0- 2.0	0° F Reset
2.0-10.0	(4 X VDC)-8
10.0-12.0	32° F Reset

Example: 3.0 VDC = (4 X 3)-8 = 4°. F of reset

When using a **current source signal**, the relationship to chilled water reset is shown below.

mA	Reset
0.0- 4.0	0 ° F Reset
4.0-20.0	(2 X mA)-8
20.0-24.0	32° F Reset

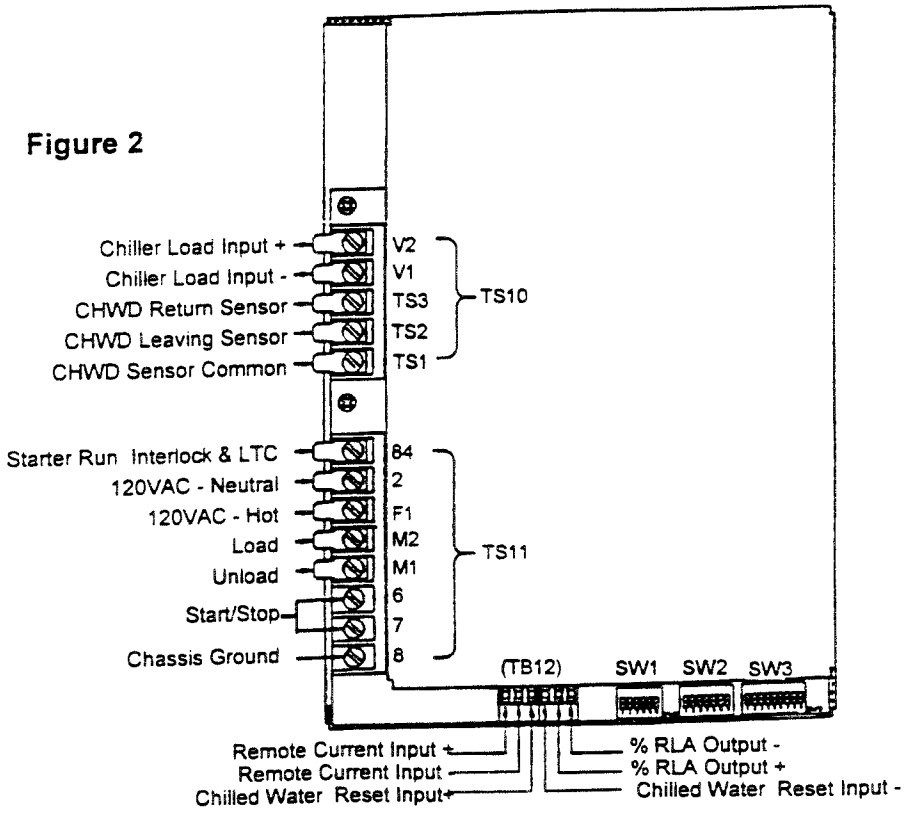
Example: 6.0mA = (2 X 6)-8 = 4° F of reset

The maximum voltage allowed from the remote device is ± 18 VDC. The maximum current allowed is ±36 mA DC.

IMPORTANT: When no remote device is connected, the switch SW2-2 should be **ON**.

CAUTION: The 4-20mA input of this module conforms to ANSI standard for 4-20mA transmitters #ANSI-MC12.1-1975. TB12 PJN4 marked "input-" for both the 0-10 and 4-20mA transmitters is at ground potential. Review of individual 4-20mA transmitters attached to this input is strongly recommended to prevent damage to this module or the 4-20mA transmitter driving this module. When the CCM is used with a non-isolated transmitter, an isolating transmitter may be required such as Trane PLU0172 and TDR0271. Contact Trane customer service for further clarification.

D. % RLA Output, TB12-5 to TB12-6



An additional output is provided which indicates the present % RLA current draw of the compressor motor. It basically is a 0 to 20 mAmp output to be monitored by an upstream device like the Tracer.

The relationship between motor % RLA and output current is:

%RLA = Current Output (mA) x 5.35
Example: Output 10 mA x 5.35 = 53.5% RLA.

Output currents greater than 20.0 mA are out of range. The allowed impedance of the monitoring device is 0.0 to 250 ohms.

Sequence of Operation for Typical Startup

Energize the chilled water pump starter K12(line 13).

Set switch S6(line 26) in the "auto" position.

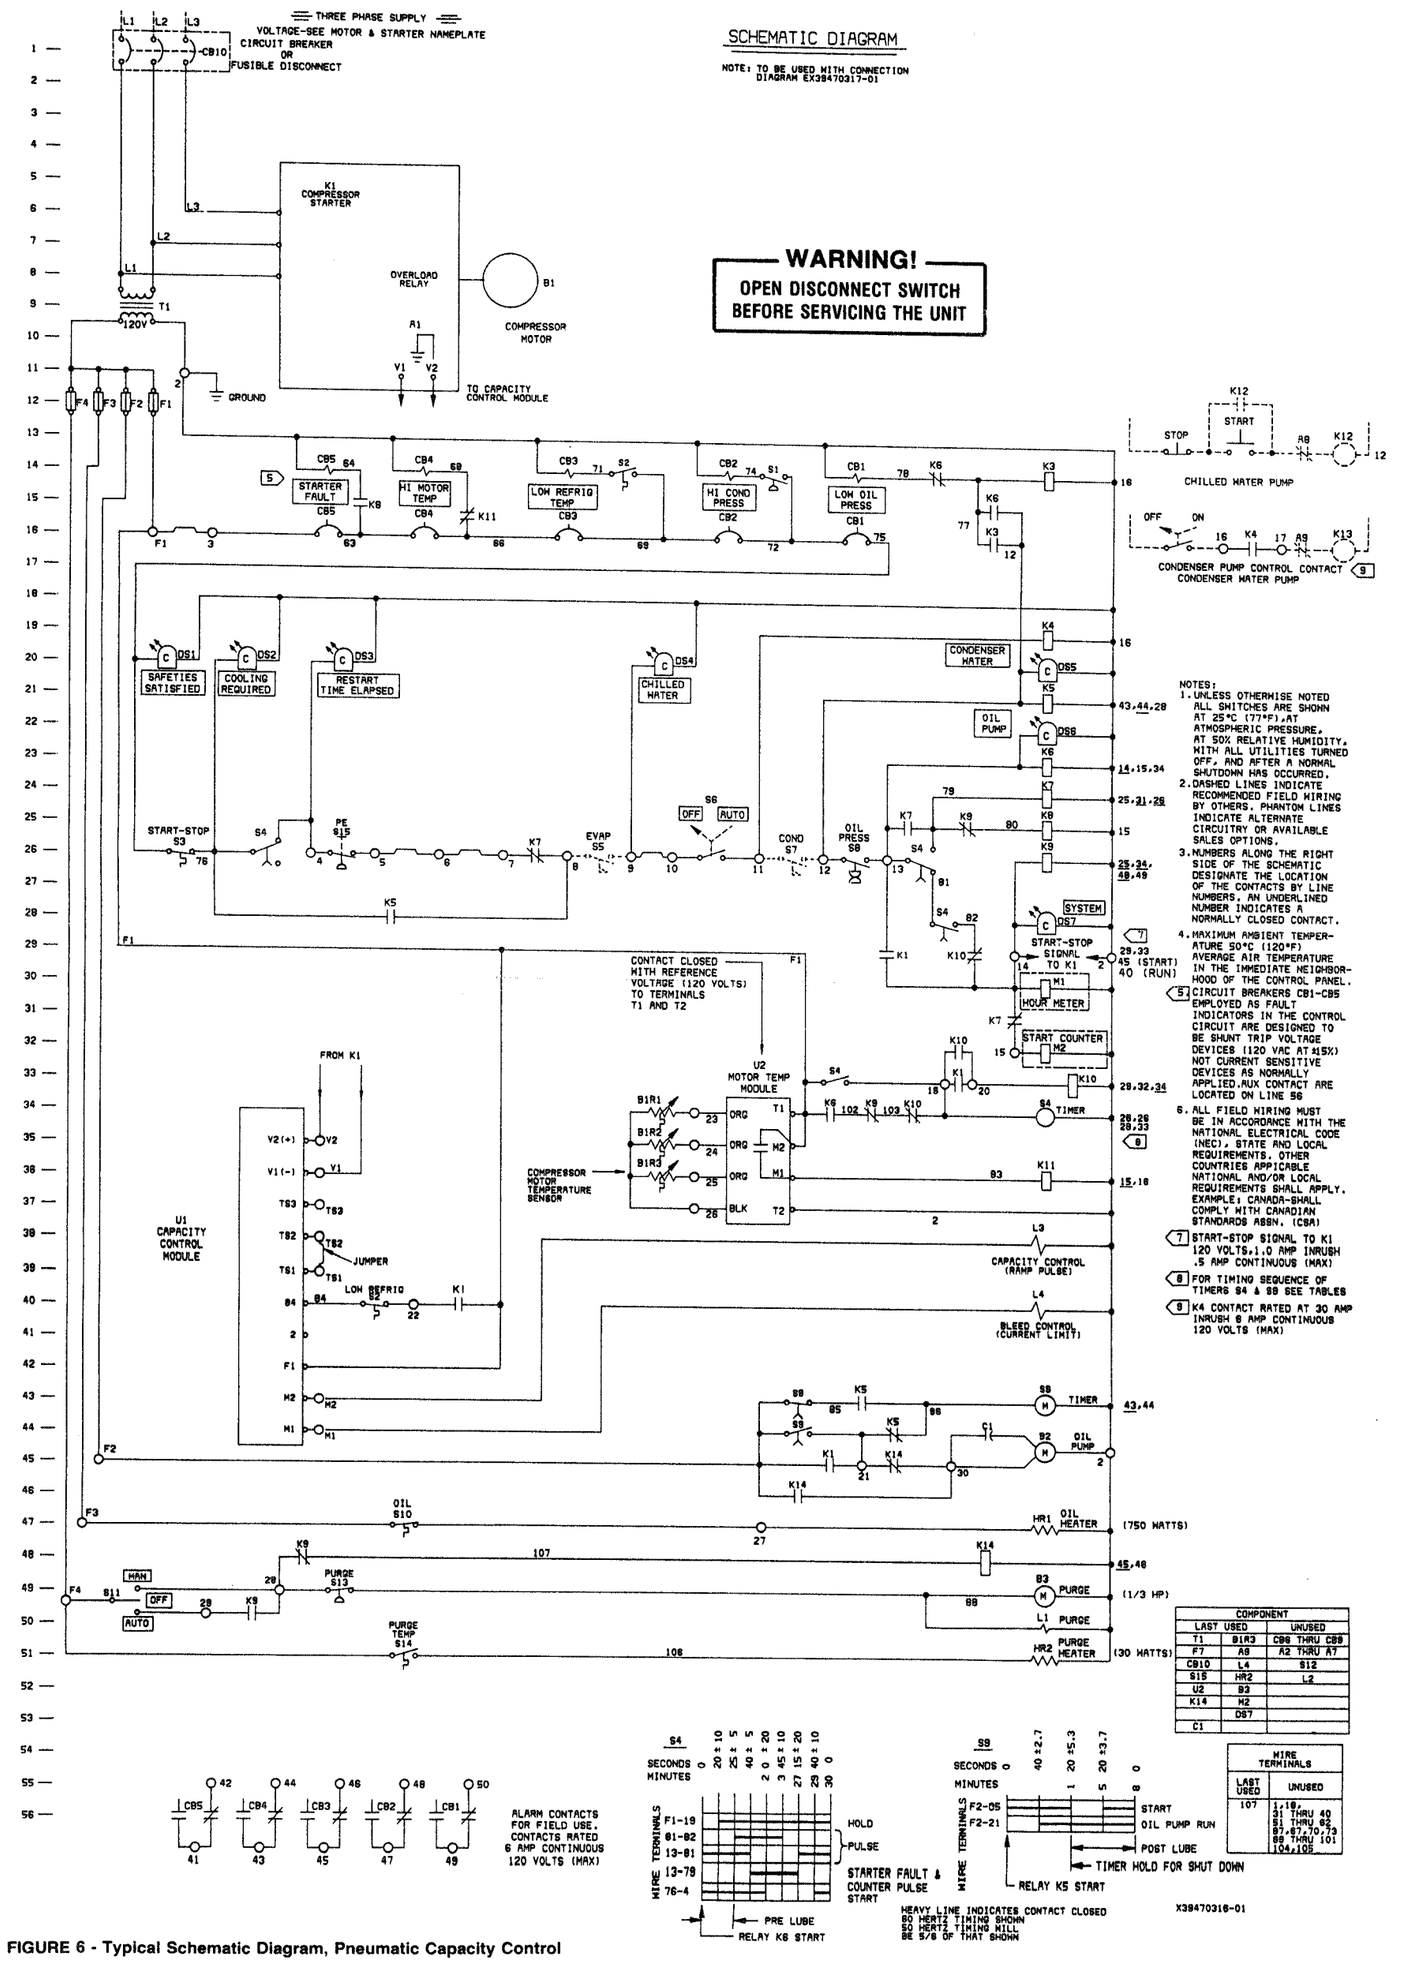
Control power flows through the string of safety controls and safety lock-out contacts(line 16). If all safeties are satisfied, light DS1(line 20) will light. Power flows to the chilled water demand switch(line 26) whose temperature sensing element is located in the return water entering the chiller. Upon a rise in return water temperature, S3 closes energizing light DS2(line 20) and feeding power to timer contact S4. If 30 minutes or more have elapsed since the previous compressor start, timer contact S4(line 26) feeds power to light DS3(line 20). Power also flows through compressor inlet vane end switch A3(if vanes are closed), through relay K7 contacts(if compressor is off) to terminal 8. If chilled water flow is proven,power feeds through flow switch S5 to light DS4(line 20). Power also feeds through switch S6 energizing relay K4(line 19). K4 contacts (line 16) close to energize the condenser water pump starter, K13. If condenser water flow is proven,power feeds through flow switch S7(line 26) to light DS5(line 20) and also energizes relay K5(line 21). One set of K5 contacts(line 43) close energizing the oil pump timer S9. In 40 seconds, timer S9 contacts(line 44) close energizing the oil pump motor B2(line 45).

The oil pump has a capacitor start-induction run single phase motor. It utilizes a current sensitive relay K15(line 45)wired in series with the run winding to switch from start to run. When the oil pump motor is first started, it draws locked rotor current, this high current draw causes K15 to close its contact(line 45) energizing the start capacitor and start

winding of the motor to begin its rotation. When the motor is fully accelerated, the current draw drops causing K15(line 45) to open its contact(line 45) and drop out the start winding putting the motor in its run configuration.

When oil pressure is established, oil pressure switch S8(line 26) closes, lighting DS6(line 22) and energizing relay K6(line 23). One set of K6 SPDT contacts(lines 14 and 15) switch to energize K3(line 14). In turn K3 contacts(line 16) close arming the Low Oil Pressure circuit interrupter CB1 (line 14). A second K6 contact(line 35) closes energizing timer S4. In 25 seconds S4 contacts(line 34) close. Twenty five seconds later S4 contacts (line 28) close lighting DS7(line 28), energizing K9(line 26) and initiating a compressor start by energizing K1(line 29). One set of K1 "start" contacts (line 29), close to maintain power to the compressor starter. Simultaneously, a second K1 "start" contact(line 34) closes energizing K10. K10 contacts(line 32) close to maintain K10 energized for the duration of anti-recycle timer S4.

A third K10 contact(line 29) opens to interrupt the "start" signal through S4 contacts(line 26). Thus to original "start" signal through S4(line 26) is maintained only long enough to energize the "start" contactor of K1.



If K1 drops out for any reason, K1 stays de-energized until anti-recyle timer S4 competes its cycle. A third K1 'start" contact(line 45) closes to keep the oil pump energized as long as K1 contacts are closed.

When K1 connects the compressor in the run configuration, K1 "run" contacts (line 40) close feeding power to terminal 84 of the capacity control module U1(line 40) (if refrigerant temperature switch S2 is closed) thus allowing U1 to open the compressor inlet vanes as necessary.

When K1 is initially energized, relay K9(line 26) is also energized K9 contacts (line 25) open keeping relay K8 de-energized. This arms the Starter Fault safety circuit 15 seconds after the initial start pulse is sent to K1. S4 contacts(line 26) switch from 13-81 to 13-79, energizing relay K7(line 24). K7 contacts(line 25) close keeping K7 energized and completing the arming of the Starter Fault circuit. If K1 opens for any reason, contacts K1(line 29) open de-energizing relay K9. K9 contacts (line 25) close energizing relay K8. K8 contacts(line 15) close tripping safety lockout CB5 and locking the unit off. When there is no longer a call for cooling or if a safety opens, compressor starter K1 and relay K5 will be de-energized. A contact of timer S9(line 44) will keep timer S9 and oil pump motor B2 energized for 7 minutes to provide lubrication during compressor coast-down.

If there is a loss of oil pressure while the compressor is running, oil pressure switch S8(line 26) opens, stopping the compressor and de-energizing relay K6(line 23). Power then feeds from terminal 12(line 26) through contacts of K2(line 16) and NC contacts of K6(line 14) to trip safety lockout CB1, locking the compressor off.

Alarm contacts(line 56) are factory wired using NC contacts of the control safety lockouts. NO alarm contacts may be used by moving one wire on each safety lockout.

NOTES:
1. UNLESS OTHERWISE NOTED ALL SWITCHES ARE SHOWN AT 25°C (77°F), AT ATMOSPHERIC PRESSURE, AT 50% RELATIVE HUMIDITY, WITH ALL UTILITIES TURNED OFF, AND AFTER A NORMAL SHUTDOWN HAS OCCURRED.
2. DASHED LINES INDICATE RECOMMENDED FIELD WIRING BY OTHERS. PHANTOM LINES INDICATE ALTERNATE CIRCUITRY OR AVAILABLE SALES OPTIONS.
3. NUMBERS ALONG THE RIGHT SIDE OF THE SCHEMATIC DESIGNATE THE LOCATION OF THE CONTACTS BY LINE NUMBERS. AN UNDERLINED NUMBER INDICATES A NORMALLY CLOSED CONTACT.
4. MAXIMUM AMBIENT TEMPERATURE 50°C (120°F) AVERAGE AIR TEMPERATURE IN THE IMMEDIATE NEIGHBORHOOD OF THE CONTROL PANEL.
5. CIRCUIT BREAKERS CB1-CB5 EMPLOYED AS FAULT INDICATORS IN THE CONTROL CIRCUIT ARE DESIGNED TO BE SHUNT TRIP VOLTAGE DEVICES (120 VAC AT ±15%) NOT CURRENT SENSITIVE DEVICES AS NORMALLY APPLIED. AUX CONTACT ARE LOCATED ON LINE 96
6. ALL FIELD WIRING MUST BE IN ACCORDANCE WITH THE NATIONAL ELECTRICAL CODE (NEC), STATE AND LOCAL REQUIREMENTS. OTHER COUNTRIES APPICABLE NATIONAL AND/OR LOCAL REQUIREMENTS SHALL APPLY. EXAMPLE: CANADA-SHALL COMPLY WITH CANADIAN STANDARDS ASSN. (CSA)
7. START-STOP SIGNAL TO K1 120 VOLTS, 1.0 AMP INRUSH .5 AMP CONTINUOUS (MAX)

FIGURE 6 - Typical Schematic Diagram, Pneumatic Capacity Control

CVHE ELECTRIC VANE MOTOR

The electric vane actuator used on the CVHB and CVHE Model CenTraVacs is a worm gear type linear actuator. It is driven by a reversable electric motor and requires approximately 60 seconds to go full stroke when given constant power.

The vane actuator utilizes a limit switch mechanism to limit the travel of the actuator and provide a signal to the control panel that the vanes are completely closed. Figure 1 is a picture of the vane motor terminal box showing the terminal strip, capacitor and limit switch mechanism.

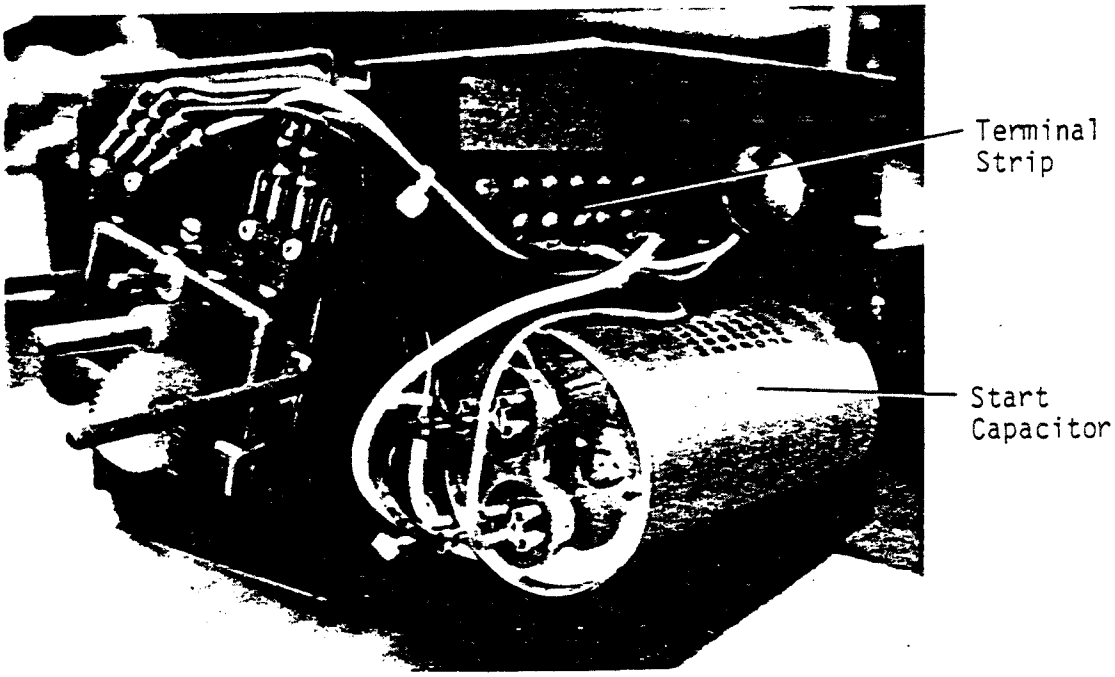

Figure 1: Electric Vane Motor Terminal Box

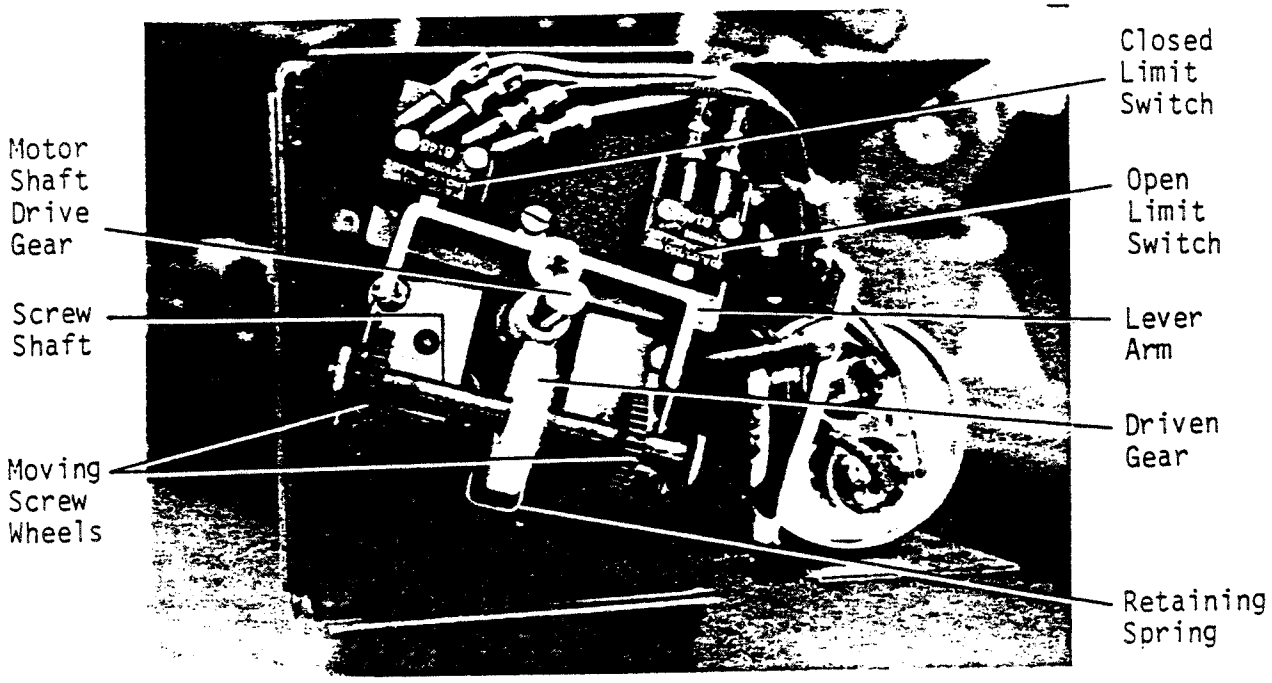

Figure 2: Limit Switch Mechanism

Limit Switch Operation

The limit switch mechanism operates as follows:

A worm drive gear is mounted on the end of the motor shaft(See Figure 2). As the motor turns the worm gear drives a screw shaft through another gear. As the screw shaft turns two moving screw wheels move back and forth on the shaft(See Figure 3). These screw wheels do not turn, they are kept from turning by a retaining spring. Their internal threading to the screw shaft is what causes them to move back and forth on the shaft. The moving screw wheels push a lever arm which in trun actuates a "full open" limit switch or "full closed" limit switch depending on the position of the actuator. (See Figure 2).

The full open limit switch breaks the open signal to the vane motor preventing it from over driving and jamming the van actuator.

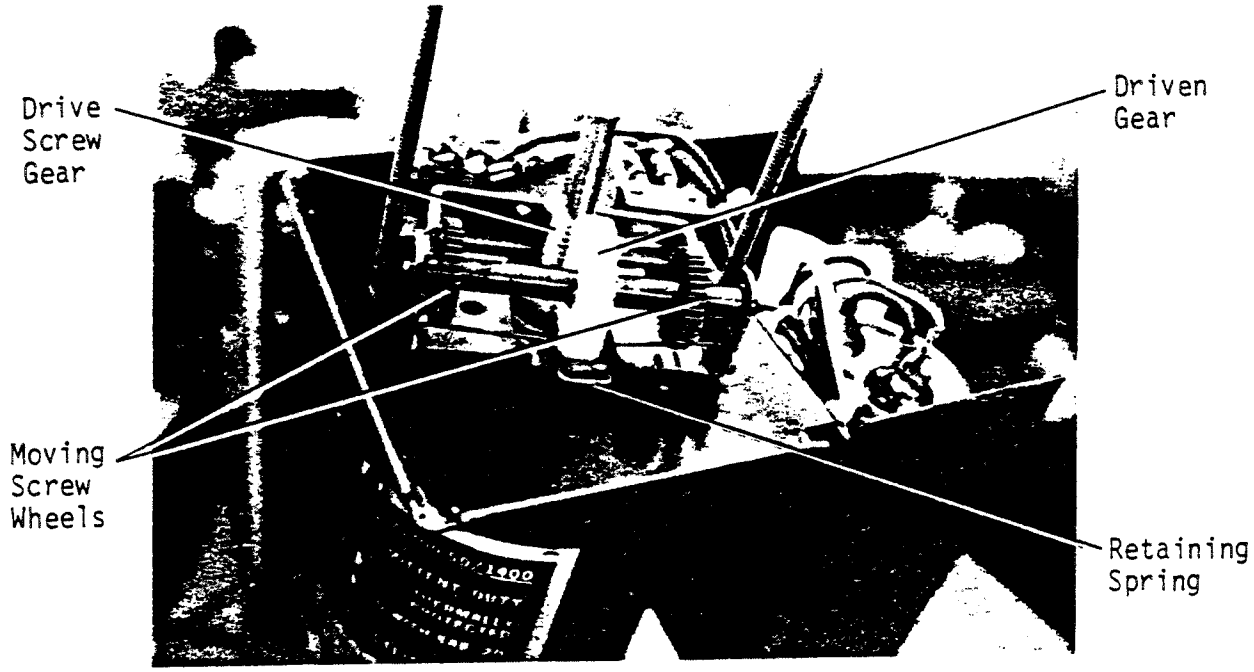

Figure 3: Limit Switch Mechanism

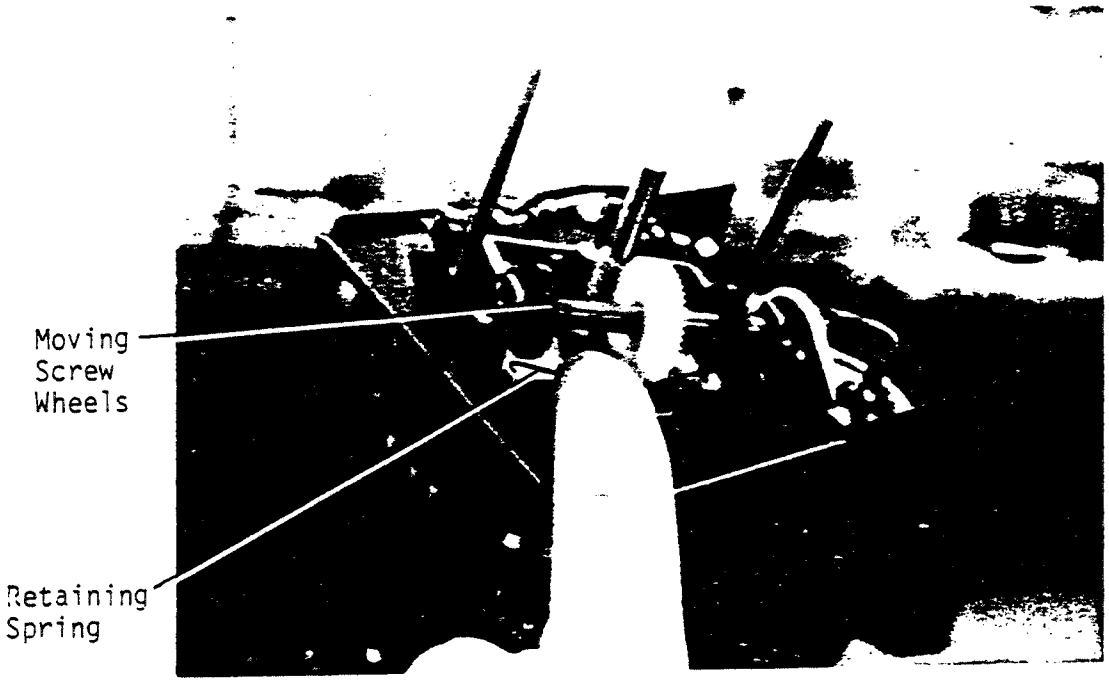

Figure 4: Limit Switch Mechanism Retaining Spring

The full closed limit switch breaks the close signal to the vane motor preventing it from overdriving and jamming the vane actuator shut. It also makes

a set of contacts which complete the control circuit allowing a start to occur(See Figure 5).

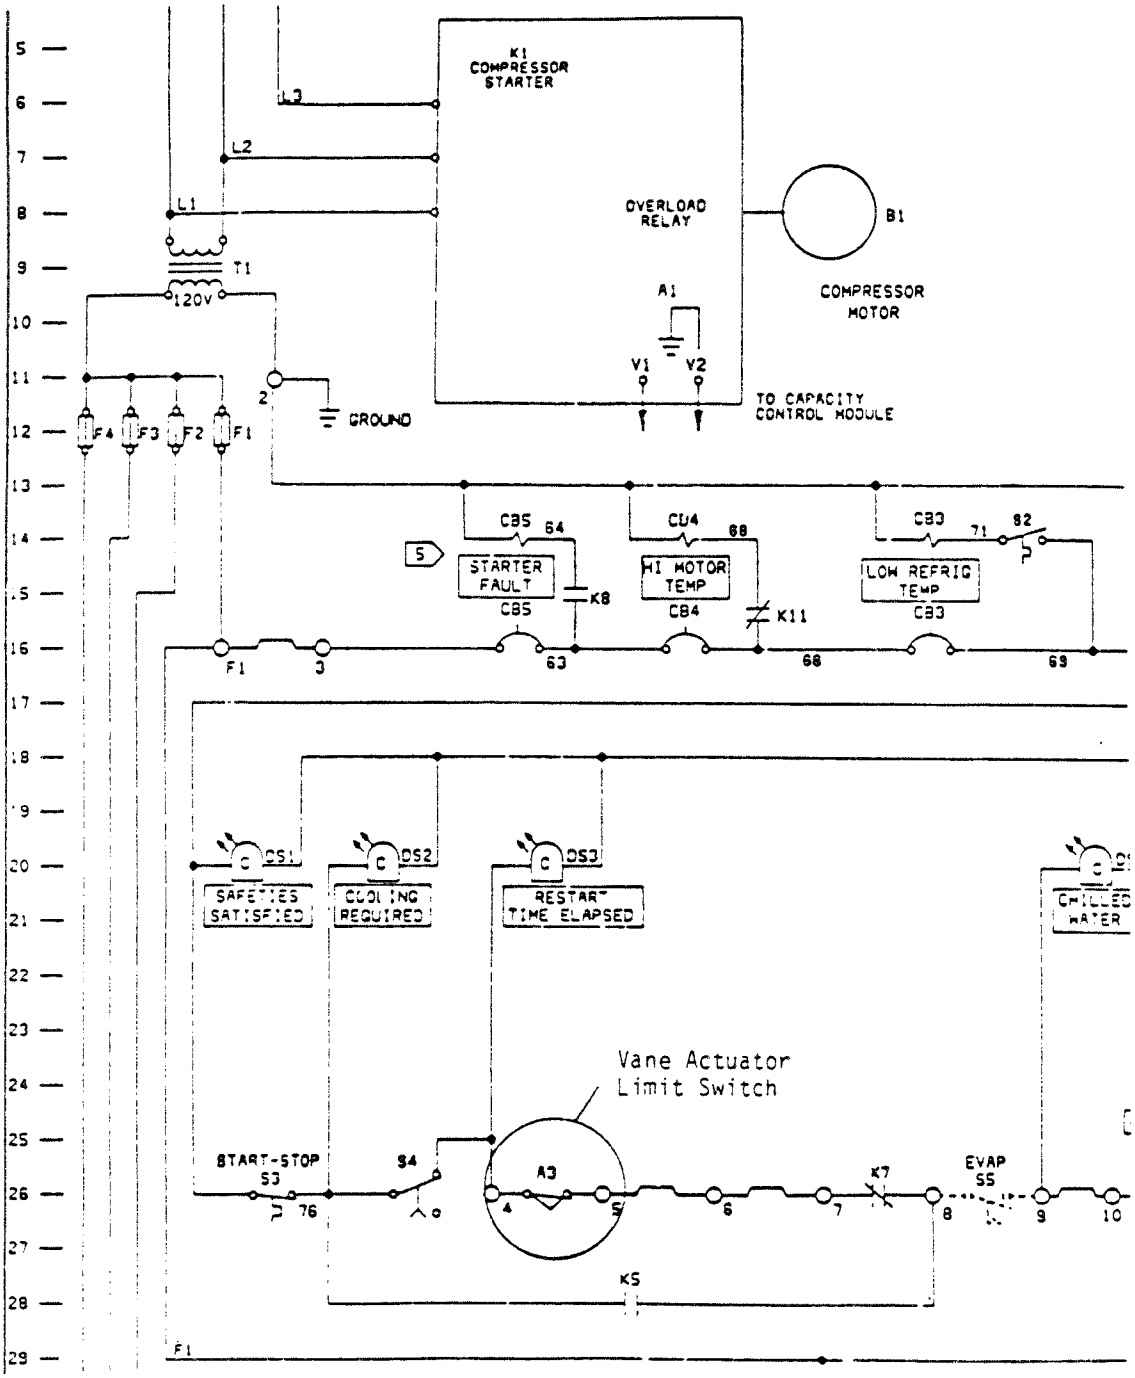

Figure 5: CVHE Schematic Diagram

Limit Switch Adjustment

To adjust the limit switch make and break points the retaining spring must be pushed down so that it disengages the moving screw wheel.(See Figure 4). The screw wheel may then be rotated as required to adjust the limit switches. These switches should be set so that the power to the motor is broken approximately 1/8 to 1/4 inch before the actuator is completely retracted or extended. If the limit switches are not properly adjusted, the vane motor may continue to be powered in the fully retracted or extended position causing the motor to heat up and cycle on its thermal overload and ultimately fail.

Maintenance

Every six months a few drops of light machine oil(SAE-20) should be applied to the vane operator shaft and spread into a light film. This will protect the shaft from moisture and rust.

The actuator motor bearings must also be lubricated by inserting a long nozzle into the lubrication points on the actuator as shown in Figure 6. Several drops of SAE-20 oil is sufficient.

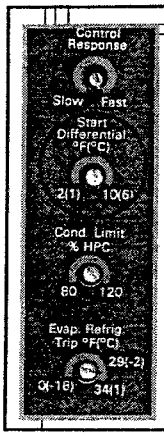
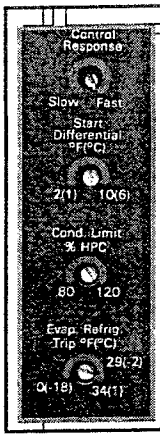
Micro Module (1U3)

Operation and Interface



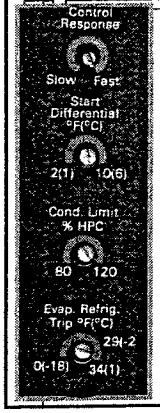
CONTROL RESPONSE

- *Controls Vane Actuator Response To Load and Unload Commands*
- *Range = 1 - 237*
- *Lower Setting = Slower Response*
- *To Display- Set Vane Control Switch To "Hold"*
- *Display Advance Until "L" Appears*
- *Use Equation to Calculate Setting*



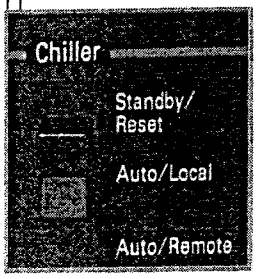
$$\frac{250}{\text{Design } \Delta T} \times \frac{\text{Actual Flow}}{\text{Design Flow}}$$

START DIFFERENTIAL



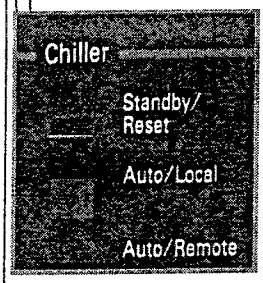
- *# Of Degrees Leaving Water Must Rise Above Setpoint For Unit To Start*
- *Controls Compressor Stop Point*
- *Range Of 2 to 10 Degrees F*
- *To Display*
  - *Control Switch to Hold*
  - *Display Advance Until "O" Appears*
- *See Table 4 on Page 14 CVHE SB-22A*

CONDENSER LIMIT (%HPC)



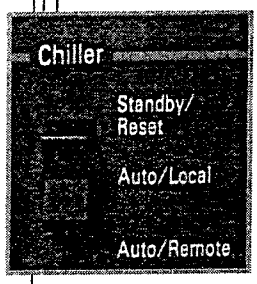
- *Prevents High Pressure Trips*
  - *Range 80 to 120% of HPC (15 or 25 Psig)*
  - *During Critical Chiller Operation*
    - *Slows Loading (90 -96% of Setpoint)*
    - *Holds (96 - 100% of Setpoint)*
    - *Regulated Unloading (100% of Setpoint)*
  - *Recommended Setting = 93%*
  - *Display Advance Until "P" Appears*
- *Condenser Limit - See Page 15 CVHE SB-22A*

Evaporator Refrigerant Temperature Trip



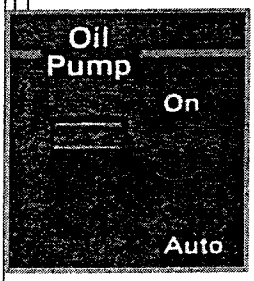
- *Set to 32 °F*
- *Display Advance Until "U" Appears*
- *Limits Loading at 5 to 6 °F > Trip Point*
- *Control Point is 2 Degrees Above Trip Setpoint*
- *Hold - ~ 2 °F > Trip Point*
- *Regulated Unload ~ 1 °F > Trip Point*
- *Hard Unload @ Trip Point*
- *Machine Shutdown After Hard Unload & Temperature Violation < 30 °F/Secs*

Chiller Control Switch



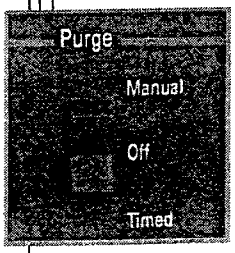
- *Standby/Reset*
  - *When Powered UCP Is Activated But Unit Operation Is Prohibited*
  - *Operating Code "AO" Is Displayed*
  - *Clears "Latching" Diagnostics*

Chiller Control Switch



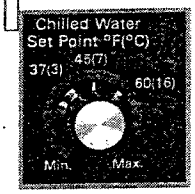
- *Auto/Local*
  - *Chiller Runs Normally Using Setpoints Set At UCM in Serviceman's Menu*

Chiller Control Switch

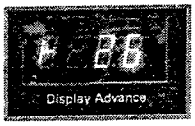


- *Auto/Remote*
  - *Unit Runs Automatically Using Remote Setpoints*
  - *Communicates Via Bi-directional Communication Link*
- *Factory Installed Chilled Water Reset Module is a "Remote Setpoint"*

Oil Pump Switch

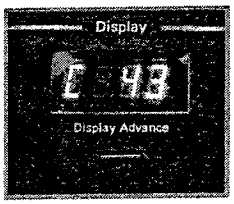


- *On = Continuous Oil Pump Operation*
  - *Service Personnel Only*
  - *Compressor Will NOT Start When Oil Pump Switch is "ON"*
- *Auto = Oil Pump Controlled By Micro*
  - *Normal Position*
  - *15 to 48 Second Pre-Lube*
  - *2 Minute Post Lube*

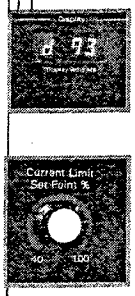


Purge Switch

- *Manual = Continuous Operation*
  - *Even in Standby/Reset*
- *Off = Off Unless Purge Timer Activated*
- *Timed = Normal Position*
  - *5 Mins/2Hrs*
  - *Auto Extend if Unit Has Purged Within Last 4 Minutes*

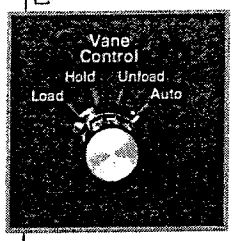


Chilled Water Setpoint



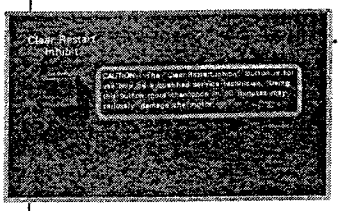
- *Vane Control Switch Set to "Hold"*
- *Display Advance Until "Ø Appears*
- *Deadband +/- 1°*

Active Chilled Water Setpoint



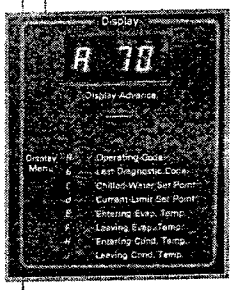
- *Toggle Between Hold (Serviceman's Menu) & Auto (Operator's Menu) to View Active or Local Setpoint*

Current Limit



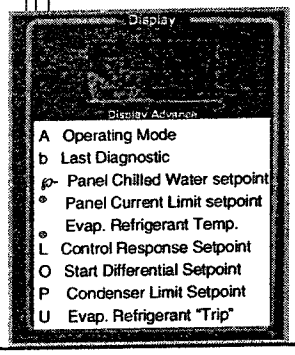
- 40%-100% of Compressor RLA
- Serviceman's Menu - Display Advance Until "" Appears
- Operator's Menu - Display Advance Until "d" Appears (For Active Setpoint)
- 1% Increments
- As Current Approaches Setpoint-
  - 1. UCM Limits Loading
  - 2. UCM Initiates "Modulated" Unloading
- At Setpoint-
  - Trips

VANE CONTROL SWITCH



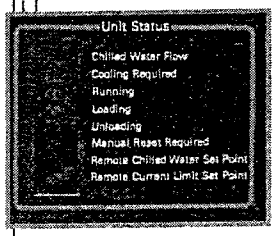
- Load - Manually Loads Compressor
  - Unless In A Limit Mode
- Unload - Manually Unloads Compressor
- Auto - UCM Controls Vane Actuator
- Hold - Vane Actuator Maintains Position
  - Unless In A Limit Mode
  - Changes Display To "Serviceman's Menu"

Clear Restart Inhibit



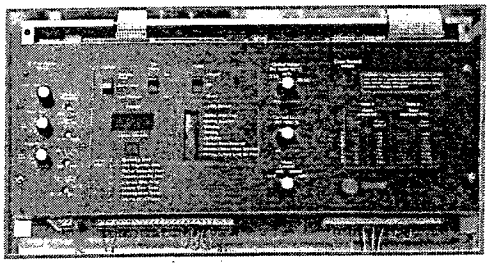
- CAUTION!
  - Service Personnel Only
  - Push Once Per 30 Minutes
    - Serious Motor Damage Possible

Operator's Menu



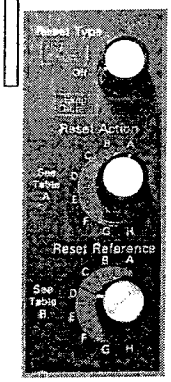
- *4 Digit Display*
- *1st Digit Is Code Prefix*
- *2nd Digit Is Blank*
- *3rd & 4th Digits Are:*
  - *Operating Mode*
  - *Diagnostics*
  - *Setpoints*
  - *Actual Temperatures*

Serviceman's Menu



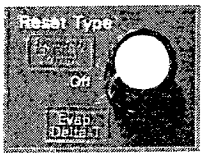
- *Turn Slide Valve Control Switch To "HOLD"*

Unit Status

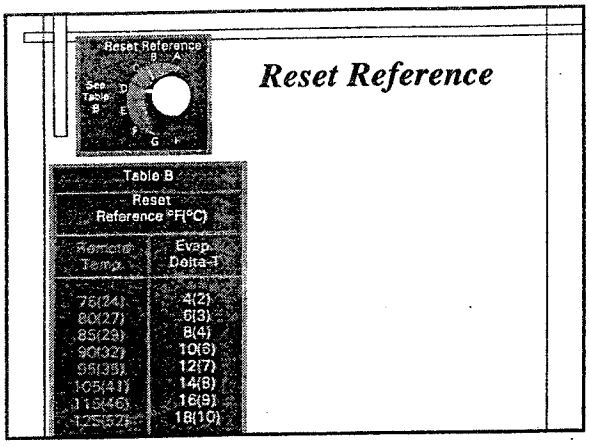


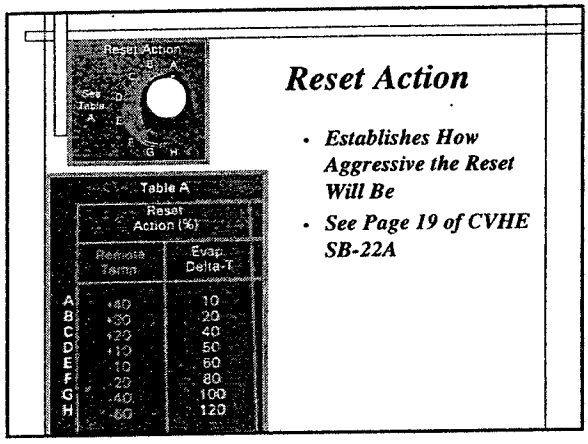
- *1. Indicates Chilled Water Flow Switch 5S2 Is Closed*
- *2. UCM Proves CW Flow and Detects a Cooling Call*
- *3. a. Unit is Running*
  b. Chiller Switch Is Set At Auto/Local or Auto/Remote
  c. Transition is Complete
- *4. UCM is Loading Compressor and Relay 1U1Q7 is Energized*
- *5. UCM is Unloading Compressor and Relay 1U1Q8 is Energized*
- *6. UCM Detects a Latching Diagnostic Condition*
- *7. & 8. Setpoint Entered From a Remote Source and Overrides Local Setting (Defaults to Local if Remote Comm. is Lost)*

IU-3 WITH CHILLED WATER RESET



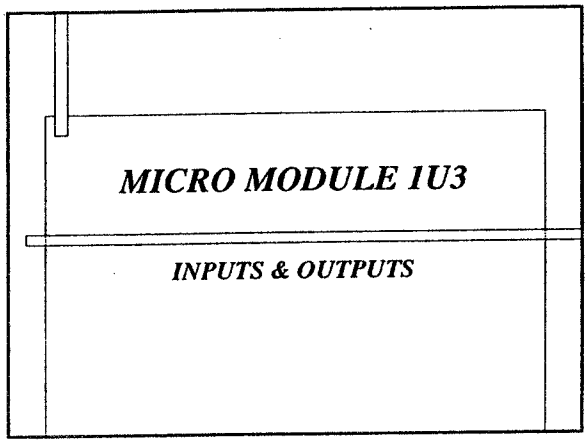
RESET SWITCHES



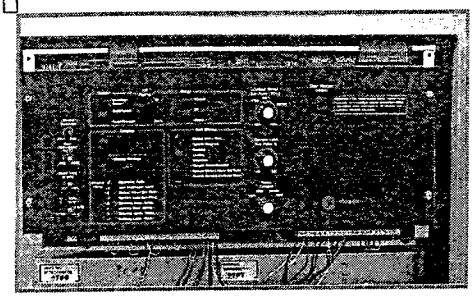


- *Reset Type*
- *Reset Action*
- *Reset Reference*

Reset Type



- *Select Chilled Water Reset Based On;*
  - *Remote Temp (Outdoor Air)*
  - *Evap Delta T*



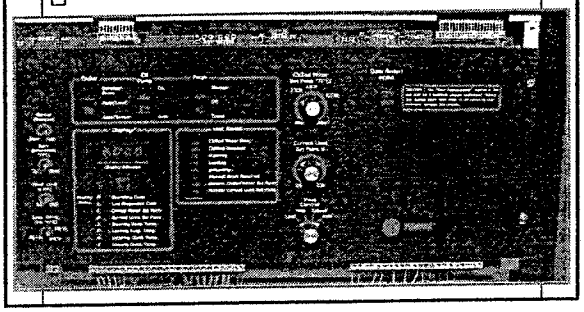
- *Establishes How Aggressive the Reset Will Be*
- *See Page 19 of CVHE SB-22A*

ANALOG/BINARY INPUT CONNECTIONS

1TB6-Terminals 1 & 2

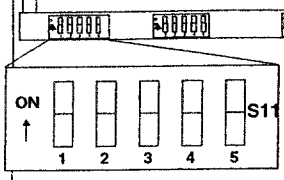
- Bidirectional Communications Link
  - Twisted Wire Pair
  - No Polarity Requirements

TERMINAL STRIP 1TB3



Terminal	Input Connections
1 & 2	Leaving Evap. Water Temp. Sensor
3 & 4	Entering Evap. Water Temp. Sensor
5,6 & 7,8	Spare Temperature Sensors
9,10,11	Condenser Refrigerant Pressure Transducer
12 & 13	Evaporator Refrigerant Temp. Sensor
14 & 15	Condenser Refrigerant Temp Sensor, Ambient Temp Sensor, GBAS Analog Input
16 & 17	External Interlock, External Inhibit
18 & 19	Free Cooling Valve Proof of Closure
20 & 21	Proof of Chilled Water Flow
22 & 23	Proof of Condenser Water Flow
24 & 25	Proof of Inlet Guide Vane Closure

TERMINAL STRIP 1TB4

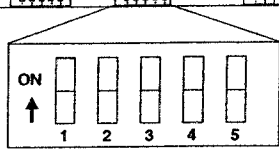


Terminal	*Input Connections*
1 & 2	*Differential Oil Pressure Switch*
3 & 4	*Running External Interlock*
5 & 6	*"Transition Complete" Contacts*
7 thru 12	*3 Phase-Sensing Input (CT's)*
13 & 14	*Oil Temperature Sensor*
15 thru 18	*Motor Winding Temp. Sensors*
19 thru 22	*Bearing Temp. Sensors*

Troubleshooting

Factory Setup for UCM DIP Switches

UCP DIP Switches - S11



- Address DIP Switch Settings

- *b E4 - Phase Loss*
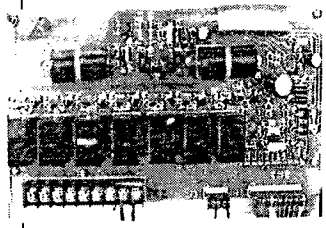
- *b E5 - Phase Reversal*
- *b E7 - High Motor Temperature*

Control Panel Diagnostics

- b E8 - Differential Oil Pressure
- b E9 - Stop Relay
- b EA - High Inboard Bearing Temp
- b Eb - High Outboard Bearing Temp
- b EC - Running Overload
- b Ed - Chilled Water Flow
- b EE - Max Acceleration Time Exceeded
- b FO - Transition
- b F1 - Running External Interlock
- b F2 - Low Oil Pressure
- b F3 - Low Oil Temperature
- b F4 - High Oil Temperature
- b F5 - High Condenser Refrigerant Pressure
- b F7 - Condenser Water Flow
- b F8 - Improper Unit Identification
- b F9 - Free Cooling Valves
- b FA - Actuator
- b Fb - Low Evap Refrigerant Temp
- b Fd - External Interlock
- b FF - Unit Control Module



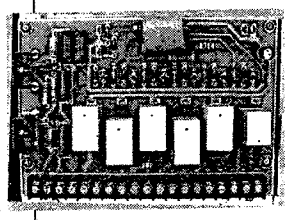
Power Supply Checkout

- Power Supply Output Module (1U2)
- Power Transformer (1T1)

Power Transformer (1T1)

- Check Fuse
- Check Power Source
- Check DC Pin Voltages
- Check AC Pin Voltages

Power Supply Output Module (1U2)



- *Check DC Pin Voltages*
- *Check AC Pin Voltages*
- *If Voltages Are Out of Range & Power Transformer Checks O.K. - Then 1U2 Is Bad*

Compressor Transition Relay (1U2K5)

- *Faulty Current-Sensing Inputs (1TB4-7 Thru 12)*
- *Defective Micro Module (1U3)*
- *Defective Power Supply Output Module (1U2)*
- *Faulty Starter Component(s) or Wiring*
- *Faulty "Proof of Transition" Circuit*

Relay Output Module 1U1

- *Check AC Pin Voltages*
- *Check DC Pin Voltages*
- *Check Voltages with Ribbon Cable Connected (Pins Loaded)*

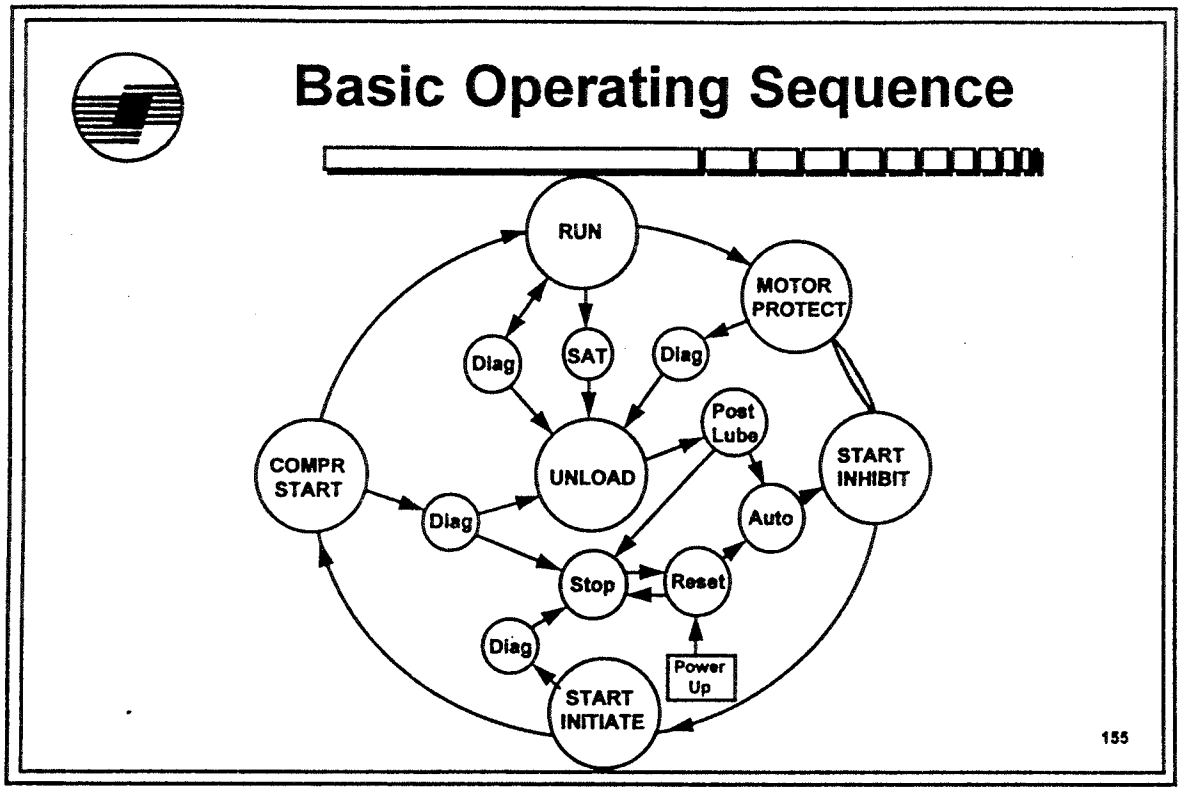
Current Transformer Checkout

- Primary CT's
  - Proper Polarity
  - Properly Sized
  - # of Turns
  - DIP Switches Properly Positioned
  - Monitor Output
- Auxiliary CT's
  - Check Voltages

Vane Control Diagnosis

- Inlet Vane Faults
  - Blown Branch Circuit Fuse (1F3)
  - Faulty Actuator Wiring
  - Defective Actuator
  - Triac Switch Failure In 1U1
  - Micro Module (1U3) Malfunction

Condenser Water Pump Relay Checkout

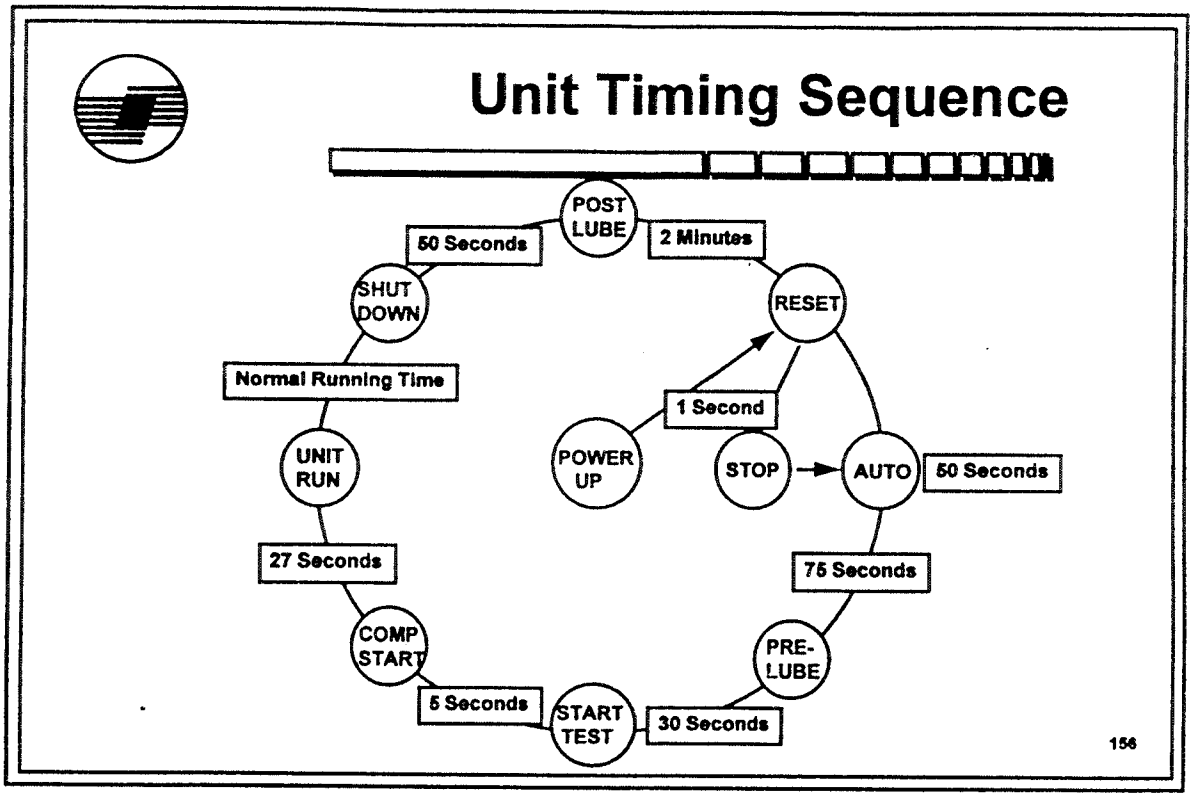


- Measure DC Pin Voltages
- Continuity Checks
- Blown Fuses
- Water Valves Open
- Condenser Water Flow Switch
- Auxiliary Contacts Closing

Remote Generic BAS CWR Interface Module (1U4)

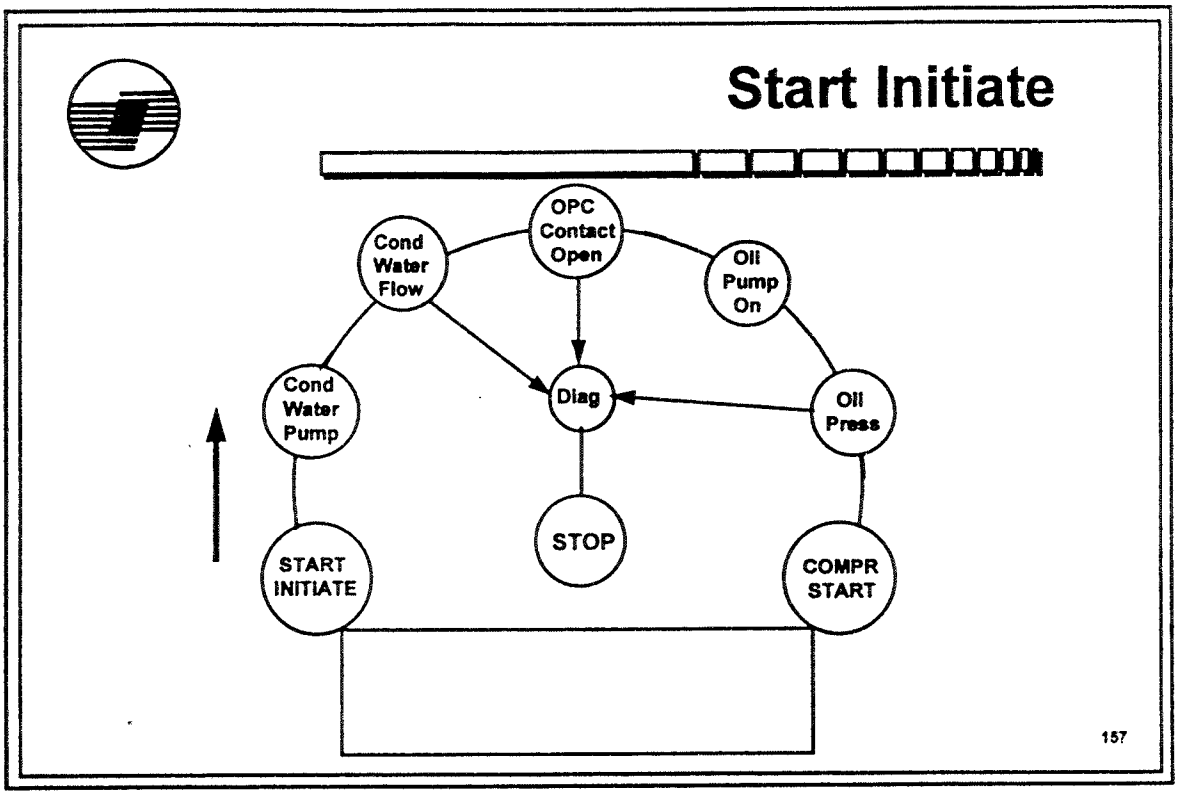
- *Used with Generic BAS Interface*
- *Accepts 0-10 VDC or 4-20mA inputs*
- *Allows Chilled Water Reset from a "Non-Trane" BAS*

System Control Panel



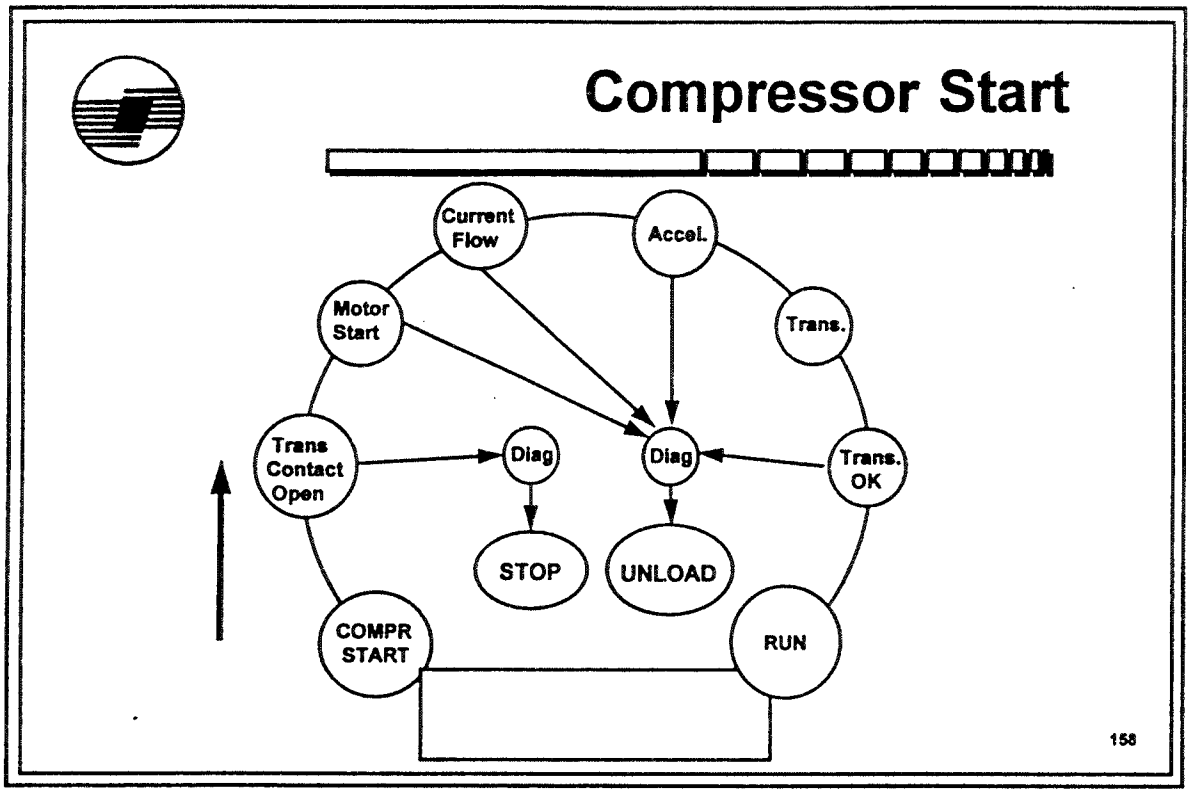
5

•This diagram is an all inclusive view that shows the full operation of the system.



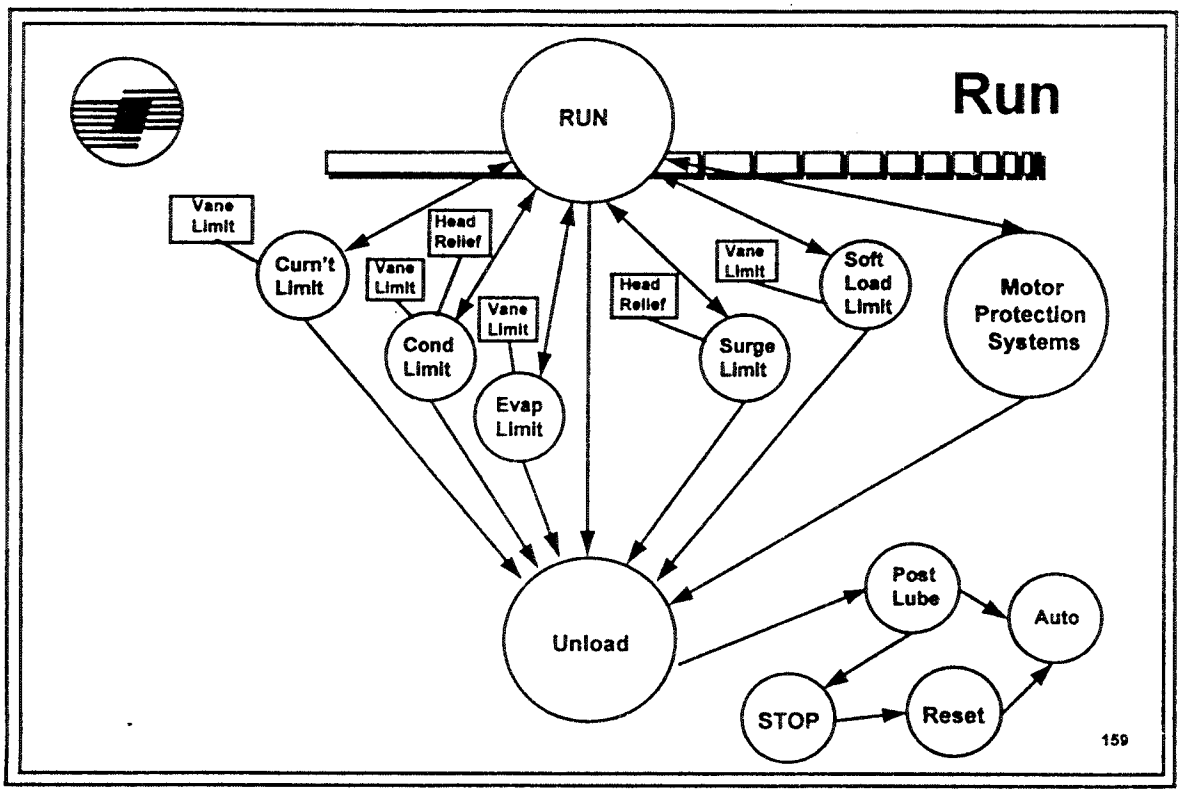
•As you notice, a series of bubbles make up the schematic drawing.

•Follow the bubbles.



•This chart shows timing from startup to shutdown.

•Notice that it takes about 2 to 3 minutes to start and stop a Centravac.



•From start initiate to compressor start many commands must occur.

•Describe the operation as presented.

•Follow the compressor start circuit to compressor run.

•Describe what you see.

•This is the run mode.

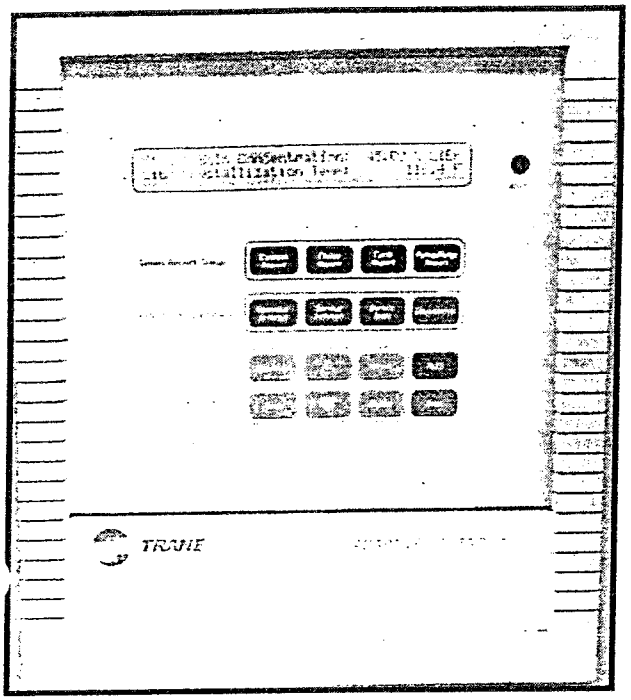
•All run functions have safeties.

•As you notice, most problem areas utilize a vane limit function that closes the vanes as trouble increases. The main objective is to keep the chiller on line, not shut down.

•Example:

Current Limit

Current Limit must hold at 102% RLA
Current Limit must trip in 20 Sec. at 112% RLA
Current Limit must trip in 1.5 Sec. at 140% RLA



During this time the vanes will be unloading at a faster rate based on the increase of amperage.ie: 1 Sec. drive/5 Sec. off
2 Sec. drive/5 Sec. off
3 Sec. drive/5 Sec. off
4 Sec. drive/5 Sec. off
5 Sec. drive/5 Sec. off
Full Drive Closed/System off

UCP 2 Adaptive Control

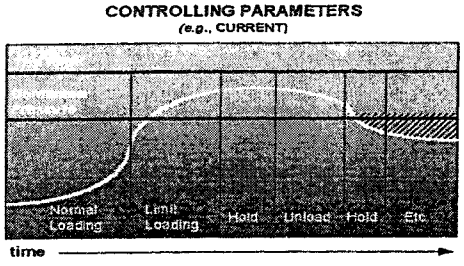
System CVHE - CVHF

1

Why Use Adaptive Control?

* What Do You Expect From A Chiller?
  - To Make the Tons When You *Need* the Tons
* Enhanced Adaptive Control Increases System Reliability
  - Centrifugal Control Strategies For:
    - Low Evaporator Refrigerant Temperature
    - Current Limit
    - Low Leaving Chilled Water Temperature
    - High Condenser Pressure
* Multi-phase Control Strategy Keeps Chiller On-line As Long As Possible, With As Much Load As Possible, *Safely*
* Limit Warning Relay - Contact Closure Notifies Operator

2



Adaptive Control

*Adaptive Control
- Keeps Chilled Water Flowing Reliably
- Provides Maximum Flexibility to Safely Meet Chilled Water Requirements
- Prevents Chiller Shut-Down When an Abnormal Condition is Encountered

*Multi-Phase Control Strategy
- Limit Loading
- Hold Loading
- Reduce Loading
- Machine Shutdown for Protection

3

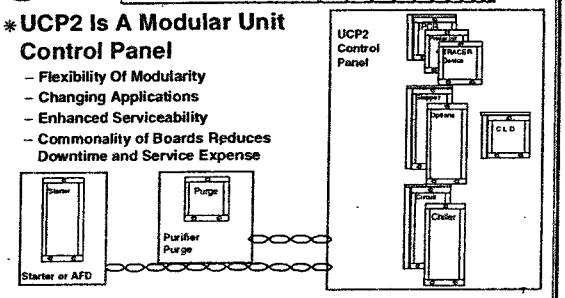
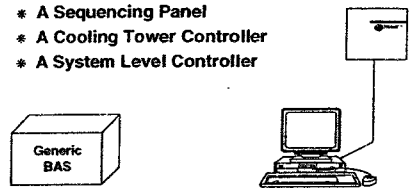
5



UCP 2 Architecture

6



What Is UCP2?

* **UCP2 Is A Modular Unit Control Panel**
  - Flexibility Of Modularity
  - Changing Applications
  - Enhanced Serviceability
  - Commonality of Boards Reduces Downtime and Service Expense

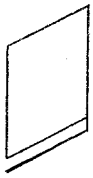
UCP2 Is Not ...

* A BAS Panel
* A Sequencing Panel
* A Cooling Tower Controller
* A System Level Controller

UCP 2 Innovations

* Modular Design
* Clear Language Display (CLD)
* More Input / Output Options Included
* Starter Module (Unit-Mounted or Remote)
* Stepper Drive Motor / Inlet Guide Vanes
* Variable Speed Drive Compressor Motor

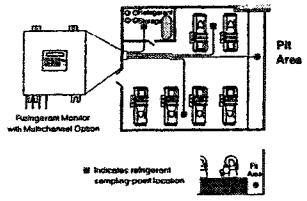
Clear Language Display



* Password Protection
  - Enable/Disable Capability
  - Multiple Passwords
* Over 200 Diagnostics w/Time and Date Stamp
  - Dedicated Diagnostic Summary Report
* Remote Clear Language Display Panel
  - Communicates With 1 - 4 UCP2 Chillers
  - Duplicates Chiller Mounted Panel Functions

10

UCP2...World's Best Early Warning Leak Detector



* Microprocessor-based Purifier Purge Plus
  - Pumpout Rate (Minutes/24 Hours)
  - Total Pumput Time
  - Total Run Time
  - Adaptive Cycle + Time to Next Purge Operation
  - Comprehensive Purge Diagnostics

11

UCP2... The World's Best Early Warning Leak Detector

* Refrigerant Monitor Integration PPM Display
  Assists in ASHRAE Standard 15 Compliance

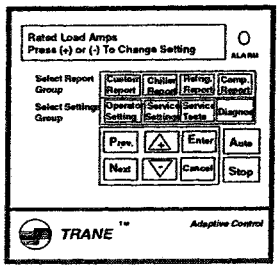
* Start Up Contactor Test
  - Disable
  - Enable
* Default = Disable

40



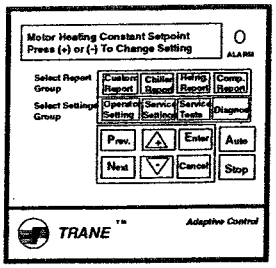
Machine Configuration Group

* Level 2 Contactor Integrity Test
  - Wye Contactor *2K1* Is Energized and Circuit Current Is Looked for.
  - If None Is Found, *2K1* Is Released and *2K3* Is Energized and Current Is Looked for.
  - If None Is Found the Unit Starts. *2K1* Is Re-energized If Current Is Found (Showing a Welded, Closed Contactor) the Unit Goes Into a Diagnostic and Locks Out.
* Used On Wye-delta Starters Only

41

Machine Configuration Group

(Continued)



* Rated Load Amps
  - Range 0 to 2500 in One Amp Increments
* ROM Default - 500

42

Machine Configuration Group

(Continued)

* Motor Heating Constant
  - Range 0 to 100 Minutes
* ROM Default = 25 Minutes
* Background Timer is Incremented by Motor Heating Constant Value Each Time Compressor Starts
* Value is Determined by How Long it Will Take Motor to Dissipate Heat
* See Page 59 CVHE OM-8A

43

Motor Heating Constant

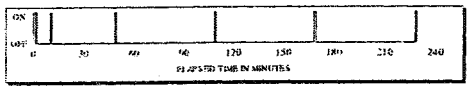
60 Cycle

* CVHE/F 230 - 320 Ton = 30 Min
* CVHE/F 360 - 500 Ton = 35 Min
* CVHE/F 560 - 800 Ton = 40 Min
* CVHE/F 890 - 1280 Ton = 50Min

50 Cycle

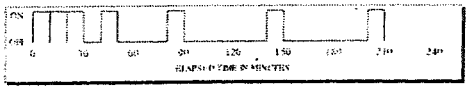
* CVHE/F 190 - 270 Ton = 30 Min
* CVHE/F 300 - 420 Ton = 35 Min
* CVHE/F 470 - 660 Ton = 40 Min
* CVHE/F 740 - 1040 Ton = 45 Min

* RI = BT - 50 Which Is Recalculated After Each Start
* Background Timer Decrements 1 Second for Each Second of Motor Operation
* Background Timer Decrements 1 Second for Every 5 Seconds of "Off" Time



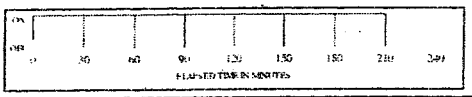
44

Restart Inhibit Time Calculation



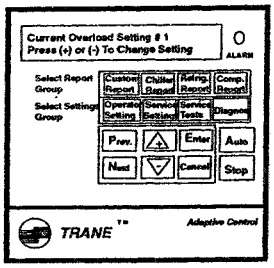
* RI = BT - 50
* Motor Constant = 30
* Machine Runs 10 Minutes @ Start
* Background Timer is Recalculated After Each Start
* RI = (30 - 10 = 20) - 50 = -30 = No Delay @ Next Start
* RI = (20 + 30 - 10 = 40) - 50 = - 10 No Delay
* RI = (40 + 30 - 10 = 60) - 50 = + 10 Delay @ Start

45



Timer Performance

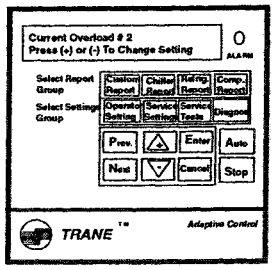
1 min



10 min

30 min

Machine Configuration Group



(Continued)

- Current Overload Setting # 1
  - Range 0 thru 31
- CT Factor = Actual RLA Divided by CT Meter Scale times 139
- CT Meter Scale = Primary Current of CT Divided by Number of Turns
- See Table in Appropriate IOM or CVHE - CLD - 1A
- Screen Supressed in FastPak w/o Starter Module

Machine Configuration Group

(Continued)

- Current Overload # 2
  - Range of Values 224 thru 255
- For Security Reasons, The Second Setting is the 8 Bit One's Complement of the First Setting
- Select Value From Table in Appropriate IOM
- Cannot be Changed From Remote CLD or Tracer

Setting Overload

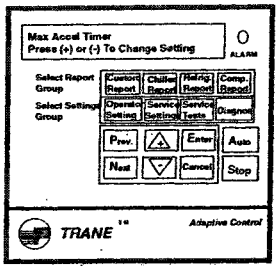
RLA (900) / CT (1000) Scale X 100 = A Number

900 / 1000 = .90 X 100 = 90

Table 3 Scale - 90
Current Overload Setting #1 - 24
Current Overload Setting #2 - 231
Warning, These two numbers must always add up to 255: This is a computer binary code.

See Page 64,65 - CVHE - M-7

Binary Numbering Code



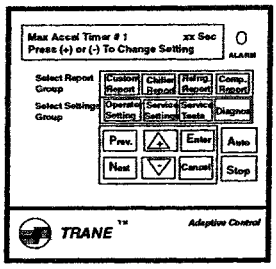
* 1 (2^0)
* 2 (2^1)
* 4 (2^2) 2 x 2
* 8 (2^3) 2 x 2 x 2
* 16 (2^4) 2 x 2 x 2 x 2
* 32 (2^5) 2 x 2 x 2 x 2 x 2
* 64 (2^6) 2 x 2 x 2 x 2 x 2 x 2
* 128 (2^7) 2 x 2 x 2 x 2 x 2 x 2 x 2
* 255

8-Bits

Binary #	1	2	4	8	16	32	64	128	=	255
24	0	0	0	1	1	0	0	0		
231	1	1	1	0	0	1	1	1		
	1	1	1	1	1	1	1	1		

Machine Configuration Group

(Continued)

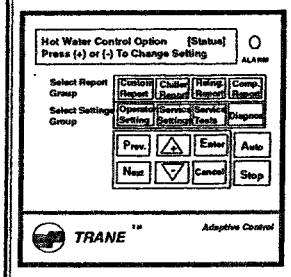


* Maximum Acceleration Timer # 1
  - Range of Values 224 thru 255
* For Security Reasons, The Second Setting is the 8 Bit One's Complement of the First Setting
* Select Value From Table in Appropriate IOM
* Cannot be Changed From Remote CLD or Tracer

52

Machine Configuration Group

(Continued)

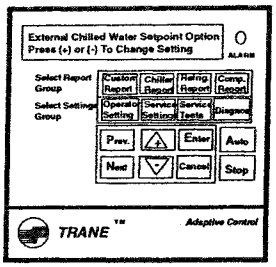


* Maximum Acceleration Timer # 1 Values
  - Variable Speed = 20
  - Y-Delta = 27
  - X Line = 6
  - Solid State = 20
  - Auto Transformer = 16
  - Primary Reactor = 11

53

Machine Configuration Group

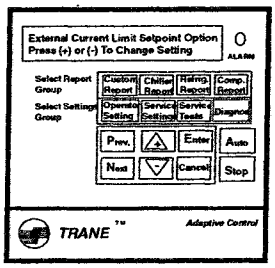
(Continued)



* Hot Water Control Option
  - Installed
  - Not Installed
* Control is Transferred to Hot Water Control
  - Controls From Leaving Condenser Water Temp
  - Evaporator Temperature is Allowed to Float
  - Typically Used When Evaporator Water is Taken From and Returned to a Lake, River etc.
* Does Not Appear if Compressor Power is "Engine Generator"

54

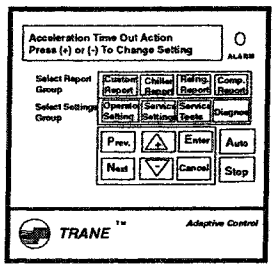
Machine Configuration Group



(Continued)

- External Chilled Water Setpoint Option
  - Installed
  - Not Installed
- Requires Options Module

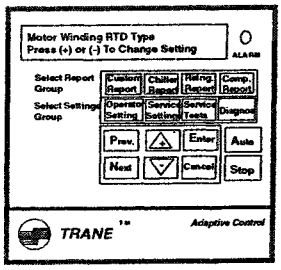
Machine Configuration Group



(Continued)

- External Current Limit Setpoint Option
  - Installed
  - Not Installed

Machine Configuration Group

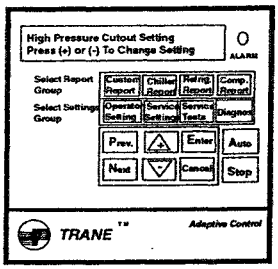


(Continued)

- Acceleration Time Out Action
  - Possible Values are Transition & Shutdown
  - If Shut Down is Selected, a MMR is issued if a Shutdown Occurs
  - If Transition is Selected an IFW Will Be Issued When Appropriate
- Not Available for FastPak w/o Starter Module

Machine Configuration Group

(Continued)

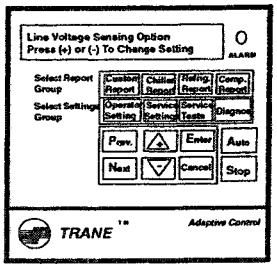


- Motor Winding RTD. Type (Resistive Temperature Device - linear Sensor)
  - Possible Values
  - 100 Ohm @ 0 C
  - 75 Ohm at 75 F
- Factory default is 75 Ohm at 75 F

58

Machine Configuration Group

(Continued)

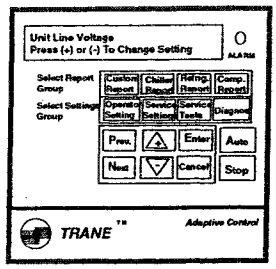


- High Pressure Cutout Setting (Vessel)
  - Range is -5 to 500 PSIG
  - Increments of 1 PSIG From -5 to +5
  - Increments of 5 PSIG From 5 to 500 PSIG
  - Factory default is 15 PSIG - Standard 25 PSIG - ASME

59

Machine Configuration Group

(Continued)

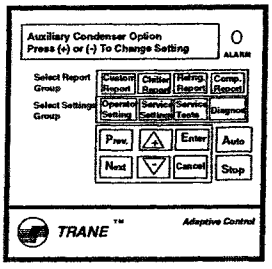


- Line Voltage Sensing Option
  - Values are Installed; Not Installed
  - Factory default is Not Installed
- Not Available On FastPak Units w/o Starter Module

60

Machine Configuration Group

(Continued)

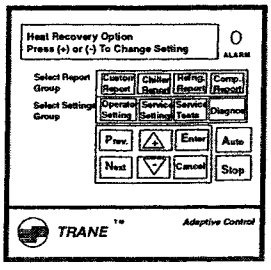


* Unit Line Voltage
  - Values = 180 through 6600 Volts in 5 Volt Increments
* ROM Default is 460 V
* Screen is Suppressed if Line Volt Sensing Option is Not Installed

61

Machine Configuration Group

(Continued)

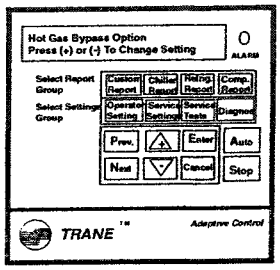


* Auxiliary Condenser Option
  - Possible Values are Installed & Not Installed
* Not Available for FastPak & Duplex Units

62

Machine Configuration Group

(Continued)

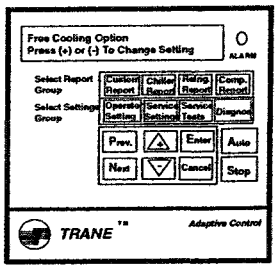


* Heat Recovery Option
  - Possible Values are Installed & Not Installed
* Not Available for FastPak & Duplex Units

63

Machine Configuration Group

(Continued)

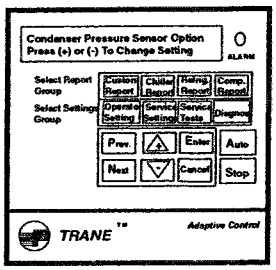


* Hot Gas Bypass Option
  - Possible Values are Installed & Not Installed
* Not Available for Duplex Units
* Inlet Guide Vane Output Must Be Set For: "Stepper Motor", If Not UCP-2 will Change it & Issue a Message

64

Machine Configuration Group

(Continued)

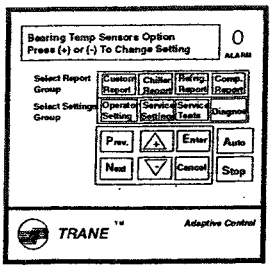


* Free Cooling Option
  - Possible Values are Installed & Not Installed
* Not Available for FastPak & Duplex Units

65

Machine Configuration Group

(Continued)

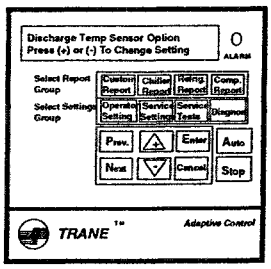


* Condenser Pressure Sensor Option
  - Possible Values are Installed & Not Installed
* Must Have Optional Condenser Pressure Transducer

66

Machine Configuration Group

(Continued)

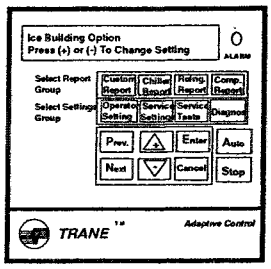


* Bearing Temperature Sensor Option
  - Value - Installed or Not Installed
* Two Temperature Sensors Installed In Oil Return Lines
* Trip Value = 180°
* Default Value = Not Installed

67

Machine Configuration Group

(Continued)

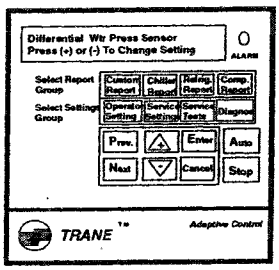


* Discharge Temperature Sensor Option
  - Values - Installed or Not Installed
* Sensor is Recommended if Hot Gas Bypass is Used to Prevent Stressing "O" Rings
* Diagnostic @ 200°

68

Machine Configuration Group

(Continued)

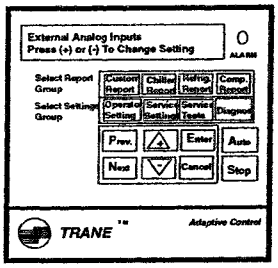


* Ice Building Option
  - Values are Installed or Not Installed
* Not Available on Duplex Units
* Unit Operates @ 100% Load During Ice Making

69

Machine Configuration Group

(Continued)

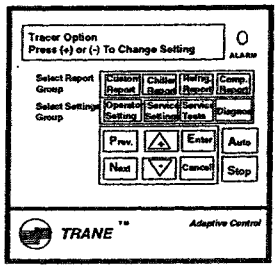


- Differential Water Pressure Sensing Option
  - Value - < 150 Psig, Installed or Not Installed
- Water Pressure is Measured on Incoming Water Line & Exiting Line
- UCP Processes Signals thru 2 Relays
- Entering Water is Measured @ De-energized

70

Machine Configuration Group

(Continued)

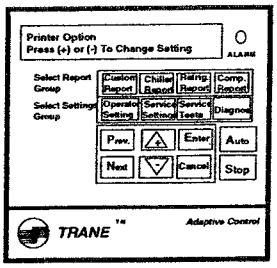


- External Inputs
  - Values 4-20 mA or 2 - 10 VDC
- Default Setting is 4-20 mA

71

Machine Configuration Group

(Continued)

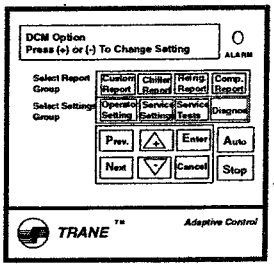


- Tracer Option
  - Values Installed or Not Installed
- If Communication is Established With a Tracer, It will Automatically be Installed

72

Machine Configuration Group

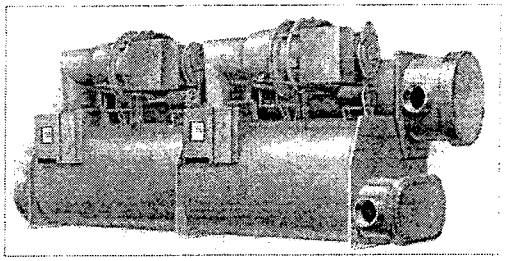
(Continued)



- Printer Option
  - Value - Installed or Not Installed
- Printer within 50 Feet of the UCP
- Can be Utilized for Diagnostic Purposes

73

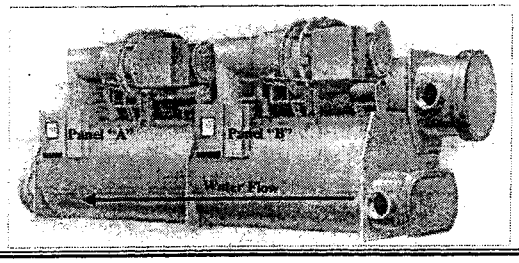
Machine Configuration Group



(Continued)

- Duplex Control Module (DCM) Option
  - Value = Installed or Not Installed
- Duplex Chiller Requires an Additional Module to Coordinate Control of Two Compressors
- Will Automatically Install When Communication is Established

74

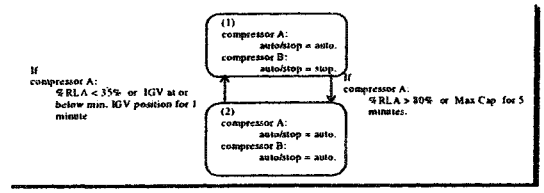


Duplex Chiller

75

Duplex Chiller Control

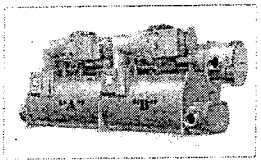
The Duplex Chiller Contains Two Full UCP2 Panels for the Control of Each Compressor



76

Features Not Supported on Duplex

* Ice Making
* Hot Water Control
* Hot Gas Bypass
* Free Cooling
* Base Loading
* Chilled Water Reset



77

Duplex Staging

78

Control Strategy

* Compressor "A" Starts & is Allowed to Load
* When Compressor "A" is at 80% of RLA for five Minutes, Compressor "B" Starts
* Compressor "A" Unloads & Both Compressors Share Load Equally
* When Compressor "A" is Operating at 35% RLA, Compressor "B" is Shut Down

79

Example

* 16^{O} ▲T Chiller (42° / 58°)
* 8^{O} ▲T Each Circuit
* 600 RLA Each Compressor

* CWSPB = RA (EEWT - CWSP) + CWSP
* RA = 8/16 or RA = .5
* CWSPB = .5 x (58 - 42) + 42 = 50°

* Same Chiller Operating @ 10° ▲T (42 / 52)

* CWSPB = .5 x (52 - 42) + 42 = 47°

80

Example

* 16^{O} ▲T Chiller (42° / 58°)
* 8^{O} ▲T Each Circuit
* 600 RLA Each Compressor

* $VELWTB = \frac{(\%RLA_A \times RLA_A)}{\%\ RLA_A \times RLA_A + \%\ RLA_B \times RLA_B} (EEWT - ELWT) + ELWT$

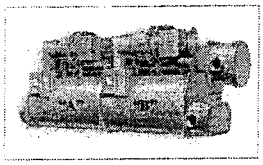
* $VELWTB = \frac{100\% \times 600}{100\% \times 600 + 100\% \times 600} (58 - 42) + 42$

* VELWTB = .5 x (58 - 42) + 42 = 50°

81

Same Chiller Operating @ 10° ▲T (42 / 52)

Compressor A = 450 Amps (75% of RLA)
Compressor B = 300 Amps (51% of RLA)



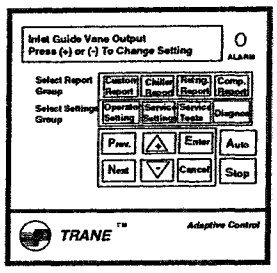
* $VELWTB = \frac{(\%RLA_A \times RLA_A)}{\%\ RLA_A \times RLA_A + \%\ RLA_B \times RLA_B} (EEWT - ELWT) + ELWT$

* $VELWTB = \frac{75\% \times 600}{75\% \times 600 + 51\% \times 600} (52 - 42) + 42$

* VELWTB = .6 x (52 - 42) + 42 = 48°

82

Virtual Leaving Water Temperature - Compr "B"



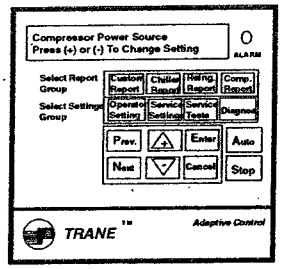
* Circuit "B" Does Not Have a Leaving Water Temperature Sensor
* DCM Must Calculate a Virtual Leaving Water Temperature (VELWTB)

$VELWTB = \frac{(\%RLA_A \times RLA_A)}{\%\ RLA_A \times RLA_A + \%\ RLA_B \times RLA_B} (EEWT - ELWT) + ELWT$

83

Machine Configuration Group

(Continued)

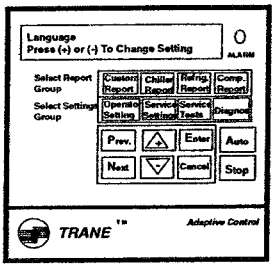


* Inlet Guide Vane Output
  - Possible Values are:
  - Stepper Motor
  - Pulsed (Induction Motor)
* If Machine is Equipped with Hot Gas Bypass, and IGV Output is Changed to "Pulsed", the Micro Will Un-Install HGB

84

Machine Configuration Group

(Continued)

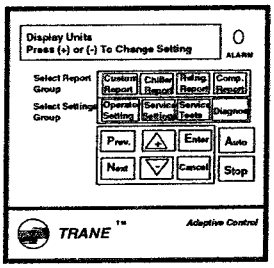


* Compressor Power Source for CVHE/F/G/B ONLY
  - Choices:
  - Utility
  - Engine/Generator

85

Service Settings

(Basic Setups)

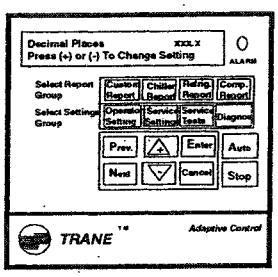


* Language Settings
  - English (Factory ROM Default)
  - Francais (French)
  - Deutch (German)
  - Espanol (Spanish)
  - Nippon (Japanese)
  - Italiano (Italian)
  - Nederlands (Dutch)
  - Portuguese

86

Service Settings

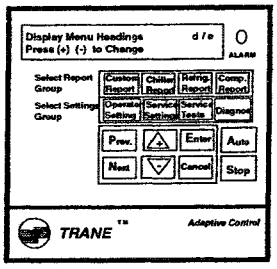
(Basic Setups)



* Display Units
  - English (Factory ROM Default)
  - SI

87

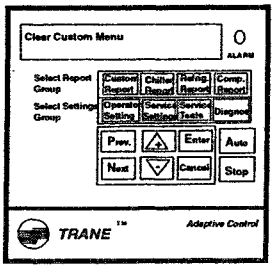
Service Settings



(Basic Setups)

* **Decimal Places**
  - **XXX.X (Factory ROM Default)**
  - **XXX.**

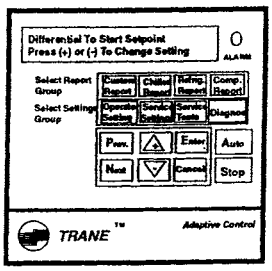
Service Settings



(Basic Setups)

* **Display Menu Headings**
  - **Enable**
  - **Disable**
* **If Disabled, the Menu Headings in Each Menu or Group Will be Suppressed**

Service Settings

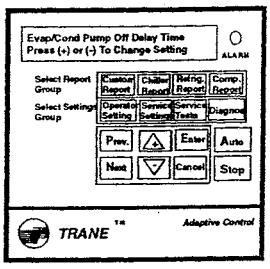


(Basic Setups)

* **Clear Custom Menu**
  - **When "Enter" Is Pushed, "Custom Menu Has Been Cleared" Appears for Two Seconds**

Service Settings

(Basic Setups)



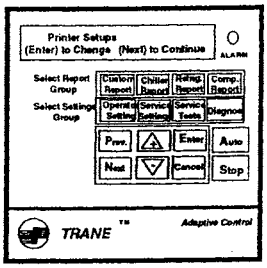
* **Differential To Start Setpoint**
  - Range is 0 TO 10 F
  - Factory Preset = 5
* **Differential To Stop Setpoint**
  - Range is 0 To 10 F
  - Factory Preset = 5

Warning: This Setting Will Control With Low Water and Refrigerant Temperature Limits.

91

Service Settings

(Basic Setups)

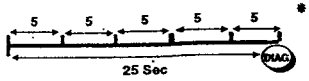


* **Pump Off Delay**
  - Range = 1 - 30 Minutes
* **If Mode is "Hot Water Control" Then Item is Condenser Pump Off Delay**

92

Service Settings

(Basic Setups)

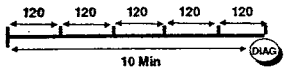


* **Printer Setups**
  - Print on Time Interval-enable
  - Print Interval Time-hours
  - Print on Diagnostic-enable
    OR
  - Number of Pre-diag.-Reports
  - Pre-diagnostic Reports-interval
  - Printer Baud Rate-300
  - Printer Parity-none
  - Printer Data Bits-8
  - Printer Stop Bits-1
  - Printer Hand Shaking-xon/xoff

93

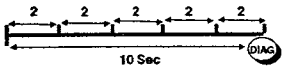
Service Settings

DEFAULT:
No. of Reports = 5
Interval = 5 Sec



Benefit: This feature freezes "pictures" of system conditions at preset time intervals leading up to a diagnostic shutdown.

- Print on Diagnostic
  - Enable (Default) /Disable
- Number of Pre-Diagnostic Reports
  - Range: 1 – 5
  - Default: 5
- Diagnostic Report Interval
  - Range: 2 – 120 Seconds
  - Default: 5 Seconds



Service Settings

Printing On A Diagnostic (Cont'd.)

MAXIMUM WINDOW:
No. of Reports = 5
Print Interval = 120 Sec

SMALL WINDOW:
No. of Reports = 5
Print Interval = 2 Sec

Printed Report

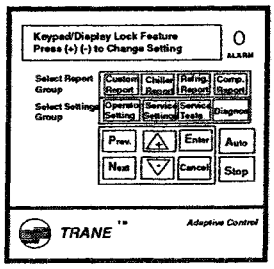
97

Service Settings

(Basic Setups)

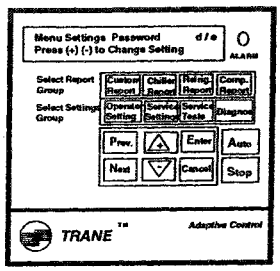


- **Clear Restart Inhibit Time**
  - For Service Engineers Only
  - Very Dangerous To The Equipment
    - Eliminates The 30 Minute Anti-Recycle Timer
    - A Second Screen Line Appears For 2 Seconds, Stating Restart Inhibit Timer Has Been Cleared

98

Service Settings

(Field Start Up)

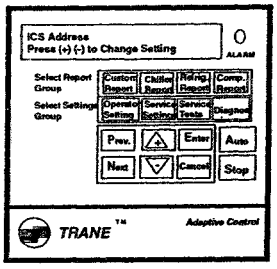


- **Keypad Lock**
  - Disables Keypad Including "Stop" Button
  - Selections: Enable or Disable
- **Press Previous & Enter to Unlock**

99

Service Settings

(Field Start Up)



* Menu Settings Password Feature
  - Permits the "Settings" in Each Menu to Be Password Protected
  - Menus can Still be Viewed but Changes Cannot be Made

100

Service Settings

(Field Start Up)

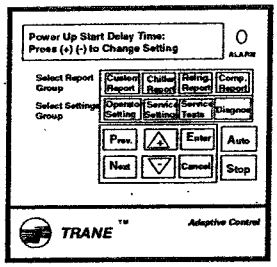
* ICS Address = Integrated Comfort System
  - 6 - Ctv's to 1 Tracer, Summit, Chiller Plant Manager
  - ICS "DIP switch" settings are in UCP2 software
  - Point Type 42

101

Service Settings

(Field Start Up)

Tracer Address List



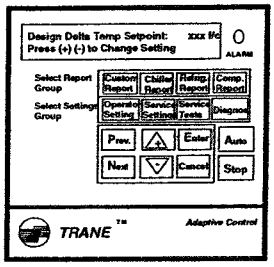
Name	Point Type	Address
Rooftop	09	1
VAV	25	35
CTV	42	65

* Tracer 100 Address Assignment 01 - 127 (65 is the default)
* Warning Refer to Current Tracer Programming Guide

102

Service Settings

(Field Start Up)

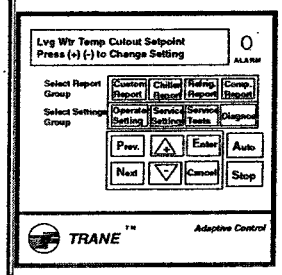


* **Power Up Time Delay**
  - Delays Start Up Of Chiller by Programmed Amount After a Power Outage
* **Range:**
  - 0 to 600 Seconds in Increments of 1 Minute
  - Multiple Chiller Delay Time

103

Service Settings

(Field Start Up)



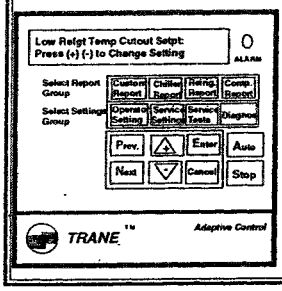
* **Design Temperature Delta "T"**
  - See Chiller Order Specs. (4 to 30 F)
  - Factory Preset is 10 F

104

Service Settings

(Field Start Up)

* **Leaving (Low) Water Temperature Cutout Setpoint (-10 to 36 F)**
  - A 1.7 F. Null Zone exists between the Chilled Water Setpoint and the Low Water Temperature cutout setpoint :



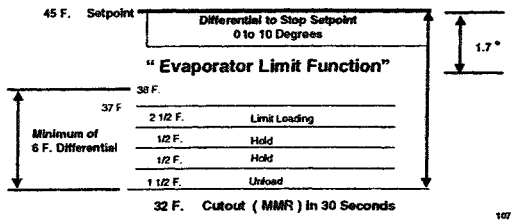
Chilled Water Setpoint	37.0	F
Low Water Temp. Setpoint	35.3	F
Differential is	1.7	F

* **If Setpoint is Adjusted Below 35.3°, "Warning: Adequate Antifreeze Required"**

105

Service Settings

(Field Start Up)

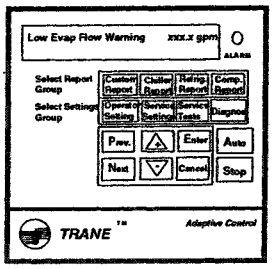


- Low Refrigerant Temperature Cutout Setpoint (-35 to 36 F)
  - A 6 F. Null Zone exists between the Chilled Water Setpoint and the Low Refrigerant Temperature cutout setpoint.

    Chilled Water Setpoint. 37 F
    Low Refrigerant Temp. Setpoint 31 F
    Differential is 6 F
- If Setpoint is Adjusted Below 28.5°, "Warning: Adequate Anti-freeze Required"

106

Freeze Protection

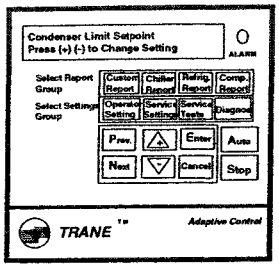


Evaporator Refrigerant Temperature Cutout

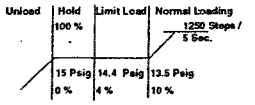
107

Service Settings

(Field Start Up)



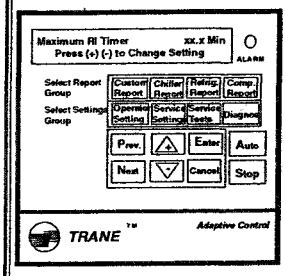
- Low Flow Warning
- Must Have Differential Water Sensing Option Installed
  - Range: 0.0 to 4.0 GMP/Ton in Increments of 0.1 GPM



108

Service Settings

(Field Startup Group)

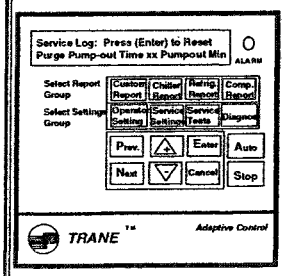


* **Condenser Limit Setpoint**
  - High Pressure Cutout
  - 80 to 120%
  - Factory default is 93%
    120% of 15 = 17 PSIG

109

Service Settings

(Field Startup Group)

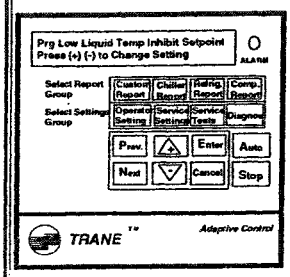


* **Maximum Restart Inhibit Setting**
  - 30 to 60 Minutes
  - Factory Default Is 60 Minutes
  - Used to Prevent Motor Overheating
  - The BI Timer Is Based on the Size of the Unit. The Minimum Time Is 30 Seconds to 60 Minute Depending on the Motor Heat (165 F.)
  - Turn to Page 63 of CVHE-M-7B and Page 78
* **Purge Control Type**
  - Micro Purge / Stand Alone Purge

110

SERVICE SETTINGS

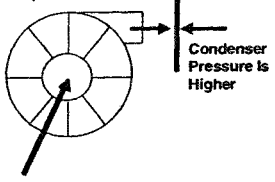
(Field Startup Group)



* **Service Log - Press Enter to reset**
  - Purge pumpout time 9999.9 min.
* **Service Log - Press Enter to reset**
  - Time since last reset 9999.9 days
* **Purge Maximum Pumpout Rate**
  - 1 to 100 min / 24 hrs.
  - Factory default is 20 min. / 24 hrs.
* **Purge Disable Pumpout Alarm**
  - Is a service tool.Can be set up to 72 hours in 1 hr. increments

111

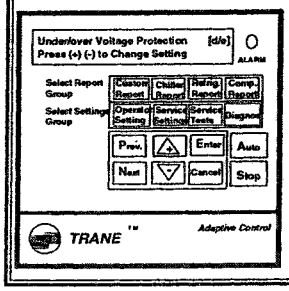
SERVICE SETTINGS



(Field Startup Group)

- Purge Low Liquid Temp. Inhibit
  - Factory default is enable
- Purge Low Liquid Temp Inhibit Setpoint
  - Range of Value is 32 to 50° F
  - ROM Default is 40 ° F
  - Not Available on Stand Alone Purge Unit

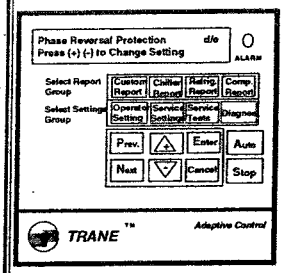
SERVICE SETTINGS



(Field Startup Group)

- Surge Protection
  - Looks at current fluctuations (2 [Was 5] in 60 seconds)
  - Measures the current change intensity (RMS current change of 1.3/1 [Was 1.4/1] within .8 second)
  - Measures the intensity for 15 minutes and Energizes the Head Relief Relay
  - After 15 Minutes - shuts the machine down
  - Factory ROM default is enabled

SERVICE SETTINGS

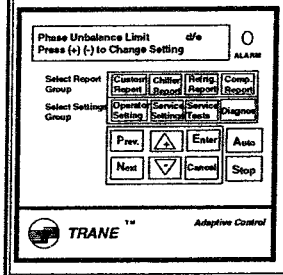


(Field Startup Group)

- Under / Over Voltage Protection
- Only Active if The Line Voltage Sensing Option Has Been Installed
  - Selection Options: Enable or Disabled
  - ROM Default = Disable

SERVICE SETTINGS

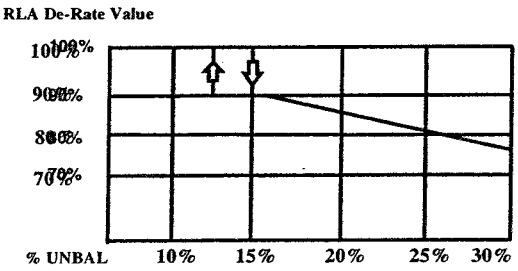
(Field Startup Group)



* **Phase Reversal Protection**
  - Clockwise Rotation Only
  - Will trip in 0.3 second after the compressor starts
  - Factory ROM default is Enable

115

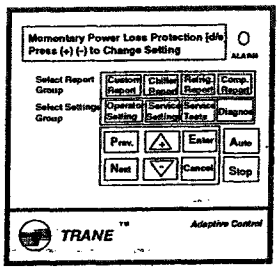
SERVICE SETTINGS



(Field Startup Group)

* **Phase Unbalance Limit**
  - Derates Motor After 15%
  - Ultimate Trip point 30% (Used to be 25%)
  - Time to trip = 30 Sec.
  - Individual sensing error 3% or 6% phase-to-phase
  - Factory ROM default is Enable

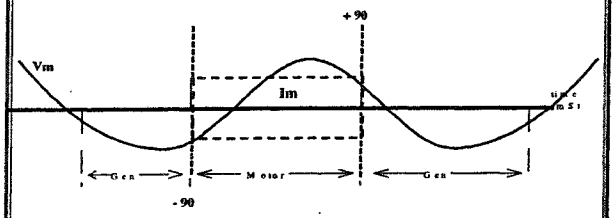
116



RLA De-rate Vs Percent Motor Current

117

SERVICE SETTINGS



(Field Startup Group)

* Momentary Power Loss
* Actually Determining if The Motor is Consuming Power or Generating Power
  - 2 Cycles Trigger- 6 Cycles Stop
  - Factory ROM default is Enable
* Screen is Suppressed if Starter Type is AFD

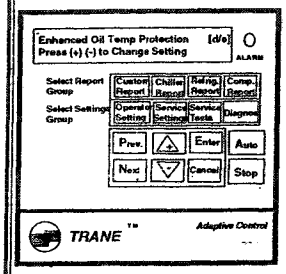
118

Momentary Power Loss

If Phase of Im +/- 90 Degrees Respect to Vm, It Is in the Motor Region

119

Momentary Power Loss



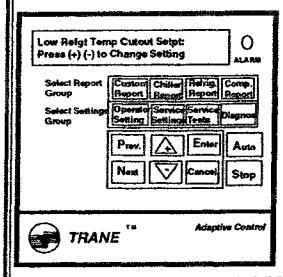
(CONTINUED)

* Looks at Relationship Between Voltage & Current
* Uses V (ab) & I [c] to Determine Power Flow
* V (ab) is Obtained From the 24 VAC Control Transformer
* I [c] is Obtained From CT Output
* Power Transformer Must be Wired to Proper Phases (Verify Wire Numbers by Use of Wiring Diagram)
* Polarity to Starter Module Must be Correct
* C/T Wiring Must be Correct

120

Service Settings

(Field Startup Group)

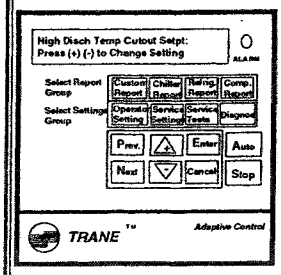


- **Enhanced Oil Protection**
- **CHVE/F/G/B, FastPak Wtr, CVGE & CVGF**
  - Selections: Enable or Disable
  - ROM Default = Enable
- **Sets Low Oil Temperature Cutout at 30° F Above Saturated Suction Temp or 100° F, Whichever is Higher**

121

Service Settings

(Field Startup Group)

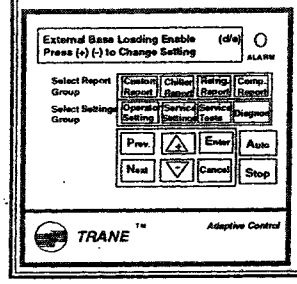


- **Oil Temperature Setpoint**
  - 100 to 160 F
  - Factory ROM default is 143° F
- **Low Oil Temperature Setpoint**
  - 80 to 140 F
  - Reset 5 F above setpoint
  - Factory setpoint is 95 F
- **Screen Suppressed When Enhanced Oil Protection is Enabled**

122

Service Settings

(Field Startup Group)

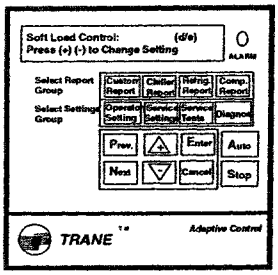


- **High Discharge Temperature Cutout**
  - Range of Values: 170 to 220°
  - Factory Pre-Set 200°
- **Not Available On Duplex**

123

Service Settings

(Field Startup Group)

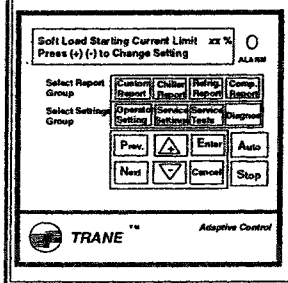


* **External Base Loading**
  - Base Loading Allows an Analog Signal to Send a Signal to Chiller to Meet a Predetermined Current Setting
  - IE: Set Load to 80% Current Limit - Chiller Goes to 80% Without Regard to Normal Load Signals
* **Default Is Disable**
  - 4 To 20 Ma.
  - 0 To 10 Vdc
  - Dip Switch Setting

124

Service Settings

(Field Start Up)

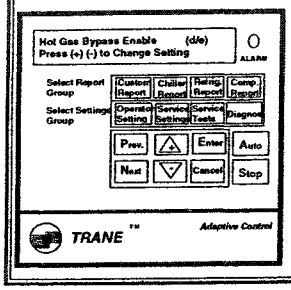


* **Soft Loading Control Enable**
  - Used to Prevent Over-current Fast Start Operation
  - Avoids Overshooting of Setpoint
  - Stabilizes Startup of Short Loop Water Systems
  - Factory Default Is Disable
* **Soft Load Starting Current Limit Setpoint** (CLS)
  - Adjustable From 40 to 100%
  - Adjustable in 1% Increments
  - Factory Default Is 100%

125

Service Settings

(Field Startup Group)

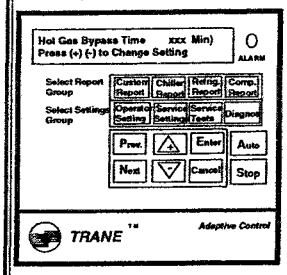


* **Soft Load Current Limit Rate of Change**
  - Adjustable From 0.5 to 5% Per Minute
  - Factory Default Is 5% Per Minute
* **Soft Load Leaving Water Temperature Rate of Change**
  - Adjustable From 0.5 to 5 F Per Minute
  - Adjustable in 0.1 to 1.0 F Per Degree

126

Service Settings

(Field Startup Group)



* Hot Gas Bypass Enable
  - Eliminates Short Cycling Due to Light Load Chiller Operation
  - Provides a False Load to the Evaporator
  - Factory Default Is Disable
* Hot Gas Bypass Timer
  - Selections: Enable/disable
  - Factory Default Enable

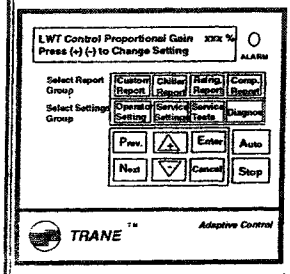
127

Service Settings

(Field Startup Group)

* Maximum HGBP Time
  - Values: 1 to 480 Minutes
* HGBP Mode IGV Target
  - After Hot Gas Bypass Mode is Entered, the IGV will "Tic" to This Setting
  - Range of Values: 0 to 30%

128



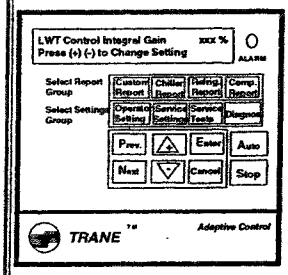
Hot Gas Bypass

* Must be Installed (Config)
* Must be Enabled (Thru Field Start Up or Tracer)
* Vanes Must be Either "Fully Closed" or "Guide Vane Closed Travel Stop" Which Ever is Larger
* When Chiller Water Temperature is .5° Below Setpoint, Mode will Change to Hot Gas Bypass
* Vane Actuator will "Tic" to "HGBP Mode IGV Target"
* Hot Gas Bypass is Active for Period Not to Exceed Maximum HGBP Time
* When Chilled Water Temperature Rises .5° above Setpoint, Hot Gas Bypass Mode will be Exited
* Limits & Differential to Stop are Active

129

Service Settings

(Field Startup Group)

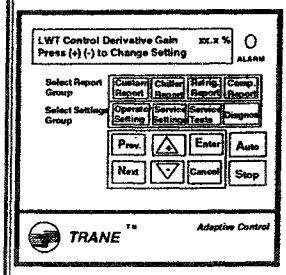


* **Leaving Water Temperature Control Proportional Gain**
  - **Range - 0 to 100%**
  - **Factory Setting 10.0%**

130

Service Settings

(Field Startup Group)

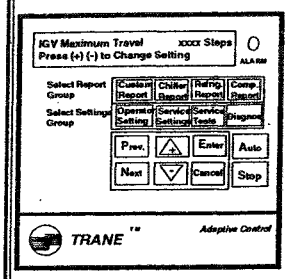


* **Leaving Water Temperature Control Derivative Gain**
  - **Range 0 to 1 %**
  - **Factory Setting - 0.110%/F**

131

Service Settings

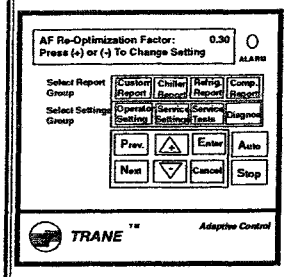
(Field Startup Group)



* **Leaving Water Temperature Control Derivative Gain**
  - **Range 0 to 10.0%**
  - **Factory Setting - 0.0%**

132

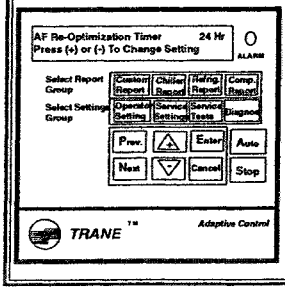
Service Settings



(Field Startup Group)

* Inlet Guide Vanes (IGV) Maximum Travel Setpoint
  - Stepper Motor
  - Range 0 to 60,000 Steps
  - Increments of 100 Steps
  - Machine Specific Set @ Factory
* IGV Closed Travel Stop
  - Range Is 0 to 30%
  - Factory Default Is 0%
* Screens Are Only Displayed If IGV Output Is Selected As "Stepper Motor"

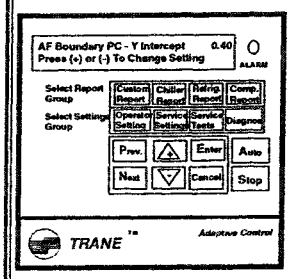
Service Settings



(Field Start Up Group)

* AF Re-Optimization Factor
  - Select: AF Re-optimization Factor
  - Enter: 0.30
* Determines Distance From Surge Line Before Optimization Begins Again
* Too Large a Value Will Delay Optimization

Service Settings

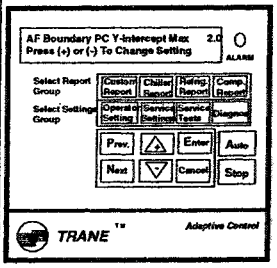


(Field Start Up Group)

* AF Re-optimization Timer
* Establishes Time for the Removal of the Surge Flag
  - Select: Enter: 24 Hrs

Service Settings

(Field Start Up Group)

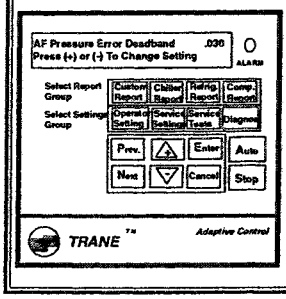


* Select: AF Boundary PC - Y Intercept
  - Enter: 0.40
* Used to Locate the Boundary Pressure Coefficient

136

Service Settings

(Field Start Up Group)

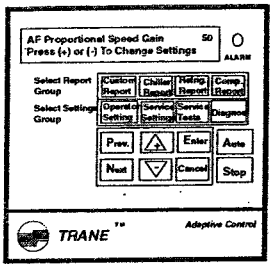


* AF Boundary PC-Y Intercept Maximum Setting
  - Enter: 2.0
* Intercept Is Never Allowed to Exceed This Value

137

Service Settings

(Field Start Up Group)

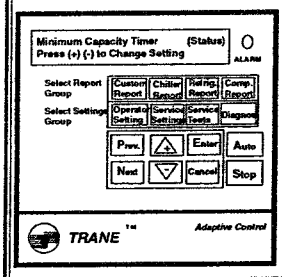


* AF Pressure Error Deadband
  - Enter: 0.30
* Defines a Region Where No Background Decreases Will Occur

138

Service Settings

(Field Start Up Group)

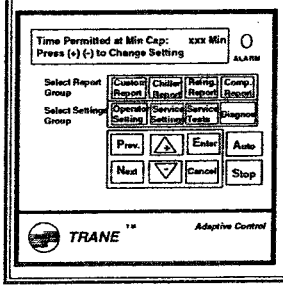


* AF Proportional Speed Gain
  - Enter: 50
* Used to Convert the Pressure Error to Difference in Hz

139

Service Settings

(Field Startup Group)

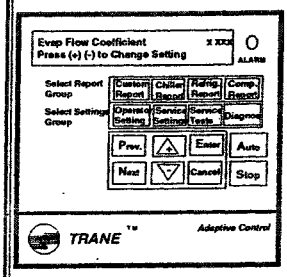


* Minimum Capacity Timer
* Non AFD Chillers, Timer Times Out When Chiller Is at Minimum IGV Position & LWT < Setpoint
* AFD Chillers, Timer Times Out When Chiller Is at Minimum Speed or Minimum IGV Position
  - Values: Enable or Disable

140

Service Settings

(Field Startup Group)

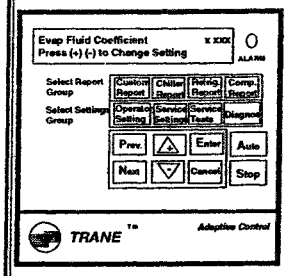


* Time Permitted at Minimum Capacity
  - Range: 1 to 480 Minutes in 1 Minute Increments

141

Service Settings

(Field Startup Group)

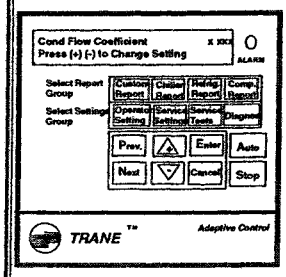


- ✱ Evaporator Flow Coefficient
  - Range 0 to 3,000
  - Factory Setting 1,000

142

Service Settings

(Field Startup Group)

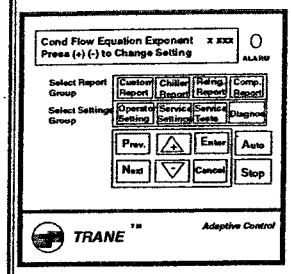


- ✱ Evaporator Fluid Coefficient
  - Range 0 to 1,000
  - Factory Setting 600

143

Service Settings

(Field Startup Group)

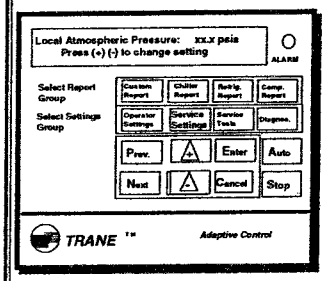


- ✱ Condenser Flow Coefficient
  - Range 0 to 2,000
  - Factory Setting 500

144

Service Settings

(Field Startup Group)



* **Condenser Flow Equation Exponent**
  - Range 0 to 1,000
  - Factory Setting 600

145

Service Settings

(Field Startup Group)

* **Local Atmospheric Pressure**
  - Range is 10 to 16 PSIA
* **Is Used for the Conversion of Temperature to Pressure**
* **Factory default is 14.7 PSIA**

146

Altitude & Temperature

PSIG	°F @ SEA LEVEL	°F @ 5000 FEET
50	26	24
52	28	25
54	29	27
56	31	29
58	32	30
60	34	32
62	35	33
64	37	35
66	38	37
68	40	38

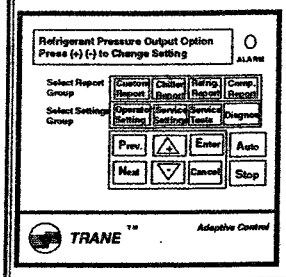
What is Absolute Pressure for 38 Degrees at Each Altitude??

66 Psig + 14.7 = 80.7 Psia @ Sea Level

68 Psig + 12.2 = 80.2 Psia @ 5,000 Feet

147

To Calculate Atmospheric Pressure

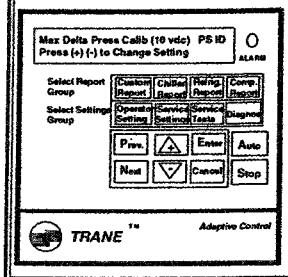


$$14.7 - \frac{\text{(Local Elevation)}}{2{,}000}$$

EXAMPLE:

$$14.7 - \frac{5000}{2000} = 12.2$$

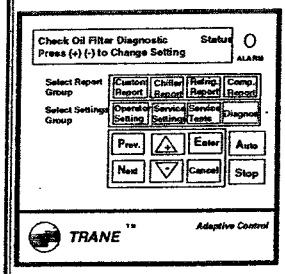
Service Settings



(Field Startup Group)

- Refrigerant Pressure Analog Output
  - Range of Values: % Cond Pressure or Delta
- Screen is Suppressed for FastPak

Service Settings

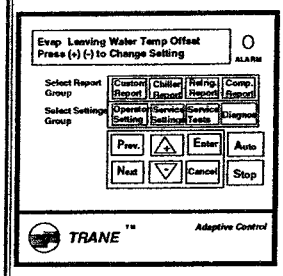


(Field Startup Group)

- Minimum Delta Pressure Calibration
  - Pressure Differential Where a 2 Vdc Output Is Required
  - Range of Value: 0 - 400 Psid
- Maximum Delta Pressure Calibration
  - Pressure Differential Where a 10 Vdc Output Is Required
  - Range of Value 0 - 400 Psid

Service Settings

(Field Startup Group)

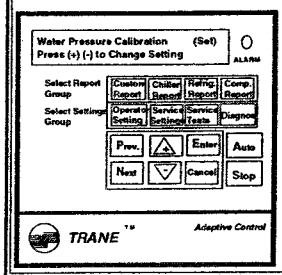


- **Check Oil Filter Diagnostic**
- **Only Displayed If Oil Pressure Transducers Are "Installed" (Fastpak)**
  - Selections: Disable or Enable
- **Check Oil Filter Setpoint**
  - Values 9 to 60 PSID in 1 PSID Increments
  - ROM Default Is 15 Psid

151

Service Settings

(Field Startup Group)

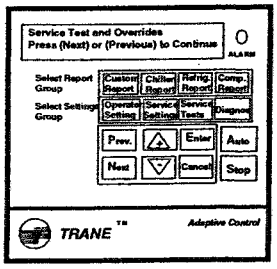


- **Evaporator Leaving Water Temperature Offset:**
  - Possible Values: -2.0 to 2.0 F in 0.1 F Increments
  - Not Available on FastPak
- **Saturated Evaporator Refrigerant Temperature Offset**
  - Possible Values: -2.0 to + 2.0 F

152

Service Settings

(Field Startup Group)

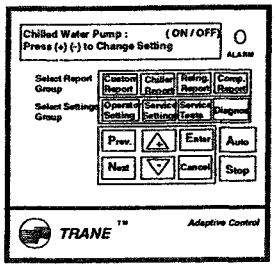


- **Water Pressure Calibration**
  - Values: Auto or Manual
- **Measured Evap Differential Water Pressure**
  - Possible Values: 0 to 25 PSID
  - Allows for Calibration
- **Measure Cond Differential Water Pressure**
  - Possible Values 0 to 25 PSI
- **Enter measured differential and Value will Return to 0 After Calibration**

153

SERVICE TESTS MENUS

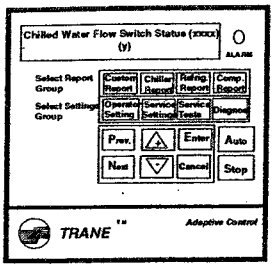
154



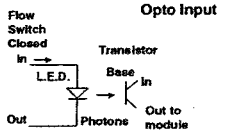
Service Tests

* Service tools Group Heading
  - This heading will remain if other headings are suppressed in the Service Settings Menu

155



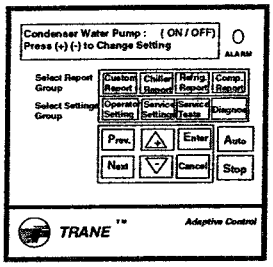
SERVICE TESTS



* Chilled Water Pump
  - Values are ON, AUTO
* Allows for Commanding the Chilled Water Pump On
* Chilled Water Pump Control Circuit Must be Wired to Chiller Module

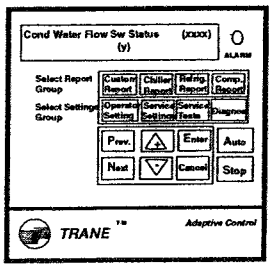
156

SERVICE TESTS

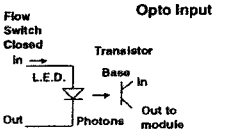


* Chilled Water Flow Switch Status
  - Values are:
    - Flow Switch is Open / No Flow
    - Flow Switch is Closed / Flow

157



SERVICE TESTS



* Condenser Water Pump
  - Values are ON, AUTO
* Allows for Commanding the Condenser Water Pump On
* Pump Control Circuit Must be Wired to The Chiller Module

158

SERVICE TESTS

* Condenser Water Flow Switch Status
  - Values are:
    - Flow Switch is Open / No Flow
    - Flow Switch is Closed / Flow

159

SERVICE TEST GROUP

Starter Dry Run :	(XX)
Press (+) (-) to Change Setting: Transition Complete Input (Y)	

* Starter Dry Run
  - Factory default is disable
  - Unit must be in STOP to activate test
  - Values for XX are:
    - Shorting Relay On
    - Run Relay On
    - Start Relay On
    - Transition Relay On
    - Start and Transition Relays On
  - Values for Y are:
    - Closed = TCI is seeing a contact closure
    - Open = TCI is seeing a contact open
    - Y - Values will change on machine operation

160

SERVICE TEST GROUP

Oil Pump :	(Status)
Differential Oil Pressure	XX.X PSID:

* Oil Pump
  - Values are ON or AUTO
  - Factory default is AUTO
  - Differential Oil Pressure is Active and will change

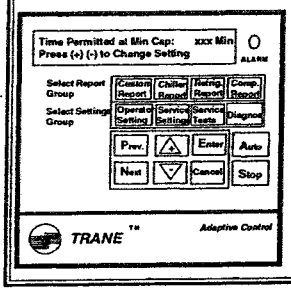
161

SERVICE TEST GROUP

Vane Control is :	(Status)
Press (+) (-) to Change Setting:	

* Vane Control Status and Vane Position Commands
  - Values are: MANUAL and AUTO
  - Factory default is AUTO
  - Can operate with unit off
* Inlet Guide Vane Position if in the Manual Mode
  - Value is XXX.X % OPEN
  - Second Line Information is Limit Mode
    - Limit Mode Values are:
      - Current limit
      - Condenser Limit
      - Evaporator Limit

Inlet Guide Vane Position :	XXX.X % Open
(Limit Mode)	



Vane Position XXX.X %	Target XXX.X % Open
(Limit Mode) (+) (-) to Change Target

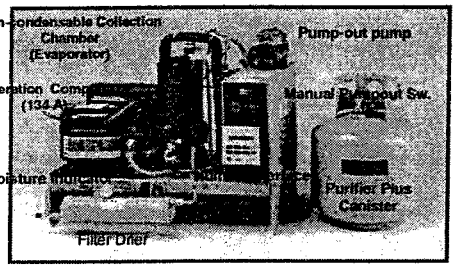
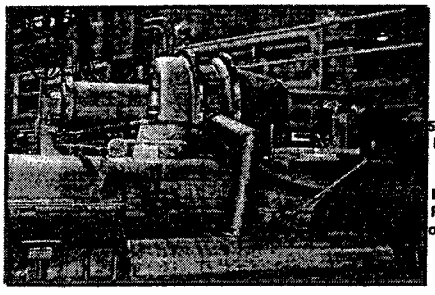
Purge System



171

PURIFIER PURGE - PRGC

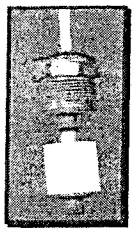


172

COMPONENTS IDENITFIED

173

PURGE SUPPLY & RETURN LINES

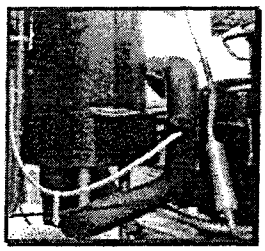


5/8" Vapor Line Into Purge

Liquid Line Return om Purge

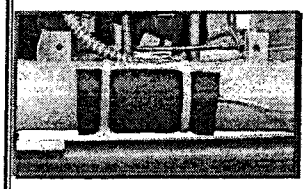
174

LIQUID LEVEL FLOAT



- Purpose to Sense Rise in Liquid & Shut Unit Down
- Avoid Purging Liquid Refrigerant

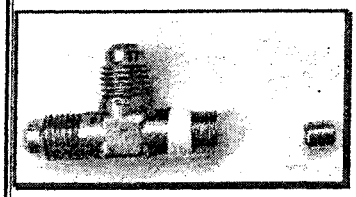
175



SATURATED SUCTION SENSOR

- Located in Suction Line Between Outlet of Purge Tank & Inlet of Compressor
- 10,000 Ohms @ 77 ° Negative Temperature Coefficient
- Initiates & Terminates Purge Pump Out Compressor

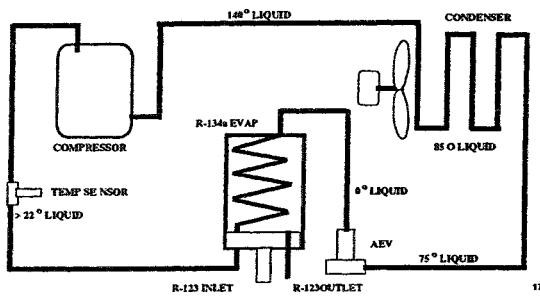
176



SATURATED CONDENSER SENSOR

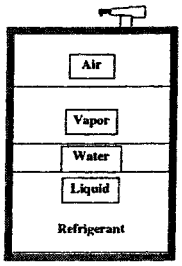
- Used to Inhibit Purge Operation When Condensing Temperatures are Low
  - Evaporator Cannot Condense Adequate Amounts of R-123
  - Refrigerant Temperature Remains Cold, Causing Pumpout Compressor to Continue to Operate
- Installed on Bottom of Filter/Drier for Retrofit
- Uses Chiller Saturated Condensing Temp for UCP-2

177



RESTRICTOR ORIFICE

* Minimizes the Amount of Refrigerant Exhausted With Air During Pump-out



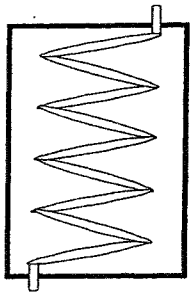
178

PURGE CIRCUIT SCHEMATIC

179

MASS OF VARIOUS GASSES

* Air = .075 # / Cu. Ft
* R-123 Vapor @ 90o = ~.33 # / Cu. Ft
* Water = 62.4 # / Cubic Foot
* R-123 Liquid @ 90o = ~ 90 # / Cu. Ft

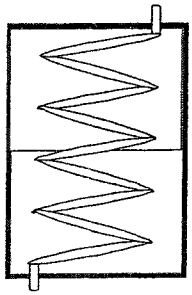


180

HOW DOES AN AEV WORK?

- Maintains a Constant Pressure in the Evaporator While The Condensing Unit is Operating
- Controlled by Suction Pressure
- When Suction Pressure Rises, Valve Tends to Close
- When Suction Pressure Falls, Valve Tends to Open
- Very Slow to Pull Temperature Down
- Sizing Should be to the Load

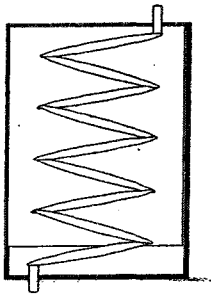
181



LACK OF NON CONDENSABLES

- R-134a Liquid Refrigerant Enters Evaporator – 0° F
  - Large Area for Transfer of Sensible Heat (Superheat)
  - Warm R-123 Vapor Transfers Heat to 134a Vapor
- R-134a Suction Vapor Exits Evaporator – Same Temperature as R-123 Condenser Gas

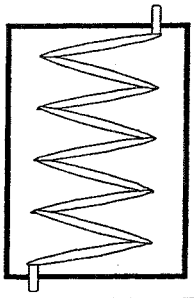
182



PRESENCE OF NON CONDENSABLES

- R-134a Liquid Refrigerant Enters Evaporator – 0° F
  - Less Area for Transfer of Sensible Heat (Superheat)
  - Warm R-123 Vapor Transfers Heat to 134a Vapor
- R-134a Suction Vapor Exits Evaporator at a Temperature Substantially Less Than R-123 Condenser Gas

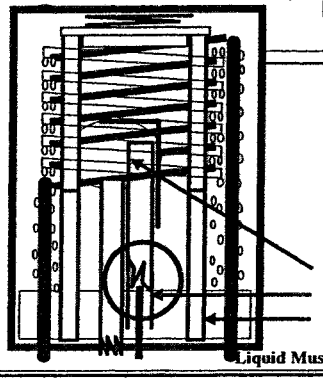
183



TANK FULL OF NON CONDENSABLES

- R-134a Liquid Refrigerant Enters Evaporator ~ 0 ° F
  - No Area for Transfer of Sensible Heat (Superheat)
  - Warm R-123 Vapor Cannot Transfer Heat into 134a Vapor
- R-134a Suction Vapor Exits Evaporator - Same Temperature as Entering Temp
- Suction Line Temperature Sensor Initiates Pumpout @ 18 ° F

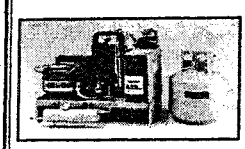
184



NON CONDENSABLES PUMPED OUT

- R-123 Refrigerant Vapor Enters Evaporator at Condensing Temperature
  - Large Area for Transfer of Sensible Heat (Superheat)
  - Warm R-123 Vapor Transfers Heat to 134a Vapor
- R-134a Suction Vapor Exits Evaporator - Same Temperature as R-123 Condenser Gas
  - Suction Line Temperature Sensor Terminates Pumpout @ 22 ° F

185



REFRIGERANT RETURN

Liquid Must Rise Over Top of Stand Pipe[186]

* **Purge Adaptive Cycle Time - Chiller On (Purge off Cycle Time) / Time to Purge Remaining (Purge Off-time Remaining Before Purge Is Allowed to Operate)**
* **Purge Adaptive Cycle Time - Chiller Off (Extended Purge off Cycle Time) / Time To Purge Remaining (Purge Off-time Remaining Before Purge Is Allowed to Operate)**

189

ADAPTIVE - CHILLER RUNNING

- Primary Function of Adaptive Mode Is to Save Energy
- Purge UCM Stores:
  - Total Pump Out Time
  - Total Chiller Run Time
- Computes Average Pump Out Time Per 24 Hours
- Computes Pump Out Time for Last Day
  - If Last Day's Pumpout Time Is Greater Than 5 Times the Average, the Last Day's Pumpout Time Will Determine "Off" Cycle; Otherwise - Use Average
- Purge Starts When the Chiller Starts
- Purge will Continue to Run Until 60 Minutes w/o Pumpout Elapses
- Purge Will Shutdown & Base Off Time on Calculated Average Pumput Time:
  - < 1 Min — 4 hour
  - 1 to 3 Min — 3 Hour
  - 3 to 5 Min — 2 Hour
  - 5 to 8 Minutes — 1 Hour
  - Greater than 8 — No Off

190

ADAPTIVE - CHILLER SHUTDOWN + 3 HRS

- Main Function is to Purge Air That is Stored In Chiller During Operation
  - Can be Trapped in Various Areas of an Operating Chiller & not Migrate to Purge Pick Up Tube Area
- A Purge Operating in First Three Hours of Shutdown Confirms Air Storage
- UCM Will Store Accumulated Pumpout Time for the Last 5 Chiller Shutdowns
- Time Period Will be Calculated Based on Average Pumpout Time
- Calculation Will Determine Amount of Run Hours Allowed Before Purge Will Run at Off + 3:
  - Less than 2 Min — 80 Hours
  - 2 to 4 Minutes — 40 Hours
  - Greater that 4 — 20 Hours
- When Purge Starts in This Mode, it Will Operate for 3 Hours or Until 30 Consecutive Minutes of Run Time w/o Pumpout have elapsed.

191

ADAPTIVE - CHILLER EXTENDED OFF

- Main Function is To Purge Air that Accumulates During Extended Off Periods
- UCM Calculates Total Pumpout Time:
  - With Chiller Operating
  - Chiller Off + 3
  - Chiller Off
- Determines Number of Days Off Before Purge Operation is Required:
  - < 1 Minute — 14 Days
  - 1 to 2 Min — 10 Days
  - 2 to 3 Min — 6 Days
  - 3 to 4 Min — 4 Days
  - 4 to 5 Min — 3 Days
  - 5 to 8 Min — 2 Days
  - 8 or Greater — 1 Day

Grounding

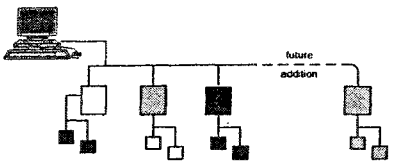
- All Grounding Shall Be Terminated At The Electrical Panel
- Printed Circuit Boards Use Even Numbers For Ground Points And Odd Numbers For Power Points- IPC Only
- All Inter-processor Communication Wires Must Be Shielded And attached To Ground

244

Inter- Processor Communications

- Reverse Polarity (Even = +, Odd = -)
- Improper Grounding
- Intermittent Connections
- Excess Run Length (1,500 Ft. Maximum)
- Loose Connections
- Corroded Terminals
- Improper Wire Size (Beldon 8760)
- Bad Printed Circuit Boards

245



UCP2 BAS Interface Options

- Generic Building Automation System
  - hardwired interface
  - analog inputs and outputs
  - binary inputs and outputs
- Tracer 100 Series and Summit
- Automation interoperability - BACnet

246

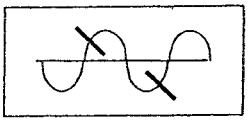
UCP2 BAS Interface Options

- Automation Interoperability
  - Open Proprietary Protocol — Custom Proprietary Translators
  - Open Standard Protocol — BACnet "Building Automation Control Network"
- ASHRAE SPC-135P
  - ARCNET or ETHERNET LAN, or RS-232 based

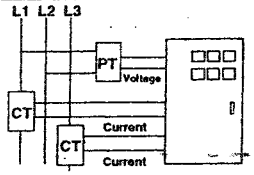
247

UCP2 BAS Interface Options

- Binary Outputs
  - Evaporator Pump Relay
  - Condenser Pump Relay
  - Compressor Running Relay
  - Alarm Relay
  - Limit Warning Relay
  - Purge Alarm Relay
  - Maximum Capacity Relay
  - Ice Making Relay
  - Head Relief Request Relay
  - Free Cooling Auxiliary Relay
  - Purge Pumpout Running Relay
- Binary Inputs
  - Chiller Auto STOP
  - Chiller Emergency STOP
  - Free Cooling Enable/Disable
  - Ice Building Enable/Disable



248

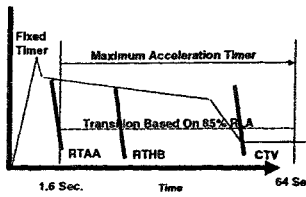


UCP2 BAS Interface Options

- Analog Outputs
  - Condenser Pressure Output
  - Percent RLA Output
  - Industry Standard Signal (4-20 mA or 2-10 vdc)
- Analog Inputs
  - Chilled Water Setpoint - Generic BAS
  - Current Limit Setpoint (Percent RLA) - Generic BAS
  - Industry Standard Signal (4-20 mA or 2-10 vdc)

249

Momentary Power Loss Protection



- 20 Times Rated Torque
- Rotor Bar And Stator Failures
- Impeller And Shaft Key Way Damage
- Starter Contactor Damage
- Current And Voltage Always Wants To Be In Phase
- Will Detect Momentary Power Loss In 2- 3 Electrical Cycles And Shutdown In 6 Cycles

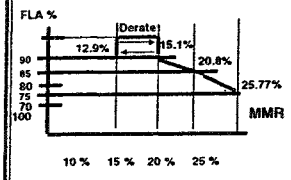
250

Starting Overcurrent Protection

	Timer 1	Timer 2
Y - Delta	= 27 Sec.	*228
Auto - Tran.	= 16 Sec.	*239
Prl. - React.	= 16 Sec.	*239
Across Line	= 6 Sec.	*249
Sol. St. Start	= 20 Sec.	*235
Vari. Speed Dr.	= 12 Sec.	*243

Choice: Shutdown or Transition

251



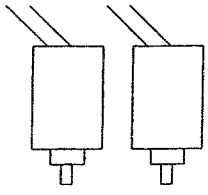
Running Overcurrent Protection

- Overload Must Hold At 102%RLA
- Overload Must Trip At 112 % RLA After 20 Seconds + - 3 Sec.
- Overload Must Trip At 140% RLA After 1.5 Seconds
- Based on Highest Phase Current

252

Phase Unbalance

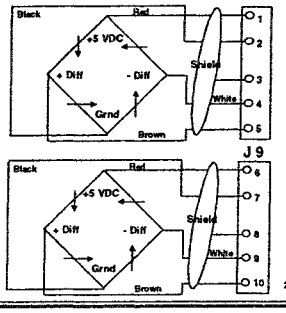
- Formula is: 100 X Sum of Dev. of Each Phase Current To The Average / By 2X Avg.
- Measured - 200, 225, 250 A
- Average Is 225 Amps
- Difference is 50 X 100 = 5000 / 500 = 10 % Unbalance
- At 25% / 30%Unbalance The UCP Will Trip But The Unit Will Unload To Try To Maintain Operation



253

Sensor Values

RTH- CTV- ABS



254

Oil Pressure Transducers

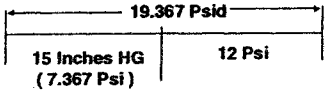
Oil Sump Pressure (-)

Oil Pump Pressure (+)

255

Oil Pressure Transducers

No More Gauges



Normal Delta " P " Oil Pressure = 12 To 18 Psi
Mounted Downstream Of The Oil Regulator
Minimum Running Oil Pressure = 9 Psid
3 Minute Compressor Time Delay At Startup (Prelube)
5 Minute Time delay after Compressor Off Cycle
Transducers are recalibrated to 0 Psid if a differential of more than 3 PSIG exists

(Warning) A Deep Vacuum Will Effect The Transducer And Recalibration Is Required

256

Oil Measurement Procedure

Measure Oil Sump Pressure = 15 inches Hg
Convert To Pressure = Divide The Oil Sump Pressure By 2.036 (15 Inches Hg : 2.036 = 7.367 Psi)
Measure Oil Pump Pressure = 12 Psi
Add 12 Psi And 7.367 Psi = 19.367 Psid (Differential)

2 to the 8 power = 264	100 000 000

259

Restart Inhibit Timing

If The Motor Is Cool (Below 165 Deg.F.) RI Timer is Automatically Set At 30 Seconds Regardless of The RI Timer
If The Motor Is Warm (Above 165 Deg.F.) RI Timer Is Automatically Set At 15 Min Plus Any RI Time Value

The Maximum RI Timer Value Is 60 Minutes, But Is Adjustable From 25 To 60 Minutes Via The BT Timer
The BT Timer Is Based on System Tons And Hz Values
The BT Timer Is Defaulted To 25 Min

The Objective Is To Keep The Motor Cool And Off Time To The Minimum

Notice

The Trane Company urges that all HVAC servicers working on Trane equipment, or any manufacturer's products, make every effort to eliminate, if possible, or vigorously reduce the emission of CFC, HCFC and HFC refrigerants to the atmosphere resulting from installation, operation, routine maintenance, or major service on this equipment. Always act in a responsible manner to conserve refrigerants for continued use even when acceptable alternatives are available. Conservation and emission-reduction can be accomplished by following recommended Trane service and safety procedures published in Trane General Service Bulletin CTB-SB-81. The information and procedures provided in CTV-SB-81 supersedes those published in this manual. Copies of this bulletin may be obtained by contacting your local Trane commercial representative.

Model Number Description

For service purposes, Trane Model CVRB Control Panel Conversion packages are assigned a multiple-character alphanumeric model number that precisely identifies each unit. An explanation of the identification code that appears on the unit nameplate is shown below.

Use of the service model number will enable the owner/operator, installing contractors and service technicians to define the operation, components and options for any specific unit.

Refer to the model number printed on the panel nameplate (mounted on the left-hand side of the UCP control panel enclosure) when ordering replacement parts or requesting service.

General Information

Literature Change History

CVRB-IN-2 (May 1995)

Original issue of manual. Describes the conversion procedures required to retrofit an older, electrically or pneumatically controlled CenTraVac® with a microcomputer-based UCP2 chiller control panel for "B" design. Includes information about the Trane Adaptive Frequency Drives for UCP2.

CVRB-IN-2A (May 1996)

Manual revised to include changes incorporated in Design Sequence "C":

- Addition of Pulse IGV Actuator
- Variable setpoint for oil differential pressure cut-out
- R113 refrigerant map
- Differential Pressure Switch option for oil flow proving

Warnings and Cautions

Notice that warnings and cautions appear at appropriate intervals throughout this manual. Warnings are provided to alert installing contractors and other personnel to potential hazards that could result in personal injury or death, while cautions are designed to alert personnel to conditions that could result in equipment damage.

Your personal safety and the proper operation of this machine depend upon precautions. The Trane Company assumes no liability for installation or service procedures performed by unqualified personnel.

About This Manual

The instructions outlined in this booklet describe the procedures required to retrofit an older model chiller (e.g. CVHE, CVHB, CVHA or PCV) with a UCP2 based control system. This manual is intended for use by experienced Trane service personnel.

Note that the installation instructions in this manual are divided into three general topic areas:

1. Existing Control Panel Removal, including removal of the existing inlet vane actuator (if required).
2. UCP2 installation including the required control panel and optional actuator assembly (if required) on both CVHE and non-CVHE centrifugal chillers.
3. Starter Panel Conversion, including general directions for modifying Wye-Delta, Auto-Transformer, Primary Reactor and Across-the-Line starters for use with UCP2.

Note: Wiring diagrams are often referenced throughout this manual. Appropriate schematic and connection diagrams ship with each UCP2 conversion package and are also included in this manual.

The UCP2 installation and check-out must be performed by qualified personnel. The check-out procedure, located at the end of this manual, for the converted starter panel and newly installed UCP2 control panel is highly recommended.

Successful completion of this check-out procedure assures that the control panel is properly installed, that all required starter and unit modifications are complete and that the chiller is operating properly.

⚠ Caution:
To prevent machine damage, contact a Trane service organization to perform the check-out procedure described at the end of this manual!

Application Guidelines

While the UCP2 control panel conversion package is specifically designed for CVHE applications, it can be applied to other, older CFC-11 and HCFC-123 water-cooled CenTraVacs® (PCV, CVHA's) whether electrically or pneumatically controlled.

The instructions also apply when converting control systems on competitor-built centrifugal chillers. Verify that Trane control strategies can be used on the application.

Please note the following:

- When the UCP2 conversion package is applied to a pneumatic chiller control system, all pneumatically-actuated valves, such as for hot gas bypass, must be replaced with electric devices.
- The UCP2 conversion package is not designed to be applied to air-cooled CenTraVacs.
- The UCP2 conversion package cannot be used in conjunction with open-transition starters.

Contents of Kit/Options

Conversion Package Contents

Each UCP2 panel conversion "kit" includes the items described below.

Note: Some UCP2/CenTraVac® retrofit applications require additional field-supplied components.

- UCP2 Chiller Control Panel with two (2) mounting brackets - Includes the Local Clear Language Display and 16 Function Keypad, see Figure 1.
- Temperature Sensors and Pressure Transducers with installation hardware including applicable bulbwells and leads. See Table 1 for list of standard sensors. Figure 3 contains a complete list of available sensors and shows their location.
- Literature including CVRB-IN-2A and the current revisions of CVHE-M-7 and CVHE-CLD-1.
- Wiring schematics located in control panel
- Replacement nameplate and nameplate laminate
- Miscellaneous electrical and mounting hardware (screws, washers, etc.)

Inlet Guide Vane Actuator Output Option - The UCP2 conversion panel can be ordered to support either a stepper motor inlet guide vane actuator or a pulse type inlet guide vane actuator. The pulse type output option uses the machine's existing induction motor inlet guide vane actuator and requires no additional hardware. In addition to the items identified above, the stepper motor output option will include the following:

- Stepper Motor Inlet Guide Vane Actuator with brackets - Some field modification to fit specific applications may be required.

Note: In non-CVHE applications, three (3) adapter brackets are required to enable installation of the new stepper vane actuator. One bracket secures the actuator to the volute, while the other two link the actuator to the actuator arm. Field fabrication of these brackets may be required in some instances.

Available Optional Kits

In addition to the standard package, several optional kits can be ordered to give the UCP2 greater capability. Use Table 5 as well as Figures 11, 12, and 13 to determine connection points.

Starter Interface Module - Required on all UCP2 applications except those with variable speed inverters by Trane. The module includes a NEMA 1 style enclosure which is suitable for attachment to the chiller starter, terminal block and three auxiliary current transformers.

Table 1 - Standard Sensors With UCP2 Retrofit Kit

Sensor	Designation	Code Number
Evaporator Entering Water Temperature	4RT1	X13790159-04
Evaporator Leaving Water Temperature	4RT2	X13790159-04
Condenser Entering Water Temperature	4RT3	X13790159-04
Condenser Leaving Water Temperature	4RT4	X13790159-04
Saturated Evaporator Refrigerant Temp.	4RT5	X13790159-02
Bearing Temperature #1	4RT7	X13790159-03
Bearing Temperature #2	4RT8	X13790159-03
Saturated Condenser Refrigerant Temp.	4RT9	X13790159-01
Oil Temperature	4RT10	X13790159-03
Condenser Refrigerant Pressure	3R3	X13790142-01
Oil Sump Pressure	4R1	X13790142-01
Oil Pump Discharge Pressure	4R2	X13790142-01

Options Module
Required to implement any or all of the following UCP2 functions:

a. Chilled Water Setpoint by External/Remote Source (e.g. Generic BAS) - Allows a remote source to set the chilled water setpoint via a 4-20 mA or 2-10 vdc signal. Range is 0 to 65° F.

b. Current Limit Setpoint (Demand Limit) by External/Remote Source (e.g. Generic BAS) - Allows a remote source to set the current limit setpoint via a 4-20 mA or 2-10 vdc signal. Range is 40 to 100%.

c. Compressor Percent (%) RLA Output - Allows a remote system (e.g. generic BAS) to receive a 2-10 vdc signal proportional to the chiller's % RLA. Range is 0 to 120% RLA.

d. Head Relief Request Output - Allows a remote system (e.g. Generic BAS) to receive a binary signal for use with compressor surge protection and condenser limit by requesting lower condenser water temperature.

e. Maximum Capacity Output - Allows a remote system (e.g. Generic BAS) to receive a binary signal indicating that the chiller is at maximum capacity.

Note: The maximum capacity relay is suppressed when the inlet guide vane actuator output is the pulse type.

f. Input for accessory sensors; which must be ordered separately.

- condenser differential water pressure transducer
- evaporator differential water pressure transducer
- heat recovery or auxiliary heat exchanger temperature sensors.

g. Ice making input/output

h. Tracer Relay, Tracer Temperature Output/Inputs

i. Free Cooling.
The module is field installed in UCP2.

Tracer Comm3 Communications Module
Required for interface between UCP2 and Tracer 100/1001/CPM panel style systems. The module is field installed in UCP2. Tracer Comm3 communications module is not compatible with SCP bi-directional communications and/or Tracer Summit systems.

Tracer Comm4 Communications Module
Required for communication between the UCP2 and Tracer Summit. The module is field installed in UCP2. Tracer Comm4 communications module will not enable communications to Tracer 100/1001/CPM panel.

Remote Clear Language Display Communications Module
Required for communications between UCP2 and the UCP2 Remote Clear Language Display Panel. The module is field installed in UCP2.

Remote Clear Language Display Panel Provides a remote clear language interface for up to four chillers equipped with UCP2 and the Remote Clear Language Display Communications Module. All functions available to the operator at the chiller are available to the user of a Remote Clear Language Display Panel. Two distinctions can be made regarding the remote display.

- The local display STOP command function has precedence over the remote display AUTO command function.
- The custom report function at the local display is separate and independent from the custom report function at the remote display.

Current Transformers
Kits have three (3) current transformers—donut type—one on each phase of line voltage, suitable for field installation in the chiller starter panel. The current transformers are inputs to the UCP2 starter module. Note that auxiliary current transformers come with required starter interface module.

Use Table 7 to determine the acceptable current transformer tap ratio(s) based upon the chiller's rated load amps (RLA). If the desired motor RLA allows the selection of multiple ratio taps, always select the transformer with the numerically smallest ratio tap. If the chiller motor RLA is less than 66% of the maximum amps for the current ratio tap selected, multiple primary turns are required. The motor rated load amps should not exceed 100% of the maximum amps of the tap selected.

If there are three current transformers in the existing starter with the desired ratio tap, they may be reused for the current transformer inputs to UCP2. If the existing current transformers are unusable, see Table 7 for proper selection.

<600 Volt Phase Voltage Kit
Includes three (3) potential transformers (transforms line voltage to 30 volts) suitable for field installation in the chiller starter. The kit is for starters with 600 volts or less and is input to the UCP2 starter module. It gives a display of phase voltage and provides under/over voltage protection (auto restart when voltage is corrected). Displayed are:

- Compressor phase voltage (a-b, b-c, c-a)
- Kilowatt usage
- Power factor

>600 Volt High Voltage Adapter Kit
Comes with three (3) 120-30 VAC potential transformers. For use on starters with existing line to 120 VAC transformers.

2300/2400 Volt Phase Voltage Kit*
Provides one (1), 3 phase transformer, line to 120 VAC.

4200 Volt Phase Voltage Kit*
Provides one (1), 3 phase transformer, line to 120 VAC.

3300 Volt Phase Voltage Kit*
Provides one (1), 3 phase transformer, line to 120 VAC.

6600 Volt/50 HZ Phase Voltage Kit*
Provides three (3), single phase transformer, line to 120 VAC

* Requires >600 Volt High Voltage Adapter Kit.

Water Pressure Transducer
The two available options are:

- <150 psig operating pressure—Includes two pressure transducers, two three-way valves and a mounting plate. Kit monitors the evaporator and condenser entering and leaving water pressures.
- >150 psig operating pressure—Includes two differential pressure transducers and mounting plate. Requires Options Module.

Compressor Discharge Temperature Sensor
Measures the compressor discharge gas temperature and provides a safety cutout on high compressor discharge temperature.

Heat Recovery/Auxiliary Heat Exchanger Sensor Kit Includes two (2) sensors for monitoring the entering and leaving water temperatures of an auxiliary heat exchanger. The kit includes wells for mounting in the heat exchanger shell. UCP2 will display the values of the entering and leaving water in the heat recovery bundle but does not provide control strategy for heat recovery. The sensor kit requires the use of an Options Module for interface to UCP2.

Outside Air Temperature Sensor
Measures outside air temperature. It is required on applications using outside air temperature based chilled water reset.

Hot Gas Bypass

Hot gas bypass with UCP2 assumes that in a retrofit situation, hot gas bypass exists on the current chiller. The necessary piping and valve are already there. UCP2 provides a new control scheme. The following are required:

- IO Module
- New 3" or 4" valve if old valve is pneumatic or not compatible with UCP2

Note: Hot gas bypass and pulse type output for the IGV actuator are mutually exclusive.

Printer Interface Module

The printer interface module provides a pre-formatted chiller log to a printer. The printer interface can be programmed via the human interface to print a chiller log on command, at the time of a diagnostic, and/or on a periodic basis. The printer interface module output is 9 pin RS-232. Maximum transmission is 50' (15.2m) to a remote printer.

Pulse Output

Required for a Pulse Type Inlet Guide Vane Actuator. IO Module is field installed in UCP2.

Note: Pulse type output for the IGV Actuator and the Hot Gas Bypass Option are mutually exclusive.

Conversion Package Inspection

Before installing the UCP2 panel, compare the data on the panel nameplate with the corresponding ordering and shipping information to verify that the proper UCP2 conversion package was shipped.

If a thorough inspection of the conversion package reveals damage or material shortages, immediately file these claims with the carrier. Specify the extent and type of damage found, and notify the appropriate Trane sales representative. Do not install a damaged component or panel without the sales representative's approval!

Control Panel Layout

See Figures 1 and 2 for illustrations of the UCP2 chiller control panel and its component layout, respectively. Tables 2 and 3 list module and equipment designations.

The installation of a UCP2 panel requires connection to devices on the chiller (see Figure 3), to external devices such as a starter (Figures 20 and 21), purge (see Figure 17), refrigerant monitor (see "Refrigerant Monitor" section) and to other miscellaneous system components (see Figure 4).

Existing Control Panel Removal

For complete descriptions of UCP2 chiller control panel features, clear language display, control options and electrical sequence(s) of operation, refer to the current revision of CVHE-M-7. A copy is included in this retrofit kit. Additional copies may be obtained by contacting the local Trane office.

To ensure that the chiller control system retrofit procedure is performed properly, carefully review the instructions in this section, and, if necessary, contact a Trane service organization before beginning the conversion process.

1. Identify all field modifications made to the existing chiller control scheme and remove or disable; then label all field-installed wiring entering the control panel.

Important! Record a detailed description of all electrical changes made during the UCP2 retrofit process. Add a copy of this report to the chiller record file for future reference.

   Look for field-installed circuits that serve as evaporator and condenser flow interlocks, as well as those that provide the following control functions: remote current limiting, remote on/off, "proof-of- running", interface with a building automation system (BAS), etc.

2. Determine how each of the field-adapted control functions identified in Step 1 will be handled by the new UCP2 chiller control panel.

Remember the UCP2 panel:

a. provides all of the control and protection capabilities previously supplied by the AGM capacity control module (U1) and Cutler-Hammer solid state overload (U2) in pre-micro electronic control systems.

b. includes isolated contacts to operate all chiller mounted devices as well as the starter control circuit.

c. requires 115 VAC control circuit power from the starter panel. (The oil pump, oil heater, vane actuator and purge compressor are all 115-volt devices.)

Note: All CVHE control circuits, whether in the starter panel or chiller control panel, are 115-volt systems.

3. Open all starter and control panel disconnect switches and secure them in that position.

⚠ WARNING!
To prevent injury or death due to electrical shock, verify that all power supply disconnect switches are locked in the OFF position before opening control panel door or disconnecting any wires.

4. Disconnect the leads from the oil heater and relabel the oil heater leads with the equivalent wire number designations in the UCP2 control scheme. The wire numbers for the UCP2 control system can be found on the connection diagrams in this manual.

5. If installing a stepper inlet guide vane actuator, determine the inlet guide vane stroke by closing and opening the vanes and accurately measuring the length of travel. Record this length because it will be used when installing the stepper actuator.

6. Disconnect all field-installed wiring entering the control panel (identified in Step 1) from the control panel terminal strips; then detach the field-installed conduit from the control panel enclosure.

7. Remove all sensors.
8. Identify all factory-installed wiring between the unit-mounted components (e.g., vane actuator, oil sump, purge, etc.) and the control panel; make sure that the existing wire numbers on these leads are readable.

Then:

a. Relabel each of these leads with its equivalent wire number designation in the UCP2 control scheme. Use the wiring diagrams that shipped with the UCP2 panel to assure that you assign the proper wire numbers.

b. Disconnect each of these wires from the control panel terminal strip.

c. Detach the existing, factory-installed machine conduit from the control panel enclosure. This conduit will be reused, wherever possible, when the new control panel is installed.

9. Disconnect the panel pressure gauge lines (if applicable) where they enter the chiller, then valve off or plug each unit opening.

   If the refrigerant is in the chiller, the pressure must be raised to 0 psig using a means, such as heat, that will not result in excessive purging. The use of nitrogen is not acceptable and violates Federal Anti-Venting Regulations.

10. Disconnect the opposite ends of any pressure gauge lines at the control panel.
11. Cut wire ties, and unbolt conduit connections, as necessary to allow removal of the control panel.
12. Unbolt the control panel from its mounting brackets and remove it from the unit.
13. Remove the chiller nameplate from the control panel enclosure and secure it to the outside of the UCP2 control panel. If the nameplate cannot be removed, transcribe the nameplate data, using a permanent marker, on the supplied additional nameplate.

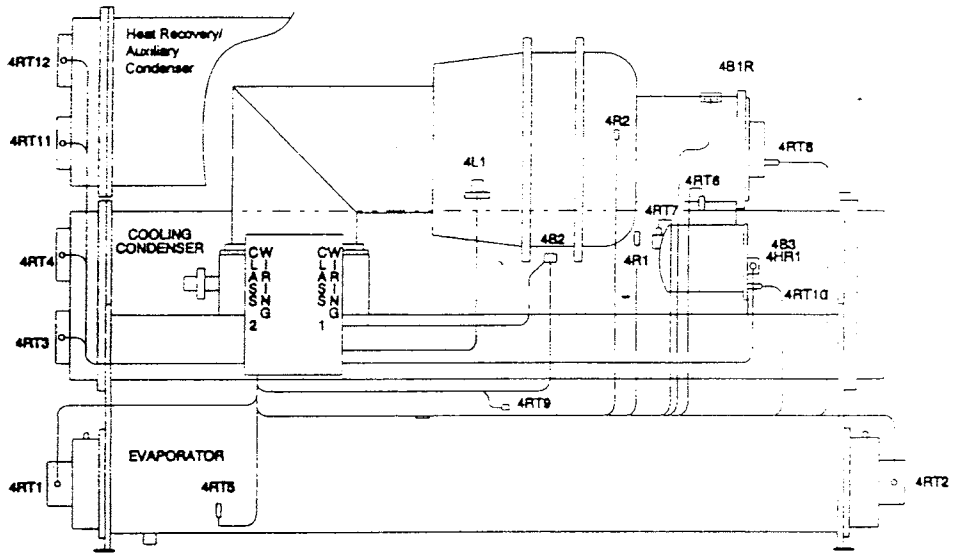
Important! The information on this original chiller nameplate is required to allow proper part identification of components not affected by the UCP2 conversion.

14. If installing a stepper inlet guide vane actuator, remove the existing vane actuator. Keep all of the connecting hardware and four of the five 115 VAC actuator leads. These will be reused when the new vane actuator is installed.

Replacing an existing CVHE control system with one based on the UCP2 control panel requires a number of wiring and hardware changes. Additional modifications are needed when this conversion is made on Model CVHB, CVHA or PCV CenTraVacs® and all competitor built chillers.

UCP2 Installation

Module Installation



All optional modules must be field installed with the supplied hardware and connected to the other modules via the Inter-Processor Communications (IPC). The IPC is a 19,200 baud asynchronous communications link.

Stack the modules as shown in Figure 2 using provided brackets.

Connect the IPC and 24 VAC between modules as shown in Figures 11, 12 and 13. Each link must have the shield connected to ground on one end and cut off and taped back on the other end.

Note: All wiring must comply with NEC guidelines as well as local codes. The Trane Company takes no responsibility for improper wiring practices.

Figure 4 -
UCP2 Field External Devices Wiring Layout Diagram

Module Dip Switch Settings

The Options module has dip switch settings used to set up the board for 2-10 VDC or 4-20 mA signal inputs. The switch settings for external current limit setpoint and external chilled water setpoint are listed below:

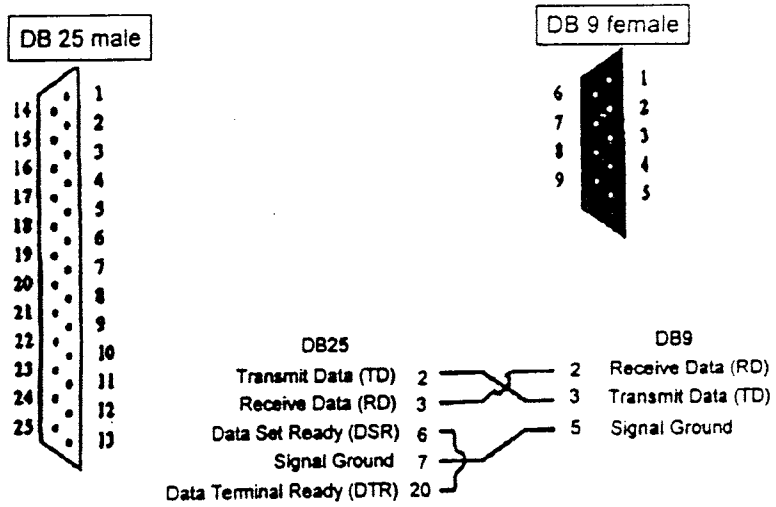
Options Module

	Switch	2-10V	4-20 mA
External Current Limit	SW2-1	Off	On
External Chilled Water	SW3-1	Off	On

Likewise, the TCI modules require that their boards be configured per the following dip switch settings.

Module	Switch SW1 Position		
	1	2	3
Tracer COM 3	Off	Off	Off
Tracer COM 4	Off	On	Off
IPC Buffer	Off	Off	On
Printer	Off	Off	On

TCI Printer Interface to Printer Setup



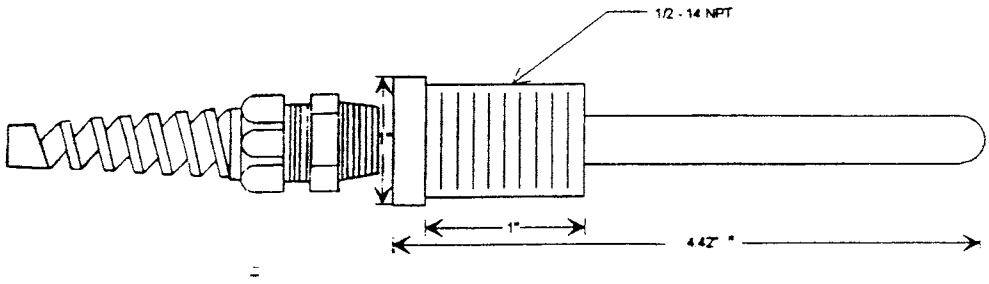
A dedicated serial printer such as Trane part number PTR0001 is recommended.

Suggested Serial Communications Settings for Printer Interface	
Baud Rate	4800
Data Bits	8
Stop Bits	1
Parity	None
Hand Shaking	Xon - Xoff

Enter these settings in the UCP2 Clear Language Display (CLD). Also enter the same settings in the printer (typically dip switches, see printer manual for details). **It is very important that the Serial Communication Settings on the CLD and the printer are exactly the same!**

See Figure 4a for printer cable connections. The pin6-pin20 connection on the DB25 is required for Trane serial printer part number PTR0001.

Figure 4 a - Serial Printer Connections



Temperature Sensor Installation

The UCP2 temperature sensors require a 1/2" bulbwell (See Figure 5 for details). When the sensor is installed in a bulbwell:

- add thermastic paste to each bulbwell before inserting the sensor
- ensure that the sensor "bottoms out" at the base of the bulbwell.

See Figure 3 for the sensors' locations. Additional instructions for installation follow.

Figure 5 -
Thermistor Bulbwell

*For Saturated Evaporator Refrigerant Temperature, the dimension is 6.62".

Standard Sensors Included in UCP2 Retrofit Kit

- **Entering Evaporator Water Temperature Sensor (4RT1) -** Install the bulbwell where the start-stop switch sensor was located; or replace the current bulbwell with the new one provided in the UCP2 Retrofit Kit. See Note 1 for external mounting information.

Note 1 - For external sensor mounting see section titled "Externally Mounted Temperature Sensors".

- **Leaving Evaporator Water Temperature Sensor (4RT2) -** Replace the existing bulbwell or mount externally. See Note 1 for external mounting information.

Note: Mount 4RT2 in a bulbwell for proper control performance on systems with short loop times.

- **Entering Condenser Water Temperature Sensor (4RT3) -** Replace the existing bulbwell or mount externally. See Note 1 for external mounting information.
- **Leaving Condenser Water Temperature Sensor (4RT4) -** Replace the existing bulbwell. Sensor may be externally mounted. See Note 1 for external mounting information.

Note: 4RT1 and 2 as well as 4RT3 and 4 must be matched pairs of sensors. Make sure they are not separated.

⚠ Caution:
If drilling into the bottom of the Evaporator or Condenser is necessary, the refrigerant charge must be removed. Failure to do so could result in avoidable refrigerant leakage to the atmosphere and a violation of the Federal Anti-Venting Laws.

- **Saturated Evaporator Refrigerant Temperature Sensor (4RT5) -** Remove the 1/4" angle valve located near the bottom of the evaporator and install the bulbwell.
- **Bearing Temperature Sensors #1 & #2 (4RT7,8) -** Read the section titled "Externally Mounted Temperature Sensors" and mount each of these sensors on the underside of the bearing oil return lines. Locate each sensor beneath the section of line that angles downward at 45°.
- **Saturated Condenser Refrigerant Temperature Sensor (4RT9) -** 4RT9 must be exposed to the leaving liquid at the bottom of the condenser upstream of any orifices or float valves. If the Condenser Refrigerant Pressure Transducer (3R3) is installed, this sensor may be externally mounted. See Section "Externally Mounted Temperature Sensors".
- **Oil Temperature Sensor (4RT10) -** Install the bulbwell in the oil sump well.

Optional Temperature Sensors

- **Compressor Discharge Temperature Sensor (4RT6)** - Replaces the High Temperature Limit Switch for Hot Gas Bypass. Generally located inside the volute.
- **Auxiliary/Heat Recovery Entering Temperature Sensor (4RT11)** - Use with heat exchangers.
- **Auxiliary/Heat Recovery Leaving Temperature Sensor (4RT12)** - Use with heat exchangers.
- **Outdoor Air Temperature Chilled Water Reset Sensor (RT1)** - Mount this sensor in the fresh air intake, or on the north wall of the building out of direct sunlight.
- **Tracer Temperature Sensor (5RT1)** - Input for a customer-supplied thermistor to monitor temperatures at a Tracer Building Automation System. Monitors ambient temperature.
- **Motor Winding Temperature Sensors 1, 2, & 3 (4B1R2,3,4)** - Uses existing motor temperature sensors. If RTD sensor is used, wire directly to terminals. If a motor temperature thermostat is currently installed, refer to the Motor Temperature Interface Section for additional wiring instructions.

Externally Mounted Temperature Sensors

To mount sensors externally:

1. Remove the paint, rust and other material from the pipe surface; then use an emery cloth to expose bare metal.

2. Secure the sensor to the pipe surface with thermally conductive, high strength, room temperature curing adhesive which bonds to most material found in the electronics industry. Make sure that the sensor retains contact with the pipe for accurate measurement.

3. Wrap the sensor with Armaflex insulation.

⚠ WARNING!
High strength adhesives typically are an eye irritant and may irritate sensitive skin. If adhesive comes in contact with skin, flush affected area with water for 15 minutes and seek medical attention. Refer to the package for additional information.

Refrigerant and Oil Pressure Transducer Installation

Install the following pressure transducers supplied with the UCP2 Retrofit Kit, see Figure 6. Connect the transducers to the UCP2 at the terminals identified in Figure 11:

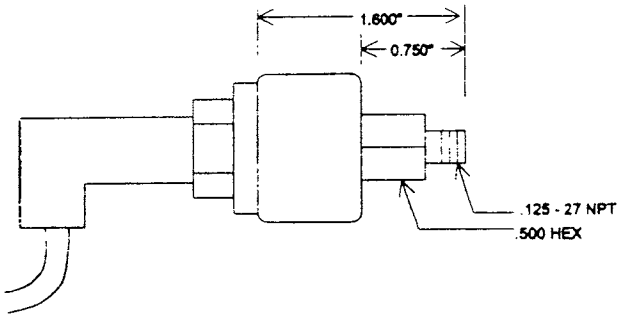
- **Oil Sump Pressure Transducer (4R1)** - Installed in the vapor space for the oil sump.
- **Oil Pump Discharge Pressure Transducer (4R2)** - Installed in the supply oil line after the filter or any shut-off valves.

Note: The oil pressure transducers (4R1, 4R2) are used to prove oil flow. Competitive chillers may operate at oil pressures higher than that found on CenTraVacs®. If installing a UCP2 conversion package on a competitive chiller, determine the oil sump and oil pump pressures of the machine. The working pressure of the transducers is between -15 and +35 psig. If oil pressures exceed the limits of the working pressure range or if the variable oil differential pressure cutout setpoint (adjustable between 6 and 35 psid) is not suitable for detecting oil flow, UCP2 will accept a binary input from a differential pressure switch. Install a field supplied oil differential pressure switch across the oil sump and oil supply line.

- **Condenser Refrigerant Pressure Transducer (3R3)** - Although installation of this supplied sensor is optional, Trane recommends installing it to improve the condenser pressure limiting function. 3R3 must be installed for proper control if the Saturated Condenser Refrigerant Temperature Sensor (4RT9) is externally mounted, due to the slow response time of an externally mounted 4RT9.

Water Pressure Transducer Installation

The Water Pressure Transducer Option monitors the condenser and evaporator water flow rate in gallons per minute (GPM) and monitors the tons of cooling produced by the evaporator at the UCP2 display.



There are two available Water Pressure Transducer Kits which require field assembly. See Figures 8 and 9 for details.

- **The <150 psig kit** is for use with Water Boxes under 150 psig. The 4L2 and 4L3 solenoid valves alternate the input to the 4R3 and 4R4 pressure transducers between the entering and leaving water lines for the shell.
- **The >150 psig kit** uses 4U1 and 4U2 differential pressure transducers and two pressure relief valves to protect the differential pressure transducers.

Note: Trane suggests attaching the mounting bracket for the water pressure transducers under the suction elbow bolts.

- **Evaporator Entering/Leaving Water Pressure Transducer (4R3)** - Use 0.25 OD tube to connect to the appropriate water box. See Figures 7 and 8 for mounting/ piping instructions.
- **Condenser Entering/Leaving Water Pressure Transducer (4R4)** - Use 0.25 OD tube to connect to the appropriate water box. See Figures 7 and 8 for mounting/ piping instructions.
- **Evaporator Differential Water Pressure Transducer (4U1)** - Use 0.25 OD tube to connect to the appropriate water box. See Figures 7 and 9 for mounting/ piping instructions.
- **Condenser Differential Water Pressure Transducer (4U2)** - Use 0.25 OD tube to connect to the appropriate water box. See Figures 7 and 9 for mounting/ piping instructions.

Figure 6 - Pressure Transducer

Water Pressure Transducers Setup

Before the UCP2 can convert the pressures into GPM's and tons, five constants must be set in the Field Startup group as listed below. Note the screens to input these constants are available only after installing the Water Pressure Transducer Option in the Service Settings - Machine Configuration.

To determine these constants, the pressure drop (Δ P) for two different flow rates (GPM) must be known. One of these points can be the design GPM and Δ P as shown on the chiller's submittal. The other point must come from the chiller sales selection information which shows Δ P versus GPM for given condensers and evaporators in various chiller sizes. Select a second point on the same line as defined by the design submittal. These points are now defined as GPM1, Δ P1, GPM2 and Δ P2 and are used in the steps listed below. Refer to the example calculation that follows.

Note: A scientific calculator is required for the following calculations. Functions must be available to take the natural log (ln) of a number and also raise a number to a power $(\Delta P1)^n$.

1. Evaporator Flow Equation Exponent:

$$n = \frac{\ln\left(\frac{GPM1}{GPM2}\right)}{\ln\left(\frac{\Delta P1}{\Delta P2}\right)} = 0.5XXX$$

The result of this equation, **n**, will be a number in the form of 0.5XXX. The digits **XXX** are entered into the UPC2 under the Evaporator Flow Equation Exponent.

2. Evaporator Flow Coefficient:

$$c = \frac{GPM1}{(\Delta P1)^n}$$

Note: n was determined in Step 1.

The result (c) should be rounded to the nearest 5 and entered into the UCP2 under the Evaporator Flow Coefficient.

3. Condenser Flow Equation Exponent:

Use the same equation as in Step 1, but with the condenser data. Enter into the UCP2 under the Condenser Flow Equation Exponent.

4. Condenser Flow Coefficient:

Use the same equation as in Step 2, but with the calculated result for **n** from Step 3. The result should be rounded to the nearest 5 and entered into the UCP2 under the Condenser Flow Coefficient.

5. Evaporator Fluid Coefficient:

Use the Table 4 to determine the Fluid Coefficient "D" and enter into the UCP2 under the Evaporator Fluid Coefficient.

Table 4 - Fluid Coefficient "D" for 40° F

Fluid	%	D
Water		418
Calcium Chloride Solution	11	386
	20	364
	30	354
Sodium Chloride Solution	5	406
	15	392
	25	392
Ethylene Glycol Solution	10	401
	30	378
	50	347
Polyethylene Glycol Solution	16	410
	30	393
	50	364

⚠ Caution:
Use of impure fluids will display incorrect data. Pressure Transducer lines may plug which can damage the transducers.

Example for Set-up

For a standard length evaporator shell with internally enhanced tubes for a CVHE 500 with evaporator bundle size of 550, contact the Sales Office for **Pressure Drop Curves** information to determine the second point. The design point is 880 GPM at a 10 ft. pressure drop.

Design:

GPM1 = 880
Δ P1 = 10

From Selection Program :

GPM2 = 1000
Δ P2 = 12.5

1. Determine Evaporator Flow Equation Exponent

$$n = \frac{\ln\left(\frac{GPM1}{GPM2}\right)}{\ln\left(\frac{\Delta P1}{\Delta P2}\right)} = \frac{ln\left(\frac{880}{1000}\right)}{ln\left(\frac{10}{12.5}\right)}$$

$$= \frac{-.1278}{-.2231} = .5729$$

729 = Exponent

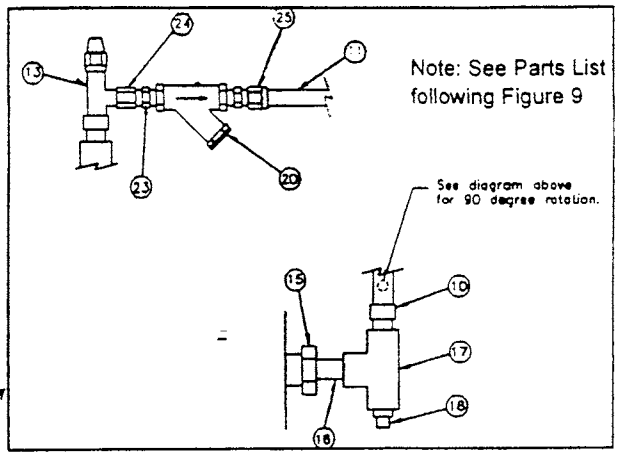
2. Determine Evaporator Flow Coefficient:

$$c = \frac{GPM1}{(\Delta P1)^n} = \frac{880}{(10)^{.5729}} = 235.29$$

235 = Coefficient

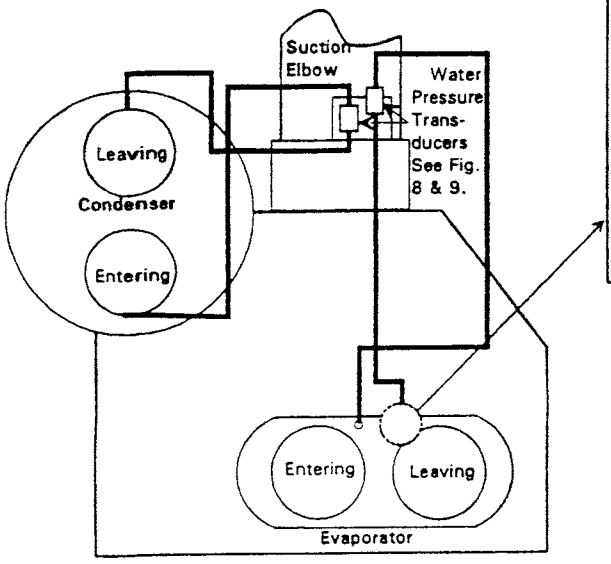
3. Repeat Step 1 for the Condenser Flow Equation Exponent using condenser data.

4. Repeat Step 2 for the Condenser Flow Coefficient using condenser data.



5. Determine Evaporator Fluid Coefficient. (Water in this example.)

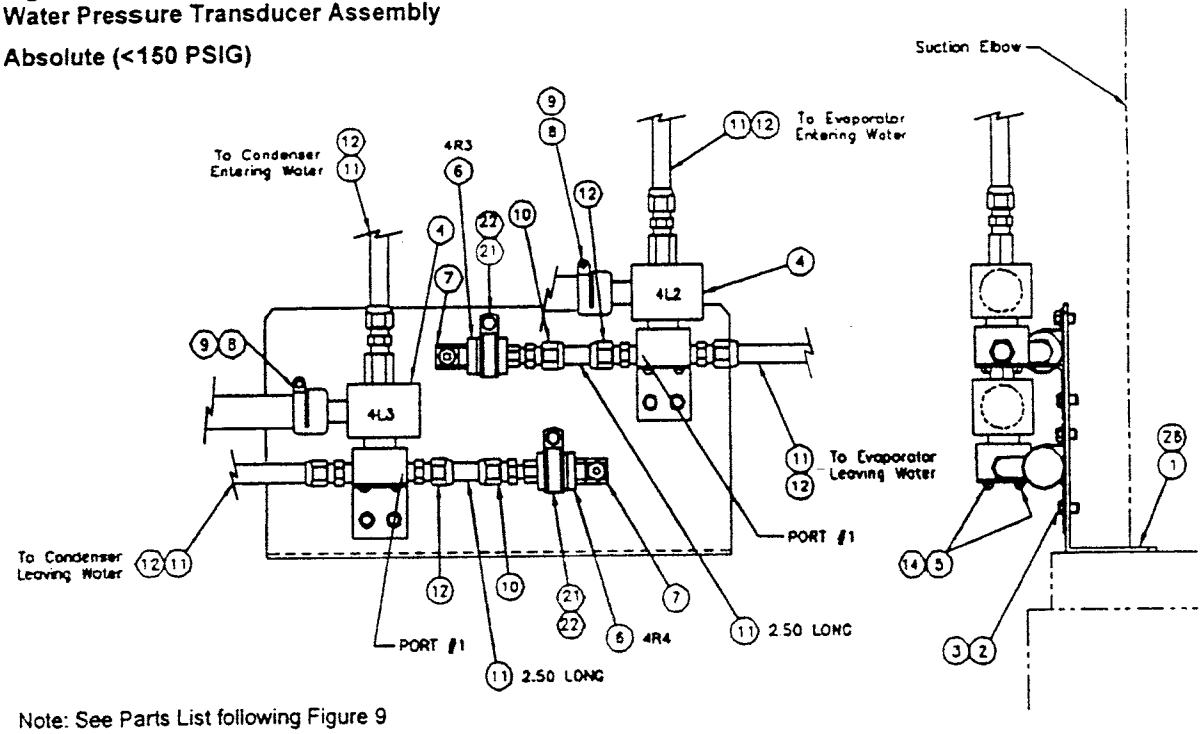
418 = Coefficient



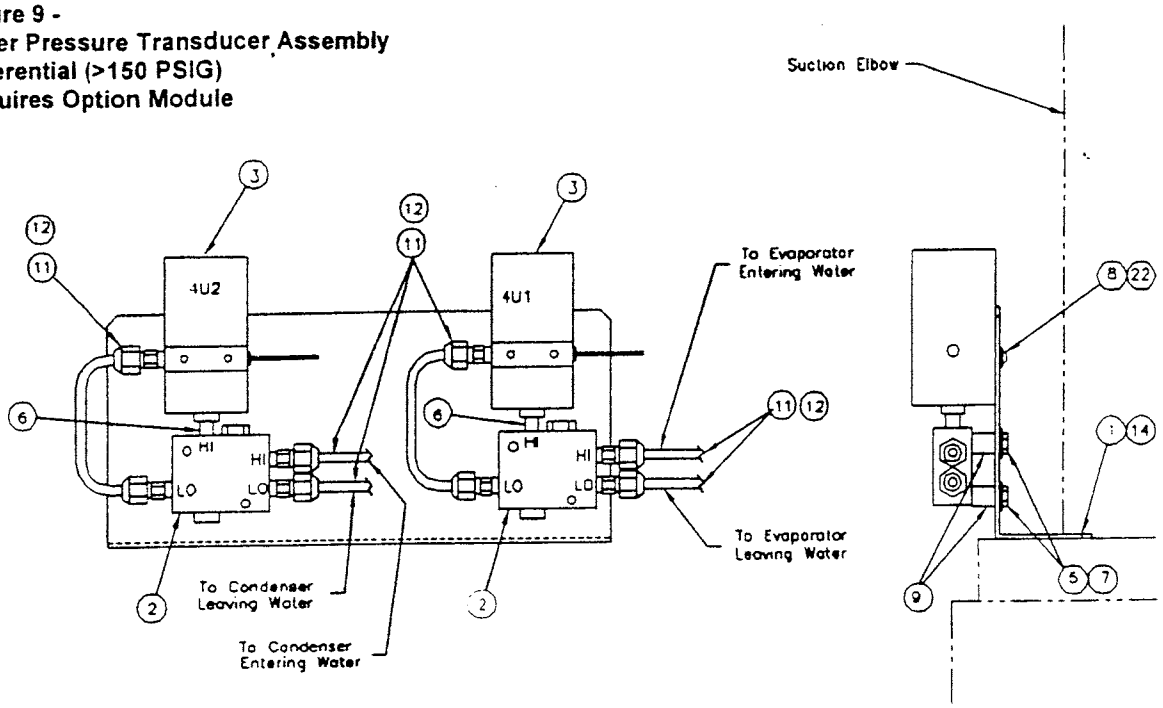
These five constants are now set in the field startup group.

Figure 7 - Water Pressure Transducer Tubing
See Figure 8 for <150 PSIG
See Figure 9 for >150 PSIG

Water Box Assemblies



— Field Tubing of Water Pressure Transducers
Note: Use copper lines
Use Teflon tape for all threaded connections



⚠ Caution:
Do not close the valve for prolonged periods. Increased temperature could result in expansion of liquid in the copper tubing which can damage the pressure transducers.

(#) Field Supplied

Condenser High Pressure Switch

The supplied switch must be installed instead of the existing switch. It is typically mounted inside the UCP2 panel. The two dry contacts on the new switch will be used with the Circuit Module (Figure 11) and the Starter Module (Figures 20 and 21). The normally open contact goes to the circuit module (1U2 pin J26-2) and the normally closed contact goes to terminal 1TB1-9 in the main control panel.

Refrigerant Monitor

There are two options:

- The 4-20 mA analog output from a refrigerant monitor can be connected to the UCP2 circuit Module, 1U2. This will allow the proportional output of the monitor to be communicated to a Tracer BAS.

  Monitors which source the 4-20 mA current, such as the Trane Model RMWC, should be connected to J5-5 (+) and J5-6 (-). Monitors which do not source their own current would connect to J5-4 (source), J5-5 (+) and J5-6 (-). See Figure 11.

  Note: Select analog for refrigerant monitor type in UCP2 menu service settings - machine configuration.

- Trane RMWD refrigerant monitors with Version two software will communicate directly to UCP2 via the interprocessor communication link (IPC).
  The connection should be made to the UCP2 stepper module 1U3 at J1-3 (+), J1-4 (-) and J1-6 (Shield to GND).

  Note: Select IPC for refrigerant monitor type in UCP2 menu service settings - machine configuration.

Stepper Actuator Binary Position Indicator (BPI)

If installing a stepper inlet guide vane actuator, the BPI must be installed on the stepper actuator. To install the BPI, set the actuator to a 90° vane position (fully open) and place the BPI in the slide track of the Inlet Guide Vane (IGV) actuator. See Figure 10. Connect ohm meter leads to the BPI wires and slide the switch from the front of the track toward the back until the ohm meter indicates switch closure (approx. 46 ohms). Mark a spot adjacent to the leading edge of the switch. Starting from the back of the track, move the switch forward until the switch closes again and mark the spot adjacent to the leading edge of the BPI switch. Move switch to the midpoint of the two marks and firmly secure with the two setscrews provided.

Figure 10 -
Typical BPI Switch Installation

NOTES

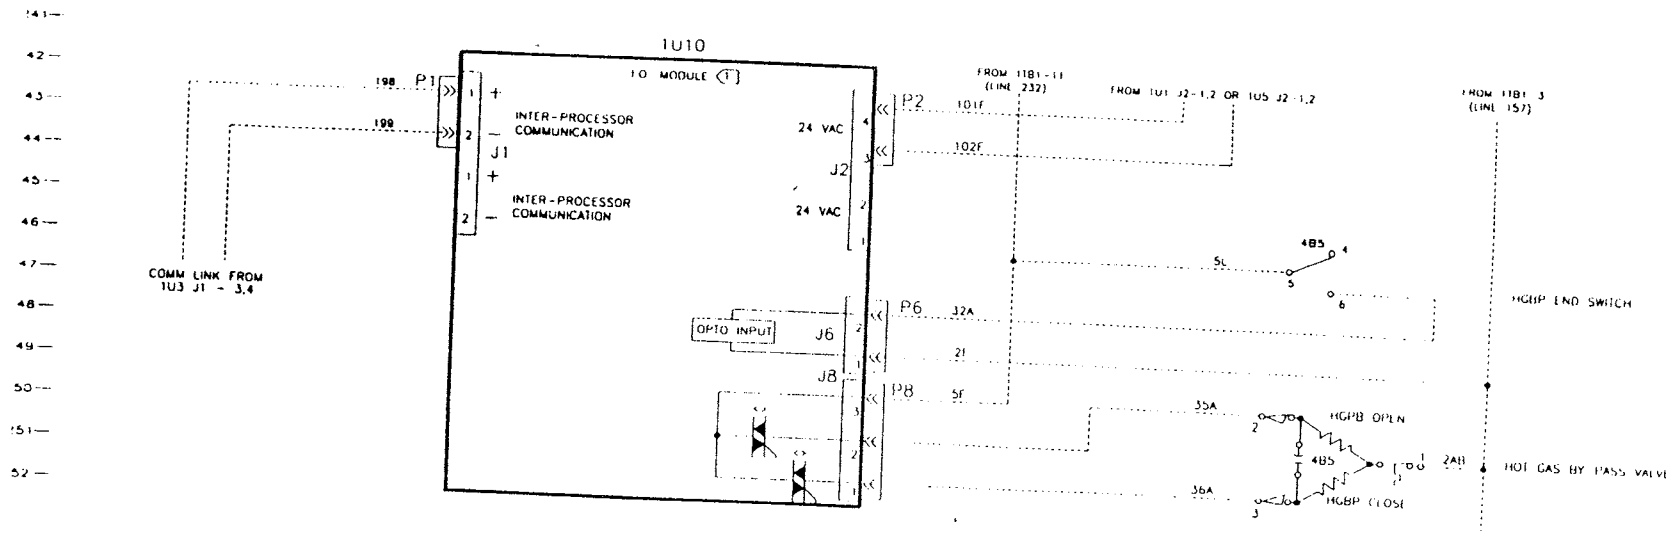
(1) IO MODULE IS USED FOR HGBP OPTION OR FOR THE PULSE OUTPUT REQUIRED WITH AN INDUCTION MOTOR VANE ACTUATOR. ITEMS ARE MUTUALLY EXCLUSIVE.

IF HGBP OPTION HAS BEEN ORDERED, IO MODULE SHIPS LOOSE. MOUNT MODULE IN PANEL AND WIRE AS SHOWN.

IF PULSE TYPE ACTUATOR WAS SPECIFIED, IO MODULE SHIPS LOOSE. FIELD WIRE THE INDUCTION MOTOR VANE ACTUATOR AND END SWITCH AS SHOWN FOR THE HGBP VALVE.

Factory Wiring

Field Wiring



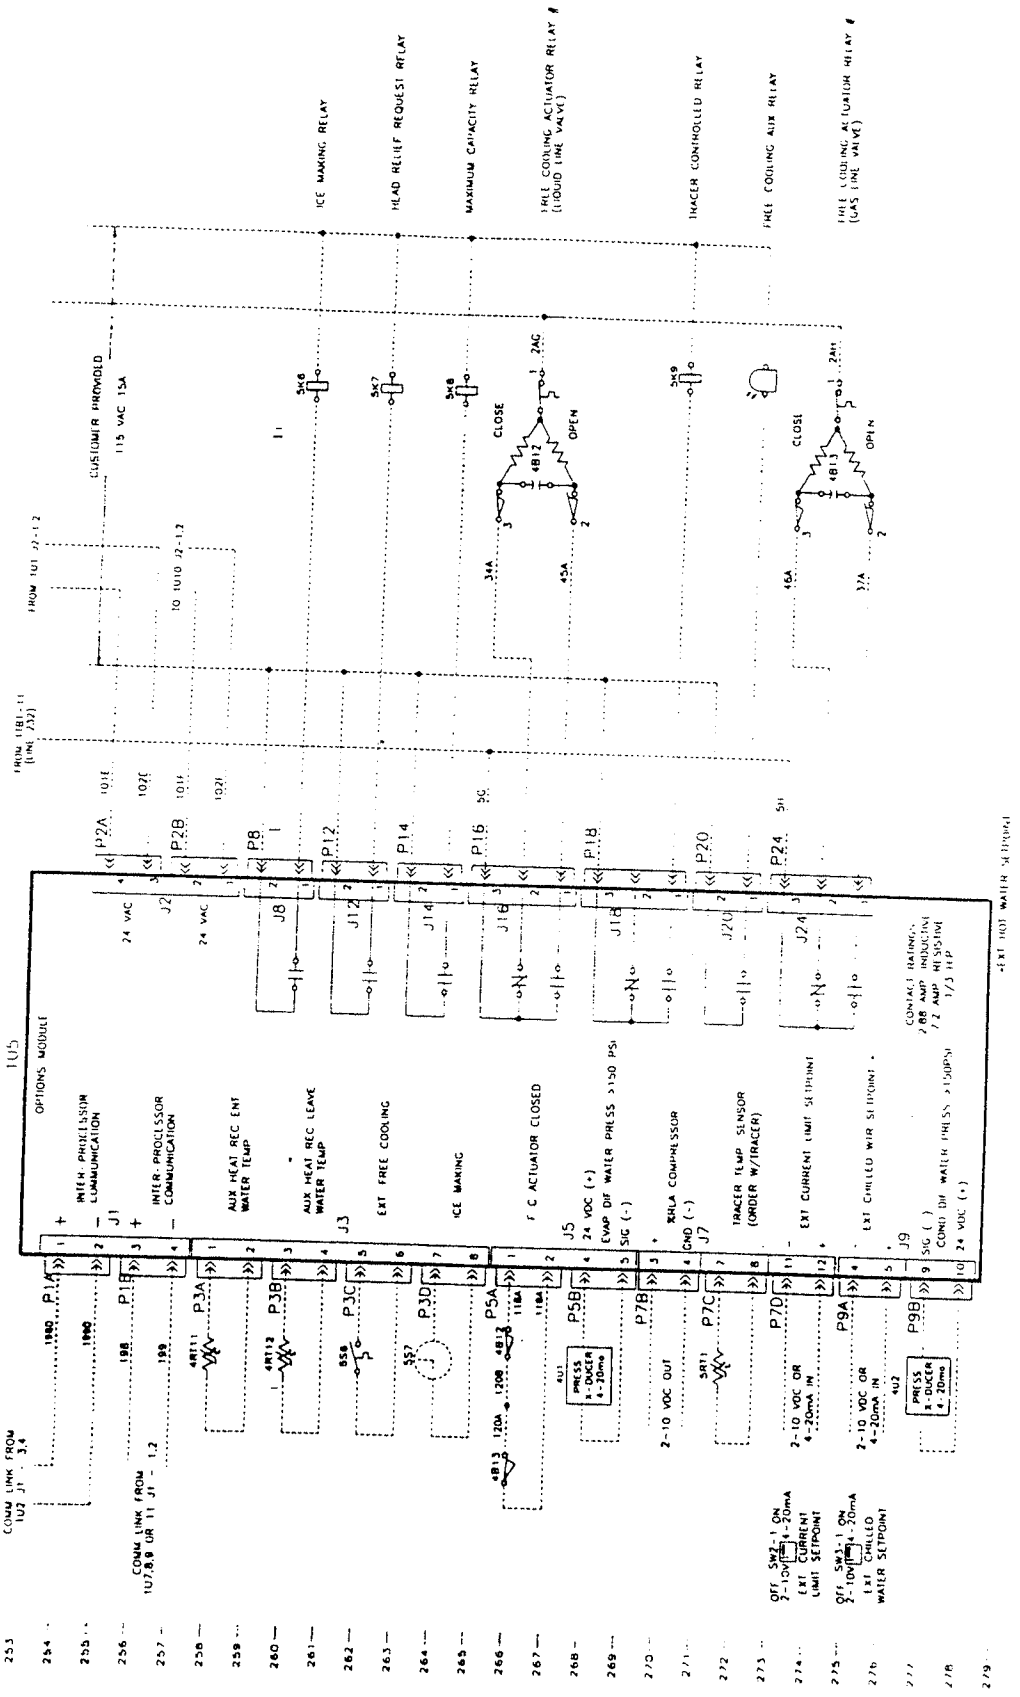


Figure 13 - (Continued) UCP2 Schematic Wiring for IO and Option Modules

Oil Pump Control

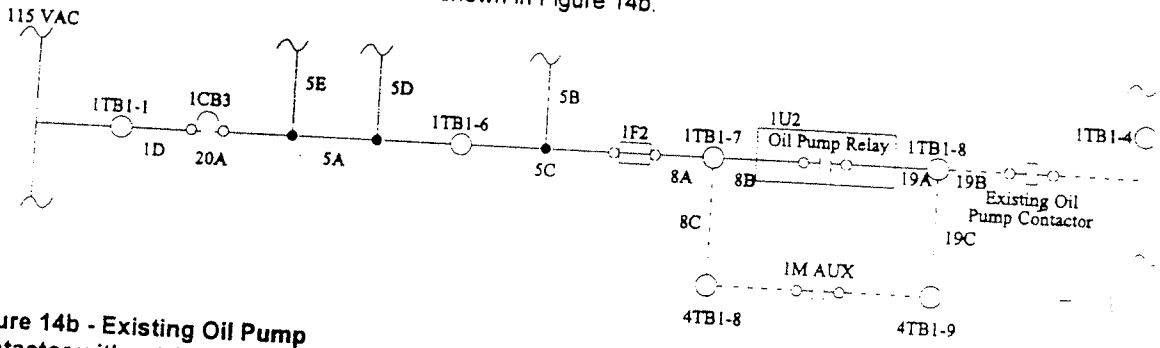
If the existing oil pump contactor coil is:

- 115 VAC—connect the existing contactor coil between Terminals 1TB1-8 and 1TB1-4. See Figure 14a.
- not 115 VAC but can be converted—adapt the contactor coil for 115V applications and complete as above, shown in Figure 14a.
- not 115 VAC and can not be converted—wire the coil of a field- supplied "line-to-115V interface relay" between Terminals 1TB1-8 and 1TB1-4, as shown in Figure 14b.

Wire the normally open "interface relay" contacts in series with, and upstream of, th existing oil pump contactor coil. See Figure 14b.

Note: With all oil pump contactor voltage, connect an auxiliary set of "start" contactor (1M) contacts between UCP2 Terminals 1TB1-7 and 1TB1-8 to assure that the oil pump is on whenever the compressor is operating.

Figure 14 a - Electrical Interface for Existing Oil Pump Motor Contactor



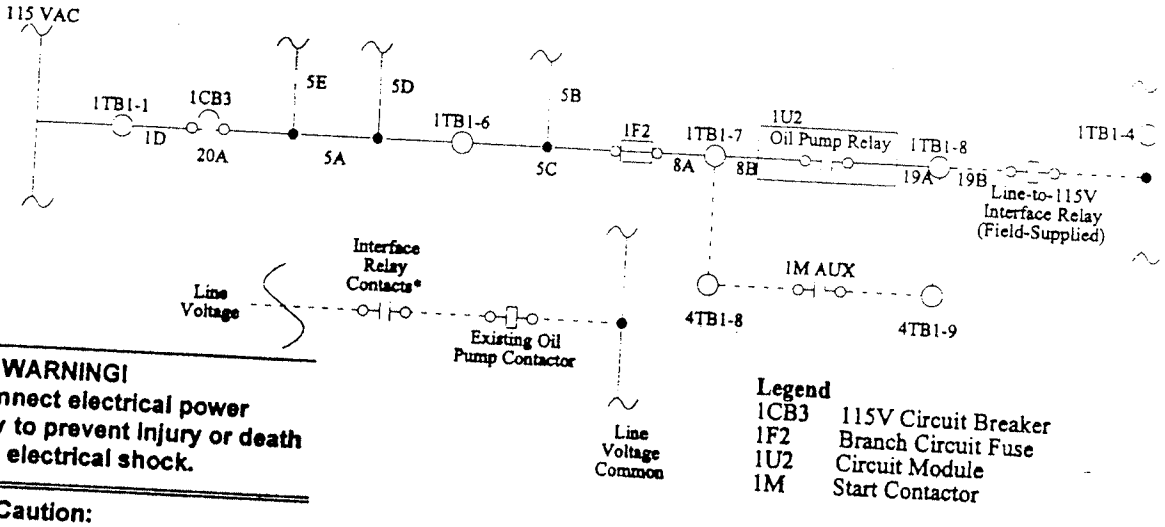


Figure 14b - Existing Oil Pump Contactor without 115V Coil

Legend

1CB3	115V Circuit Breaker
1F2	Branch Circuit Fuse
1U2	Circuit Module
1M	Start Contactor

⚠ WARNING!
Disconnect electrical power supply to prevent injury or death due to electrical shock.

⚠ Caution:
Use copper conductors only to prevent equipment damage (unless otherwise specified).

*When coil is not 115 volts, wire a set of normally-open contacts in a series with the existing oil pump motor contactor coil.

Note: The Oil Pump Relay coil is not shown, since closure of the Oil Pump Relay contacts is governed by Circuit Module (1U2) control logic.

Motor Temperature Interface

There are two motor temperature interface options:

- To convert a chiller with the Robertshaw module and RTD sensors, connect Circuit Module Terminals 1U2-J3-1,3,5 and 6 directly to the RTD terminals on the motor.

Note: These circuits are low voltage (i.e., less than 30 volts), and must be separated from higher voltage circuits.

⚠ Caution:
To prevent possible control malfunction due to electrical noise, never route low-voltage circuits with other conductors carrying 30V or more!

- If the chiller's motor temperature sensing device is a thermostat, connect it to an isolation relay and resistors (all field-supplied) that simulate the three RTD sensors presently used for motor temperature protection. The resistor in the common leg is brought into series with the other three resistors by CR-1. This causes an increased voltage drop which the UCP2 recognizes as a high temperature. See Figure 15.

Note: To assure proper operation, the thermostat's contacts must be normally closed and open on a rise in motor temperature.

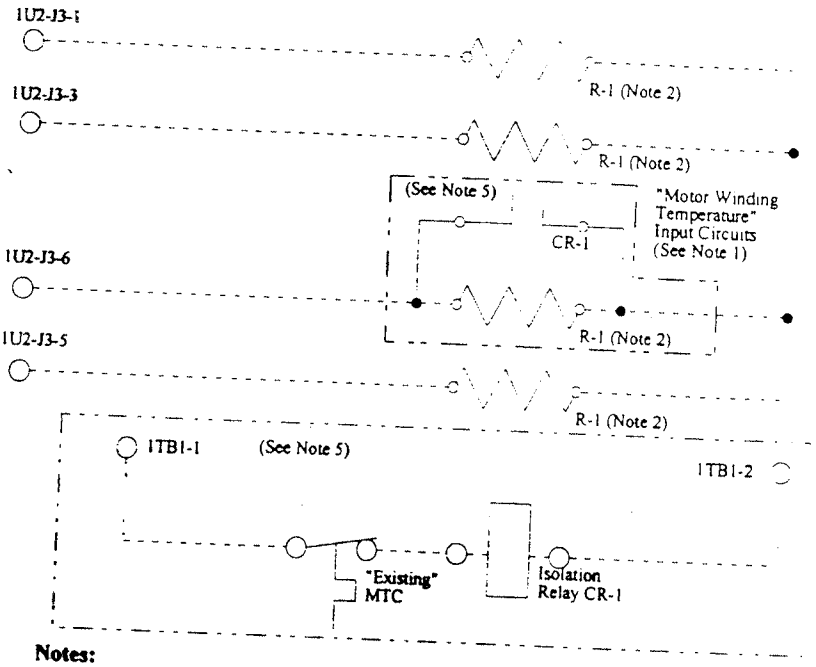

Figure 15 - Interfacing Existing Motor Temperature Thermostat w/UPC2 Control Panel (See Note 3)

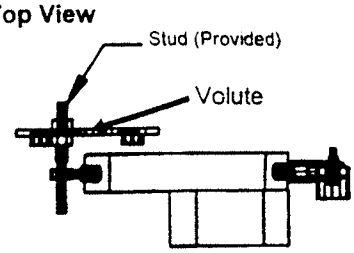
⚠ WARNING!
Disconnect electrical power supply to prevent injury or death due to electrical shock.

⚠ Caution:
Use copper conductors only to prevent equipment damage (unless otherwise specified).



Notes:

1. Wiring to micro module 1U2's terminal strip is low voltage (i.e. less than 30 volts).
2. "R-1" resistors are of carbon composition, and are rated at 75 ohms/0.5 watt.
3. This electrical configuration must be used whenever the existing motor temperature control (MTC) is a thermostat. Notice that the thermostat must include normally-closed contacts that open on a rise in temperature.
4. The "CR-1" isolation relay and 4 "R-1" resistors must be field-supplied.
5. Required to simulate three RTD sensor motor protection.

Stepper Inlet Guide Vane Actuator Installation

If installing a stepper inlet guide vane actuator, use the provided mounting brackets and the existing connecting hardware to mount the actuator.

Note: Do not connect the guide vanes at this time! Vane motor travel must be checked before the guide vanes are connected to the actuator; see "Post-Conversion UCP2 Panel/Chiller Check-out".

The vane motor leads and the Binary Position Indicator (BPI) must be wired to the UCP2 Panel, as shown in Figure 11, and connected to the Stepper Module (1U3).

The stepper actuator provided in the UCP2 conversion package is 1-3/8" longer, when fully retracted, than the pneumatic actuator used on "older" CenTraVacs®. Therefore, the existing linkage must be modified to ensure that the vanes are closed when the actuator is retracted.

Use the actuator mounting plate, piston yoke and mounting hardware provided to install the new electric actuator as shown in Figure 16.

The motor can be rotated 180° to accommodate existing hardware. Additional hardware may be field fabricated if necessary.

⚠ Caution:
When mounting the actuator, make sure that the 0° vane position corresponds with the actuator fully closed. Failure to do so could result in severe damage to the machine.

Note: When the new stepper actuator is installed on either PCV-2C through PCV-3J units, or CVHA-022 through CVHA-038 units, change the motor stroke from 5" to 4". (See Step 2 of "UCP2 Panel/Chiller Check-out" for instructions.) Also, the stroke of the actuator will be toward the compressor. Note the orientation shown in Figure 16.

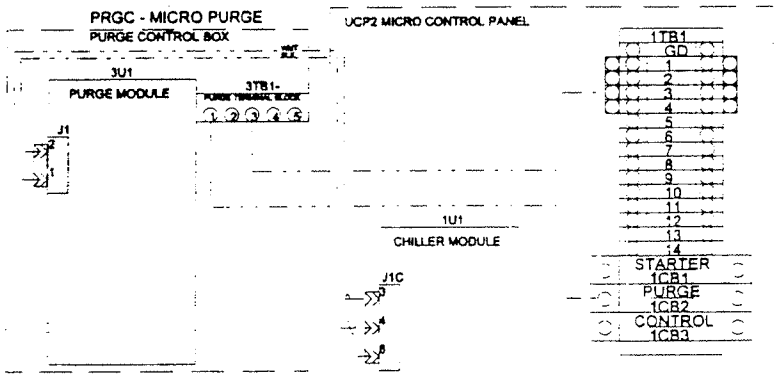
Purge Control

The Purifier Purge™ model PRGC contains a Purge Module (3U1) that requires connection to the IPC and 115VAC. Refer to Figure 17a for connection diagrams. Older model Purifier Purges (PRGA and PRGB) as well as most competitor built purges require connections similar to Figure 17b. Trane PRGB terminal designations are used for convenience. If installing a non-Trane purge, refer to manufacturer's literature to determine connection points.

When using a PRGC, check that J1-5 and J1-6 on the Purge Module are not jumpered. The UCP2 controls the purge in this configuration.

Note: The purge type must be selected from the UCP2 menu screen in the field Start-up Service Setup Group Purge Control/Type. Only the PRGC Purifier Purge can communicate with the UCP2.

Figure 17a -
PRGC - Purifier Purge™



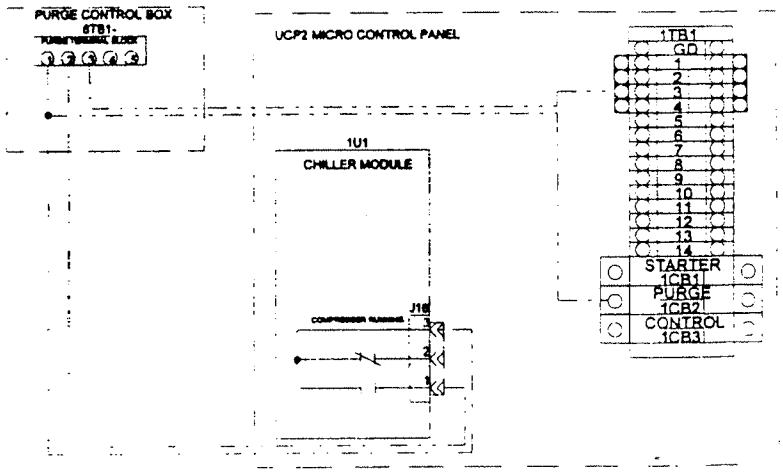


Figure 17b -
Models PRGA & PRGB - Purifier Purge™

Starter Panel Conversion

Starter panel conversion varies with existing starter type and starter control voltage.

To ensure that the starter panel retrofit procedure is performed properly, carefully review the instructions in this section; and, if necessary, contact a Trane service organization for assistance before beginning the conversion process.

Important! Record a detailed description of all electrical changes made during the UCP2 starter retrofit process. Keep a copy of this report in the chiller record file for future reference.

Starter and Auxiliary Starter Panel Connections

The starter panel must be rewired as shown in the diagrams in Figures 20 and 21. The schematics in Figures 20 and 21 show typical wiring for Wye-Delta, Auto Transformer, Primary Reactor and Across-the-Line starters. Use Figures 20 and 21 and the starter manufacturer's drawings to determine the proper connection points in the starter.

It is important to determine proper connections to the start relay (5K1), transition relay (5K2), proof of transition (2M Aux) and condenser high pressure switch functions.

A start and transition relay is recommended for retrofit applications since it is not possible to predetermine control voltages.

Table 6 lists equivalent contactor designations for Trane supplied Wye-Delta starters. For other starter types and manufacturers, the function of each contactor must be determined and the equivalent Trane contactor identified **before** beginning the wiring.

Current Transformers (CT) must be installed at this time:

- See Table 7 for correct selection
- See Figure 20 for the two-stage CT arrangement for retrofit applications
- See Post Conversion Section for setup

Important! To maintain correct polarity, wire CT's exactly as shown in Figures 20 and 21.

The following connect to the Starter Module in the Auxiliary Starter Box, as shown in Figures 20 and 21:

- Inter-Processor Communication
- Line to auxiliary Current Transformers
- 24 VAC Power
- Transition Complete Signal (except for Across-the-Line)

See Potential Transformer Installation Section for information on optional transformers.

Table 6 -
Typical Wye-Delta Starter Designations

Control Type	Shorting Contactor	Transition Contactor	Start Contactor	Run Contactor	Pilot Relay	Transition Relay	Transition Complete
Generic	S	1A	1M	2M	1CR	1CR/T.C.	T.C.
AGM	K25	K26	K27	K28	K23 & K24	A1	K27 Aux
UCP1	2K3	2K4	2K1	2K2	2K5	K5	2K2 Aux
UCP2	2K3	2K4	2K1	2K2	5K1	5K2	2M Aux

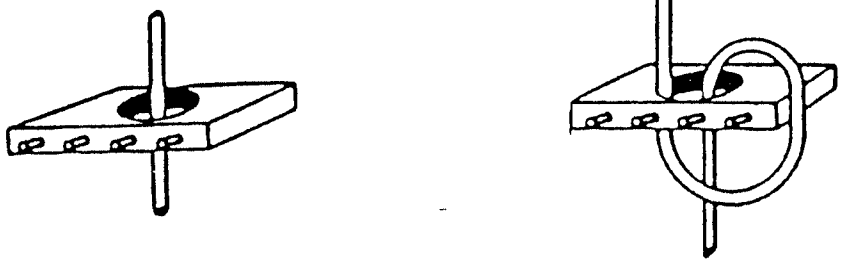
Adaptive Frequency Drives for UCP2

The drive should be mounted according to the manufacturer's instructions. These instructions are detailed in Westinghouse Instruction Manual Part No. 9075A05 for the Accutrol 700. If this manual did not ship with the drive, contact ABU Technical Service. Follow all installation procedures for mounting and power wiring to the drive.

All control wiring field connections to the drive are made to the factory installed Starter Module inside the Adaptive Frequency Drive enclosure. See Figure 22 for non-bypass, Figures 23 and 24 for manual bypass, or Figures 25 and 26 for Solid State bypass.

With all bypass installations, the starter type on the UCP2 must be selected in the machine configuration menu as Adaptive Frequency Drive. Additional relays are used to transfer control from one starter module to the other by disconnecting the IPC, 24 VAC module power supply and 115VAC control power supply to the Starter Module not in use. The normally closed contacts on the Condenser High Pressure cutout are switched to the appropriate Starter Module.

On manual bypass, two additional relays are used. One transfers the Oil Pump Interlock from the existing Wye-Delta starter to the AFD. The other relay brings in the 1M and 2M power contactors configuring the starter in the three-lead Delta configuration.



Note: Check schematics that ship with the drive for unlabeled terminal designation for the bypass relay.

Table 7 - Current Transformer Selection
See Note Below

Line CT Part No.	Ext.	Line CT Ratio	CT Terminal Connections	No. of Primary Turns *	RLA Ranges	Meter Scale

		1500:5	X1 to X4	1	720.0 to 1080.0	1500

Note: See Post-Conversion Check-Out, Step 4.
* See Figure 18 for examples.

Figure 18 - Example of One and Two Turns

⚠ WARNING!
Disconnect electrical power supply to prevent injury or death due to electrical shock.

⚠ Caution:
Use copper conductors only to prevent equipment damage (unless otherwise specified).

Potential Transformer Installation for 3 Phase Voltage Monitoring (Optional)

The potential transformers (PT's) are used to measure line voltage:

- Less than 600 VAC line— a single PT per phase is used to step the signal down to a proportional 30 VAC for input into the starter module (2U1).
- Greater than 600 VAC line—a large PT is used to step from line to 120 VAC and a smaller PT steps the voltage to 30 VAC. The large PT is a three phase type except for the 6600 VAC/50 Hz where three single phase PT's are used.

a. <600 Volt (Digit 9 = 1) -
The black leads are connected to the line from Phase A-B, B-C and C-A. The green ground wire is connected to chassis ground. Field provided wires connect the 2U1 Module to the spade terminals on the P.T.'s. See Figures 20 and 21.

b. >600 Volt (Digit 9 = 2) -
The line-to-120 VAC transformer's secondaries are connected to the primary (black) leads of the provided transformer. If the line-to-120 P.T. is a three phase type, the Phase A-B, B-C and C-A connections must be made similar to Figures 20 and 21. If the line-to-120 VAC P.T. is a single phase type, ensure that the proper phasing is maintained similar to Figure 19. The green wire is connected to ground and the white wires to the 2U1 module.

c. 2300/2400 VAC, 4200 VAC, or 3300 VAC/50 Hz P.T.'s (Digit 9 = 3, 4 or 5) -
The primaries (A, B and C) of the three phase P.T. are connected to the >600 volt 120:30 P.T. as described above.

d. 6600 VAC/50 Hz P.T.'s -
The H1-H2 terminals of the single phase P.T.'s are connected to phases A-B, B-C and C-A respectively. The secondaries connect to the >600 volt generic P.T.'s primaries directly. See Figure 19.

Note: The <600 volt transformer as well as the 120:30 VAC potential transformer may be mounted in the auxiliary starter box.

Use Table 8 for fusing information for 5F1, 5F2 and 5F3.

⚠ DANGER!
Do NOT connect the primary (black leads) of the 120:30 VAC Potential Transformer to line. Doing so could cause an explosion resulting in severe injury or death.

⚠ Caution:
Do NOT connect the secondaries of the line-to-120 VAC potential transformer to the UCP2 starter module. Doing so will cause damage to the module.

Figure 19 -
Potential Transformer Installation
6600 VAC/50 Hz

Post-Conversion Check-out

⚠ Caution:
To prevent machine damage, contact a Trane service organization to perform the check-out procedures described in this section.

Starter Panel

All wiring in the starter must be re-checked and the contactor logic verified before starting the unit.

UCP2 Panel / Chiller

1. Verify all wiring is connected correctly and that all wires are numbered properly. Make sure all -piping is completed.
2. Perform the following steps only if a stepper inlet guide vane actuator has been installed.
   a. Check and adjust vane travel before connecting the actuator to the guide vanes. Power up the UCP2 and choose Inlet Guide Vane Output Type <Stepper Motor> from the Machine Configuration menu and Vane Control <Manual> from the Service Tests menu. Verify that the actuator operates from 0-100% (0-5" stroke) open.
   b. Connect the guide vane to the actuator.
   c. Connect the vane linkage to the actuator motor.
   d. In the Field Start-up Service Settings group, set the Inlet Guide Vane (IGV) Maximum Travel Setpoint to the previously measured stroke (in the Existing Control Panel Removal Section) X 11,000 steps (i.e., a 5" stroke equals 55,000 steps).
   e. In the Service Tests Group, change the vane control status to manual, go to the next menu and increase vane position slowly until the vanes are physically open 100%. If the vanes are not open, increase the IGV Maximum Travel Setpoint by 1,000 steps. Repeat this process as often as necessary. The vane position will not correspond to the percentage shown on the screen.

⚠ Caution:
The Inlet Guide Vane Actuator may go beyond the designed travel limits of the linkage. Failure to properly identify the fully open position can cause the actuator to over travel and break the vane linkage.

   f. When the vanes are fully open, press <Next> until the screen showing IGV actuator steps is displayed. The number of steps should be recorded and entered as the new IGV Maximum Travel setpoint.
3. Perform the following steps only if a pulse inlet guide vane actuator is installed.
   a. Power up the UCP2 and choose Inlet Guide Vane Output Type <Pulsed> from the Machine Configuration menu.
   b. In the Service Test menu, choose Manual Loading/Unloading Duty Cycle <50%>.
   c. Next, choose IGV Control <Load> or <Unload> in the Service Test menu. Measure the duty cycle (full open to full close or vice versa) in seconds.

d. Divide this number by 2 to obtain stroke time. Input this value at Inlet Guide Vane Stroke Time in the Field Start-up menu.

4. Configure all settings in the Operator Settings, Service Settings, Service Tests, and Diagnostics groups as required in CVHE-M-7.

Note: In the Service Test Group - Starter Dry Run should be disabled since this does not apply to retrofit installations using pilot relays to control the starter.

Note: In order to calculate the Current Transformer Factor, evaluate the following formula:

CT Factor = (Actual Motor RLA)/ (CT Meter Scale from Table 7) x 138.89%

Use the CT Factor to determine the current Overload Settings #1 and #2 on Table 9.

5. Run the chiller through the normal operating range to determine that the controls are properly configured and installed.

This completes the retrofit installation procedure. Proper configuration of the UCP2 for optimal performance is covered in CVHE-M-7.

Instructions

The following pages highlight revisions to the CVHE-CLD-1. These are important changes that impact the set-up of the UCP2 Control Panel Conversion package. Items that have been revised are separated by menu type and are underlined.

Compressor Report

Inlet Guide Vane Position

The following screen will be suppressed if "Inlet Guide Vane Output" is set to "Pulsed".

Inlet Guide Vane Position:	XXX.X Open
Inlet Guide Vane Position:	XX.X Degrees

Refrigerant Pressure Analog Output Option

Rfgt Pressure Output Option:	[status]
Press (+) (-) to Change Setting	

Possible values for status are: % Cond; Factory Default.
Delta.

Min Delta Pressure Calibration

The following will be displayed only if the "Refrigerant Pressure Analog Output Option" is set to "Delta".

Min Delta Press Calib (2 VDC)	XXXX PSID/kPa
Press (+) (-) to Change Setting	

The range of values is 400 Psid (0-2758 kPa) in increments of 1 Psid/kPa.
Factory Default is 0 Psid (0 kPa).

Max Delta Pressure Calibration

The following will be displayed only if the "Refrigerant Pressure Analog Output Option" is set to "Delta".

Max Delta Press Calib (10 VDC)	XXXX PSID/kPa
Press (+) (-) to Change Setting	

The range of values is 1-400 Psid (7-2758 kPa) in increments of 1 Psid/kPa.
Factory Default is 30 Psid (207 kPa).

IGV Stroke Time

The following will be displayed only if the "Inlet Guide Vane Output" is set to "Pulsed".

```
Inlet Guide Vane Stroke Time:        XXX Sec
Press (+)(-) to Change Setting
```

The range of values is 15 to 100 Seconds in increments of 1 Second. Factory Default is 45 Seconds.

Low Differential Oil Pressure Cutout

```
Low Diff Oil Press Cutout:           XX psid/kda
Press (+)(-) to Change Setting
```

The range of values is 6 to 35 psid in increments of 1 psid. Factory Default is 9 psid.

Refrigerant Type

Help Note: This is important for correct temperature to pressure conversion.

```
Refrigerant Type:                    [type]
Press <+> <-> to Change Setting
```

Possible values type are: R11, R12, R134a, Water, R22, R113. Factory Default is R123.

Hot Gas Bypass Option

This option is mutually exclusive with the pulsed IGV output. If this option is installed, the "Inlet Guide Vane Output" shall be set to "Stepper Motor".

```
Hot Gas Bypass Option:               [Status]
Press (+) (-) to Change Setting
```

Possible Values for Status are: Installed, Factory Default is Not installed

If the Hot Gas Bypass Option is set to Installed and the Inlet Guide Vane Output is currently Pulsed, the Inlet Guide Vane Output will be set to Stepper Motor and the following will be displayed for 3 seconds to indicate the change.

```
Inlet Guide Vane Output
Has been Set to  Stepper Motor
```

IGV Output Type

The pulse option is mutually exclusive with HGBP. If this item is set to "Pulsed", the "Hot Gas Bypass Option" shall be set to "Not Installed".

```
Inlet Guide Vane Output:                [Y]
Press (+) (-) to Change Setting
```

Possible Values for Y are: Stepper Motor, Factory Default
Pulsed

If Inlet Guide Vane Output is set to Pulsed and Hot Gas Bypass Option is currently set to Installed, the Hot Gas Bypass Option will be set to "Not Installed" and the following will be displayed for 3 seconds to indicate the change.

```
Hot Gas Bypass Option
Has Been Set to Not Installed
```

Vane Control Status/Vane Position Commands

The following screens will be displayed only when "Inlet Guide Vane Output" is set to "Stepper Motor". The status of the Vane Control is as follows:

```
Vane Control Is:                    [Status]
Press (+)(-) to Change Setting
```

The possible values of [Status] are: Manual, Factory default is Auto.
If the vane control status is "Auto" the following is displayed:

```
Inlet Guide Vane Position      XXX.X%
[Limit Mode]
```

If the vane control status is "Manual" the following is displayed.
When the Vane Control status is transitioned from "Auto" to "Manual", the manual target is initialized to the current vane position.

```
Vane Pos XXX.X%                Target XXX.X% Open
[Limit Mode]<+> <-> to Change Target
```

The possible values of [limit mode] are: Current Limit, Condensing Limit, Evap Limit, Blank

Vane Control Status/Manual Load and Unload

The following screen will be displayed only when the "Inlet Guide Vane Output" is set to "Pulsed".

```
IGV control Is:                     [Status]
LWT  =  xx.x  f/c                       [Y]
```

The possible values of [status] are "Auto", "Hold", "Load", or "Unload". Factory Default is "Auto".
The possible values of Y are "Current Limit", "Condenser Limit", "Evap Limit", and "(+)(-) and (Enter)".
The latter is displayed when there are not limits operating.

Manual Loading/Unloading Duty Cycle

The following screen will be displayed only when the "Inlet Guide Vane Output" is set to "Pulsed".

Manual Loading/Unloading Duty Cycle:	xx%
Press (+)(-) to Change Setting	

Range of Values is 0 to 50% in increments of 1%. Factory Default is 30%.

Vane Position

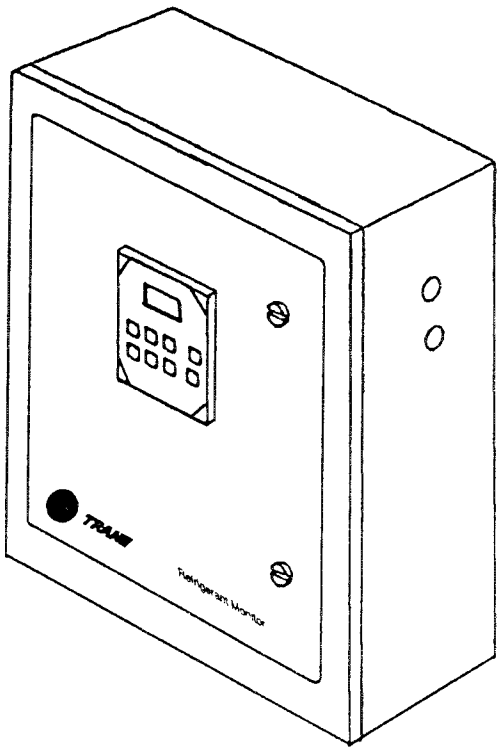
The following screen will be displayed only when the "Inlet Guide Vane Output" is set to "Stepper Motor".

Inlet Vane Position:	XXXX Steps
Inlet Guide Vane Position:	XX.X degrees

Hot Gas Bypass Valve Control Status/Manual Open and Close Commands

If HGBP is installed in the unit the following screen shall be displayed.

HGBP Valve Control Is:	Status
LWT = XX.X fc	[Y]



The possible values of [status] are "Auto", "Open", "Hold" or "Close". ROM Default is "Auto".
The possible values of Y are "Current Limit", "Condenser Limit", " Evap Limit" and "(+) (-) and (Enter)".
The latter is displayed when there are no limits operating.

Model Number

Unit Model Number

For service and replacement purposes, the Trane Model RMWD Refrigerant Monitor is assigned a multiple-character alphanumeric model number that precisely identifies each unit. The model number key is shown here.

Use of the model number will enable the owner/operator, installing contractor, and service technician to define the characteristics of any RMWD unit. Be sure to refer to the model number when ordering replacement parts or requesting service.

General Information

Literature Change History

RMWD-TSR-1 (May 1996)

Original issue of the trouble shooting manual pertaining to Trane™ Model RMWD Refrigerant Monitor design sequence "A0".

Introduction

This document provides troubleshooting and repair information for the Trane RMWD style Refrigerant Monitor. Included is a discussion of the internal diagnostic test the instrument processor performs on the flow system hardware during start-up in addition to performance under normal operating conditions. Finally, unit diagnostic messages are described and specific component tests are provided.

Unit Description

The Trane™ Model RMWD Refrigerant Monitor circulates room air through a sensing cell to provide a continuous indication of refrigerant vapor concentration. It is intended for indoor use in mechanical equipment rooms which house air conditioning or refrigeration equipment or in areas where bulk refrigerants are stored.

The monitor utilizes infrared photoacoustic sensing technology, allowing accurate measurement of refrigerant vapors with minimum interference from other chemicals in the vicinity. The instrument is compound-specific and factory calibrated for the specific refrigerant of interest. It is capable of measuring down to 1 parts-per-million (ppm) and displaying refrigerant concentrations from 0-1,000 ppm. The monitor can signal alarms at three different concentration levels. These alarms are factory set, but can be easily adjusted in the field. A unit "trouble" alarm indicates internal problems with the instrument. A level alarm or a trouble alarm condition will cause the display to flash with a message and activate a dry contact relay(s) which can be used to control external alarm lights or horns, start emergency ventilation, or signal a building management system.

The refrigerant level alarm relays can be configured as latching or non-latching. 0-10 VDC and 4-20 mA analog outputs are provided for connection to a data recorder or building management system. These analog outputs can be scaled as 0-100 ppm or 0-1000 ppm. The standard unit monitors one zone. The optional multi-channel scanner can be factory or field installed to monitor up to four zones.

General Information

Infrared Photoacoustics

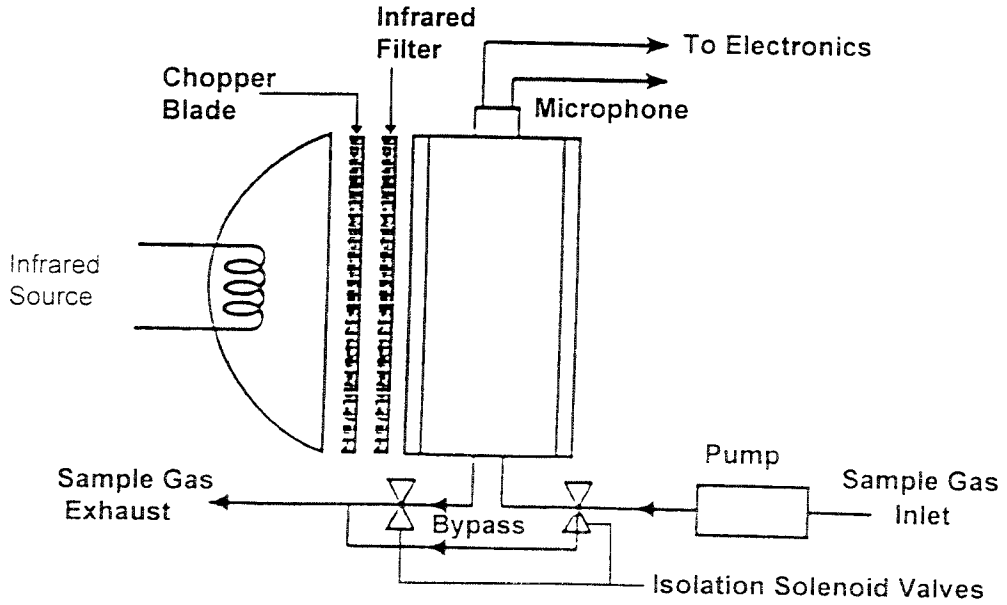
Increased industrialization together with a growing concern for human safety and the environment have stimulated the demand for sensitive and reliable methods of detecting trace amounts of pollutants and toxic gases. The advantages of infrared photoacoustic gas detection which the Trane RMWD refrigerant monitor uses include greater sensitivity, high immunity to interferents, fast response time and low maintenance.

The RMWD refrigerant monitor detects toxic gases by a process called infrared photoacoustic spectroscopy. The photoacoustic effect is the emission of sound by an enclosed sample on the absorption of chopped infrared light.

Portions of the Infrared Photoacoustics section reprinted with permission from Brüel and Kjær Instruments, Inc.

When a gas is irradiated with light, it absorbs some of the incident light energy, proportional to the concentration of the gas. The absorbed light energy is immediately released as heat and this causes the pressure to rise. When the incident light is modulated at a given frequency, the pressure increase is periodic at the modulation frequency. Pressure waves, or sound waves as they are commonly known, are easily measured with a microphone. They are audible if their frequency is between 20 Hz and 20 kHz.

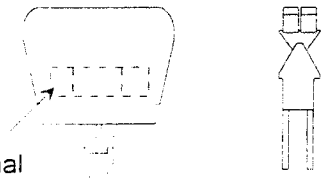
The intensity of the sound emitted depends on a number of factors; the nature and concentration of the substance and the intensity of the incident light.



The selectivity which can be achieved in spectroscopy is due to the fact that substances absorb light of specific wavelengths which are characteristic of that substance.

The sequence of events in this process are.

- gas sample is sealed in measurement chamber
- chamber is irradiated with pulsed, narrow-band light
- gas absorbs light proportional to its concentration and converts it to heat
- gas heats and cools as the light is chopped
- temperature fluctuations generate pressure waves,
- pressure waves are detected by microphone



The main parts of a photo-acoustic set-up (see Figure 1) are a chamber to contain the gas sample, a light source, a means of modulating the light (usually a chopper), a detector to measure the sound (usually a microphone) and a method of processing the signal. The signal is interpreted by the electrical components into a parts per million (ppm) display.

RMWD Style Refrigerant Monitor

Monitor Installation

- Securely mount vertically on wall away from vibration sources using four mounting tabs
- Monitor Installation, Operation and Maintenance manual, RMWD-IOM-1, or the latest revision, has detailed installation information
- Application engineering manual REF-AM-3, or the latest revision, Refrigeration System Equipment Room Design, has further recommendations regarding sampling locations to meet ASHRAE 15 guidelines

Wiring

- Monitor should have a dedicated power source to make sure it is always on even if other equipment is off
- Monitor will accept 100-240 volts a.c., 50 or 60 Hz
- Fuses (FUS 0927), jumper (PLU 0528) and fuse holder (HLD 0167 - black "key") ship with monitor in small box and are inserted in terminal strip, see examples at left for location.
- Monitor alarm contact ratings: Resistive: 7.2 amps at 120 volts a.c., 5.0 amps at 240 volts a.c.; Inductive: 2.88 amps pilot duty, 1/3 HP, 7.2 FLA, 43.2 LRA

Note: Monitor has a NEMA 4 rated enclosure. Use the plugged knockouts provided. Do not cut holes for wiring because shavings may short the electronics. Any added holes may compromise NEMA 4 integrity of the enclosure.

Trouble relay energizes during normal operation which closes normally open contacts. If monitor trouble occurs, relay is de-energized and contacts open

- Auxiliary input
  - 4-20 mA signal can come in to monitor from another device like an oxygen monitor - 18 AWG shielded wire is recommended, maximum of 250 feet (76 m)
  - level 3 alarm contacts change on excessive refrigerant concentration or mA signal
- 4-20 mA and 0-10 volt d.c. analog outputs
  - proportional to displayed refrigerant concentration
  - software selectable for 0-100 or 0-1000 ppm
  - 18 AWG shielded wire is recommended
  - 500 feet (152 m) max. length

Status LED's on main circuit board (see Figure 3)

- **Power:** green if normal
- **Alarm levels if refrigerant concentration exceeds setpoints:**
  Level 1 - amber
  Level 2 - red
  Level 3 - red
- **Ready:** green if normal
- **Trouble:** red if diagnostic appears

Filters

Change sample filters (ELM1144 - end of line, FLR1396 - inside monitor) regularly depending on the cleanliness of the equipment room. A flow loss condition at the monitor indicates a change may be required.

**Figure 2 - Typical RMWD Monitor
Major Component Locations**

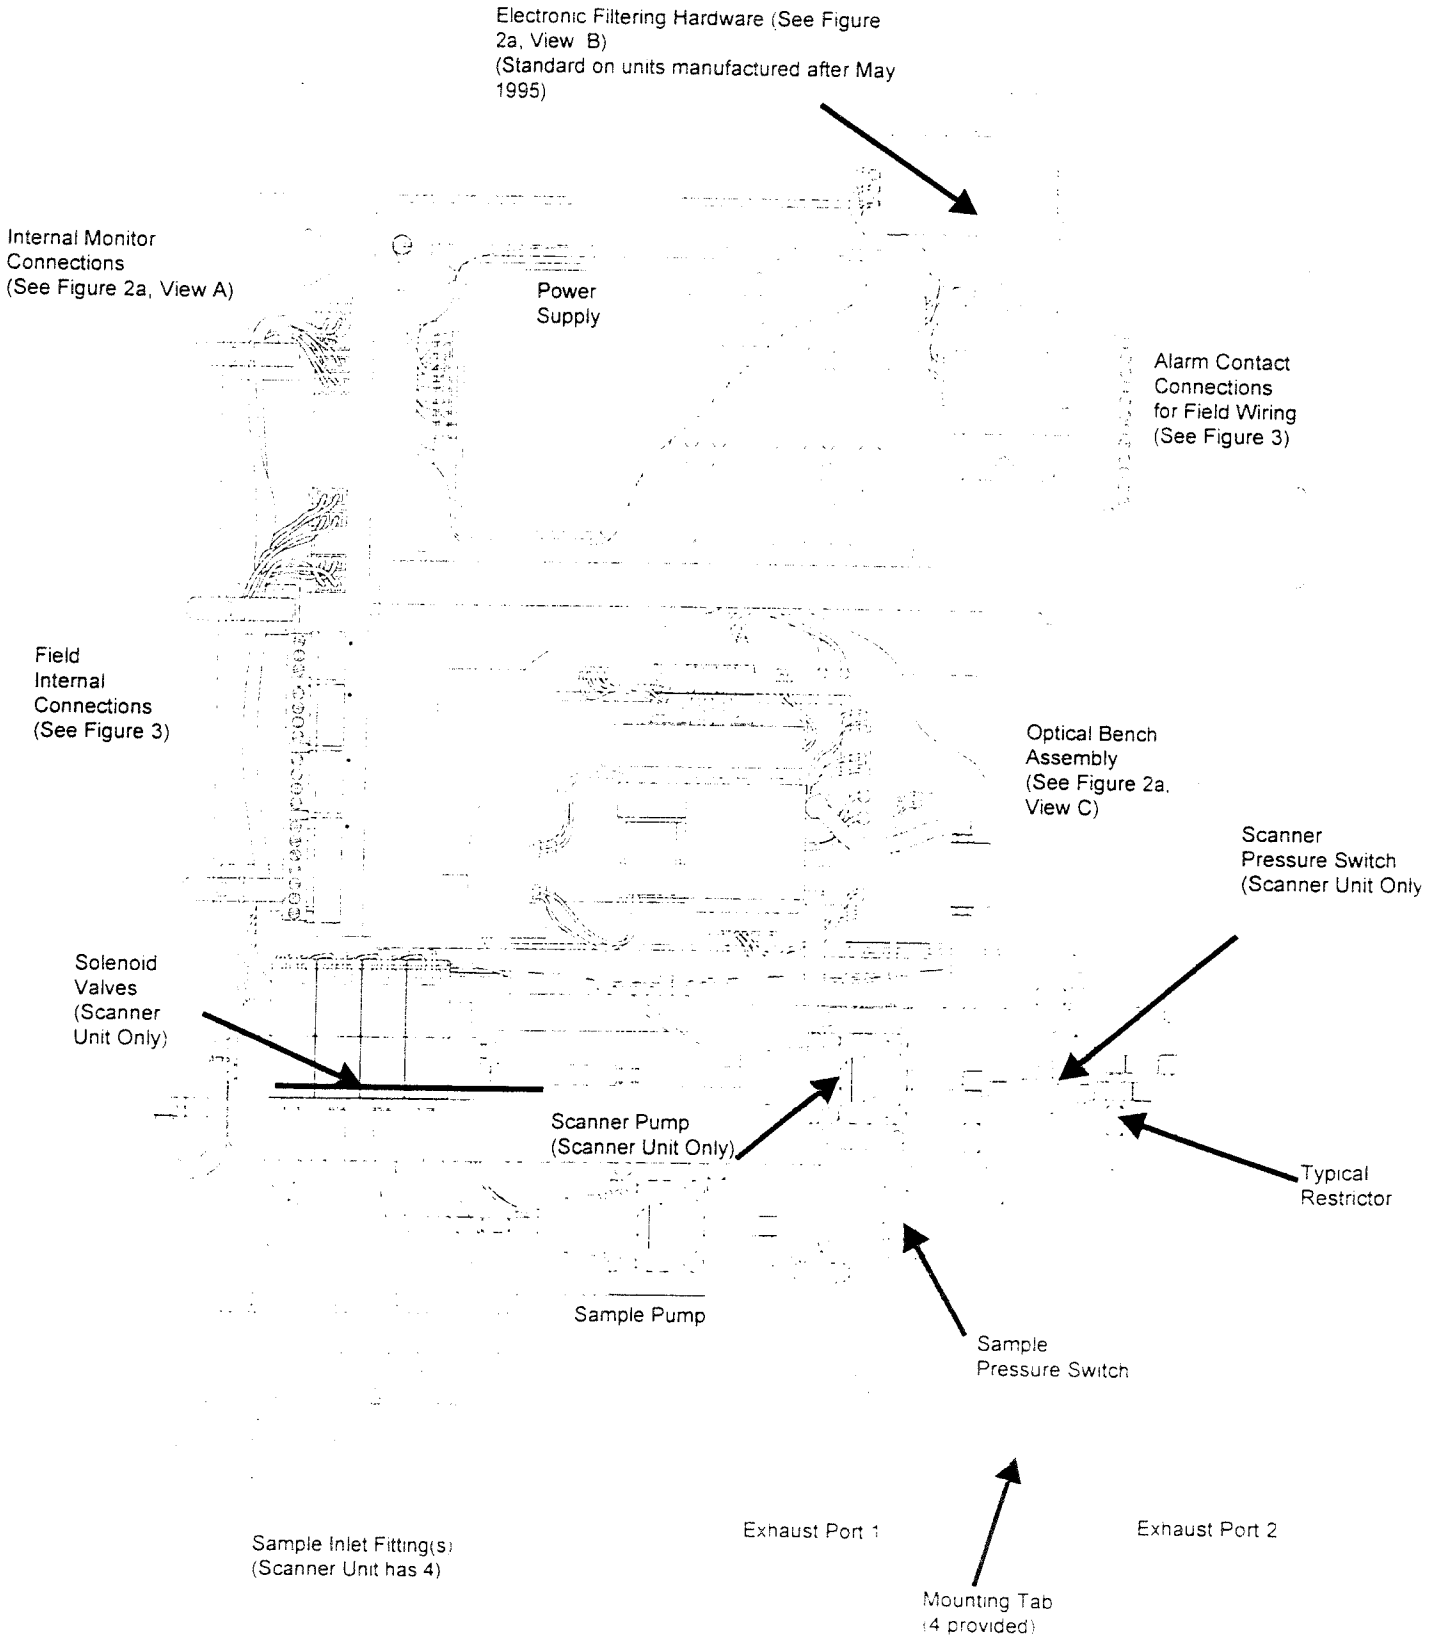

Figure 2 a - Typical RMWD Internal Wiring Connections

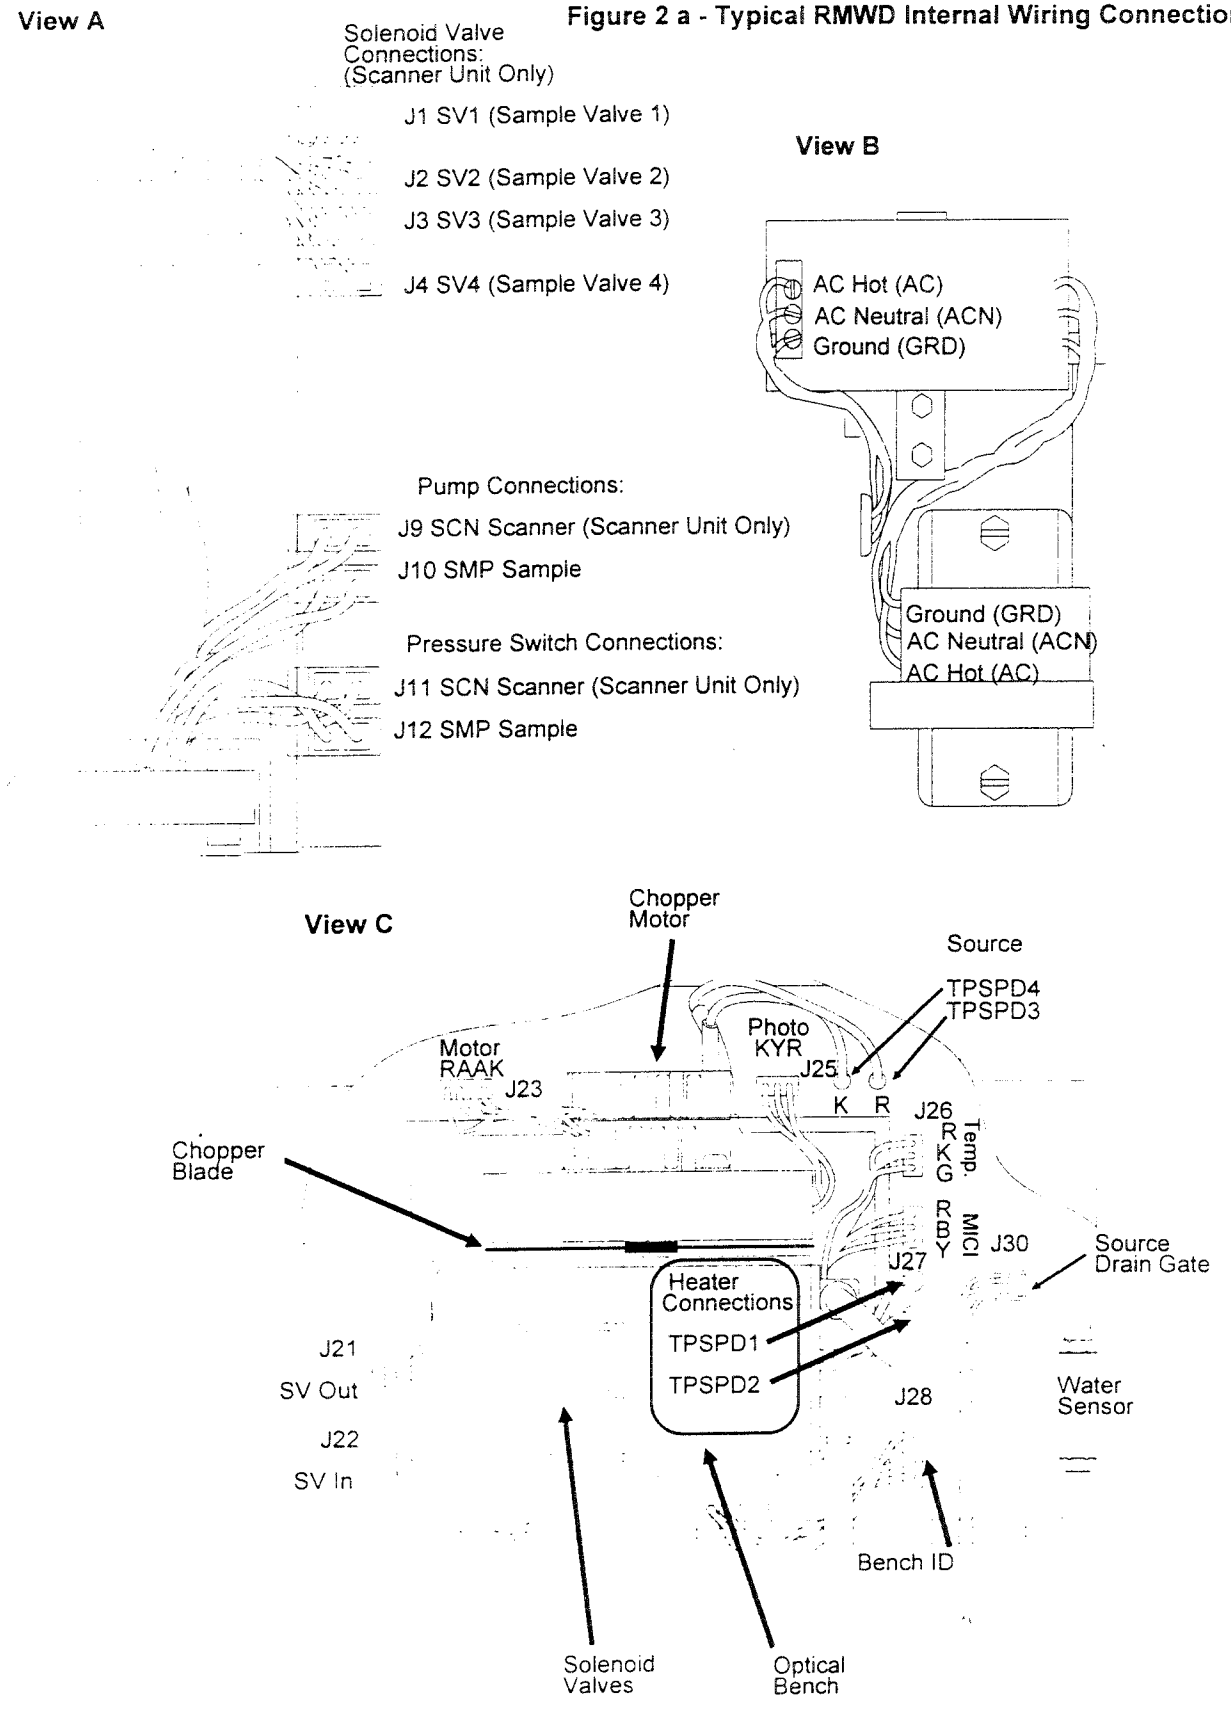

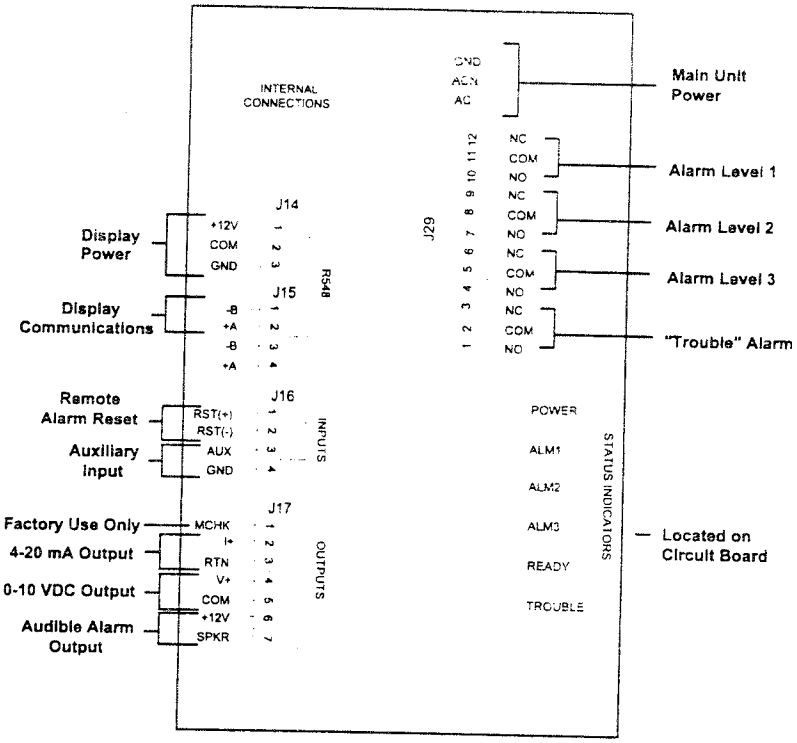

Figure 3

Remote Mounted Wiring

Unit Mounted/UCP2 Wiring

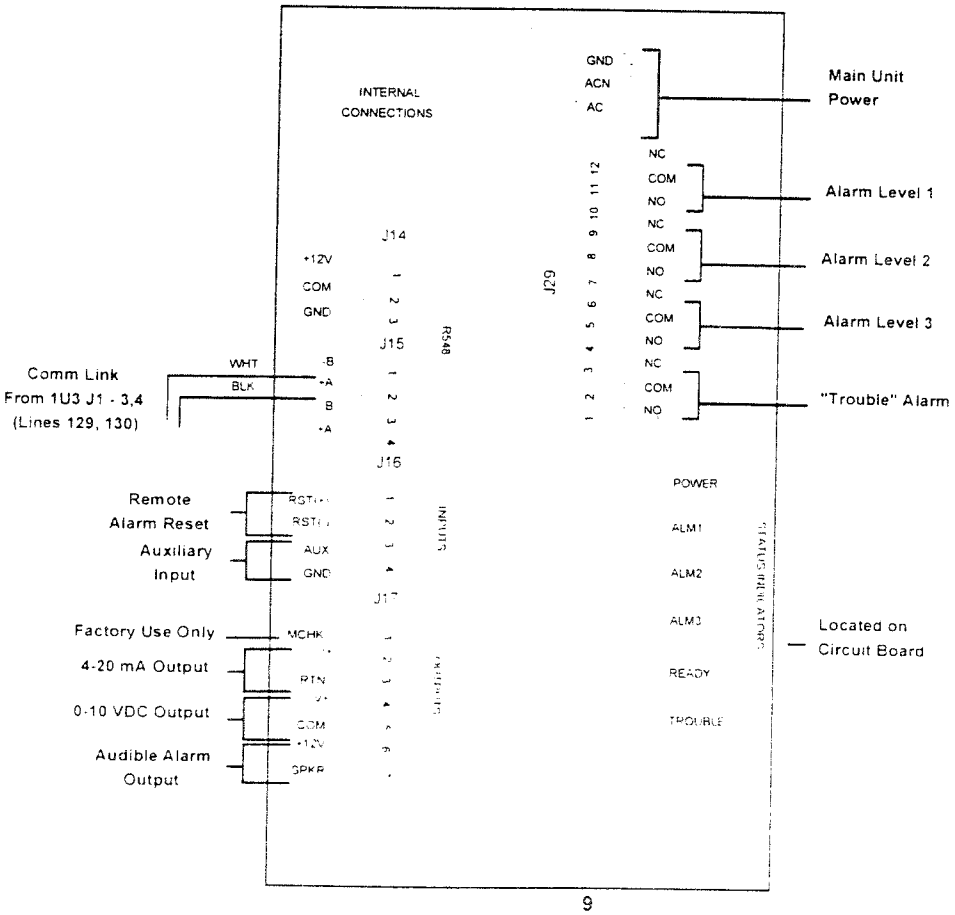

Figure 4 - UCP2 Schematic Wiring for Clear Language Display, Stepper and Circuit

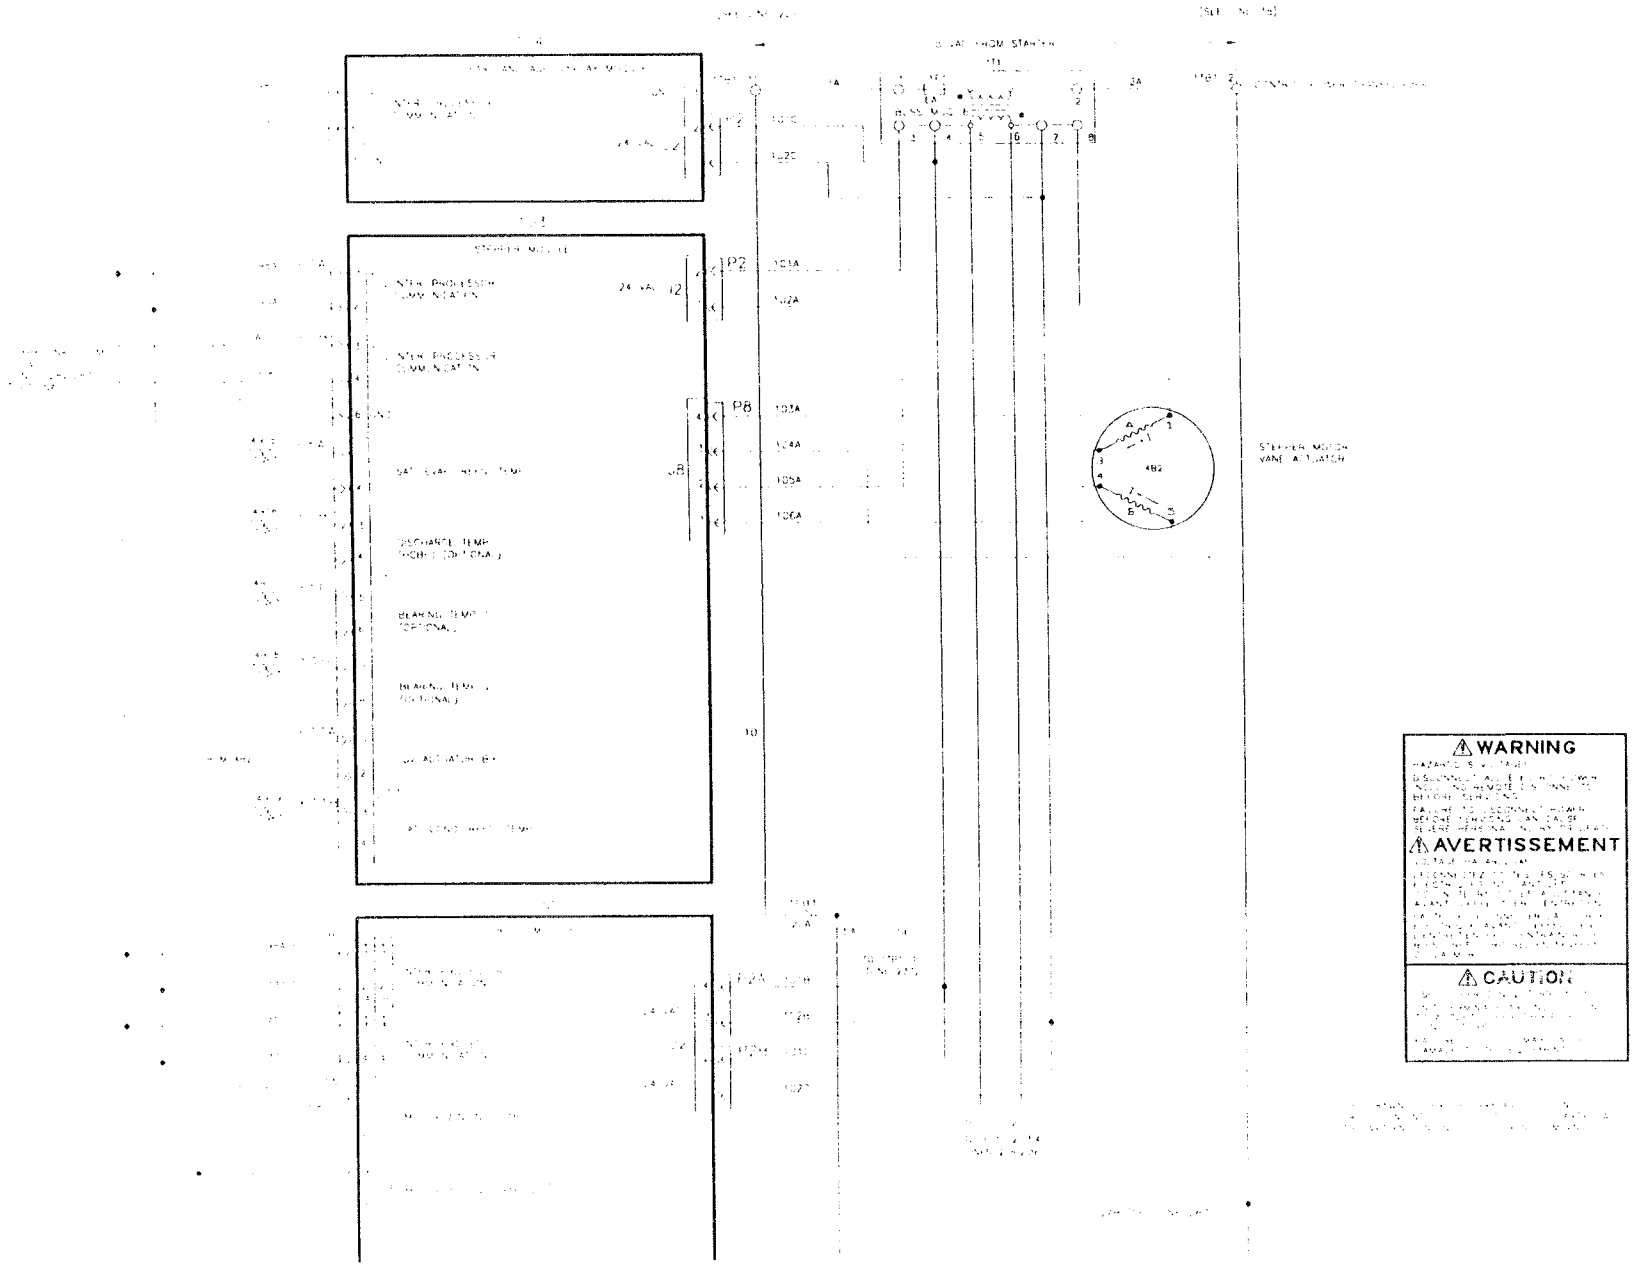

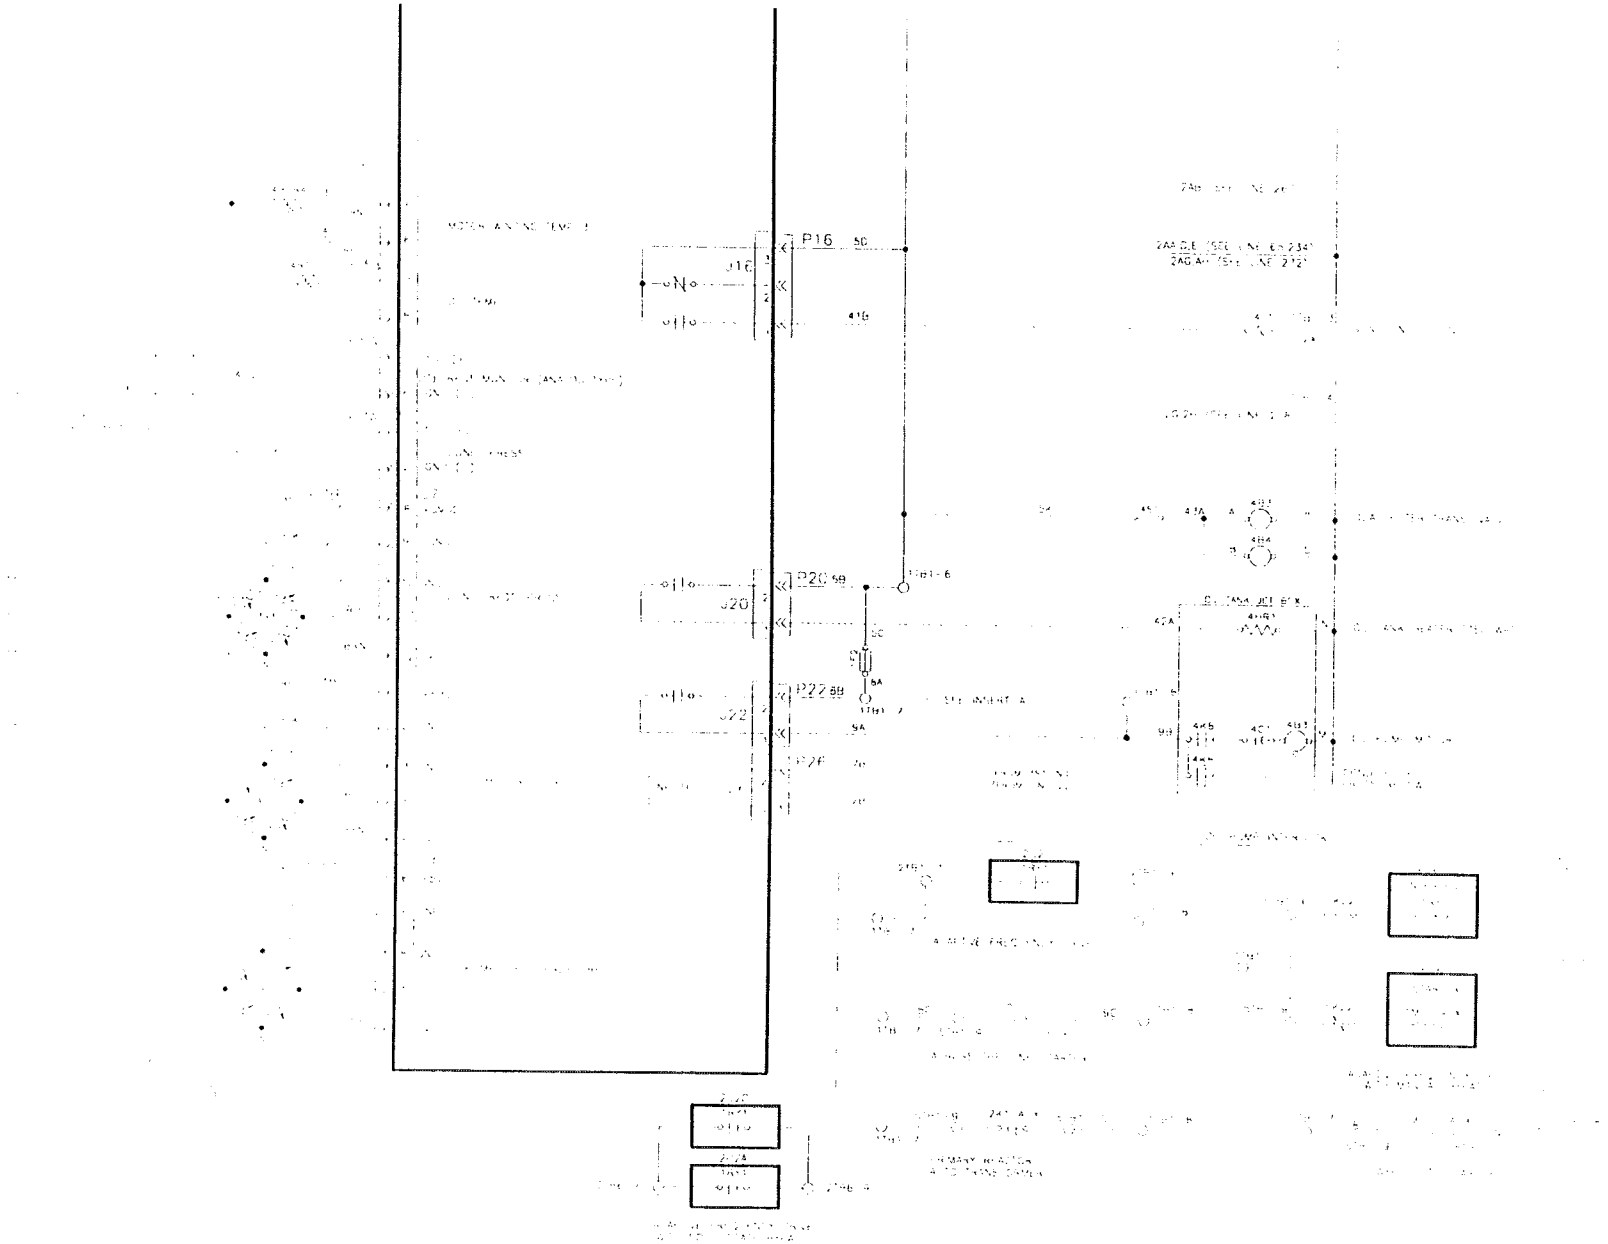

Figure 4 - UCP2 Schematic Wiring for Clear Language Display, Stepper and Circuit

Refrigerant Monitor / UCP2 Connections

Two options exist:

- **Analog**: Alarm setpoint changes, etc. are done from the monitor's keypad. The UCP2 will only display the current parts per million (ppm) and has no control over the monitor. The UCP2 must be configured for analog type refrigerant monitor to display the ppm readout. Run 18 AWG shielded, twisted wire to the following terminals. **Note**: the maximum distance is 500 feet (152 m).

UCP2 - 1U2 (Circuit) Module		Refrigerant Monitor
J5-5	To	J17-2
J5-6	To	J17-3

See Figure 4 for wiring details.

- **IPC**: All settings and control of the refrigerant monitor is done through the UCP2 keypad. **Note:** To meet UL requirements, a green light (KIT2990) must be present in the monitor's door to show that power is applied. The UCP2 must be configured for IPC which will allow the refrigerant monitor screens in UCP2 to become active. Run 18 AWG shielded, twisted wire to the following terminals - 500 feet (152 m) maximum.

UCP2 - 1U3 (Stepper) Module		Refrigerant Monitor
1U3 J1-3	To	J15-1
1U3 J1-4	To	J15-2
J1-6, Use for ground		

See Figure 4 for wiring details.

Note 1: See software issues for related refrigerant monitor and UCP2 compatibility.

Note 2: KIT 3032 adds a human interface at the monitor to a RMWD monitor which doesn't have one.

Note 3: Control is from UCP2 or human interface on the monitor, not both.

Tracer Connections

- If UCP2 exists:
  A UCP2 TCI Comm 4 module (to Summit) and a TCI Comm 3 module (to Tracer 100) will upload the ppm display from the refrigerant monitor if configured in UCP2 as an analog monitor. If the refrigerant monitor is configured and connected IPC to UCP2, the ppm and any monitor diagnostics are passed up to Tracer.
- No UCP2:
  Tracer 100 Series does not accommodate connecting the Refrigerant Monitor directly to the Tracer. It would need to be connected to a PCM or UPCM. Tracer Summit BCU's each have two (2) Universal Input points that can be configured to interface the Refrigerant Monitor analog and / or binary outputs.

What Tracer does with the information depends on the sequence of operation for the job, what points are to be set up for alarms and how the Tracer is programmed. Contact BASD for details.

Battery Backup - The micro processor has a battery backup and the computer chip is non-volatile so that settings and memory are not lost when power is off to the unit. The unit itself does not have a battery backup to continue monitoring during a power outage.

Run Test Monitor - Alarm contact relays can be tested by using the span gas from the calibration kit. Change the alarm contact setpoints below the concentration for the span gas and apply the span gas to the sample inlet. The contacts should change state.

Software Issues

A white label located in the top of the monitor enclosure shows the manufacturing date. The software version number for the human interface is displayed during warm-up. This information is also found in the Status Menu.

Design sequence A, Software version 1.0 - The first date codes in production were mid-August 1994. The optional audible alarm will sound on a level 3 alarm.

Design sequence A, Software version 2.0 - This started in production on March 2, 1995 and allows communication / programming from the UCP2. Therefore, the monitor could function without the clear language display. This version will support the optional monitor mounted audible alarm selectability for alarm levels 1, 2 or 3. The audible alarm can also be set to alarm for a monitor trouble condition. Note that this is independent of the three alarm levels. Refrigerant R-12 monitors are fully supported by software.

Design sequence A, Software version 2.0 - UL label applied starting April 1, 1995. At the same time additional electronic hardware was added to the bench circuit to minimize interference from radiated electrical noise such as radio pagers, etc.

Design sequence A, Software version 3.0 - All refrigerant monitors with a date code of June 20, 1995 or later have version 3 of refrigerant monitor software. This software will change the analog output so it doesn't go to 2.0 mA during monitor check. This situation caused nuisance diagnostics on the UCP2.

Version 2 software will allow the UCP2 to communicate directly with the refrigerant monitor via the IPC (inter-processor communication link). The UCP2 must have software released on February 17, 1995 or later, and the modules must have the extensions as shown below.

Description	CTV X-Code	RTHB X-Code
Chiller Module (required UCP2 module)	X13650450-08	X13650499-05
Clear Language Display Module (required UCP2 module)	X13650448-07	X13650448-07
TCI Comm4 Module (optional UCP2 module)	X13650457-05	x13650457-05
TCI Comm3 Module (optional UCP2 module)	X13650460-05	X13650460-05
TCI Printer Interface Module - (optional UCP2 module)	X13650458-05	X13650458-05

General Information

Monitor Cross-Sensitivity

The Trane Refrigerant Monitor is factory calibrated specifically for the refrigerant of interest. With the large number of different chemicals and refrigerants in equipment rooms, it is very important that an air monitoring device be as resistant to cross-sensitivity as possible. The photo-acoustic technology used in this instrument is one of the most selective available; however, the instrument may respond, in varying degrees, to other chemicals that may be in the monitored area. Listed below are the instrument's sensitivity to 100 ppm of other commonly used refrigerants when calibrated for the specific refrigerant listed. These are typical values for reference only.

Example: A monitor calibrated for HCFC-123 will display 4 ppm when exposed to 100 ppm of HCFC-22.

Calibrated for HCFC-123

Refrigerant	Response
CFC-11	<1 PPM
HFC-134a	140 PPM
HCFC-22	4 PPM
CFC-113	80 PPM

Calibrated for CFC-11

Refrigerant	Response
HCFC-123	3 PPM
HFC-134a	20 PPM
HCFC-22	30 PPM
CFC-113	25 PPM

Calibrated for HCFC-22

Refrigerant	Response
HFC-134a	25 PPM
CFC-11	16 PPM
HCFC-123	35 PPM
CFC-113	39 PPM

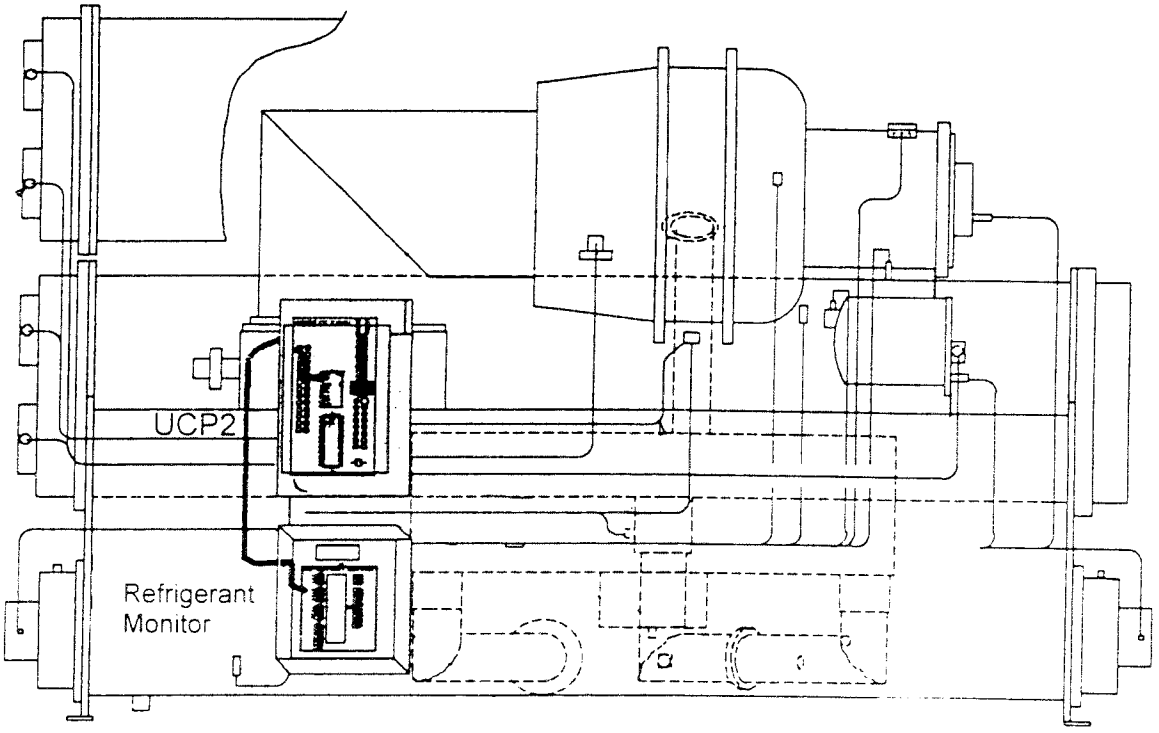
Calibrated for HFC-134a

Refrigerant	Response
HCFC-22	1 PPM
HCFC-123	8 PPM
CFC-11	2 PPM
CFC-113	17 PPM

Due to the large number of possible interferants other than refrigerants, it is impractical to list them. Direct any questions regarding specific interferants that are expected to be in the monitored area to your local Trane office.

Note: Cross-sensitivity data not verified during UL testing.

The optional Trane unit mounted refrigerant monitor is operationally identical to the remote mounted monitor, except for the clear language display. This has been replaced by a plain, painted front panel, with a green light to indicate power is present. The unit mounted monitor also has some additional stiffeners and hardware to eliminate the transmission of any vibration.



The menu screen "Refrigerant Monitor Type" at the UCP2 human interface allows the selection of two possible values:

- 01 - Analog Monitor
- 02 - IPC Monitor

When **IPC Monitor** is entered, the menu asks for a password prior to accessing the settings and then rotates through a series of screens to initiate the monitor. The password, UCP2 set-ups, inputs, calibration and diagnostic menus are found in the latest revision of CVHE-CLD-1 under the heading "Refrigerant Monitor Settings Group".

The unit mounted refrigerant monitor is designated 4U1 on Trane wiring diagrams. Although the Interprocessor Communication can go to any IPC connection, it was placed at the stepper module 1U3 since this was an open connection.

Figure 5 - Typical Unit Mounted Refrigerant Monitor

Monitor Control

RMWD refrigerant monitor control is from either the unit mounted CLD or the UCP2 (CVRB) clear language display but not both. One clear language display on the unit or UCP2 cannot be used to control more than one monitor.

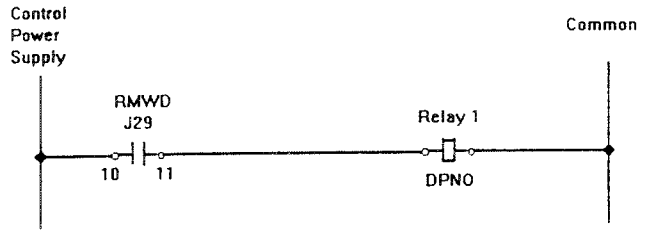
Method for controlling two or more devices from a single monitor alarm contact:

The dry contacts in the refrigerant monitor can be used to control multiple devices such as lights, buzzers, exhaust fan contactors, etc. The Technical Specifications section of this manual lists the monitor contact ratings which should not be exceeded. The preferred method for powering multiple devices is shown in Figure 6 which shows a relay powered through the monitor's alarm contacts. The relay's contacts then power the other devices. This provides isolation so that sensitive components like the Trane tower light can be wired to the same circuit as an exhaust fan contactor.

Clear Language Display (CLD)

All setup, alarm, diagnostic, measured concentration and calibration information for the monitor is accessed through an eight button, two line, 16 character backlit clear language display (CLD) mounted in the unit front panel.

Items to check:



- The chip may have a terminal that appears to be in place, but is actually bent over on top of the socket, making occasional contact. Look under the chip.
- Touch the keypad to assure that the display has not been turned off. Try more than one key in case it is a keyboard problem. Check the keyboard connector on the CLD board.
- On the RMWD from the top pin in the main board to the bottom the voltages are as follows:
  - J 14 - 1, +12 vdc
  - J 14 - 2, Common - 0 vdc
  - J 14 - 3, Ground - 0 vdc
  - J 15 - 1, -B + 1.6 to GND
  - J 15 - 2, +A + 2.3 to GND
    Measured 0.7 to 0.8 from A to B
  - J 15 - 1, -B to + A, + 0.7 vdc

If the display is not lit, check the connection on the CLD board with the red and black wires which powers the display light.

R-12 "Undefined" Message

The R-12 monitors, version 1.0, were coded so there was no way to put R-12 onto the clear language display. A compromise was to use the word "undefined". Version 2.0 or later software fully supports R-12 monitors.

Figure 6 - RMWD Wiring for Controlling Two Devices from One Alarm Contact

Contact Rating: See Technical Specifications pages

Start-Up

Start-Up Sequence

The start-up diagnostic test for a single point unit and the start up diagnostic test for a scanner unit are two different tests. A single point unit must be configured as a single point unit (Channel Scanner Not Installed) and a scanner must be configured as a scanner (Channel Scanner Installed). The display will confirm if the unit is configured as a scanner by showing a channel number with the instrument read-out. The instrument runs the diagnostic test prior to allowing the operator to reconfigure the unit. Installing or not installing a scanner is an option only when the unit has just been powered up and in warm-up mode. Changes in this Settings Menu, if necessary, must be made at this point. The operator must then wait a minimum of eight seconds, power off and restart the unit to check that the change was stored in memory.

During start up and while the unit is performing the flow diagnostic test, the sample inlet(s) and exhausts should not be blocked or the unit will fail this test. Put a sample filter on each used and unused channel, so that on initial power up or a power failure, the scanner sees all channels open.

A unit that has failed a start-up diagnostic test will continue to display a flow loss error even if the problem that caused the unit to generate this error is corrected. To correct the problem, the unit must be powered off, restarted and successfully pass the appropriate flow diagnostic test to eliminate the flow loss error display.

A unit that has generated a flow loss error during normal operation will respond to the correction of the problem that caused the error and the error display will clear. A scanner unit may however take one scanner cycle to finally clear the error message. Check the READY LED on the right side of the main board for instantaneous indication of the instrument's status.

A single point unit will only generate a Bench Flow Loss. A scanner unit generate either a Bench Flow Loss error or a Scan Flow Loss error. Bench Flow Loss will take precedence over Scan Flow Loss in a scanner unit with both faults.

The bench pressure switch actually changes state during the diagnostic test and normal operation. **Shorting the terminals of this switch will NOT resolve the bench flow loss**. It will cause the unit to fail the start up diagnostic test or fail during normal operation. The scan pressure switch is required to switch during start-up once and remain closed during normal operation. **Do not short either of the pressure switches.**

The pressure switches measure the differential pressure across the two orifice restrictors (see Figure 9). There is no flow through the switch.

Bench Flow Loss

⚠ Caution:
Use care when handling tubes and fittings. The fittings are rigid and easily broken.

Single Point Units

Disconnect all inlet and exhaust tubing outside the monitor enclosure. This will isolate the problem to within the monitor or in the external tubing and filter(s).

The bench solenoid valves open and close every 3.5 seconds. Check for bubble activity at EXHAUST Port 2 as shown in Figure 10. Low flow or no flow at this port is most likely caused by a defective pump or saturated inline particle filter.

Check for bubble activity at EXHAUST Port 1. Flow will start and stop depending on if bench solenoid valves are open or closed. If flow does not completely stop, one or both of the bench valves are defective or the inlet fitting to the optical bench may be loose.

Use a voltmeter to measure the logic input from the pressure switch (negative lead to chassis, positive lead to black wire of SMP PRSS connector on left of main board). Set the range of the voltmeter to 0.00 (range hold auto-ranging voltmeters) and monitor the logic level switch every 3.5 seconds during normal operation.

A pressure switch that is always open may be the result of a defective pressure switch, loose tubing connecting to pressure switch or a clogged restrictor in the tubing.

A pressure switch that is always closed may be the result of a loose fitting to the inlet of the optical bench in addition to the same causes for a switch always open.

If the Bench Flow Loss error is the result of the unit failing the start-up diagnostic test, restart the unit while monitoring the logic input of the bench pressure switch. The result should match the bench pressure switch logic input as shown in Table 1.

A pressure switch that is not switching fast enough to follow the test sequence is most likely the result of deterioration in pressure switch performance but may be one of the reasons stated previously.

The fittings on the inline filter are glued and any attempt to remove or change the direction of the fittings will break the seal and/or crack the filter housing. A cracked filter fitting will not generate a Bench Flow Loss error in a single point unit. However, it will cause sample dilution. Replace the entire filter assembly if a problem is suspected.

A leak in the brass union fittings for the sample inlet or exhausts will not generate a Bench Flow Loss error, however, these fittings should be changed if a leak is suspected.

Reconnect all tubing when done. Use an end of line filter on each input line. Limit the length of tubing on any one port to 150 ft. (45.7m) (total length of sample and exhaust lines). Do not combine exhaust lines.

Table 1 - Single Point Unit Start-Up Diagnostic Routine

	Duration (Sec)	Bench Inlet Valve	Bench Outlet Valve	Bench Pressure Switch
Start Up Test	12	Closed	Closed	Open
	1	Open	Open	Closed
	1	Open	Closed	Open
	1	Open	Open	Closed
	1	Closed	Open	Open
Cycle repeats like this during Normal Operation	3.5	Open	Open	Closed
	3.5	Closed	Closed	Open
	3.5	Open	Open	Closed
	3.5	Closed	Closed	Open

Bench Flow Loss

⚠ Caution:
Use care when handling tubes and fittings. The fittings are rigid and easily broken.

Scanner Units

Disconnect all inlet and exhaust tubing outside the monitor enclosure.

Check flow at EXHAUST port 1 (see Figure 10). The bench valves cycle on and off every 3.5 seconds.

No or low flow at this port is most likely caused by a defective sample pump or saturated particle filter. It may also be caused by a defective scanner valve. Allow the channel scanner to scan all four lines to determine if low flow is associated with one or all of the scanner lines.

If the flow does not vary slightly between two different levels every 3.5 seconds, this could indicate a defective bench valve or a loose inlet fitting to the optical bench.

Use a voltmeter to measure the logic input from the pressure switch (negative lead to chassis, positive lead to black wire of SMP PRSS connector on left of main board). Set the range of the voltmeter to 0.00 (range hold auto-ranging voltmeters) and monitor the logic level switching every 3.5 seconds during normal operation.

A pressure switch that is always open may be the result of a defective pressure switch, loose tubing connecting to pressure switch or a clogged restrictor in the tubing.

A pressure switch that is always closed may be the result of a loose fitting to the inlet of the optical bench in addition to the same causes for a switch always open.

If the Bench Flow Loss error is the result of the unit failing the start up diagnostic test, restart the unit while monitoring the logic input of the bench pressure switch. The result should match the bench pressure switch logic input as shown in Table 2.

Table 2 - Scanner Unit Start-Up Diagnostic Routine

	Duration (Sec)	Scan Valve 1	Scan Valve 2	Scan Valve 3	Scan Valve 4	Bench Inlet Valve	Bench Outlet Valve	Bench Pressure Switch	Scanner Pressure Switch
Start Up Test	12	Scan	Scan	Scan	Scan	Closed	Closed	Open	Closed

	1	Scan	Scan	Scan	Scan	Open	Open	Open	Closed
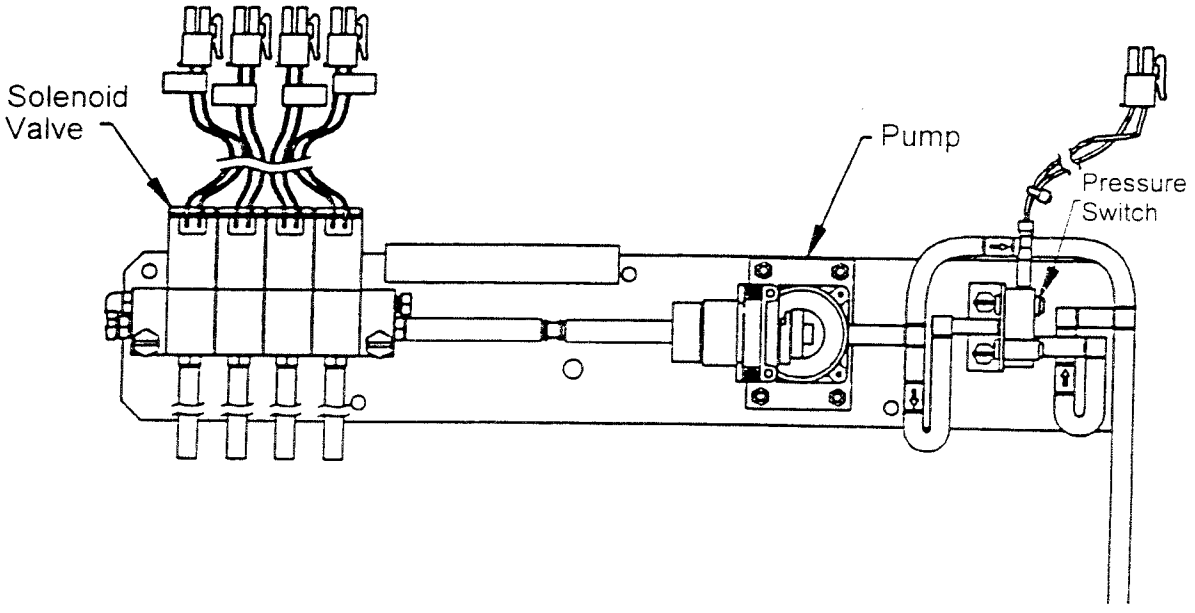
	1	Sample	Sample	Sample	Sample	Open	Open	Closed	Open
Cycle repeats like this during Normal Operation	3.5	Sample	Scan	Scan	Scan	Open	Open	Closed	Closed
	3.5	Sample	Scan	Scan	Scan	Closed	Closed	Open	Closed
	3.5	Sample	Scan	Scan	Scan	Open	Open	Closed	Closed
	3.5	Sample	Scan	Scan	Scan	Closed	Closed	Open	Closed

Bench Flow Loss

⚠ Caution:
Use care when handling tubes and fittings. The fittings are rigid and easily broken.

The scanner manifold valves allow flow to the scanner pump when not energized (normally open port) and will be noted as Scan in Table 2 to indicate that flow from this line is directed to the scanner pump. The scanner manifold valves will redirect flow to the sample pump when energized (normally closed port) and will be noted as Sample in Table 2 to indicate that flow from this line is directed to the sample pump.

A pressure switch that is not switching fast enough to follow the previous test sequence is most likely the result of deterioration in pressure switch performance but may be due to one of the reasons stated earlier.



The fittings on the inline filter are glued and any attempt to remove or change the direction of the fittings will break the seal and/or crack the filter housing. A cracked filter fitting will cause a scanner unit to fail a diagnostic start up test and generate a Bench Flow Loss error. Replace the entire filter assembly if a problem is suspected.

A leak in the scanner manifold valves or the fittings on that block will cause the unit to fail a start up diagnostic test and the generation of a flow fail error. A leak to the sample side will cause a bench flow loss error and a leak to the scanner side will cause a scanner flow loss error. Any leak in solenoids or fittings and tubing leading to the sample pump will cause a bench flow loss. If a problem is suspected with the scanner manifold/valves, the entire assembly should be replaced.

A leak in the brass union fittings for the sample inlet or exhausts will not generate a Bench Flow Loss error, however, these fittings should be changed if suspected of leaking.

Reconnect all tubing when done. Use an end of line filter on each input line. Limit the length of tubing on any one port to 150 ft. (45.7m) (total length of sample, and exhaust lines). **Do not** combine exhaust lines.

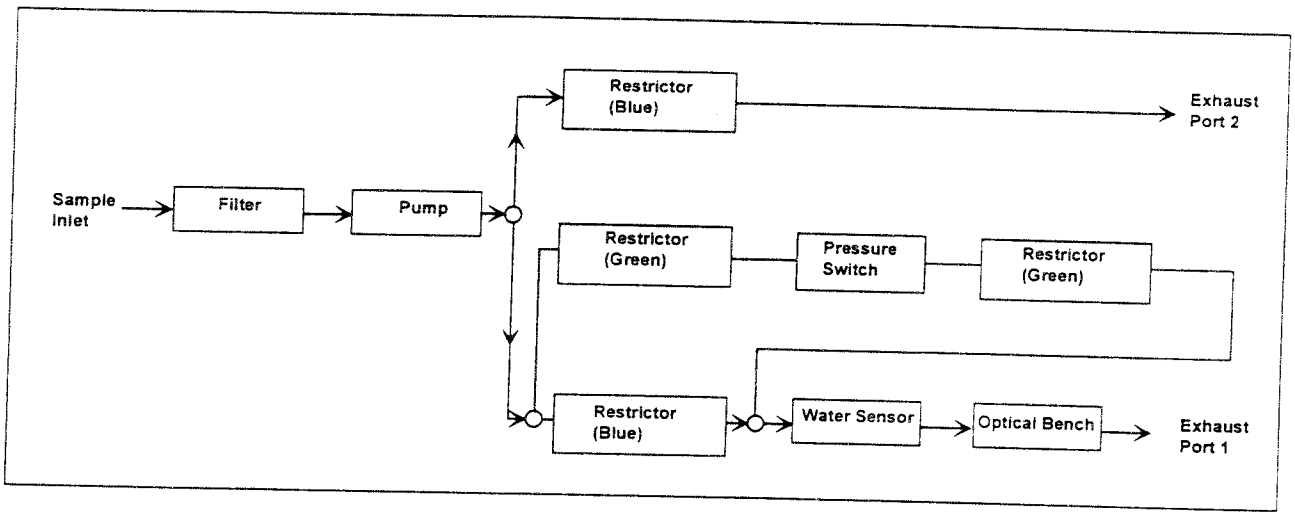
Figure 8 - Scanner Assembly

Scan Flow Loss

⚠ Caution:
Use care when handling tubes and fittings. The fittings are rigid and easily broken.

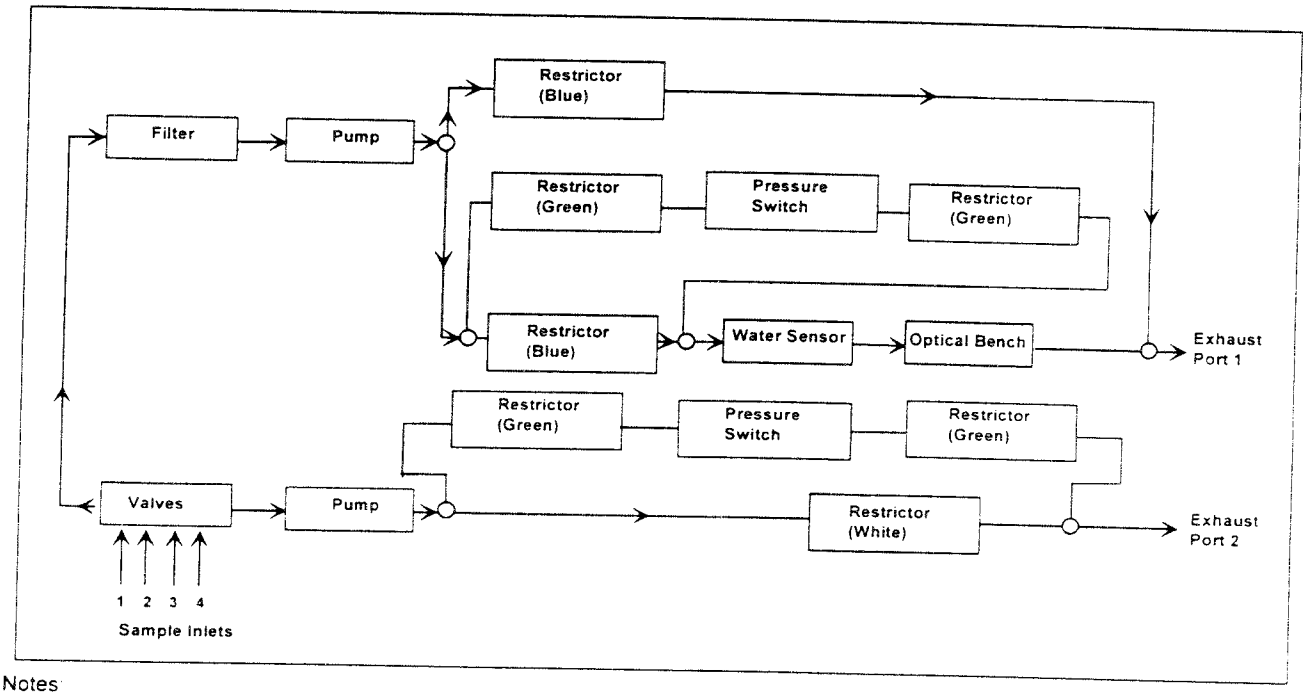
Scanner Unit

Disconnect all inlet and exhaust tubing outside the monitor enclosure.



During normal operation, the scan pressure switch is closed. Check flow at EXHAUST port 2 (see Figure 10). Low or no flow indicates a defective scanner pump. If the flow is sufficient, use a voltmeter to test the logic input of the scan pressure switch (negative lead to chassis, positive lead to black wire of SCN PRSS connector on left of main board). Set the range of the voltmeter to 0.00 (range hold auto-ranging voltmeters). This should remain **closed** during normal operation. If there is flow but the switch is open, the probable cause is a defective switch, loose tubing to the switch or clogged restrictor in the tubing leading to the pressure switch ports.

The scan flow switch is tested only once during the diagnostic test. It remains closed during normal operation. If the unit generates a Scan Flow Loss error as a result of failing the diagnostic test, monitor the output at EXHAUST port 2 (see Figure 10). Restart the unit and about 25 seconds into the diagnostic test, the flow should dip to zero for one second and the scanner pressure switch should open (check logic input of scanner pressure switch in Table 2). If the flow does not cease entirely for that one second, there is a leak in the scanner valve assembly and/or the fittings and tubing between that assembly and the scanner pump. If the flow does actually drop to zero but the pressure switch does not respond, then look for a defective pressure switch, loose tubing and/or clogged restrictor to the switch.



Reconnect all tubing when done. Use an end of line filter on each input line. Limit the length of tubing on any one port to 150 ft. (45.7m) (total length of sample and exhaust lines). Do not combine exhaust lines.

Instrument Flow Diagram

Figure 9 Single Channel Monitor

Monitor with 4 Channel Scanner

Notes:

1. Restrictor Orifice Diameter by Color Code
   Green = 0.007"
   Blue = 0.020"
   White = 0.030"
2. Arrow on restrictor indicates flow direction

Module Diagnostic Messages

Display:	Communication Lost With Module
Description:	The clear language display (CLD), or UCP2 if no CLD is used, is not communicating with the monitor.
How does it affect unit operation:	Monitor will continue to operate in the READY mode. Alarm condition outputs will continue to be energized if ppm readings exceed setpoints. LED's on monitor will display correctly. This diagnostic does NOT cause the monitor to enter a Trouble Status condition. You can scroll through the CLD or UCP2 menu items and see the ppm readings for the data last collected before communication failure. The CLD may even read *READY* if that was the operating condition before the communication failure.
What causes the diagnostic:	The diagnostic is the result of a loss of communication with either the CLD or UCP2. In both cases the communication transfer is via wires connected to J15, terminals 1 and 2.
How to troubleshoot:	Check to be sure the wires are in place at the monitor and CLD, or UCP2. The connection points are J15, terminals 1 and 2. **Can not connect to both CUP2 and CLD.** If using twisted pair to the UCP2, be sure the cable shield is grounded at the UCP2. Check to be sure the connector and its screws are secure, at the monitor and CLD or UCP2. **Note:** Control is from UCP2 or Human Interface on the monitor but not both.
What components to test:	Clear Language Display Wiring - as described

Display:	**Trouble** (plus diagnostic message or channel data)
Description:	Malfunction of the monitor diagnosed by internal operational checks.
How does it affect unit operation:	Any diagnostic listed below causes the monitor to enter a *Trouble* Status condition. There are two levels of *Trouble*. Major, are those conditions that may result in inaccurate data collection. Minor, are those that are informational in nature but do NOT affect the accuracy of sample data measurements. A Major *Trouble* condition will result in turning On the red trouble LED, the Trouble relay switching, and the Clear Language Display (CLD) will flash when at the operating mode menu. Optional unit mounted alarm will sound if it was installed and if it is programmed. It can be quieted by pressing the + key (plus key). This optional alarm will NOT sound with Version 1.0 monitor software. A Minor *Trouble* condition will NOT turn on the red LED, sample measurements will continue, alarm conditions will be output. The CLD will flash trouble status but indicate *READY* mode, the green LED will indicate the same. Reset - If a Major diagnostic occurs during start-up, the unit must be turned OFF to reset after fixing the problem. Minor diagnostics will clear even if they occur during startup. If the diagnostic occurs during the Normal mode of operation then repair of the failure cause will reset the red LED and trouble relay, followed by the clearing of the CLD within 2 minutes. Refrigerant level alarms are disabled during Major *Trouble* diagnostic. Bench sampling and read-out continues during the *Trouble* condition
What causes the diagnostic:	Any of the following diagnostics put the monitor in this status condition. Major: RAM Loss, IR Source Fail, Chopper Fail, Temp Sensor Fail, Bench Flow Loss, Scan Flow Loss, Out Of Temp Rng, Rfgt Lvl to Low Minor: Aux Input Fail, Ext Reset Fail
How to troubleshoot:	See the individual diagnostics
What components to test:	See the individual diagnostics

Module Diagnostic Messages

Display:	RAM Loss
Description:	The monitor module has lost the data in its battery backed RAM.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. Monitor operation will be severely affected.
What causes the diagnostic:	The diagnostic occurs if the RAM information has been changed. *RAM loss* diagnostic occurs for one of two reasons: Could occur after programming the calibration coefficients into the memory through the factory setup menu. It could also occur in the event of RAM loss (possibly due to a battery failure on the main board).
How to troubleshoot:	Cycle power off, then back on to see if the message clears. After it clears a calibration should be performed to confirm accuracy. If calibration has deviated significantly, then one of the coefficients has probably changed and there would probably be other machine problems occurring. With the *RAM loss* condition, several of the menu items will be scrambled and not make sense.
What components to test:	Battery cannot be changed, monitor chassis assembly must be replaced.

Display:	IR Source Fail
Description:	The infra-red optical source has failed.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. The monitor operation will be severely affected. After power up, monitor will NOT cycle through start-up in its normal sequence. May display *Communication Lost With Module* on start-up. Sample reading may vary in the presence of refrigerant, but will NOT be accurate. Will reset without cycling power, even when problem occurs on start-up.
What causes the diagnostic:	Failure of the bench source light.
How to troubleshoot:	Cycle power off, then back on to see if the message clears. Check the resistance of the light source, wires located at the top of the bench near the motor. Label on the board is "Source". Resistance should be about 5 ohms across the light. If the resistance is significantly higher, i.e. 1K ohms, then the light has failed. Check the power at the Source terminals, one of the two terminals should read nominally 5.0 Vdc to ground.
What components to test:	Check unit circuit board wiring to source, near top of bench. Light cannot be changed, monitor chassis assembly must be replaced.

Display:	Chopper Fail
Description:	The optical Bench photo interrupter has failed.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition The monitor will display ppm but accuracy is affected. Will reset without cycling power, even when problem occurs on start-up.
What causes the diagnostic:	When the chopper blade stops or slows this diagnostic occurs
How to troubleshoot:	Chopper blade is fragile. When turned by hand, it is normally very resistant to rotation. It does NOT spin freely. Check wiring to the chopper motor. Listen for a bent chopper blade that might be rubbing
What components to test:	None Chopper motor, bench and printed circuit board must all be replaced as an assembly

Module Diagnostic Messages

Display:	Temp Sensor Fail
Description:	The bench temperature sensor has failed.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition When viewing the Status Menu, the bench temperature will be blank. The monitor will display ppm but accuracy is affected because the temperature sensor determines how much heat to add to the bench. Will reset without cycling power, even when problem occurs on start-up.
What causes the diagnostic:	Failure of the bench temperature sensor, located on the upper right of the bench.
How to troubleshoot:	Check the wiring to the sensor, located at the upper right corner of the bench assembly, terminal labeled "Temp"
What components to test:	Check the resistance of the temperature sensor, after unplugging from the board: Red to Black = 7.5 Meg Ohms Red to Green = 7.5 Meg Ohms Black to Green = 40 K Ohms From top to bottom: Red, Black, Green

Display:	Scan Flow Loss
Description:	Flow loss through the bypass circuit of the scanner.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* Status condition. Bench sampling and read-out continue during the trouble condition, but accuracy could be affected due to flow problem.
What causes the diagnostic:	The diagnostic is the direct result of the incorrect signal being received from the scanner pressure switch. The scanner pressure switch simply reacts to the flow through the scanner bypass circuit by measuring the pressure drop across a restrictor in the hose. The switch makes and breaks as the flow changes. Pressure switch set-points are non-adjustable. There is an adjustment screw, but adjustment is NOT recommended. The switch contacts are normally open, and close above a pressure of 1.0 +/- 0.2 (0.8 to 1.2) inches water column. They will open again as the pressure drops below 0.5 inches water column. Normal scanner flow involves the scanner pump supplying a constant supply of sample air, plus the switching of the four scanner sequencer valves. Normal operation results in a constant flow to the exhaust port from three of the four inlets, bypassing the bench. During the start-up scanner flow sequence is not the same. Refer to the table representing the start-up sequence. You will find a one second period just before normal operation begins where all four scanner sequencer valves are directing flow to the bench which result in no flow at the scanner pressure switch. Therefore, simply jumpering the switch results in a scanner flow loss if the machine goes through startup.
How to troubleshoot:	Check components involved. Using voltmeter confirm 5.0 vdc to ground on black wire at the switch. With voltmeter on red wire and ground note cycling of switch during the one second cycle at startup. Then it should remain closed throughout the normal operation. Programming - If the monitor programming is set for a single channel with a scanner installed or vice-versa *Bench Flow Loss* will be indicated.
What components to test:	Wiring - verify that the pressure switch is connected to SCN PRSS terminal Leaks - especially on scanner units where the diagnostic has occurred on start-up Pressure switch; Pump; Hoses and Restrictors; Filters Four Channel Sequencer valves - four channel scanner units only

Module Diagnostic Messages

Display:	Out of Temp Rng
Description:	The refrigerant monitor is out of the temperature range where it can measure refrigerant.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. If heater is disconnected or not working, the monitor will continuously stay in warm-up. The monitor will display ppm but accuracy is affected. Will reset without cycling power, even when problem occurs on start-up.
How to troubleshoot:	Troubleshoot the same as *Temp Sensor Fail*
What components to test:	None

Display:	Rfgt Lvl Too Low
Description:	The displayed refrigerant level is less that -4 ppm
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. The monitor will display ppm but accuracy should be questioned. Will reset without cycling power, even when problem occurs on start-up
What causes the diagnostic:	When monitor displays a level less than -4 ppm
How to troubleshoot:	Vibration: Fluctuating readings from -200 to 0 have been observed. Remove the monitor from its location to verify vibration caused the diagnostic. Other vibration sources should also be investigated. Electrical radiated noise: Disconnect outputs and use an extension cord power supply from an alternate source to see if the noise source can be isolated. Look for intercoms, walkie talkies, switchgear, etc.

Display:	Rfgt Mon Fail
Description:	Severe problem with monitor.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Major *Trouble* status condition. The monitor will display ppm but accuracy is affected. Will reset without cycling power, even when problem occurs on start-up.
What components to test:	None

Display:	Aux Input Fail
Description:	Auxiliary Input is not functioning.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Minor *Trouble* status condition. The monitor will display ppm. Will reset without cycling power, even when problem occurs on start-up.
How to troubleshoot:	Uninstall Auxiliary input if one doesn't exist.
What components to test:	Check Auxiliary input wires.

Module Diagnostic Messages

Display:	Bench Flow Loss
Description:	Flow loss to the optical bench.
How does it affect unit operation:	This diagnostic causes the monitor to enter a *Trouble* Status condition. Bench sampling and read-out continue during the trouble condition, but accuracy could be affected due to flow problem. If Scan Flow Loss is also detected it will not be displayed until this condition has cleared.
What causes the diagnostic:	The diagnostic is the direct result of the incorrect signal being received from the bench pressure switch. The bench pressure switch simply reacts to the sample flow through the bench by measuring the pressure drop across a restrictor in the hose. The switch makes and breaks as the flow cycles. Pressure switch set-points are non-adjustable. There is an adjustment screw, but adjustment is NOT recommended. The switch contacts are normally open, and close above a pressure of 1.0 +/- 0.2 (0.8 to 1.2) inches water column. They will open again as the pressure drops below 0.5 inches water column. Normal bench flow involves the bench pump supplying a constant supply of sample air, plus the bench inlet and outlet solenoids opening and closing. Normal operation results in a constant flow to the exhaust port, bypassing the bench, plus a 3.5 second flow, and 3.5 seconds no flow through the bench itself. During the start-up bench flow sequence is not the same. Also, this sequence varies for a scanner or single channel monitor. Refer to Table 1 for single point units and Table 2 for scanner units start-up sequence for both units.
How to troubleshoot:	Check components involved. Using voltmeter confirm 5.0 vdc to ground on black wire at the switch. With voltmeter on red wire and ground note cycling of switch in 3.5 second intervals, open - closed - open... At the same time as you are watching the switch action, using a glass of water watch for the flow - no flow - flow cycling from the hose leaving the bench by observing the bubble activity. On single circuit machines this can be checked at exhaust port one. Four channel units require disassembling the hose at exhaust port one to separate the bench hose. Programming - If the monitor programming is set for a single channel with a scanner installed or vice-versa *Bench Flow Loss* will be indicated. Refer to the Bench Flow Loss section of this guide.
What components to test:	Wiring - verify that the pressure switch is connected to SMP terminal Leaks - especially on scanner units where the diagnostic has occurred on start-up. Pay particular attention to the hose from the four sequencer valves to the bench pump. Pressure switch; Pump; Hoses and Restrictors; Filters Four Channel Sequencer valves - four channel scanner units only

Display:	Ext Reset Fail
Description:	The external reset switch has failed or the jumper is missing.
How does it affect unit operation:	This diagnostic causes the monitor to enter a Minor *Trouble* Status condition,. All latching alarms will act as non-latching. Bench sampling, readout, and alarms continue during this trouble condition. The internal red LED labeled trouble is NOT turned on because the monitor remains in the *READY* mode.
What causes the diagnostic:	The diagnostic is the direct result of the incorrect signal being received from the INPUT terminals. The correct signal is provided by a normally closed contact or jumper wire.
How to troubleshoot:	Check to be sure the jumper wire is in place if no external reset switch has been installed. The connection points are J16, terminals 1 and 2. Check to be sure the connector and its screws are secure. If an external switch is installed, using voltmeter confirm that the resistance across these terminals is zero.
What components to test:	Wiring - check as above External reset switch (normally closed switch), not provided by Trane

Quick Problem Checks

A. Bench flow loss - Check installation to be sure all lines are open at the bottom of the panel. In this order:

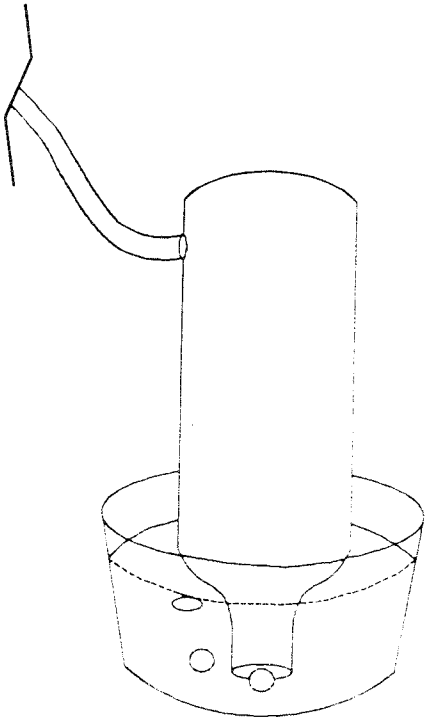
1. Inspect switches and tubing for kinks and cracks.

2a. Bench pressure switch will open and close during normal operation. 0 and 5 volts d.c. (switching) will be seen on a voltmeter by placing leads on the terminals of the pressure switch.

2b. Scanner pressure switch (scanner unit only) must be closed all the time.

3. Are the restrictors installed in the right direction? Arrow indicates flow. See Figure 9 for details.

4. After switches and tubing are checked. look at the pump. Rotate to insure the crank is not rubbing anywhere.



5. Remove cover from bench and listen for solenoid activity. Should be switching Open / Close during a 7 second cycle.

6. Using a glass of water, observe the bubble activity at the exhaust ports (see Figure 10). Port 1 should be cycling on / off, Port 2 should be nearly constant. (Single point monitor only.)

7. Is the monitor programmed properly, check if scanner is installed, or not. Then re-start.

Notes: Bench Flow Loss display does not clear the display immediately, but it does clear itself after two minutes. If in doubt as to whether or not the condition has cleared, observe the LED trouble light on the circuit board. It will turn off immediately after the problem has cleared.

Figure 10 - Measuring bubble activity, see step 6.

Quick Problem Checks

If a bench flow loss condition occurs during start-up (warm-up) it will be necessary to power-down and restart the monitor to clear the diagnostic.

Bench flow loss will occur on a four channel monitor programmed for single channel operation because the four scanner channels are all blocking airflow to the bench circuit. To avoid this problem, program properly or remove the bench circuit inlet tube from the left side of the four solenoids.

Check bench flow problems by measuring flow through the bench circuit. During the 3.5 second cycle, flow can be grossly checked with use of a bottle cap (approximately 1-1/8 inch diameter), or a soda bottle (approximately 3/4 inch diameter). The following bubble rates per 3.5 second cycle can be expected:

	Flow Loss	Normal Flow
Bottle Cap	2	6
Bottle	4	8

See Figure 10.

B. Refrigerant level too low - If the output is erratic and bounces from a low reading to a normal reading, suspect problems resulting from either vibration or radiated electrical noise. See **Module Diagnostic Messages** for further information.

C. Refrigerant Conversion - The monitor can not be converted from one refrigerant to another in the field - it must be sent back to the factory for recalibration.

D. Diagnostic Conditions - Any diagnostic condition causes a "Trouble Status" condition on the monitor. The Trouble relay closes and the front display flashes when at the Operating Mode menu. Optional unit mounted alarm will sound if it is installed and programmed. Pressing the "+" key will quiet the alarm. Refrigerant level alarms are disabled. Bench sampling and readout continue during the trouble condition.

Table 3 - Diagnostic Relay Conditions

Condition	Normally Open Contacts	Normally Closed Contacts
Off	Open	Closed
On - Ready	Closed	Open
Trouble	Open	Closed

Calibration Procedure

Introduction

This section details the recommended field calibration check procedure for the Trane Model RMWD refrigerant monitor. The monitor is factory calibrated for the specific refrigerant desired however, it is recommended that the calibration be checked annually at a minimum, and a log kept detailing any adjustments required. The appropriate Installation, Operation and Maintenance manuals for this instrument should be referenced to assist in operating the display and identifying components or connection points.

General Information

- Kit TOL 0170 includes:
  - regulator
  - span gas scrubber (FLR 1404)
  - zero scrubber (FLR 1403)
  - connecting tubing and fittings
  - carrying case and instructions (calibration gas **is not** included)
- Calibration gas -
  - R-11: TOL 0171
  - R-22: TOL 0172
  - R-123: TOL 0173
  - R-134A: TOL 0174
  - zero gas: TOL 0175

The RMWD test regulator releases just over 2.0 liters per minute. A 100 liter bottle would last about 50 minutes.

The used calibration gas canisters and the various filters are not considered hazardous waste due to the small concentration of refrigerant. If a large number of canisters or filters were being dumped, this might be an issue and require further investigation. Local codes apply.

Calibration Procedure

Material Required

1. Trane Calibration Kit containing:
   - Zero Gas Scrubber
   - Flow Regulator
   - Interconnecting Tubing and Fittings
   - Span Gas Scrubber
   - Carrying Case
2. A canister of the specific refrigerant span gas

Ths calibration check should be performed only by qualified personnel familiar with the instrument and its operation.

⚠ Warning!
During the calibration procedure, the monitor is not in service and any alarms that may occur during the calibration sequence will not be recognized. This could create a hazardous condition.

Preparing for Calibration

1. Ensure the area surrounding the monitor is free from any gas hazard. Operate permanent or portable ventilation as necessary.
2. Access the calibration menu using the display located on the unit front panel. See the Installation, Operation and Maintenance manual for details on the use of the monitor's various menus.
3. Page through the display by pressing <Next> until you get to the "Calibration" main menu. Press <Enter> to begin calibration check routine.
4. Enter the Field Calibration password, " - + - - + + ".
5. The monitor will go into the Monitor Check Mode and the refrigerant concentration based on the current unit calibration will be displayed. All new alarms will not be recognized.
6. Remove the gas sampling tube from the monitor sample inlet. Disconnect sample channel #1 if a scanner is installed.

Zero Calibration Check

1. The first routine is used to check the unit Zero calibration. Press <Next> to proceed to the Refrigerant Zero screen. Press <Enter> to begin Zero Calibration. The display will read "Starting Cal, Please Wait". If a channel scanner is installed, it will be locked onto channel #1. Refer to Figure 11 for connection information.

Note: Either a Zero Gas Scrubber or a canister of Zero gas can be used to check the zero setting on a Model RMWD monitor.

2. When the "Connect Zero Gas" screen is displayed, connect the Zero Gas Scrubber or the Zero Gas Canister to the (continued) sample port on the monitor as shown in Figure 11. Use sample port #1 if a scanner is installed. Press <Next> to continue.

⚠ Caution:
Be sure Zero Scrubber is used and not Span Gas Scrubber.

Note: If a Zero Gas canister is used, connect as shown in Figure 11 except substitute Zero canister for Span Gas canister. A Span Gas scrubber must be used whenever pressure gas is applied to the unit to avoid over pressurization.

Calibration Procedure

3. "Open Valve" will be displayed. If the Zero gas canister is used, open the regulator to allow gas to flow. If a scrubber is being used, disregard this step. Press <Next> to continue to Step 4.

4. The next screen will display the sample concentration based on the current unit calibration. After waiting at least three minutes, press <Enter> to adjust zero setting. If reading is zero, press <Cancel> twice to exit Zero calibration routine and move to Refrigerant Span routine.

5. If <Enter> was pressed to adjust, the unit will lock onto the reading. Use the (+) and (-) keys to adjust displayed reading to zero. Press <Enter> when finished. Monitor will store new Zero setting.

6. Either "Successful Calibration" or "Cal Failed" will be displayed. If calibration was successful, the display will proceed to the Span Calibration. If calibration failed, the unit will revert back to the previous zero value. Press <Enter> to repeat Zero Calibration. Shut off Zero Gas flow if canister is being used.

Refrigerant Span Calibration Check

1. At the "Refrigerant Span" screen, press <Enter> to Calibrate. The display will read "Starting Cal Please Wait". Refer to Figure 12 for connection information.

2. Connect the Span Gas canister to Sample Port #1 when the display prompts you to do so. Also, remove any caps on the span gas scrubber. Press <Next> to continue.

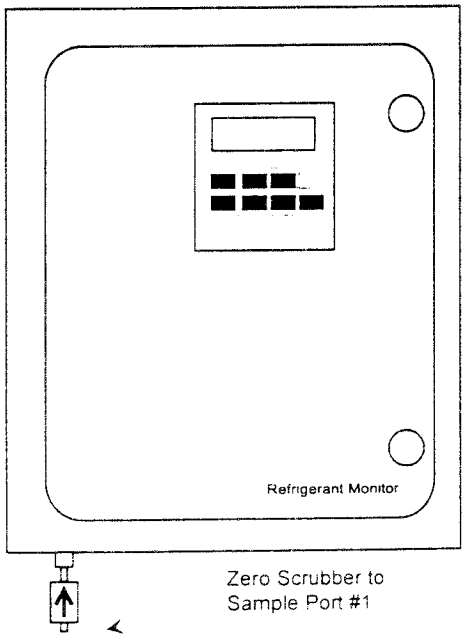
3. Open the regulator valve when instructed and press <Next> to continue.

4. After at least three minutes and the displayed value is stable, compare the displayed PPM value to what is listed on the calibration span gas canister. If the displayed value differs from the value on the canister, press (+) or (-) to change the displayed value to match to match the calibration gas value. Press <Enter> to continue. The display will read "Starting Cal".

Calibration Procedure

5. Either "Successful Calibration" or "Cal Failed" will be displayed. If the calibration was successful, the new span values have been stored and will be used for all future readings. Press <Next> three times then <Enter> to return the instrument to operation. If the Calibration failed, the monitor will revert back to the values previously stored. Press <Enter> to retry span calibration.
6. Disconnect the span gas canister and connect all sample lines that may have been removed. Unit is ready to be put back into service.
7. Log the date and note any adjustments made on a monitor calibration log.
8. Return all parts to the Calibration Kit carrying case.

Figure 11 - Zero Calibaration Check Connections



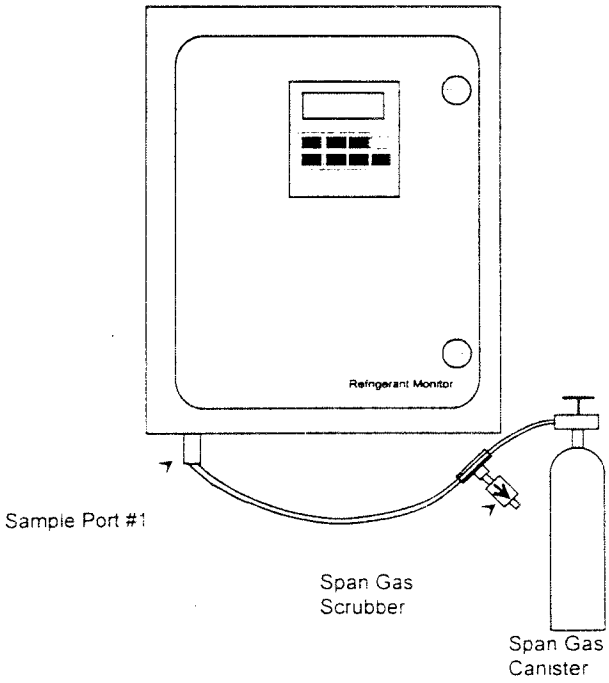


Figure 12 - Span Calibration Check Connections

Note: If Zero Gas is used, connect canister to Sample Port #1 using connect arrangement similar to what is shown in Figure (Span), substituting the Zero Canister for the Span Canister and the Zero Scrubber for Span Gas Scrubber.

Pressure Switch Checkout

Testing Procedure

Equipment

- Pressure Gauge 0 - 3 inches H_20 range
- Pressure Source
- Ohm Meter
- Tubing Harness shown below

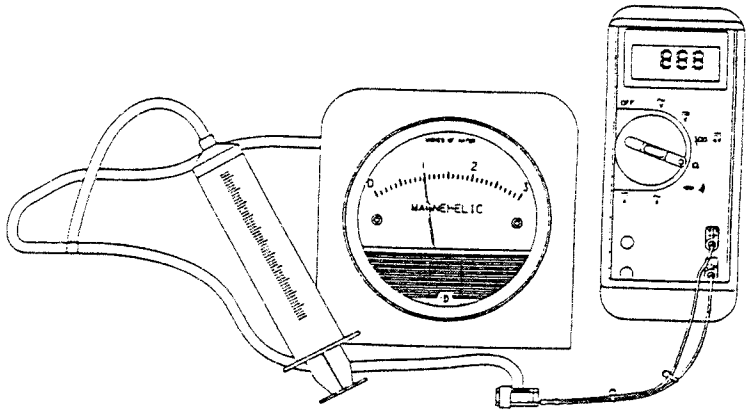
Setup

See Figure 13

Procedure

1. Connect tubing to high pressure port of switch.
2. Use syringe to vary pressure in range of 0 - 3.0 inches H_20 four times.
3. Return pressure to zero.
4. Gradually apply pressure until ohm meter indicates closure of switch.
5. Note pressure that is required to generate closure. Pressure must be > 0.8 inches H_20 open and < 1.2 inches H_20 closed.
6. Increase pressure to 2.0 inches H_20.
   Note: Contact resistance at 2 inches H_20 is <= 50 ohms.
7. Reject a switch which does not meet specifications in steps 5 and 6.

Figure 13 - Pressure Switch Testing Equipment



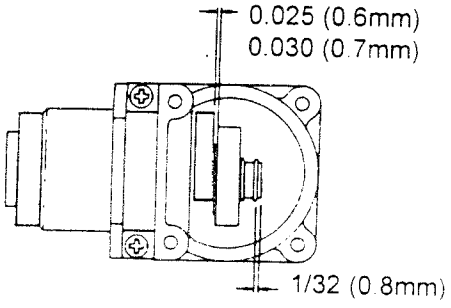


Figure 14 - Pump clearances

Technical Specifications

Mechanical

Enclosure

NEMA-4 rated. Hinged door with 2 quarter-turn latches. Beige with black face plate.

Mounting

4 mounting tabs provided on back of enclosure.

Weight

Single channel unit = 42 lbs. operating, 45 lbs. shipping. 4-channel scanner unit= 45 lbs. operating, 49 lbs. shipping.

Sample Pumping Rate

0.75 LPM minimum with 150 feet of 1/8" ID sample tubing.

Electrical

Inputs

Power Input - The refrigerant monitor will operate from a source of AC power of 100 VAC to 240 VAC, 50 to 60 Hz. Power input not to exceed 80 watts in single channel operation.

Auxiliary Input - 4 to 20 mA Input referenced to ground. Input impedance is 200 (± 4) Ω resistive.

Remote Reset - An input will be provided to remotely reset latched alarm relay(s). On activation, all latched alarms will be reset. Maximum distance from monitor to contacts is 300 feet using shielded 18 AWG twisted pair wire.

Outputs

Analog - Two analog outputs are provided to indicate refrigerant gas concentration. These outputs may be used independently and simultaneously.

Ranging for both outputs is common.

Ranges selectable by software:
0 to 100 PPM
0 to 1000 PPM

The resolution on each range is 1 PPM.

4 to 20 mA: Sourcing current to module ground. Load = 200 ohms maximum.

0 to 10 VDC: Sourcing referenced to module ground. Output current to 7 mA maximum.

Relays - Relay contact ratings are as follows:

Resistive load:
-7.2 Amps @120 VAC
-5.0 Amps @240 VAC

Inductive load:
-2.88 Amps Pilot Duty
-1/3 HP, 7.2 FLA, 43.2 LRA

Audible alarm output:
12 VDC, 100Ω load maximum

Gas Sensing Characteristics

Gas Sensitivity

Standard factory calibration for HCFC-123, CFC-11, HCFC-22 and HFC-134a. Special factory calibrations for other refrigerants are available.

Alarm levels

Alarm levels are software adjustable in steps of 1 PPM over the following ranges:

Alarm Levels:

HCFC-123	Low Limit	High Limit
Alarm Level #1	3 PPM	Lowest of 30 PPM or Alarm Level #2 -1
Alarm Level #2	Alarm Level #1 + 1	Alarm Level #3 - 1
Alarm Level #3	Alarm Level #2 +1	1000 PPM

All other refrigerants	Low Limit	High Limit
Alarm Level #1	3 PPM	Alarm Level #2 -1
Alarm Level #2	Alarm Level #1 + 1	Alarm Level #3 - 1
Alarm Level #3	Alarm Level #2 +1	1000 PPM

Technical Specifications

Factory Default Values Are:

Accuracy Rating

Refrigerant	Level 1	Level 2	Level 3
HCFC-123	30	90	300
CFC-11, HCFC-22, HFC-134a, CFC-12, CFC-113, CFC-114, CFC-500, CFC-502	30	90	1000
Ammonia	10	25	50

Note: These are the current recommended alarm level values at the time of printing. They can be easily adjusted as required.

Precision - Accuracy depends upon both precision and calibration standard accuracy. For negligible effect, calibration standard inaccuracy must be less than 1/10 precision inaccuracy.

0- 50 PPM = ± 1 PPM

51-1000 PPM= ± 10% of reading

Reference Operating Conditions:
Ambient Temperature = 23 ± 10°C
Atmospheric Pressure = 28.5 ± 2 in. Hg
Relative Humidity = 50 ± 20%
Line Voltage = 120 VAC

Calibration Standards:
Reproducibility - The reproducibility over a 12 month period will be within ± 1 PPM In the range 0 - 50 PPM under reference operating conditions.

Response Time

90% of a step change in 75 second maximum (at analyzer input). There is an additional transport time of 30 seconds with 150 foot of 1/8" tubing at a flow of 0.75 LPM. Additional scanner dwell time = 30 seconds per point. If a reading is observed greater than the threshold value, the scanner will dwell at that point for an additional 60 seconds.

Repeatability

Zero stability due to ambient, ±1 PPM with a maximum temperature change of 2.78°C per hour.

Linearity

0 to 100 PPM: linear

100 to 1000 PPM: ± 2% of full scale reading

Noise immunity

± 1 PPM with a zero gas filter attached.

Warmup Time

2 hours maximum (20 minutes typical)

Environmental

Temperature range

Operating: 0°C - 50°C
Temperature effect within this range is ± 0.3% of reading per °C.

Non operating: -10 to 60°C

Humidity

Operating and non operating; 5 to 95% R.H. Non condensing, over the operating temperature range.

Pressure

Operating: 10.2 PSIA to 15.66 PSIA

Non operating:
2.17 PSIA to 15.66 PSIA

Agency Listing

This refrigerant monitor is listed under the UL 2075 performance standard. UL has also tested and verified the monitor to CSA standard C22.2 #205. The ammonia unit has not been investigated by UL and is not covered under this listing.

LITERATURE FILE NO. CTV-SG-2

COMPRESSOR DISASSEMBLY A, B, C AND D DESIGN SEQUENCE

SECTION 8.2

JULY 1984

This section describes disassembly of the Model CVHE CenTraVac compressor. The procedures given may be used for compressor in the 013 through 125 size range with certain variations. For a list of tools required, see Section 9.1 of this Service Guide.

Disassembly

WARNING: BEFORE WORKING ON THIS OR ANY ELECTRICAL EQUIPMENT, ALWAYS DISCONNECT THE ELECTRIC POWER SUPPLY. FAILURE TO DO SO MAY RESULT IN SERIOUS PERSONAL INJURY OR DEATH FROM ELECTRIC SHOCK.

1. Disconnect all electric power. Before starting disassembly it is first necessary to remove all the refrigerant from the chiller. After the refrigerant has been removed, evacuate the chiller to 4mm Hg to remove all refrigerant vapor. After the chiller has been evacuated, pressurize the chiller with dry nitrogen until the evaporator pressure gauge reads 0 psi. See Figures 1, 2 and 3.

WARNING: USE ONLY DRY NITROGEN WHEN PRESSURIZING THE CHILLER. THE USE OF OXYGEN OR ACETYLENE MAY CAUSE A VIOLENT EXPLOSION RESULTING IN SERIOUS PERSONAL INJURY OR DEATH.

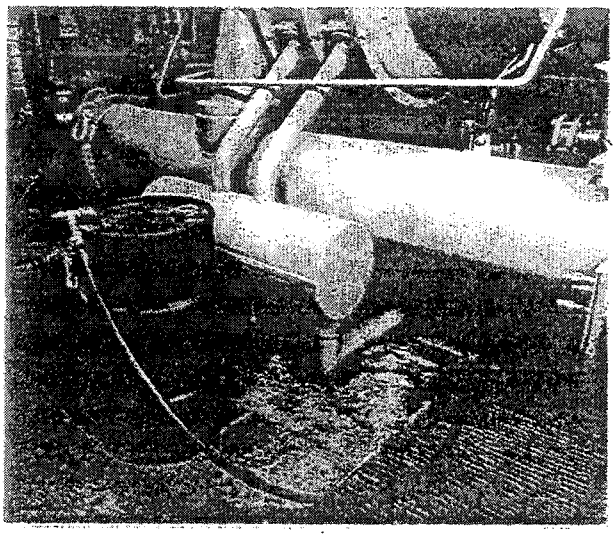

FIGURE 1 - Removing Refrigerant

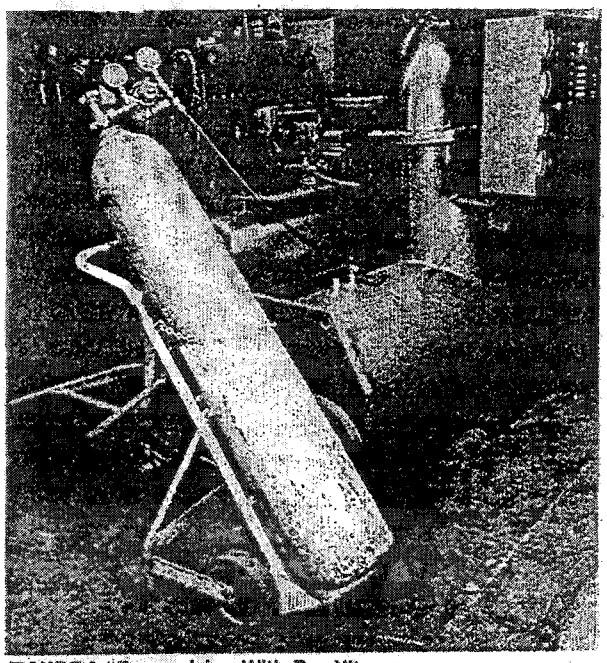

FIGURE 2 - Pressurizing With Dry Nitrogen

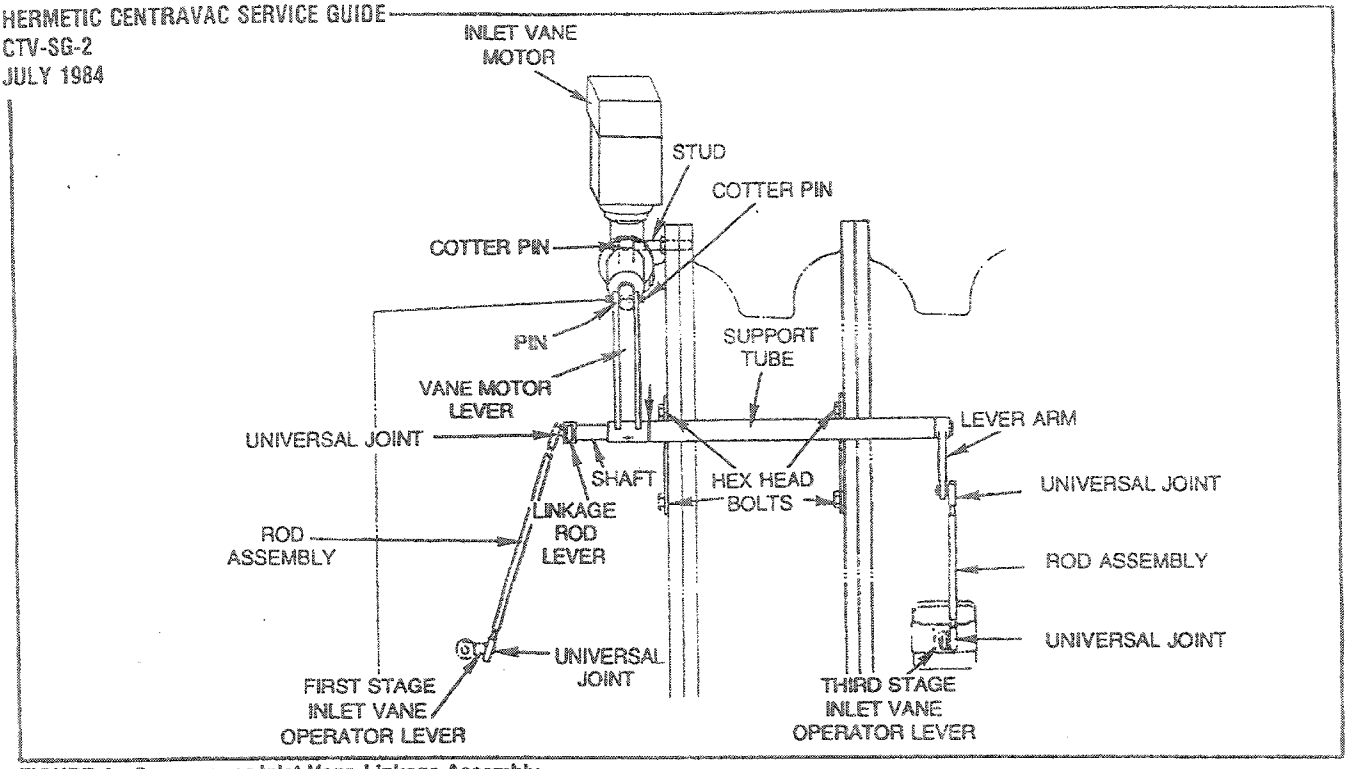

FIGURE 4 - Compressor Inlet Vane Linkage Assembly

FIGURE 5 - Disconnecting Linkage

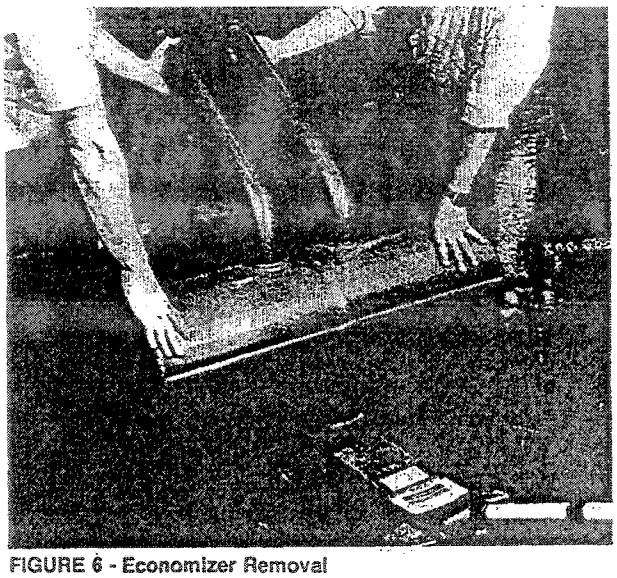

FIGURE 6 - Economizer Removal

2. Mark and disconnect all power leads to the inlet vane actuator motor. Remove the conduit assembly from the actuator motor. See Figure 4.

3. Remove the inlet vane actuator linkages.

   a. Disconnect the universal joints at the first and third stage inlet vane operator levers. See Figures 4 and 5.
   b. Remove four 5/8"-11x2" hex head bolts securing the vane drive support assemblies to the compressor castings. See Figure 4.
   c. Remove the cotter pin securing the vane operator stud.
   d. Slide the vane motor off the stud and remove the entire vane linkage assembly and vane motor from the chiller.
   e. Remove the linkage assembly from the vane motor by removing the cotter pin. The vane motor is now free and can be removed.

4. Before disassembling the compressor, scribe lines on the exterior of all compressor castings in two locations, 90 degrees apart. This must be done so that all components are precisely realigned during reassembly. Failure to complete this step may result in misalignment of the suction elbow and possible distortion of the compressor. This can result in seal-to-impeller interference and/or impeller failure.

It will be noticed at this point that some compressors will have been equipped with dowel pins. The dowel pins will have to be removed. These are removed by first removing the nut on the exposed end of the dowel pin. Then slip some washers or a bushing over the threads. Reinstall the nut and as the nut is tightened down, the pin will be pulled out of place. These dowel pins are installed on chillers which must be disassembled in order to move them into the equipment room during installation. The dowel pins allow for precise reassembly of the compressor components in their original position.

5. Remove the economizer to allow for compressor volute clearance.

6. Remove the compressor suction elbow.

a. Cut the 7/8-inch vent line between the oil sump and suction cover area. Sand all paint off the pipe at the point where the cut is to be made. Make the cut using a tubing cutter in a straight section of pipe. This will facilitate reassembly using a sweat connection.
b. Disconnect and remove the control panel support bracket. See Figure 9.
c. Attach a sling with overhead chain hoist to the suction elbow to support its weight.
d. Remove the bolts on the suction cover and evaporator connections. Remove the suction elbow. See Figure 10.
e. Cover the evaporator suction pipe with plywood to prevent entry of dirt and debris into the evaporator. See Figure 11. Coat all bare metal surfaces with a light coat of compressor oil to prevent rust formation.

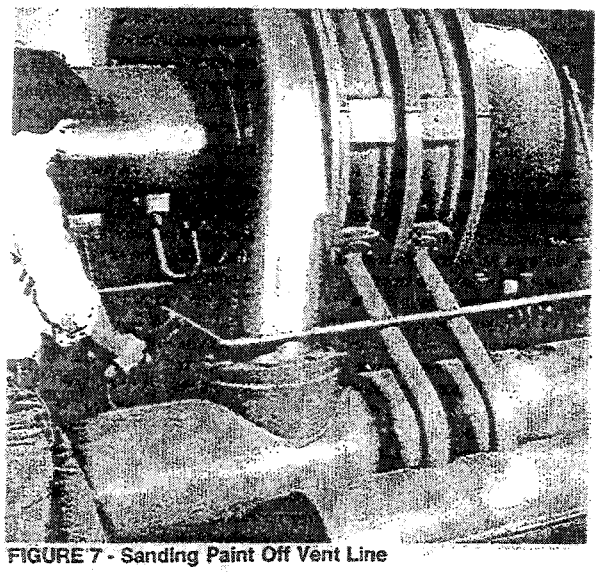

FIGURE 7 - Sanding Paint Off Vent Line

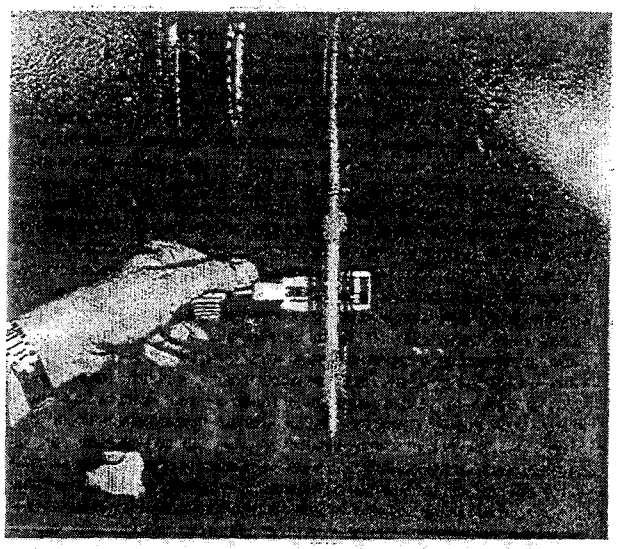

FIGURE 8 - Making the Cut

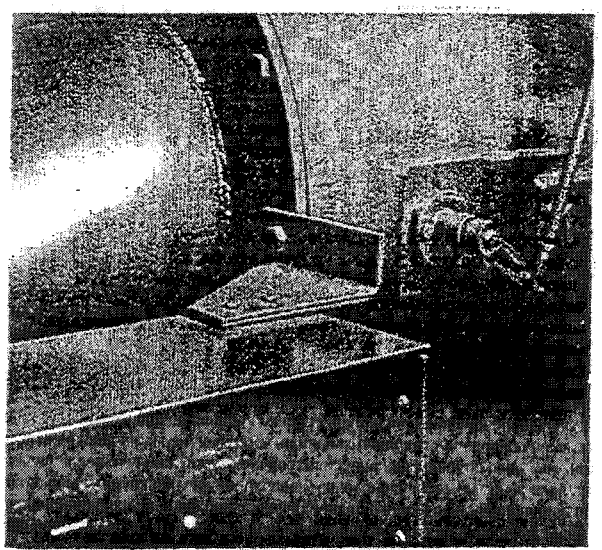

FIGURE 9 - Control Panel Support Bracket

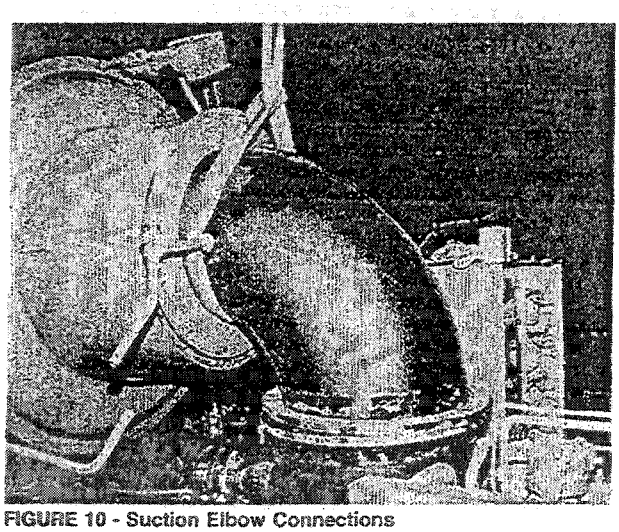

FIGURE 10 - Suction Elbow Connections

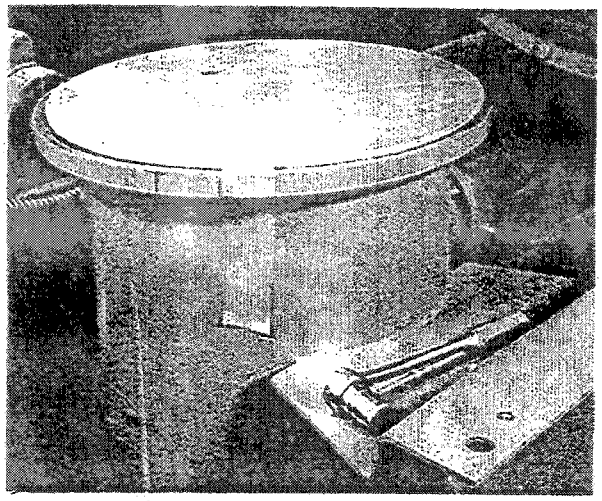

FIGURE 11 - Suction Elbow Evaporator Connection With Protective Cover

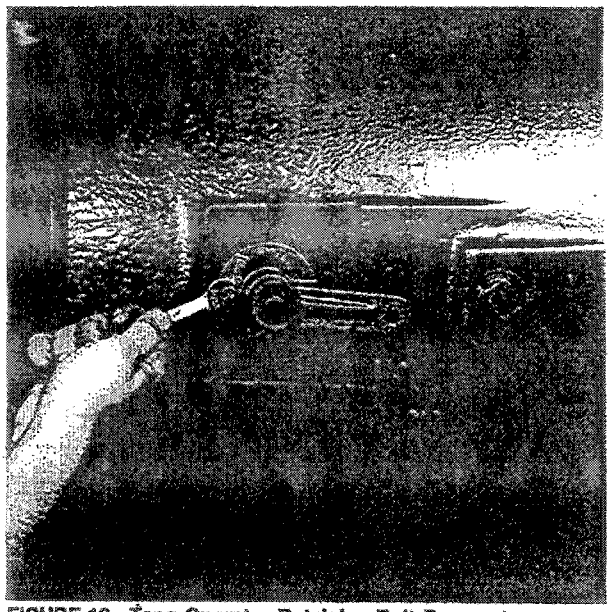

FIGURE 12 - Tang Operator Retaining Bolt Removal

FIGURE 13 - Tang Operator

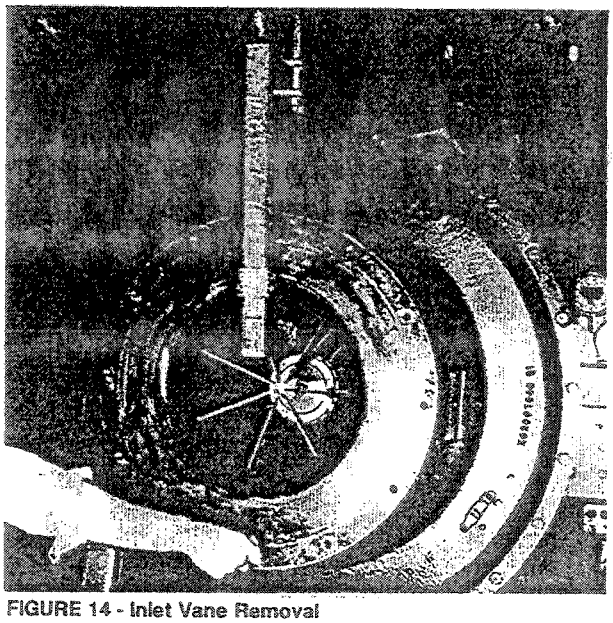

FIGURE 14 - Inlet Vane Removal

7. Remove the first stage inlet vane assembly.

   a. Loosen and remove the 5/16"-18x1" hex head bolts and lockwashers securing the tang operator to the suction cover. See Figure 12. Remove the tang operator assembly. See Figure 13.
   b. Remove the 5/16"-18x3/8" screws countersunk in the suction cover. Hold the cover in place since it will slide out when the setscrews are removed.
   c. Remove the inlet vane assembly. The tool shown in Figure 14 can be fabricated locally using the drawing in Figure 15.

   If this tool cannot be fabricated, a five-foot section of heavy duty pipe can be used for removal of the inlet vane assembly. Slide the pipe between the vane blades at the top of the vane housing. A chain or sling should be positioned around the pipe as close as possible to the vane housing. The pipe is used as a fulcrum to lift the weight of the inlet vane assembly and then slide the assembly out of the suction cover a short distance. A chain or sling can then be wrapped around the housing just inside the flanged outer portion while the assembly is allowed to rest on the inside of the suction cover. The housing should then be lifted slightly and removed from the suction cover. The weight of the assembly is given in Table 3.

8. Remove the first stage impeller nose seal. Refer to Figure 16.

   a. Measure and record the seal clearance for indication of excessive wear. Figure 17 illustrates how to make the measurement using a feeler gauge. Mark the seal for TOP and FIRST STAGE. Table 1 provides proper clearance specifications.
   b. If so equipped, bend the tabwasher tab back allowing the hex head bolts which secure the seal to be removed. The tabwashers can be replaced by ramp washers during reassembly, or new tabwashers should be used.
   c. Remove the seal.

TABLE 1 - Clearances

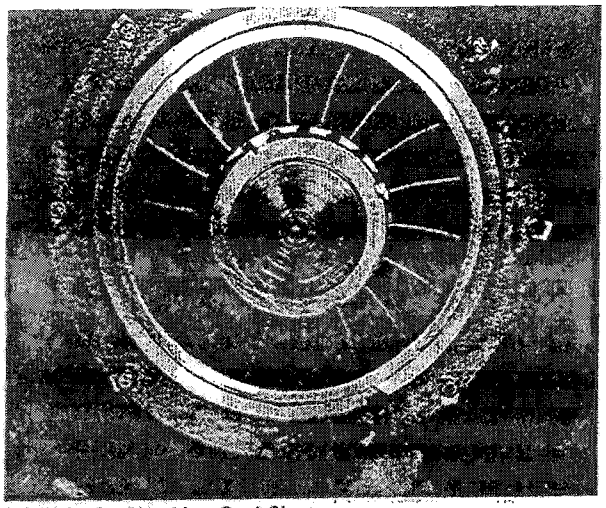

FIGURE 17 - Checking Seal Clearance

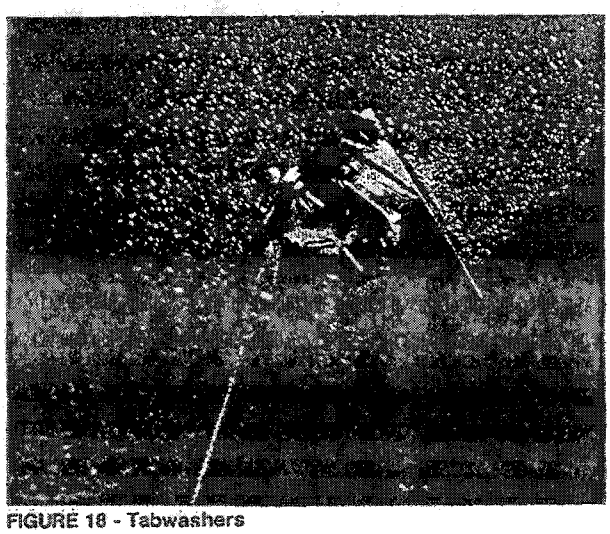

FIGURE 18 - Tabwashers

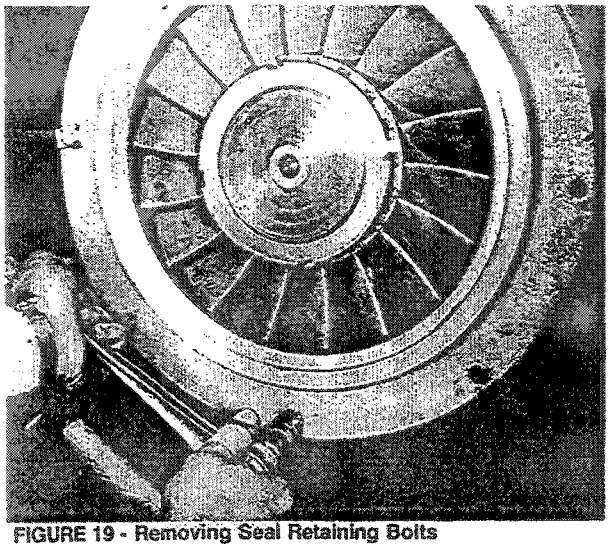

FIGURE 19 - Removing Seal Retaining Bolts

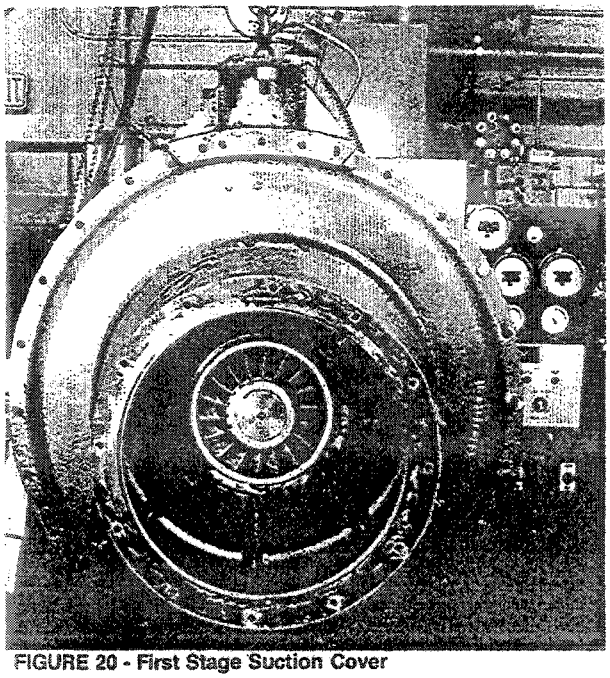

FIGURE 20 - First Stage Suction Cover

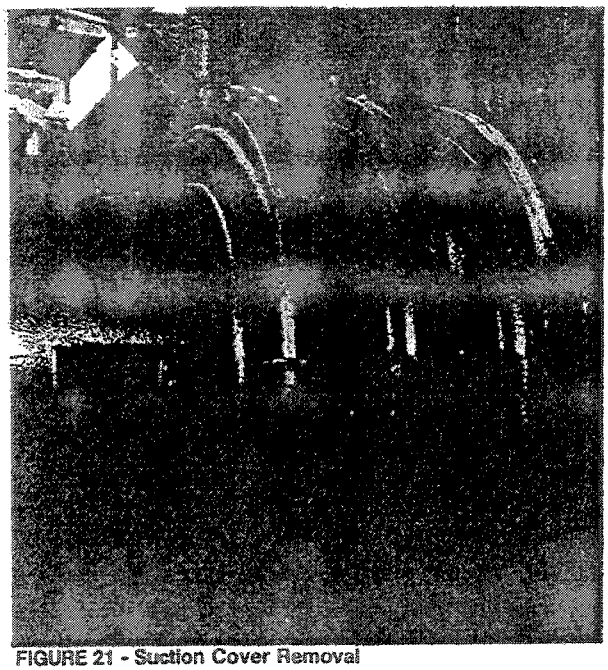

FIGURE 21 - Suction Cover Removal

FIGURE 22 - Suction Cover Lifting Tool

9. Remove the suction cover and O-ring.
   a. Disconnect the 1/4-inch oil drain line between the bottom of the suction cover nd oil sump.
   b. Attach rigging to the suction cover for lifting. Remove two bolts from the suction cover, 180 degrees apart on the horizontal centerline and insert guide pins. A lifting tool (part number TOL-89) is available from The Trane Company. The tool shown in Figure 20 and 21 is not available, however Figure 22 illustrates the proper tool.
   c. Remove a bolt near the top of the suction cover and insert a long bolt as shown in Figure 21.
   d. Remove all bolts except the one at the top and two bolts near the bottom. See Figure 20.
   e. Loosen the upper bolt and the lower bolts. Pry the cover away at the top and loosen the top bolt enough to attach the lifting tool. See Figure 23.
   f. Attach the overhead hoist, take the weight off the remaining bolts and then carefully remove the suction cover. See Figure 23. Also remove the suction cover O-ring. Lightly coat all bare metal surfaces with compressor oil.

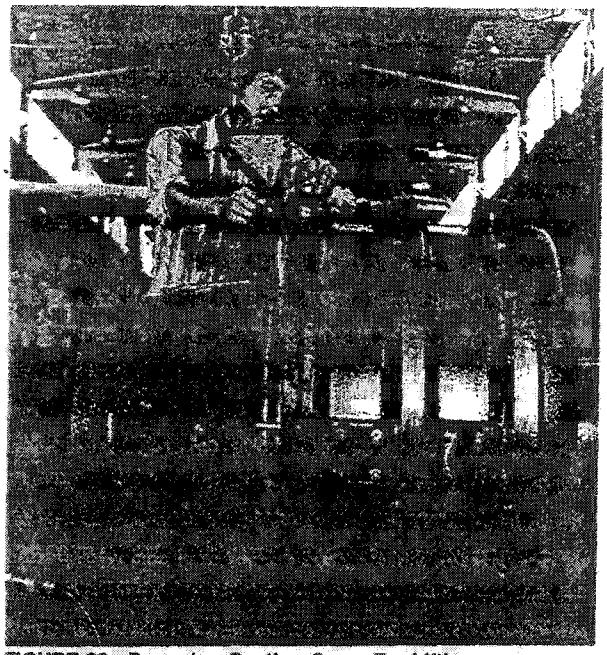

FIGURE 23 - Preparing Suction Cover For Lifting

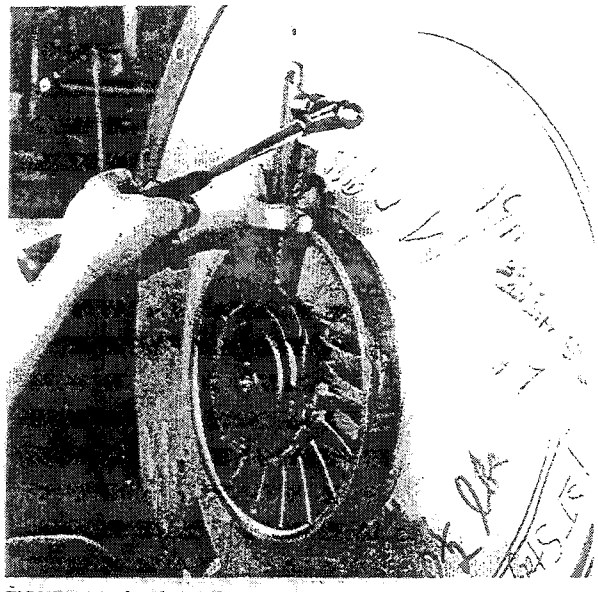

FIGURE 24 - Locknut Removal

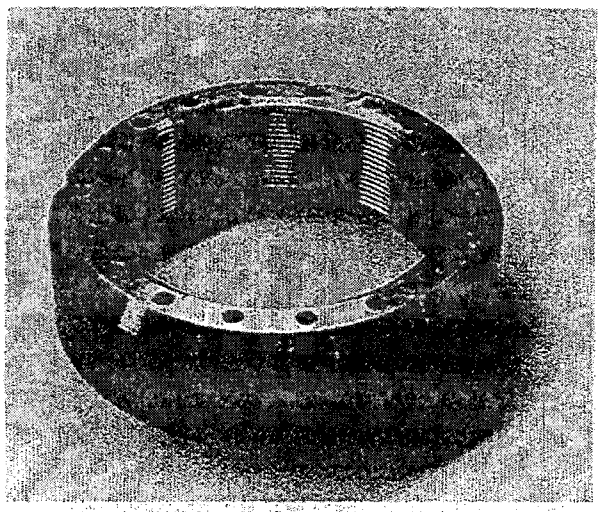

FIGURE 25 - Balancing Locknut

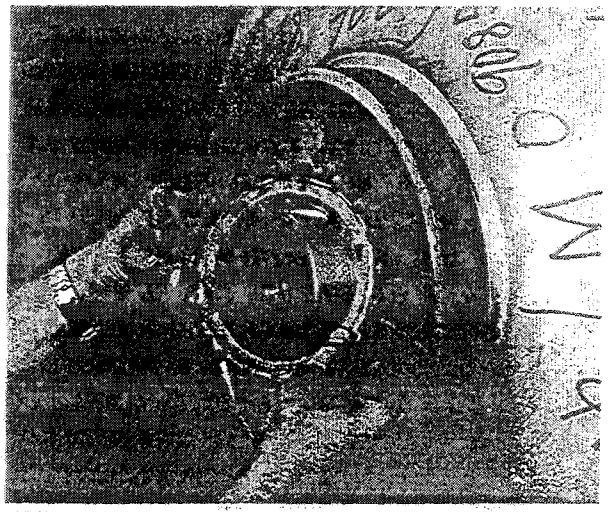

FIGURE 26 - Lockwasher

10. Remove the first stage impeller.

NOTE: UNITS ARE EQUIPPED AS STANDARD WITH A LOCKNUT AS SHOWN IN FIGURE 24. REMOVAL OF THIS LOCKNUT IS DESCRIBED IN THE FOLLOWING STEPS. SOME COMPRESSORS MAY BE EQUIPPED WITH A BALANCING LOCKNUT WHICH IS SHOWN IN FIGURE 25. THIS LOCKNUT HAS SMALL HOLES IN THE FACING SURFACE FOR THE PURPOSE OF INSTALLING BALANCING SCREWS. IF THERE ARE BALANCING SCREWS IT IS VERY IMPORTANT THAT BEFORE REMOVING THE BALANCING LOCKNUT THAT IT BE MARKED SO THAT ITS POSITION RELATIVE TO THE SHAFT KEYWAY IS MAINTAINED DURING REASSEMBLY.

DURING DISASSEMBLY IT IS IMPORTANT THAT ALL COMPONENTS BE MARKED AND IDENTIFIED RELATIVE TO ITS POSITION IN THE COMPRESSOR ASSEMBLY. FOR EXAMPLE, "NUT TO IMPELLER" OR "IMPELLER TO SPACER". BE SURE TO MARK EACH COMPONENT BEFORE DISASSEMBLY WITH IDENTIFICATION AND RELATIVE POSITION. COAT COMPONENTS LIGHTLY WITH COMPRESSOR OIL TO PREVENT CORROSION.

a. Bend the lock tab securing the impeller locknut.
b. Remove the impeller locknut and lockwasher. Use a spanner wrench. See Figures 24 and 26. This has right-hand threads.
c. Remove the springwasher.
d. Remove the spacer (CVHE 013 through 080 units only).
e. Remove the impeller. It may be necessary to use a puller. Mark the impeller FIRST STAGE. See Figure 27.
f. Remove the impeller key and shims from behind the impeller. See Figure 28.
g. Remove the spacer.

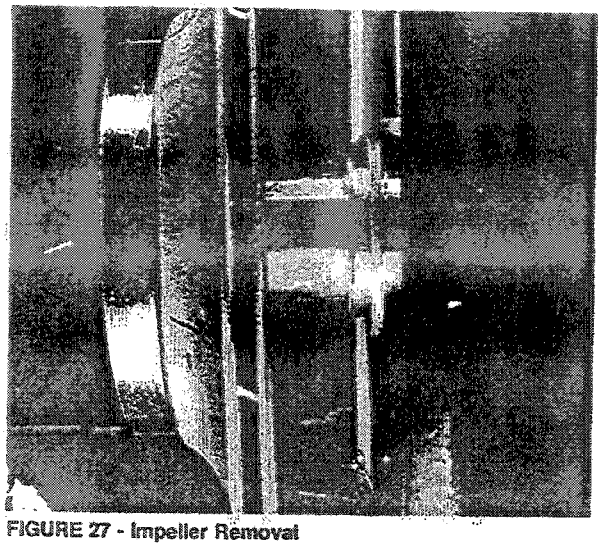

FIGURE 27 - Impeller Removal

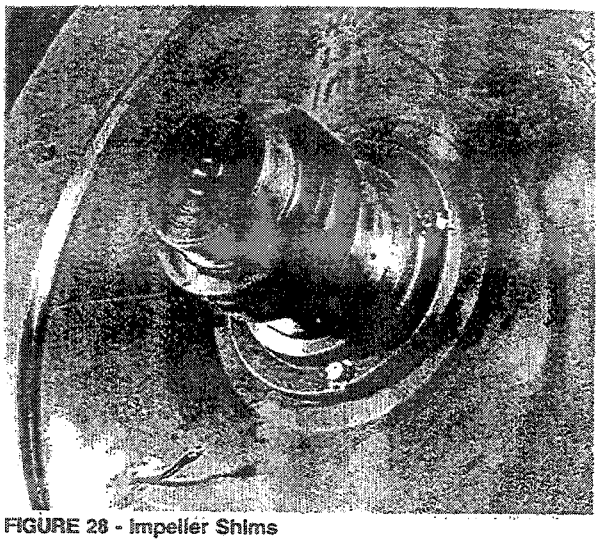

FIGURE 28 - Impeller Shims

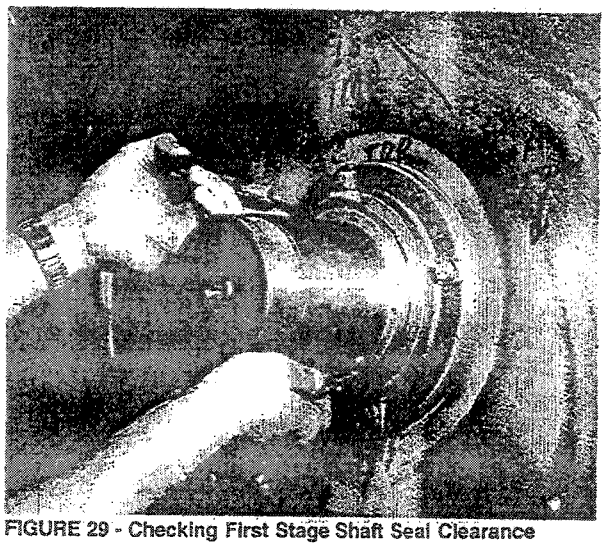

FIGURE 29 - Checking First Stage Shaft Seal Clearance

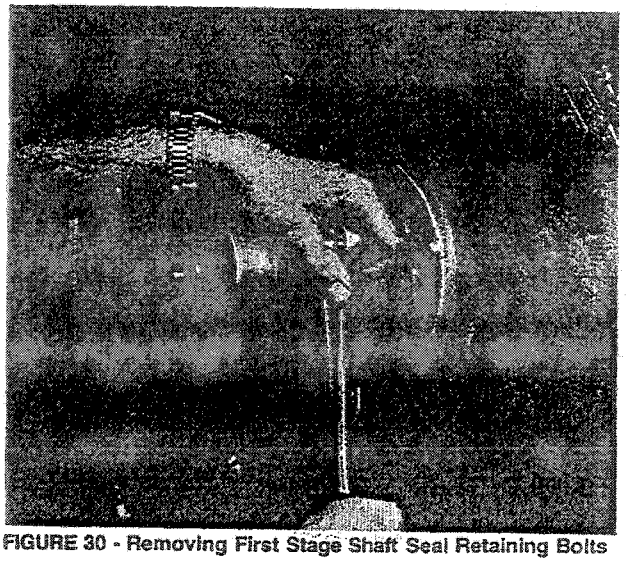

FIGURE 30 - Removing First Stage Shaft Seal Retaining Bolts

11. Remove the first stage shaft seal.
    a. Check the seal clearance for wear and record measurement. Proper clearances are given in Table 1. See Figure 29. Mark the seal for TOP and FIRST STAGE.
    b. Loosen and remove 3/8"-16x1" bolts and tab or rampwashers which secure the seal to the vane plate. See Figure 30.
    c. Remove the seal.
12. Remove the shaft spacer. See Figure 31.
    a. Removal may require the use of a puller. See Figure 32. Lightly coat the spacer with compressor oil.
13. Remove the first stage diffuser plate. See Figures 33 and 34.
    a. Remove 3/8"-16 socket head screws, 180 degrees apart.
    b. Mark the diffuser plate for TOP and FIRST STAGE.

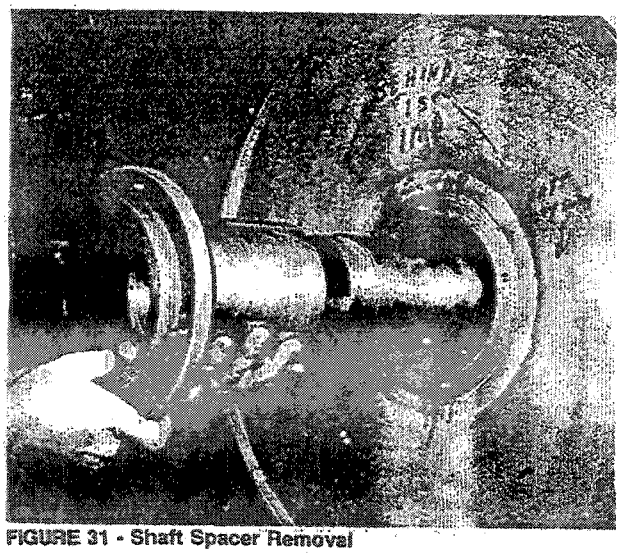

FIGURE 31 - Shaft Spacer Removal

c. Install two 3/8"-16x6" or longer guide pins in the two bolt holes. See Figure 33.
d. Remove the remaining socket head screws.
e. Back the plate away far enough to attach the lifting rig. Support the plate on the guide pins. Lifting the plate can be accomplished by using a nylon sling, rope or steel cable instead of the lifting tool shown in Figure 34. Insert the sling or cable through the center of the plate and through the clearance between the shaft and hole in the plate. Lift the plate directly by the sling or cable.

14. Remove the second stage shroud assembly. See Figure 35.

a. Leave the guide pins installed in Step 13 in place.
b. Mark the TOP of the shroud assembly.
c. Remove the 1/4"-20x3/4" flathead screws securing the shroud assembly. See Figure 35.
d. Attach a lifting sling or cable as in Step 13E. Remove the shroud, guiding it clear with the guide pins. See Figure 36. Lightly coat the shroud with compressor oil.

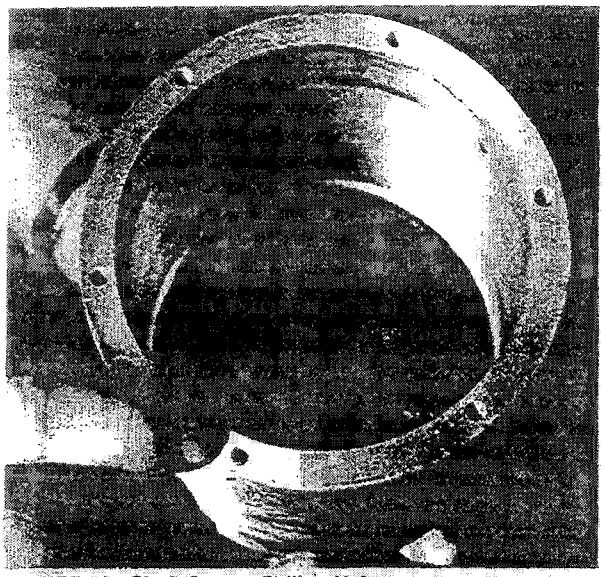

FIGURE 32 - Shaft Spacer Pulling Holes

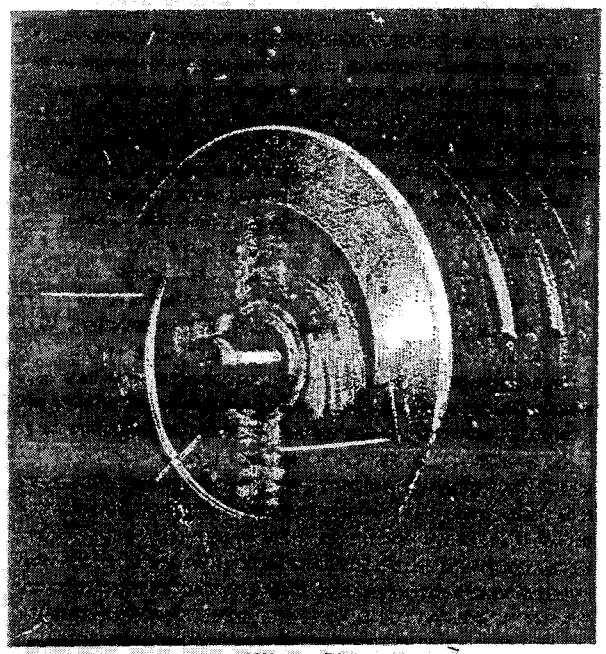

FIGURE 33 - First Stage Diffuser Plate

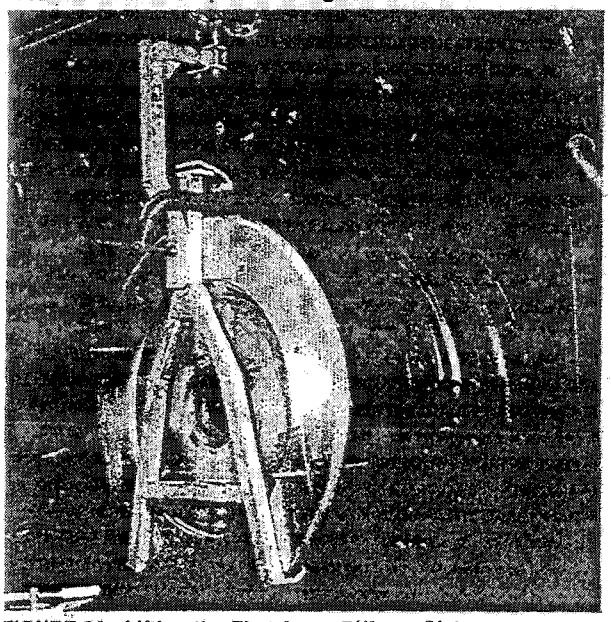

FIGURE 34 - Lifting the First Stage Diffuser Plate

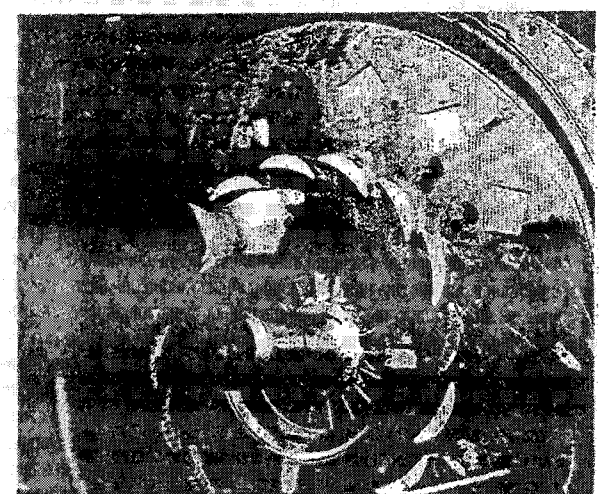

FIGURE 35 - Removing the Second Stage Shroud Retaining Bolts

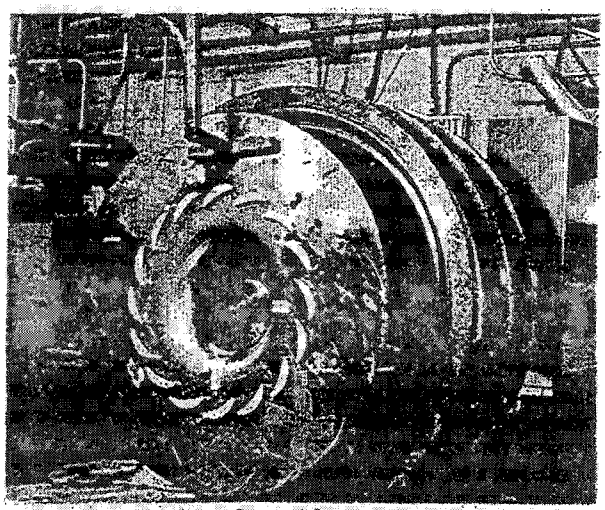

FIGURE 36 - Lifting the Second Stage Shroud

15. Remove the second stage impeller nose seal. Refer to Figure 37.
    a. Measure and record the seal clearance for indication of wear. See Figure 38. Table 1 provides proper clearances.
    b. Mark the seal for TOP and SECOND STAGE.
    c. Remove the 3/8"-16x1" hex head screws and tab or rampwashers.
    d. Remove the seal. See Figure 39.
16. Remove the second stage suction cover and O-ring.
    a. Scribe two marks, 90 degrees apart on the outer surface of the casting and mating casting. This will allow precise alignment of the components when reassembling the compressor.
    b. Remove two of the 5/8"-11x2" bolts and insert two guide pins in place, 180 degrees apart. See Figure 40.
    c. Attach the lifting rig to the suction cover. Remove the remaining bolts securing the suction cover and then remove the suction cover. Coat all bare metal surfaces with compressor oil to prevent corrosion. See Figure 41.
17. Remove the second stage impeller and shim in front of impeller. See Figure 42.
    a. A puller may be necessary to remove the impeller.
    b. Mark the impeller SECOND STAGE.
    c. Remove the key and shims from behind the impeller. These must also be marked SECOND STAGE. Lightly coat the components with compressor oil.

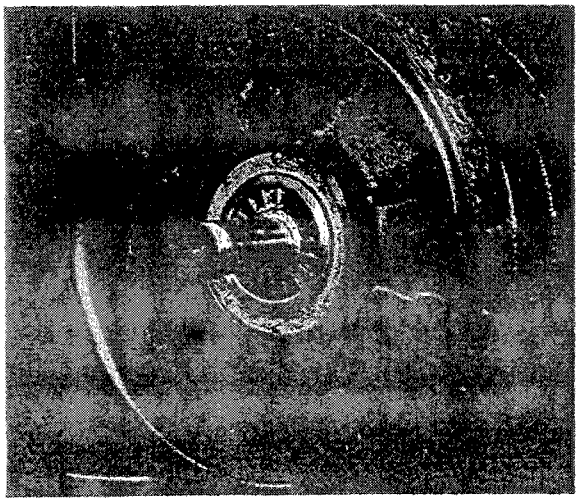

FIGURE 37 - Second Stage Impeller Nose Seal

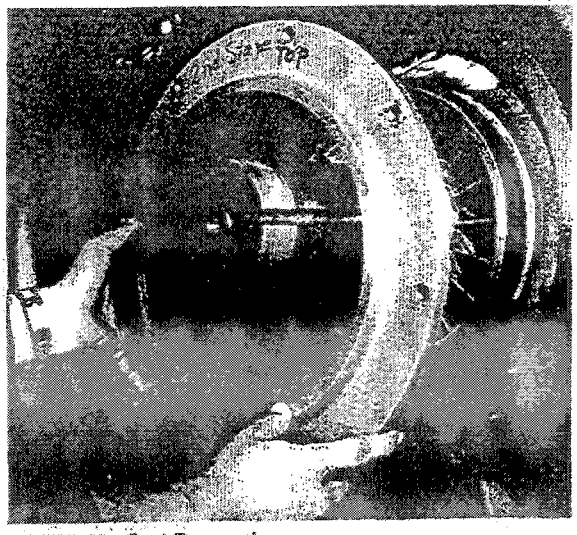

FIGURE 39 - Seal Removal

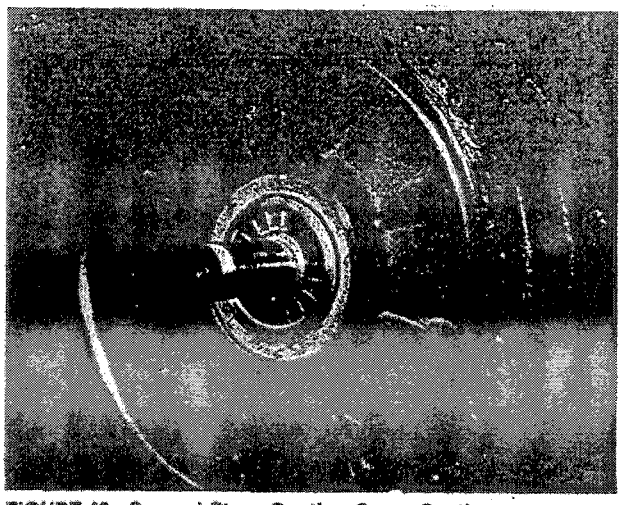

FIGURE 40 - Second Stage Suction Cover Casting

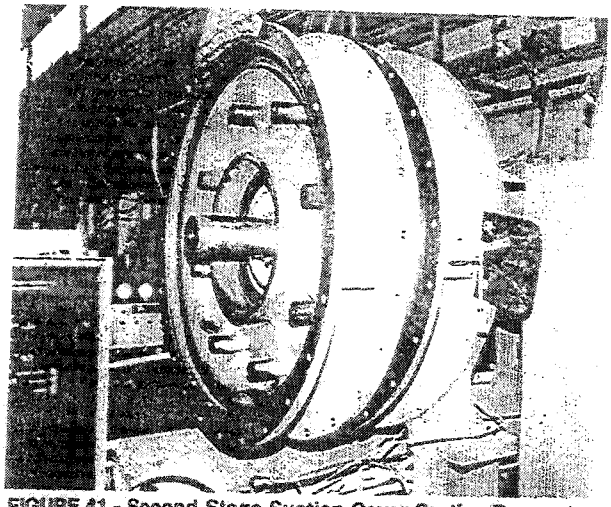

FIGURE 41 - Second Stage Suction Cover Casting Removal

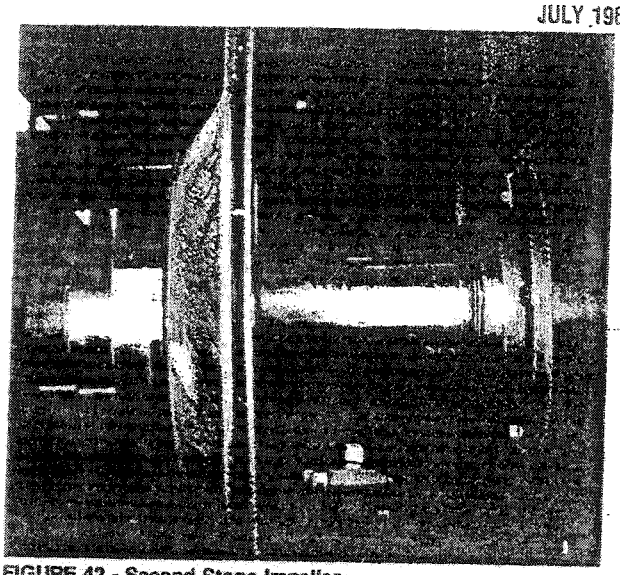

FIGURE 42 - Second Stage Impeller

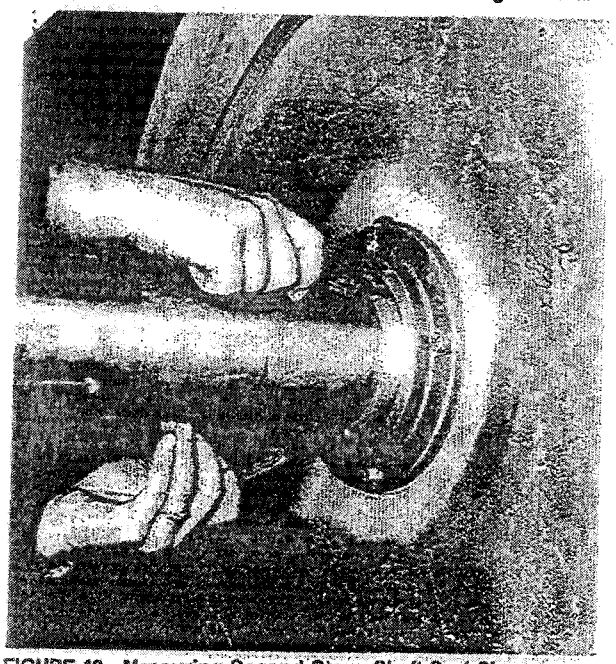

FIGURE 43 - Measuring Second Stage Shaft Seal Clearance

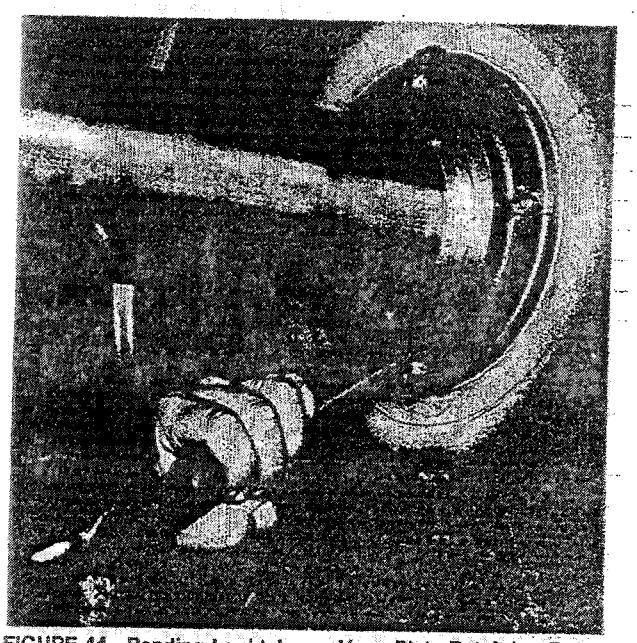

FIGURE 44 - Bending Locktabs on Vane Plate Retaining Bolts

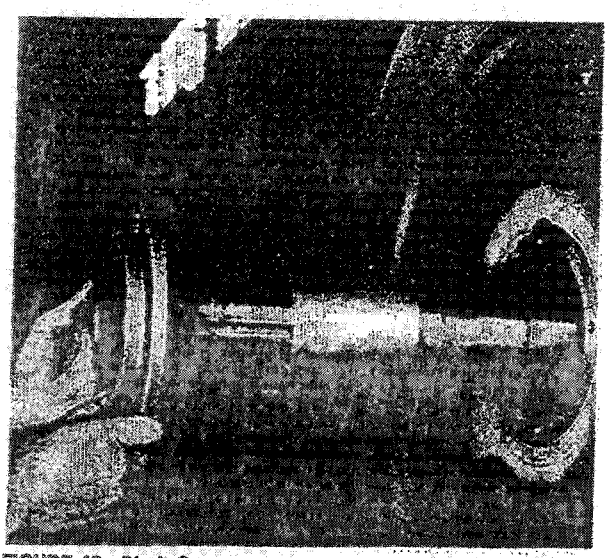

FIGURE 45 - Shaft Spacer

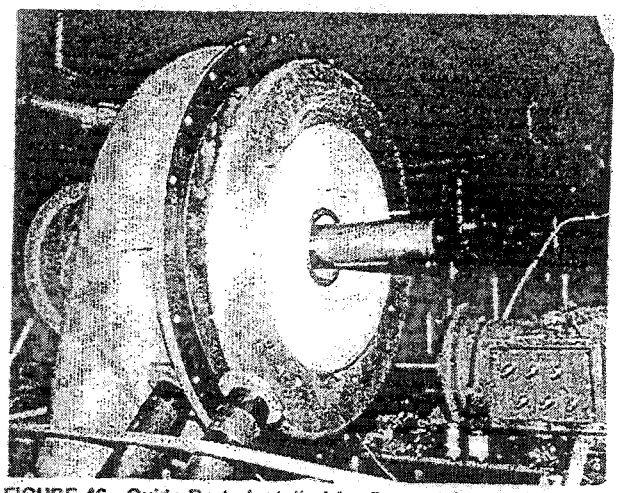

FIGURE 46 - Guide Rods Installed for Second Stage Diffuser Plate Removal

18. Mark and remove the second stage shaft seal.
    a. Measure the seal clearance and record for wear indication. Proper clearances are given in Table 1. See Figure 43.
    b. Mark the seal for TOP.
    c. Remove the 3/8"-16x1" bolts and tab or rampwashers which secure the seal to the vane plate. See Figure 44.
    d. Remove the seal. See Figure 45.

19. Remove the shaft spacer. It may be necessary to use a puller. See Figure 45.

20. Remove the second stage diffuser plate.
    a. Mark the plate for TOP.
    b. Remove two 38"-16 socket head screws, 180 degrees apart and insert 3/8"-16 guide pins. See Figure 46.
    c. Remove the remaining socket head screws.
    d. Attach a lifting rig or sling as described in Step 13E and remove the vane plate. Lightly coat the plate with compressor oil.

21. Remove the third stage vane operator assembly. See Figures 48, 49, 50 and 51.
    a. Remove the 1/2"-13x1/2" hex head screws securing the vane operator assembly. See Figure 50.
    b. Remove the vane operator and gasket. See Figure 51. Lightly coat all bare metal surfaces with compressor oil.

22. Remove the third stage shroud and vane assembly.
    a. Mark the assembly for TOP.
    b. Leave the guide pins installed in Step 20 in place. See Figure 52.
    c. Remove the 1/4"-20x3/4" flathead screws securing the shroud. See Figure 53.
    d. Attach a sling or cable as in Step 13E to the shroud and remove the shroud and vane assembly. See Figure 54. Lightly coat the components with compressor oil.

23. Remove the third stage impeller nose seal.
    a. Mark the seal for TOP and THIRD STAGE.
    b. Measure and record seal clearance for wear indication. Table 1 provides proper clearances. Figure 55 illustrates the clearances being measured. Measure the clearance all the way around the seal. Remove the 3/8"-16x1" hex head screws and tab or rampwashers. See Figure 56.
    c. Remove the seal. Lightly coat the seal with compressor oil.

24. Scribe two marks, 90 degrees apart in the third stage suction cover casting and mating casting. This will allow precise alignment of the components during reassembly of the compressor. Remove the third stage suction cover casting and O-ring.
    a. Remove two 5/8"-11x2" bolts, 180 degrees apart and insert 5/8"-11x6" guide pins as shown in Figure 57.
    b. Attach lifting rig to the suction cover.
    c. Remove the remaining bolts securing the suction cover and remove. See Figure 58. Lightly coat all bare metal surfaces with compressor oil for protection from corrosion.

25. Remove the third stage impeller and shim in front of impeller. See Figure 59.
    a. Mark the impeller for THIRD STAGE.
    b. The use of a puller may be required for removal.
    c. Remove the key and shims after removing the impeller.
    d. Lightly coat all components with compressor oil to prevent corrosion.

26. Remove the bearing oil seal and gasket.
    a. Measure and record the seal clearance for wear indication. Refer to Figures 60 and 61. Measure the seal clearance all the way around as shown. Proper clearancesare 0.0005 inches minimum and 0.003 maximum.
    b. Mark the seal for TOP. This is important since the seal has a small oil drain hole in the back which must be correctly aligned during reassembly. This is shown in Figure 62.
    c. Remove the hex head screws and tab or rampwashers securing the seal and gasket. See Figure 63.

27. Remove the bearing oil seal mounting plate and gasket.
    a. Mark the plate for TOP.
    b. Remove two 3/8"-16x1" socket head screws and insert two guide rods.
    c. Remove the remaining screws and remove the plate and gasket. Use a nylon rope to lift the plate as described in Step 13E. Place a container under the plate since some oil will drain out. Lightly coat the plate with compressor oil.

This ends the compressor disassembly procedure. Inspect all components for damage or excessive wear. Do not reassemble the compressor using faulty components. Clean each component and apply a light coat of compressor oil to protect the components from moisture and corrosion (especially O-ring and gasket surfaces). Refer to Section 8.3 for reassembly procedures.

LITERATURE FILE NO. CTV-SG-2

COMPRESSOR REASSEMBLY A, B, C AND D DESIGN SEQUENCE

SECTION 8.3

JULY 1984

This section describes reassembly of the Model CVHE CenTraVac compressor. It is assumed that the compressor motor is installed. Notice that at Step 15, two different procedures are given, depending on the size of the compressor.

Tool Requirements

The following tools should be gathered before proceeding:

05,CVHE lifting tool, Trane part number TOL-89
Inlet vane lifting tool
Guide pins, some 8 to 10 inches in length, some 4 to 6 inches in length. Several of each should have 5/8"-11 threads and several should have 3/8"-16 threads. These are used for assembly of diffuser plate flow shrouds and oil seals.
Threaded rod, 1/4"-20, used for impeller and spacer installation.
Large spanner wrench for compressor sizes 013 through 080.
Small spanner wrench for compressor sizes 089 through 125.
Rigging chains or straps. Chains are especially useful where overhead space is limited.

NOTE: Figures 62 and 63 are cutaway views of the CVHE compressor. Refer to these figures when reassembling the compressor. Table 1 provides critical clearance measurements.

NOTE: For balance purposes, the impellers must be installed so that the shaft key is in the up position. Also, alignment marks made on each compressor component during disassembly must be mated so that the balance of the compressor is maintained. This is extremely critical if the compressor is equipped with a balancing locknut. Maintaining the proper alignment of components will minimize the need for trim balancing.

Whenever a compressor is rebuilt due to motor replacement, an assortment of locknuts for the shaft should be available to insure proper assembly. This is necessary due to different machining tolerances of shaft threads and the internal threads of the locknut.

The balance locknut should be installed as it was before disassembly if no rotating components are changed. If a rotating component (for example an impeller) is changed, the locknut should be reinstalled with no balance weights installed since this will adversely affect the balance of the compressor. A properly fitting spanner wrench should be used to tighten the locknut to prevent damaging the outer surface of the locknut. If the outer surface is damaged, the locknut will have to be replaced so that the compressor can be trim balanced.

REASSEMBLY

1. Install the bearing oil seal mounting plate as shown in Figure 1.
   a. Clean all dirt and debris from the plate.
   b. Install the plate with a new gasket. Use two pieces of 3/8-inch guide pins to locate the plate. Be certain that the TOP (all components should have been marked during disassembly) is in the proper position.
   c. Tighten the 3/8"-16x1" socket head screws to 24 ft.-lbs. torque. Once several bolts are in place, the guide pins can be removed and mounting bolts installed in their place.
2. Install the bearing oil seal. See Figure 2.
   a. Measure the shaft runout with a dial indicator. The maximum allowable runout is 0.0012 inches Total Indicated Runout (TIR) at the end of the shaft. Refer to the information describing compressor motor reassembly for details on how to measure shaft runout and end float. If the compressor is of "A" or "B" design sequence it will be necessary to pre-load the thrust bearing to obtain an accurate indication of runout. Refer to the procedure for reassembly of "A" and "B" design sequence compressor motors.

PRINTED IN U.S.A.

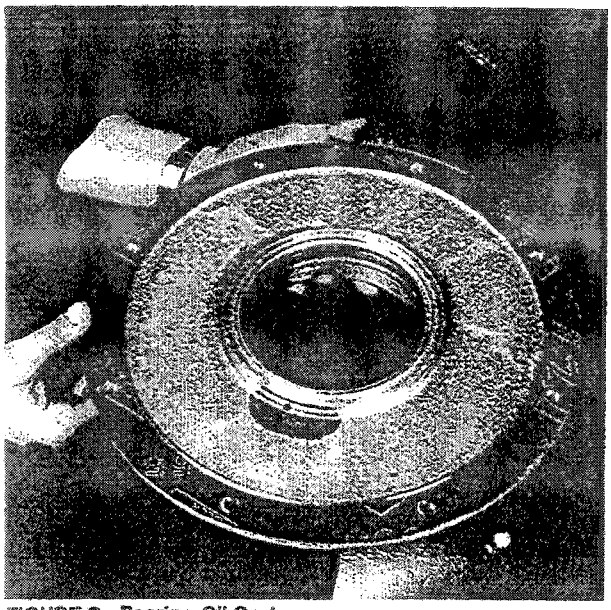

FIGURE 2 - Bearing Oil Seal

b. Install the seal with new gasket and tab or ramp washers and bolts. INSTALL THE SEAL WITH THE OIL DRAIN HOLE IN THE BACKSIDE OF THE SEAL FACING DOWN AND TOWARDS THE MOTOR. See Figure 2.
c. Tighten the retaining bolts very lightly.
d. Set the seal-to-shaft clearance at 0.002 inches minimum and 0.004 inches maximum. See Figures 4 and 5.
e. Tighten the retaining bolts to 24 ft.-lbs. and then recheck the clearance.
f. Bend the tabwashers to secure the bolts. See Figure 6.

3. Install the third stage impeller. See Figure 7.

a. Clean the impeller, compressor shaft, impeller key and shims to remove all dirt, debris, oxidation, etc. Examine the impeller carefully for defects. Inspect the keyway

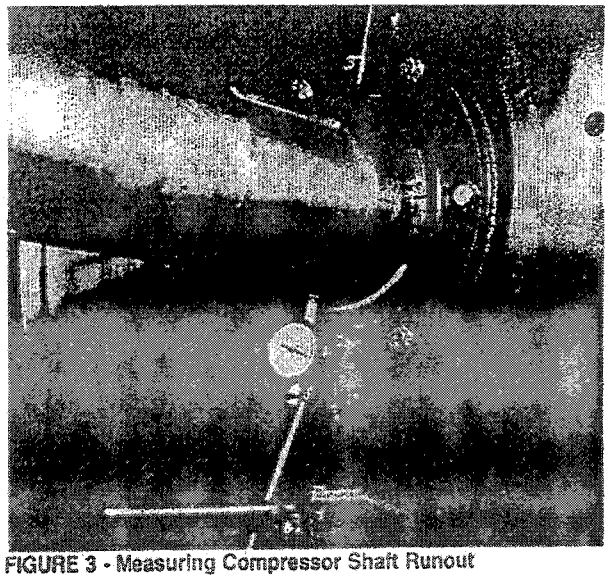

FIGURE 3 - Measuring Compressor Shaft Runout

TABLE 1 - Clearances

IMPELLER SEAL RING CLEARANCE			
COMPR SIZE	1ST STG	2ND STG	3RD STG
013 thru 014	.0295/.0195	.024/.0165	.024/.0165
015 thru 020		.0295/.0195	
022			.0295/.0195
023 thru 032	.033/.022		
035		.033/.022	
036 thru 045	.0365/.0245		
049 thru 050			.033/.022
055		.0365/.0245	
056 thru 071	.043/.0285		
079 thru 080			.0365/.0245
089 thru 112	.046/.031	.043/.0285	
125			.043/.0285
SHAFT TO SEAL CLEARANCES 1ST STAGE — 0.018/0.024 IN. 2ND STAGE — 0.018/0.024 IN. 3RD STAGE — 0.002/0.004 IN.			

TABLE 2 - Dimension Tolerances (Width), Key and Shaft and Impeller Keyways

	MINIMUM/MAXIMUM DIMENSION (INCHES)
Key	0.498/0.500
Shaft Keyway	0.5005/0.5035
Impeller Keyway	0.5010/0.5030

with dye penetrant for indication of cracks. Use the following dye penetrant components to inspect the impeller (Table 2 provides key and keyway tolerances):
- Manufacturer: Magnaflux
- Brand name: "SpotCheck"
- Penetrant number: SKL-HF/SKL-S
- Developer number: SKVD-NF
- Cleaner number: SKC-NF

Discard the impeller if cracks are found. Do not attempt to repair any cracks in an impeller. Examine the seal surface of the impeller for defects. If there are scratches deeper than 1/16-inch, replace the impeller.

b. Measure the shaft outside diameter and the impeller bore inside diameter. The clearance must be not less than 0.0005 inches or greater than 0.0025 inches.
c. Lubricate the shaft and impeller bore with "Lubriplate" or equivalent.
d. Slide the impeller on the shaft.
e. Add shims as necessary to line up the innermost discharge surface of the impeller with the diffuser plate as shown in Figure 8. The surfaces must be level with one another or, at most, the impeller surface may be no more than 0.005 inches above the diffuser plate surface.
f. Insert the impeller key and install the impeller with the keyway in the up position.
g. Measure the impeller nose runout. Mount the dial indicator as shown in Figure 9. Also check the runout at the very end of the shaft to insure that the shaft is true. This procedure is outlined in Step 2. Rotate the impeller by hand and observe the dial indicator. The maximum allowable nose runout on the impeller is 0.003 inches. If the runout exceeds this amount the shims should be inspected for the presence of foreign material. Refer to Figure 10. Recheck the runout. Replace the impeller if runout is still excessive.

4. Install the third stage suction cover casting. Align the scribe marks which were made during disassembly. See Figure 11.
   a. Clean dirt, debris and oxidation from the suction cover. Use a solvent which leaves no residue such as Virginia 10 or equivalent. Clean the O-ring groove. There should not be any nicks or chips in the O-ring groove which might deform the O-ring. Remove all old sealing compound from the O-ring groove. Clean the mating surface also.
   b. Apply LocTite 515 "Gasket Eliminator" to the O-ring groove (1/8-inch bead). Insert the new O-ring in the groove and then apply some sealer to the exposed area of the O-ring.
   c. Use guide rods to position the cover. Insert the retaining bolts to secure the cover, remove the guide rods and then tighten the retaining bolts to 150 ft.-lbs.
5. Install the impeller nose seal.
   a. Clean the seal to remove all dirt and debris. Inspect the labyrinth grooves for wear or damage. Replace the seal if cracked, warped or worn beyond clearance tolerances. Clearance specifications are found in Table 1.
   b. If the seal is reused, be sure it is installed with the TOP in the proper position.
   c. Install the seal and lightly tighten the bolts with rampwashers in place.
   d. Set the seal radial clearance according to Table 1. If the new seal clearance is too tight, the seal may be lightly sanded with sandpaper to achieve the proper clearance. See Figure 12.
   e. Tighten the seal bolts to 24 ft.-lbs. and recheck the radial clearance. Readjust as necessary.
6. Install the third stage inlet vane assembly. Refer to Figure 14.
   a. Clean the assembly with solvent and a lint-free rag. If any of the inlet vane assembly components are worn excessively, replace the assembly.
   b. Lift the assembly into place using a nylon sling or cable through the center of the assembly.
   c. Install two 3/8-inch guide pins through the holes in the inlet vane assembly plate and into the third stage suction cover. The guide pins are used to help locate the inlet vane assembly and then the second stage diffuser plate. See Figures 14, 15 and 18. Install the vane assembly with the TOP in the proper position. Position the inlet vane assembly on the suction cover casting and secure with the 1/4"-20 flathead screws. See Figure 15.
   d. With the inlet vane assembly installed, the vane operator arm will be visible through the tang operator hole. See Figure 16.
   e. Tighten the 1/4"-20 flathead screws to 6 ft.-lbs. torque. The head of these screws must not protrude into the diffuser passage. See Figure 15.

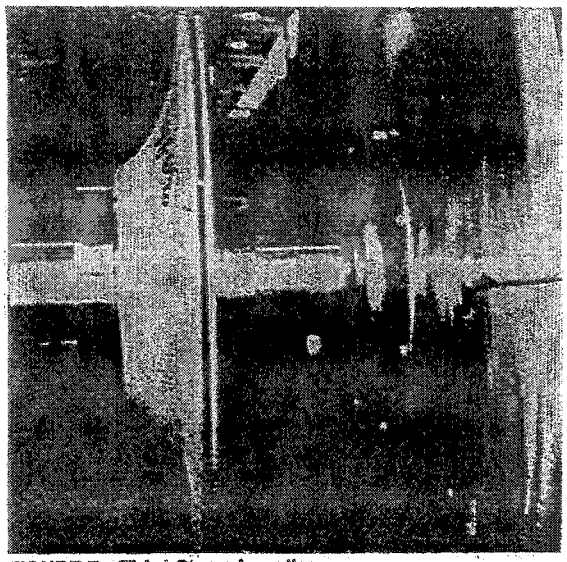

FIGURE 7 - Third Stage Impeller

FIGURE 8 - Aligning Third Stage Impeller Discharge with Diffuser Plate

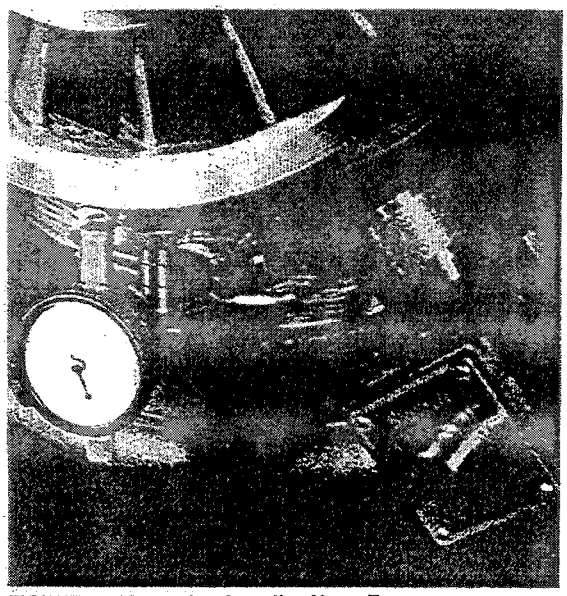

FIGURE 9 - Measuring Impeller Nose Runout

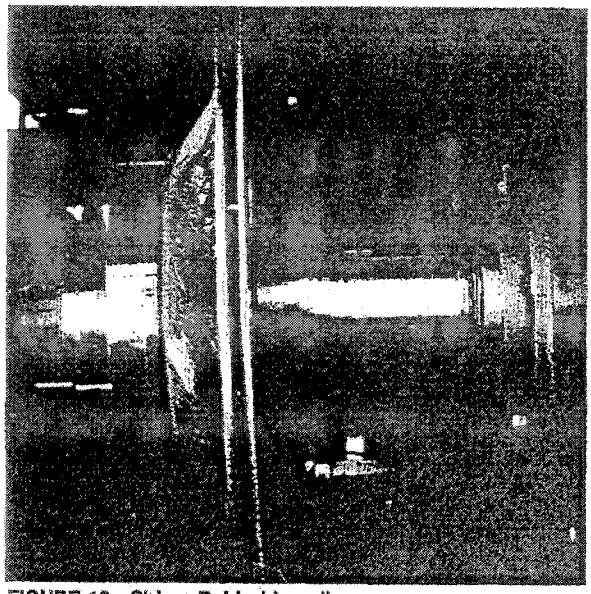

FIGURE 10 - Shims Behind Impeller

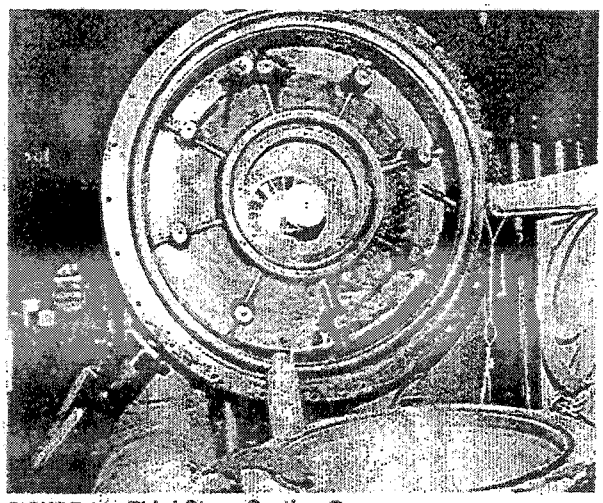

FIGURE 11 - Third Stage Suction Cover

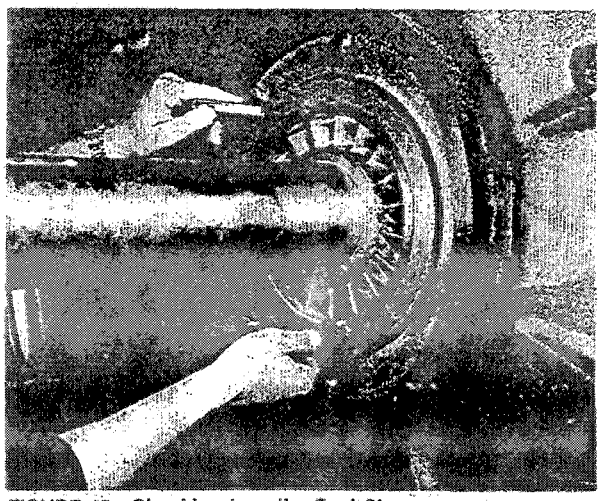

FIGURE 12 - Checking Impeller Seal Clearance

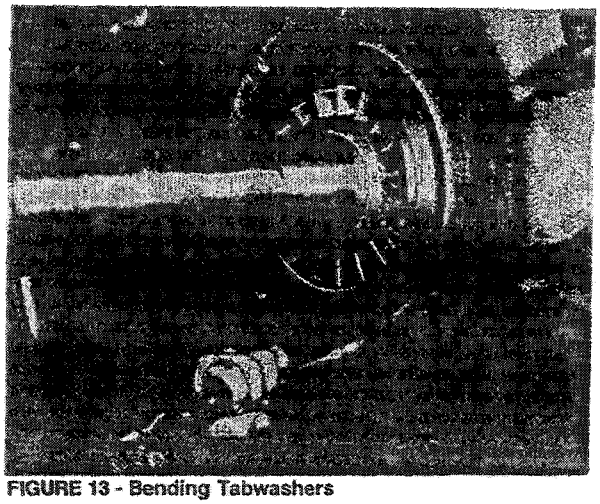

FIGURE 13 - Bending Tabwashers

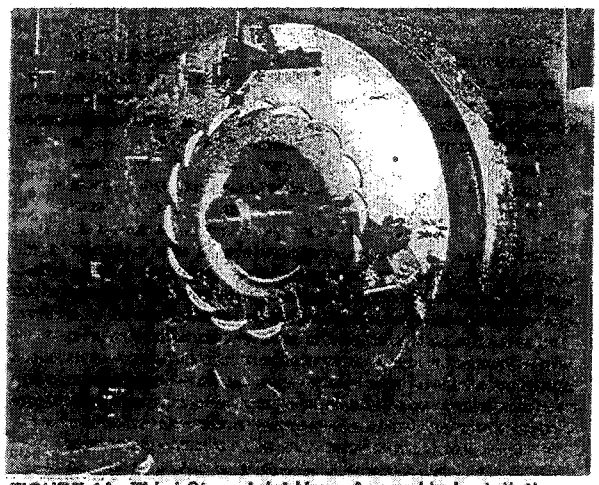

FIGURE 14 - Third Stage Inlet Vane Assembly Installation

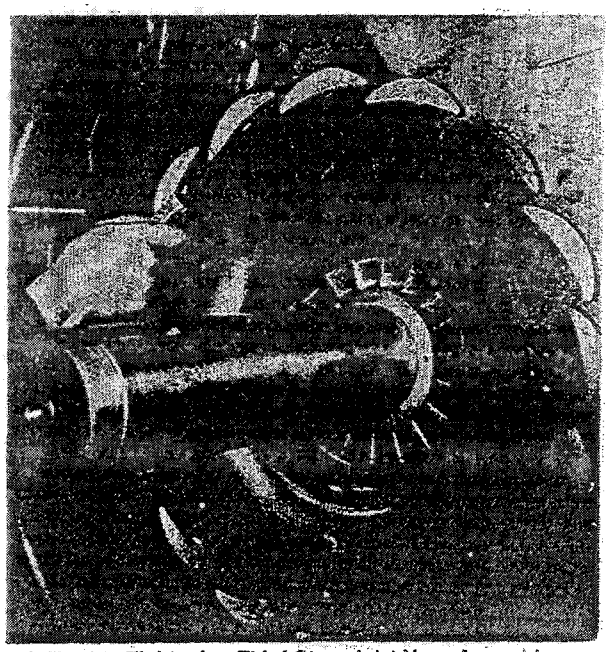

FIGURE 15 - Tightening Third Stage Inlet Vane Assembly Retaining Screws

FIGURE 16 - Inlet Vane Operator

f. Install the shim that was between the spacer and the impeller. The steel shim is necessary to prevent aluminum-to-aluminum contact. If no shim was in place, use a 0.020-inch shim and realign the impeller discharge with the diffuser plate as instructed in Step 11D.

7. Install the third stage vane operator assembly.

   a. Clean the operator assembly with solvent and lint-free rag.
   b. Insert the vane operator into the suction cover and connect to the inlet vanes. Use a new gasket on the operator flange. Refer to Figure 16.
   c. Tighten the retaining bolts to approximately 60 ft.-lbs. or until the gasket just begins to extrude from between the flanges.
   d. Operate the vane assembly with the external operator to verify that the assembly works and is properly positioned.

8. Install the second stage diffuser plate. Make sure the TOP is positioned properly.

   a. Clean the plate and mating surface to remove all dirt, debris, oxidation, etc. Use solvent and a lint-free rag.
   b. Using guide rods, move the diffuser plate into position. Use the second stage impeller to center the plate. There must be equal distance around the impeller. With the diffuser plate centered around the impeller and shaft secure the diffuser plate with socket-head capscrews and tighten to 24 ft.-lbs. Refer to Figure 19. Minimum radial clearance between the impeller and diffuser plate is 0.030 inches.

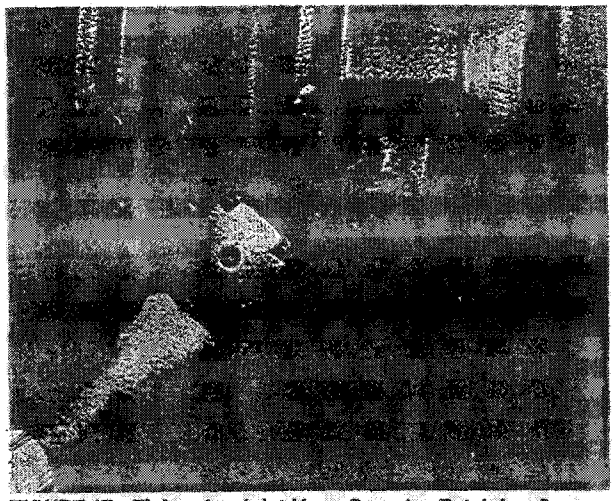

FIGURE 17 - Tightening Inlet Vane Operator Retaining Screws

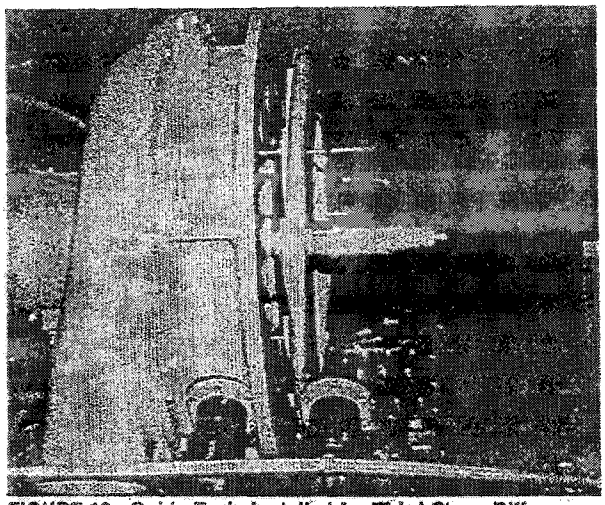

FIGURE 18 - Guide Rods Installed for Third Stage Diffuser Plate Installation

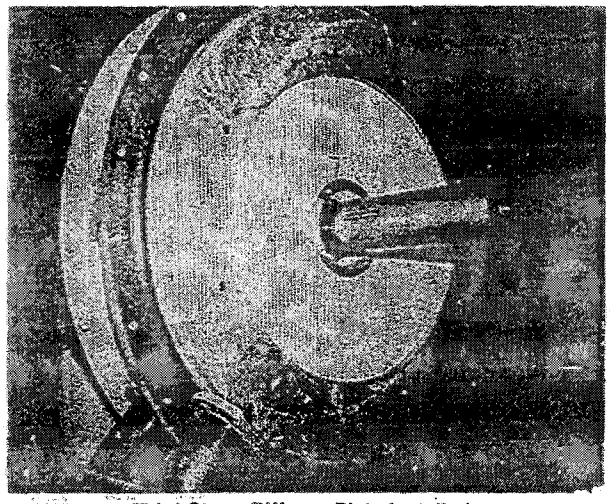

FIGURE 19 - Third Stage Diffuser Plate Installed

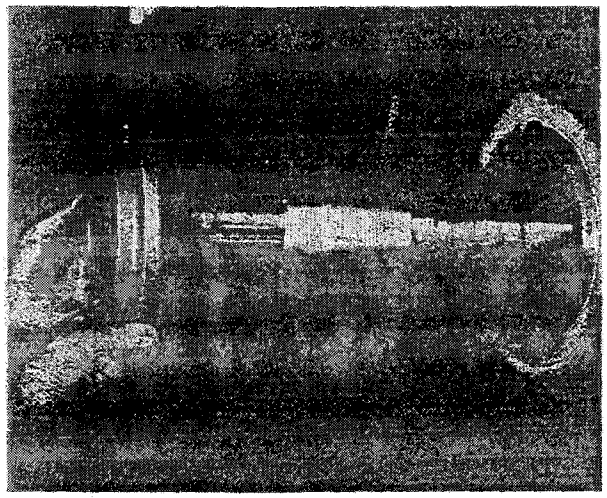

FIGURE 20 - Impeller Spacer Installation

9. Install the impeller spacer. See Figure 20.
   a. Thoroughly clean the spacer.
   b. Lubricate the spacer with compressor oil.
   c. Install the spacer with the pull-off holes away from the motor and align the reference mark made during disassembly. See Figure 21.
10. Install the second stage shaft seal.
   a. Clean the seal and inspect the labyrinth grooves for excessive wear.
   b. Install the seal with the TOP in the correct position. Refer to Figure 20.
   c. Secure the seal loosely with bolts and tab or ramp washers.
   d. Set the seal clearance at 0.018 inches minimum and 0.024 inches maximum radial clearance. See Figure 22.
   e. If a new seal is used and the clearance is too tight — the seal may be lightly sanded with sandpaper to achieve the required clearance.
   f. After the proper clearance is set, tighten the retaining bolts to 24 ft.-lbs.
   g. Recheck the seal clearance. Reposition as necessary.
11. Install the second stage impeller.
   a. Thoroughly clean the impeller and compressor shaft. Use a solvent and lint-free rag. Inspect the impeller for wear, cracks, warpage, etc. Examine the seal surface of the impeller for scratches. If there are any scratches deeper than 1/16-inch, discard the impeller. Use dye penetrant as described in Step 3. Table 2 provides keyway dimensions.
   b. Measure the inside diameter of the impeller shaft bore and the outside diameter of the shaft. The clearance between the components must be not less than 0.0005 inches or greater than 0.0025 inches.
   c. Lubricate the impeller bore with compressor oil or Lubriplate.
   d. Add shims as necessary behind the impeller to line up the innermost discharge surface of the impeller with the diffuser plate surface. The surfaces must be level with one another or at most the impeller surface may be no more 0.005 inches above the surface of the diffuser plate. See Figure 24. Insert the key and install the impeller with the keyway up. See Figure 25.

FIGURE 21 - Spacer Pull-Off Holes

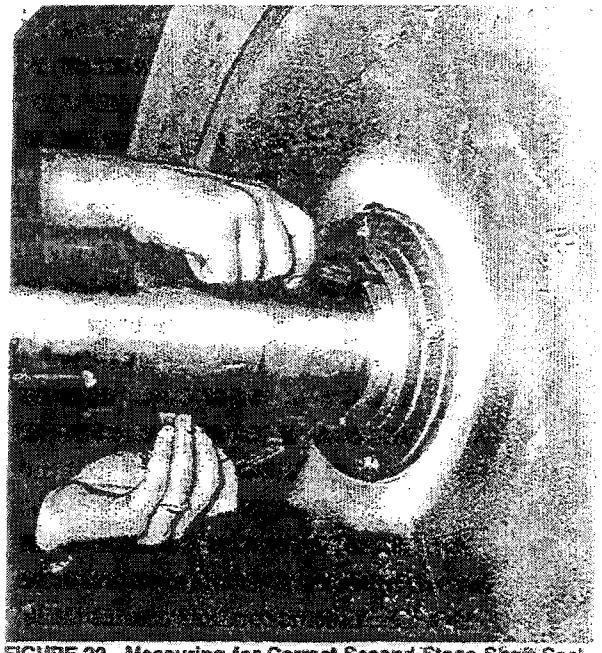

FIGURE 22 - Measuring for Correct Second Stage Shaft Seal Clearance

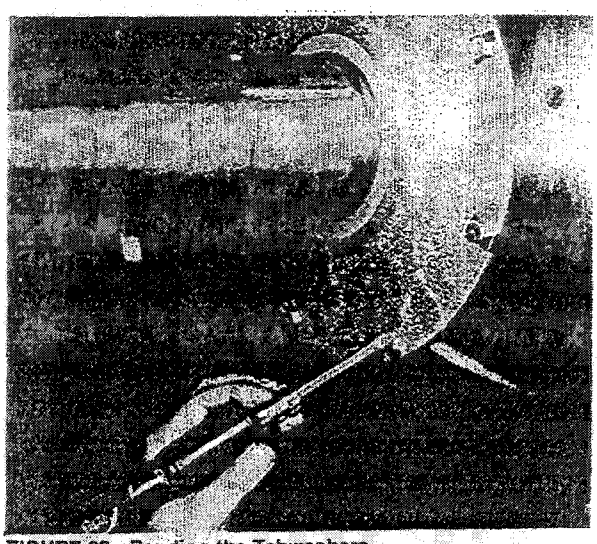

FIGURE 23 - Bending the Tabwashers

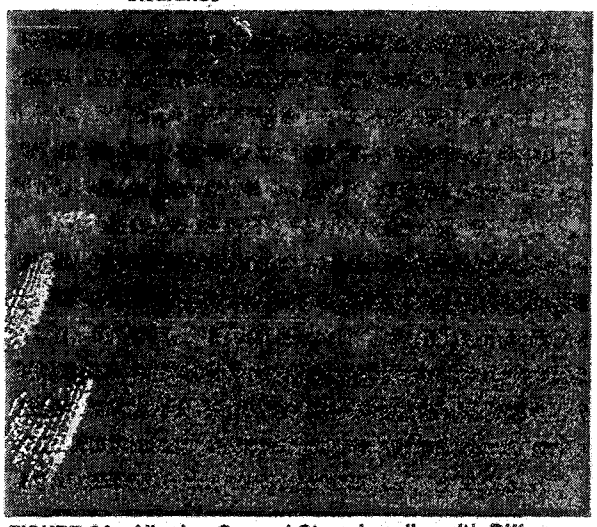

FIGURE 24 - Aligning Second Stage Impeller with Diffuser Surface

FIGURE 25 - Impeller Key and Impeller

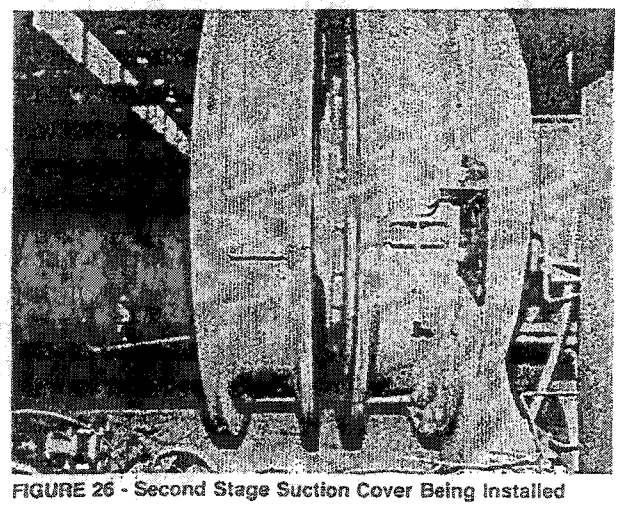

FIGURE 26 - Second Stage Suction Cover Being Installed

1. Thoroughly clean all surfaces. Clean the O-ring grooves. Use solvent (Virginia 10 or equivalent).
2. Apply a 1/8-inch bead of LocTite 515 "Gasket Eliminator" to the O-ring groove in the suction cover. Insert the O-ring, then apply the sealant to the exposed area of the O-ring.
3. Lift the suction cover and using guide rods move it into position. Do not bump or damage the impeller or shaft during this process.
4. Install the suction cover retaining bolts and tighten them to 150 ft.-lbs.

12. Measure the impeller nose runout by mounting a dial indicator as shown in Figure 28. Rotate the impeller by hand and observe the dial indicator. The nose runout tolerance is 0.003 inches. If the runout exceeds 0.003 inches, look for burrs or debris between the impeller shims. Recheck the runout. Replace the impeller if runout is still excessive.

13. Install the second stage impeller nose seal. Refer to Figure 29.

    a. Thoroughly clean the seal and examine the labyrinth grooves for excessive wear. Any damage that will cause the impeller seal clearance to be out of tolerance requires that the seal be replaced.

    b. Install the seal with the TOP properly positioned. Lightly tighten the 3/8"-16x1" bolts with rampwashers.

    c. Set the seal clearance according to Table 1. See Figure 30.

    d. Tighten the retaining bolts to 24 ft.-lbs. and then recheck the clearance. Readjust the clearance as necessary to achieve the proper clearance. If the clearance is too tight, the seal may be lightly sanded to achieve the proper clearance.

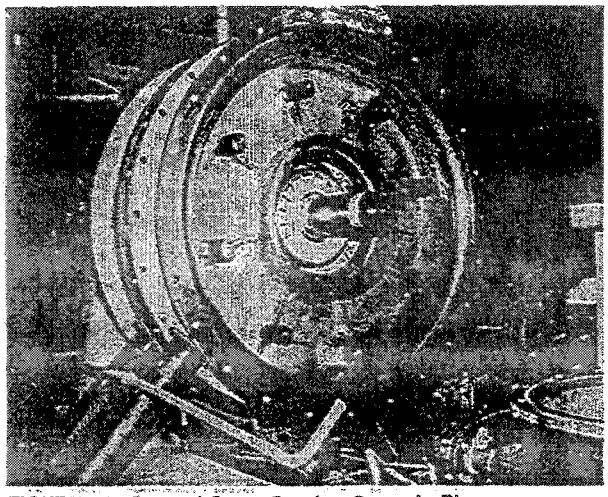

FIGURE 27 - Second Stage Suction Cover in Place

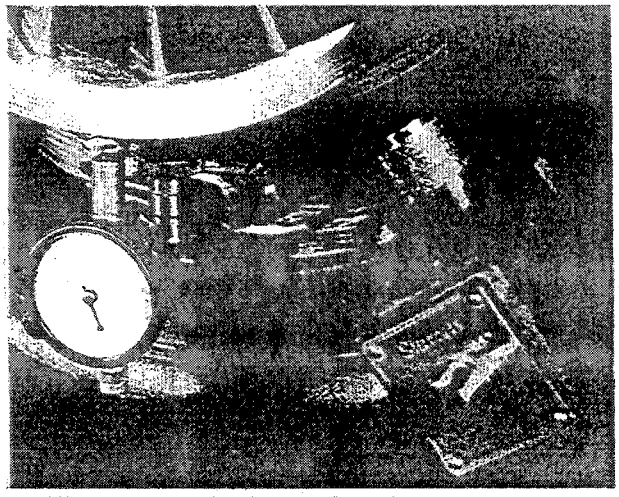

FIGURE 28 - Measuring Second Stage Impeller Nose Runout

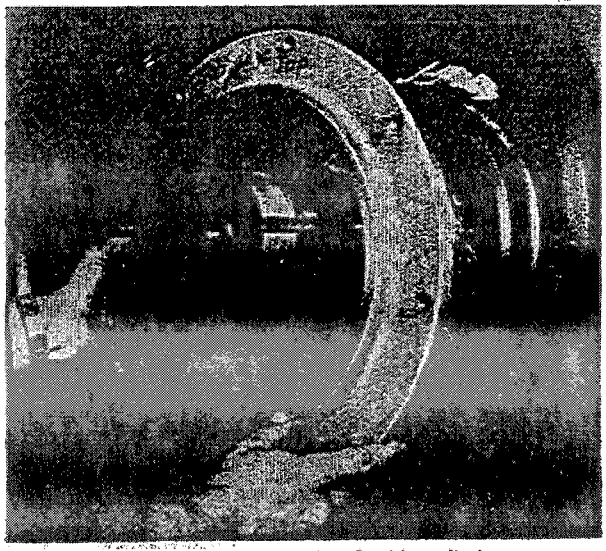

FIGURE 29 - Second Stage Impeller Seal Installation

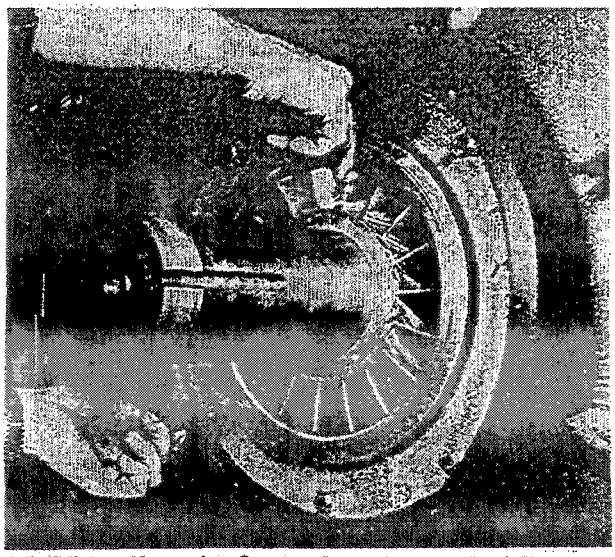

FIGURE 30 - Measuring Second Stage Impeller Seal Clearance

14. Install the second stage vane shroud. See Figure 31.

    a. Clean the shroud and all mating surfaces using solvent (Virginia 10 or equivalent) and a lint-free rag.
    b. This component may be lifted using a nylon sling or cable through the center of the shroud. Lift the shroud up and onto the 3/8"-16 guide pins.
    c. Install the shroud with the TOP correctly positioned.
    d. Tighten the 1/4"-20x3/4" flathead screws to 6 ft.-lbs. The heads of these screws must not protrude into the diffuser passage. Note that the inlet vanes on the shroud are fixed and are not moveable.
    e. Install the shim that was between the spacer and the impeller. The steel shim is necessary to prevent aluminum-to-aluminum contact. If no shim was in place, use a 0.020-inch shim and realign the impeller discharge with the diffuser plate as instructed in Step 11D.

15. Install the first stage diffuser plate. See Figure 32.

    a. Clean the plate and all mating surfaces using solvent (Virginia 10 or equivalent) and a lint-free rag.
    b. Use a rope or nylon sling to lift plate and guide rods to move the plate into place with the TOP up. See Figure 33.
    c. Use the first stage impeller to help position the diffuser plate. See Figures 34 and 35. The diffuser plate must be centered with respect to the impeller. The diffuser will have to be raised to center it. Use feeler gauges to obtain equal clearance around the impeller. The minimum clearance is 0.030 inches.
    d. With the plate in the proper position, tighten the socket head capscrews to 24 ft.-lbs.

NOTE: THE FOLLOWING PROCEDURE IS FOR CVHE 089 THROUGH 125 UNITS ONLY. Refer to Figure 62, Detail A.

    a. Install the spacer ring. (CVHE 089 and 090 units only).
    b. Install the spacer sleeve and align the reference marks made during disassembly. This spacer is very similar to the impeller spacer used in Step 16 except that it makes the step for shaft reduction.
    c. Proceed with Step 17.

16. Install the impeller spacer.

    a. Thoroughly clean the spacer with solvent (Virginia 10 or equivalent) and a clean lint-free rag.
    b. Lubricate the spacer with compressor oil.
    c. Install the spacer with the pull-off holes away from the motor and align the reference marks made during disassembly.

17. Install the first stage shaft seal. Refer to Figure 37.

    a. Clean the seal and all mating surfaces using solvent (Virginia 10 or equivalent) and a lint-free rag. Examine the labyrinth grooves for excessive wear. If the seal is found to be outside of the specifications given in Table 1, replace the seal.
    b. Install the seal with the TOP correctly positioned. Lightly tighten the retaining bolts with ramp washers. Refer to Figure 38.
    c. Set the seal clearance at between 0.018 inches minimum and 0.024 inches maximum. See Figure 39.
    d. Tighten the bolts to 24 ft.-lbs. and recheck the clearance. Readjust the clearance as necessary. If the seal is new and the clearance is too tight, the seal may be lightly sanded with sandpaper to achieve the proper clearance.

18. Install the first stage impeller. See Figure 40.

    a. Clean the impeller and compressor shaft. Inspect the impeller for wear, cracks, warpage and scratches on the seal surface. If there are scratches deeper than 1/16-inch, replace the impeller. Inspect the impeller keyway using dye penetrant as described in Step 3. Table 2 gives proper keyway dimensions.
    b. Measure the impeller bore inside diameter and the shaft outside diameter. The clearance must be not less than 0.0005 inches or greater than 0.0025 inches.
    c. Lubricate the impeller bore or the shaft with compressor oil. Insert the key and then install the impeller with the keyway up.
    d. Add shims as necessary to align the inner discharge surface of the impeller with the first stage diffuser plate surface. The surfaces must be level with one another or at most, the impeller surface may be no more than 0.005 inches above the diffuser plate surface. Also recheck the impeller to diffuser plate radial clearance. The clearance between the impeller and diffuser plate must be no less than 0.030 inches. See Figures 41 and 42.

19. Install the spacer if provided.

20. Install the spring washer.

***NOTE:** The spring washer must be installed so that it compresses and flattens towards the impellers. Therefore, the tapered portion must be such that it tapers towards the compressor motor.*

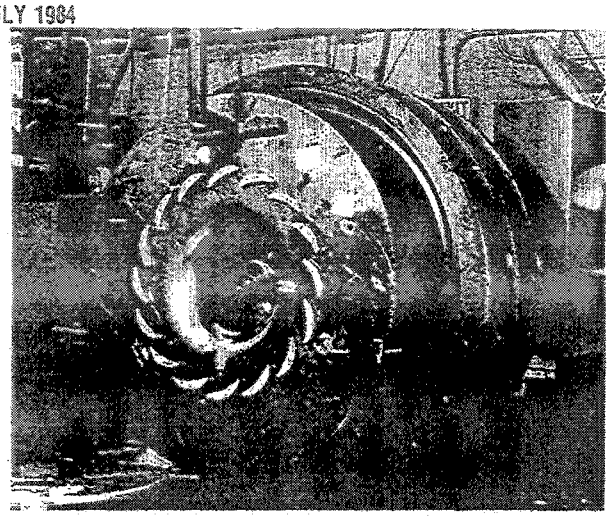

FIGURE 31 - Second Stage Vane Shroud Installation

FIGURE 38 - First Stage Seal Installation

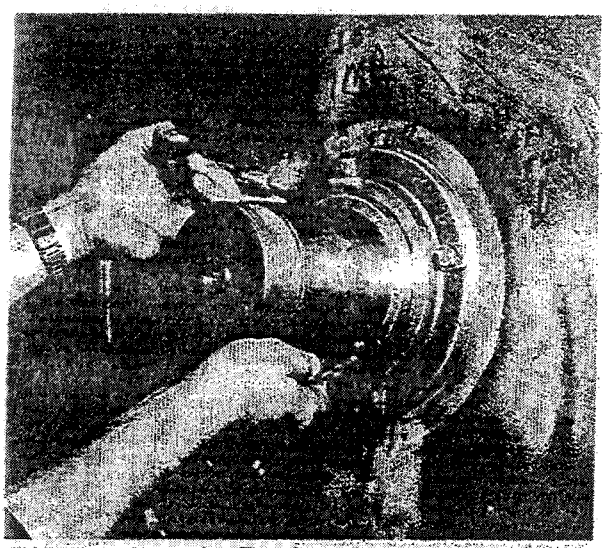

FIGURE 39 - Measuring First Stage Seal Clearance

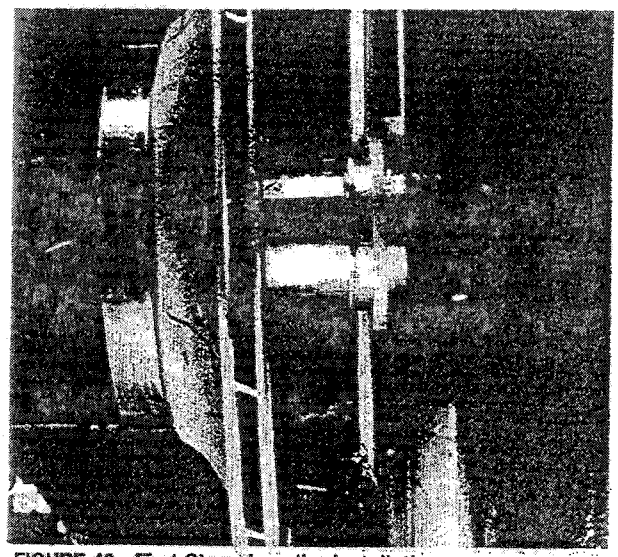

FIGURE 40 - First Stage Impeller Installation

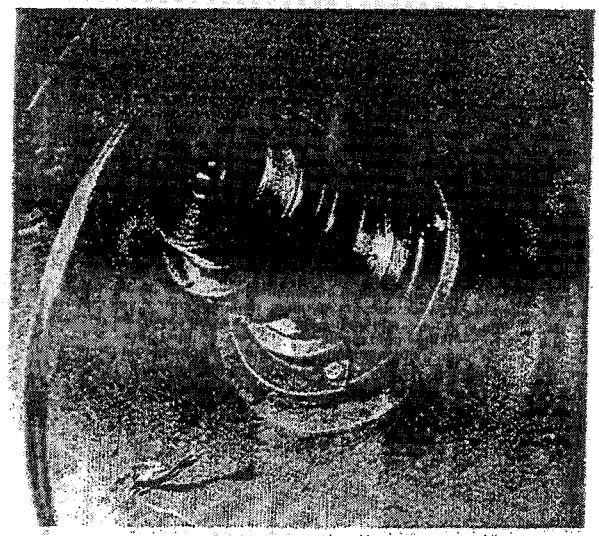

FIGURE 41 - Impeller Shims

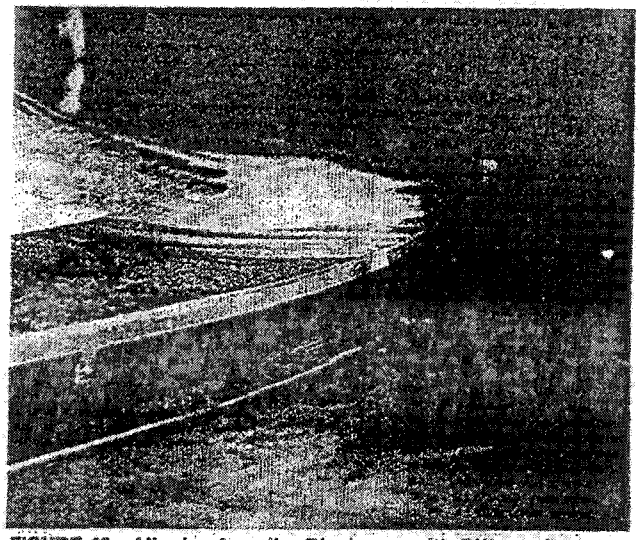

FIGURE 42 - Aligning Impeller Discharge with Diffuser Plate

21. Install the lockwasher and locknut. See Figure 43.

    a. The locknut can be selected by use of the following chart. Refer to the appropriate parts list for proper identification. The balance locknut must fit properly on the shaft for proper operation. Proper fit is achieved when the locknut selected is turned on the shaft four or five threads and no looseness can be felt when trying to move the locknut back and forth with slight force. The locknut should require only manual force until it makes contact with the spring washer.
    b. Tighten the locknut to achieve solid metal-to-metal contact. This is approximately 115 ft.-lbs. torque. Care must be taken to compress but not completely flatten the springwasher. Also, the locknut must be positioned such that a lockwasher tab aligns with a slot in the locknut.
    c. Bend over the lockwasher tab into the locknut slot.

CHART 1 - Locknut Usage

REASON FOR REBUILD	STD. LOCKNUT	LOCKNUT USAGE BALANCE LOCKNUT WITH WEIGHTS	NEW BALANCE LOCKNUT*
Non-Rotating Component Replacement (O-Ring, Vanes, Etc.)	X	X (If Originally Equipped)	
Rotating Component Replacement (Impeller, Spacer, Etc.)			X
Motor or Bearing Replacement			X

*The new balance locknut is necessary if the compressor needs to be trim balanced.

22. Measure the first stage impeller nose runout. See Figure 45.

    a. Mount the dial indicator on a solid surface.
    b. Rotate the impeller by hand and observe the dial indicator. The runout must not exceed 0.003 inches. If the runout exceeds this tolerance inspect behind the impeller for burrs or debris between the shims. Recheck the runout. If the runout is still excessive, replace the impeller.

23. Install the first stage suction cover. See Figure 46.

    a. Thoroughly clean the suction cover and all mating surfaces. Clean the O-ring grooves. Use LocTite "Chisel" cleaner.
    b. Apply a 1/8-inch bead of LocTite 515 "Gasket Eliminator" to the O-ring groove. Insert the O-ring and then apply a bead of "Gasket Eliminator" to the exposed portion of the O-ring.
    c. Using the tool shown in Figure 47 and guide pins, move the suction cover into position. Align the scribe marks on the outside of the cover with the scribe marks on the mating surfaces. This will insure proper alignment when the compressor is completely assembled.
    d. Tighten the retaining bolts to 150 ft.-lbs. Remove the guide pins and replace them with the appropriate retaining bolts.

24. Install the first stage impeller nose seal.

    a. Clean the seal and mating surfaces with solvent (Virginia 10 or equivalent) and a clean lint-free rag. Examine the labyrinth groove for excessive wear. If the seal does not meet the clearance specifications given in Table 1, replace the seal.
    b. Install the seal with the TOP correctly positioned. Lightly tighten the retaining bolts with rampwashers in place. See Figure 48.
    c. Set the seal clearance according to Table 1.
    d. Tighten the 3/8"-16x1" bolts to 24 ft.-lbs.
    e. Recheck the seal clearance and readjust the clearance as necessary.

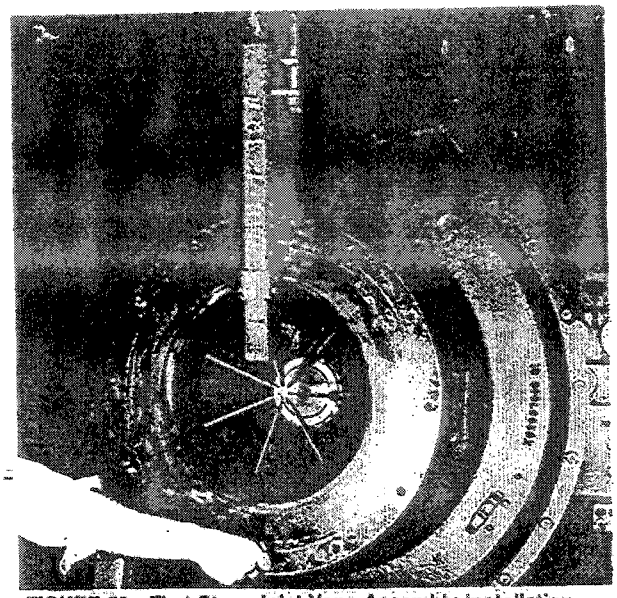

FIGURE 50 - First Stage Inlet Vane Assembly Installation

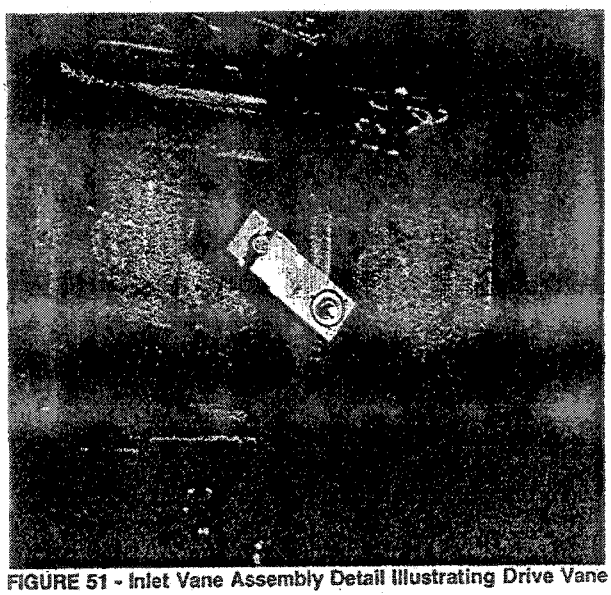

FIGURE 51 - Inlet Vane Assembly Detail Illustrating Drive Vane

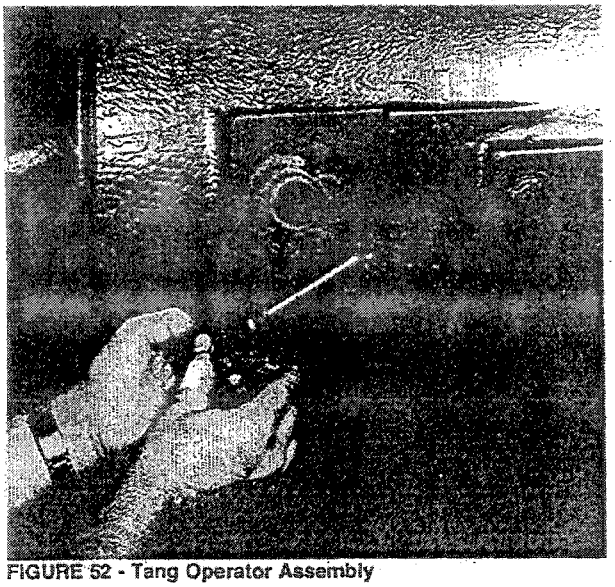

FIGURE 52 - Tang Operator Assembly

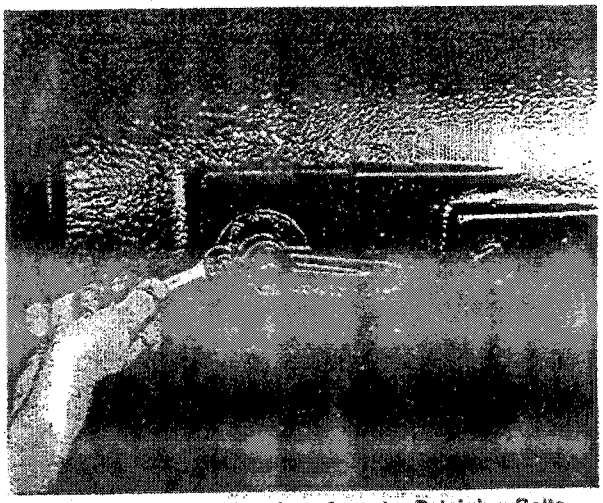

FIGURE 53 - Tightening Tang Operator Retaining Bolts

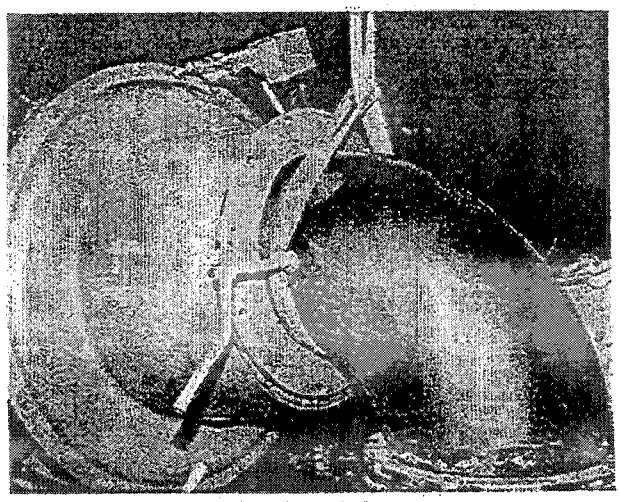

FIGURE 54 - Suction Elbow Installation

25. Install the first stage inlet vanes.
    a. Clean the inlet vane assembly. Inspect the components for excessive wear or damage. Replace as necessary.
    b. Insert the assembly into the suction cover. This may be accomplished using a fixture similar to that shown in Figure 50, or use the following procedure:
        1. Slide one end of a 5-foot section of heavy duty pipe between the vane blades at the top of the vane housing. The pipe should have a small tab welded to it to prevent the assembly from sliding off.
        2. Position a chain or sling around the pipe as close to the vane housing as possible.
        3. The pipe is used as a fulcrum to lift the weight of the assembly and then slide the assembly into the suction cover. This procedure requires two men.

NOTE: The vane assembly will not stay in position without holding it there. It is very possible that the assembly will slide out of position unless it is held there. Exercise proper attention.

    a. Position the inlet vane assembly so that when inserted into the suction cover the tang operator connects with the proper drive vane. See Figure 51.
    b. Secure the assembly with three 5/16"-18x3/8" setscrews. See Figure 50.

26. Insert the tang operator assembly. Refer to Figure 52.
    a. Clean the assembly using solvent and a clean lint-free rag.
    b. Apply a 1/8-inch bead of LocTite 515 "Gasket Eliminator" to the O-ring groove. Insert the O-ring and then apply "Gasket Eliminator" to the exposed portion of the O-ring.
    c. Engage the tang with the vane assembly inside the suction cover.
    d. Secure with three 5/16"-18x1" capscrews. Tighten to 14 ft.-lbs. See Figure 53.
    e. Check for smooth and free inlet vane operation making sure the tang operator is properly positioned.

27. At this point the vibration characteristics of the compressor should be measured. This initial test is an air run with the compressor motor being run at reduced voltage. A final vibration check will be necessary after the chiller is charged with refrigerant and restarted.

28. Install the suction elbow. See Figure 54.
    a. Remove the protective covers which were installed during disassembly.
    b. Clean the suction elbow and all mating surfaces. Pay particular attention to all gasket surfaces and O-ring grooves. Use LocTite "Chisel" cleaner.
    c. Apply a 1/8-inch bead of LocTite 515 "Gasket Eliminator" to the O-ring groove. Insert the O-ring and then apply a bead of "Gasket Eliminator" to the exposed portion of the O-ring.
    d. The suction elbow may be lifted using a sling as shown in Figure 54. Set the suction elbow in place and start tightening the retaining bolts as shown in Figure 55.
    e. Dial indicators should be used as shown in Figure 55 to monitor the horizontal and vertical movement of the compressor. Movement must be less than 0.010 inches. If the movement becomes greater than this, loosen the retaining bolts and start over with the tightening sequence.
    f. Tighten the support bolts at the motor end of the compressor.

29. Reconnect the oil sump vent line. Use a sweat coupling to silver solder the line together. Bleed nitrogen through the line to prevent the formation of oxides which will contaminate the lubrication system.

30. Reattach the control panel support bracket. See Figure 56.

31. Reattach the suction cover drain line. See Figure 57.

32. Reconnect the inlet vane actuator and linkages. Move the linkages by hand to assure proper operation.

33. Reinstall and reconnect the economizer. See Figure 58. Clean all mating surfaces prior to reassembly. Use new gaskets.

34. After the compressor is completely reassembled, the chiller must be restarted as if it were a new chiller. This includes pressure testing the chiller, evacuation, charging and all other procedures included in the initial start-up of a new chiller.

Compressor Motor Removal and Replacement

SECTION 8.4

June 1986

This section describes the procedures required to remove and reinstall the compressor motors of Model CVHE CenTraVacs. The information presented here applies to all motors, regardless of compressor size.

WARNING: Before working on this equipment, always disconnect all electrical power. Failure to do so may result in serious injury or death due to electrical shock.

Motor Removal

1. Disassemble the compressor. (A compressor disassembly procedure is outlined in Section 8.2 of this service guide.)

2. **CVHEs w/Unit-Mounted Starters.** Remove the factory-mounted starter panel from the motor terminal casting. Label and remove all motor power leads and starter panel interconnecting wiring.

CVHEs w/Remote-Mounted Starters. Label and disconnect the motor power leads; then remove the conduit box.

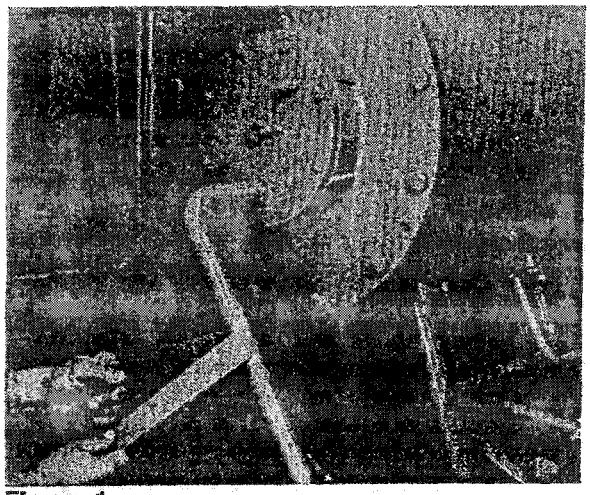

Figure 1
Removing Paint from the Oil Drain Line

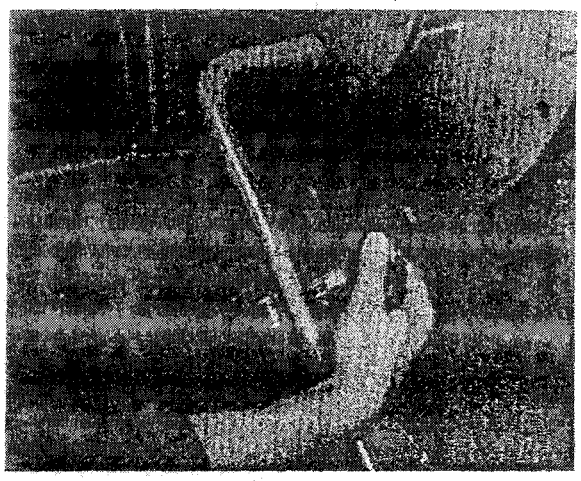

Figure 2
Cutting the Drain Line

Figure 3
Cutting an Oil Supply Line

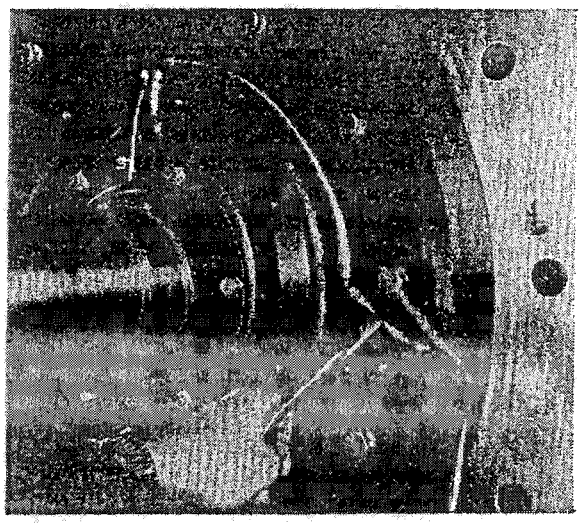

Figure 4
Unsweating the Internal Oil Supply Line

3. Label and remove the motor winding temperature sensor leads.

4. Disconnect and cap the oil return lines, as well as the oil supply line to the thrust bearing. Also, disconnect the internal oil supply line to the compressor shaft-end roller bearing; see Figures 1 through 4. Notice that the internal line can be disconnected by unsweating the coupling (Figure 4).

5. Disconnect the refrigerant supply and drain lines from the motor; to do this, simply unbolt the drain line flanges from the motor. See Figures 5, 6 and 7.

6. Attach lifting slings to the compressor motor as shown in Figure 8.

7. Remove the bolts that secure the motor to the back bracket; see Figure 7.

8. Loosen and remove 2 of the bolts that secure the motor to the third-stage volute casing. Insert a guide pin into each of these bolt holes.

9. Remove the remaining bolts, and carefully pull the motor straight out until the shaft clears the volute casing. See Figures 8 and 9.

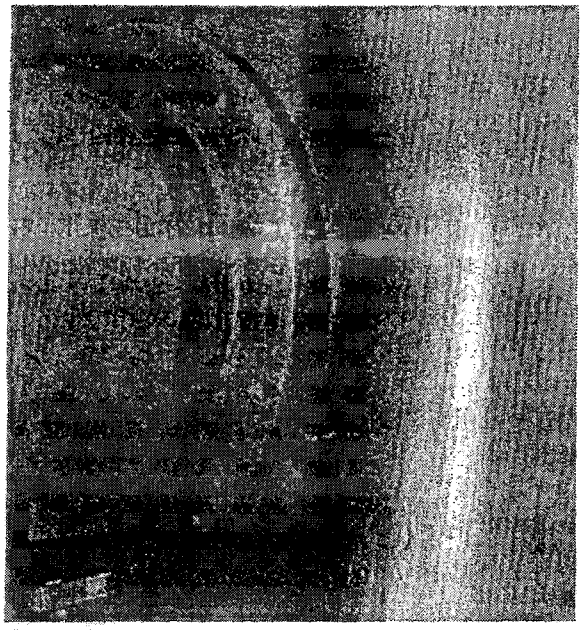

Figure 9
Removing the Motor

Be sure to adhere to the following guidelines whether the motor just removed will be reused, or if a replacement motor will be installed:

[ ] **Motor Storage.** Store the motor (original or replacement, as applicable) in a clean, dry location that is protected from dirt and extreme variations in temperature and humidity; the minimum temperature acceptable for motor storage is 40 F.

Special care must be taken to ensure that the storage temperature of the motor is always above the dew point of the surrounding air; this will protect the motor windings from the damaging effects of condensation.

The oil-lubricated roller bearings of new replacement motors are "run" tested at the factory with a rust-preventive oil that protects the bearing and bearing structure from corrosion; however, this bearing oil is drained before shipment. Therefore, to protect the bearings and bearing structures of a new or reused motor during storage, add 1 pint of rust-preventive oil (e.g., Texaco Preservative Oil No. 30, or equivalent) to each bearing—while rotating the shaft by hand—every 90 days.

Note: If the motor storage period will exceed 12 months, contact the factory for special instructions and additional storage precautions.

[ ] **Mechanical Inspection.** Visually inspect the motor exterior for rust. If external rust is present, remove the shaft-extension/bearing bracket and check the motor interior for rust. All rust—particularly that on the motor interior and shaft-extension/bearing bracket—must be removed before the motor is installed!

Also, rotate the motor shaft by hand to verify that it turns freely; at the same time, add oil to each bearing oil inlet.

Note: Since the bearings are designed for pressure lubrication, the oil pressure system must be connected to the motor—and the proper bearing pressure must be established—before the motor is started.

[ ] **Electrical Test.** Meg-test the motor winding insulation to ensure that the motor windings did not absorb moisture during storage or transit. Use a 500 VDC megohm insulation tester to check insulation resistance between the motor windings and the motor housing; make sure that these measurements are taken at—or corrected to—68 F. The insulation resistance measured should be above the minimum value shown on the curve in Figure 10.

Once the test is complete, discharge the motor windings by touching the motor terminal studs with a ground wire connected to the motor housing.

Note: If the insulation resistance reading obtained is less than the minimum value shown on the curve (Figure 10), the compressor motor must be dried out before it is installed on the unit.

[ ] **Drying Out Wet Motor Windings.** To dry out wet motor windings, apply a single-phase voltage of approximately 5% of the voltage value indicated on the motor nameplate. For 6-terminal, low-voltage motors, connect the motor as described on the nameplate for across-the-line starting; then apply single-phase voltage to Terminals T1 and T2. For 3-terminal, high-voltage motors, apply the single-phase voltage between Terminals T1 and T2.

It is impossible to predict the amount of time that will be required to dry out the motor windings since it varies with motor size and the amount of moisture that the windings have absorbed. As a guideline, continue the "drying out" process until the insulation resistance/ground readings become fairly constant. Remember that successive insulation readings must be made at the same temperature to assure an accurate interpretation of the windings' moisture content; readings taken at different temperatures will vary considerably.

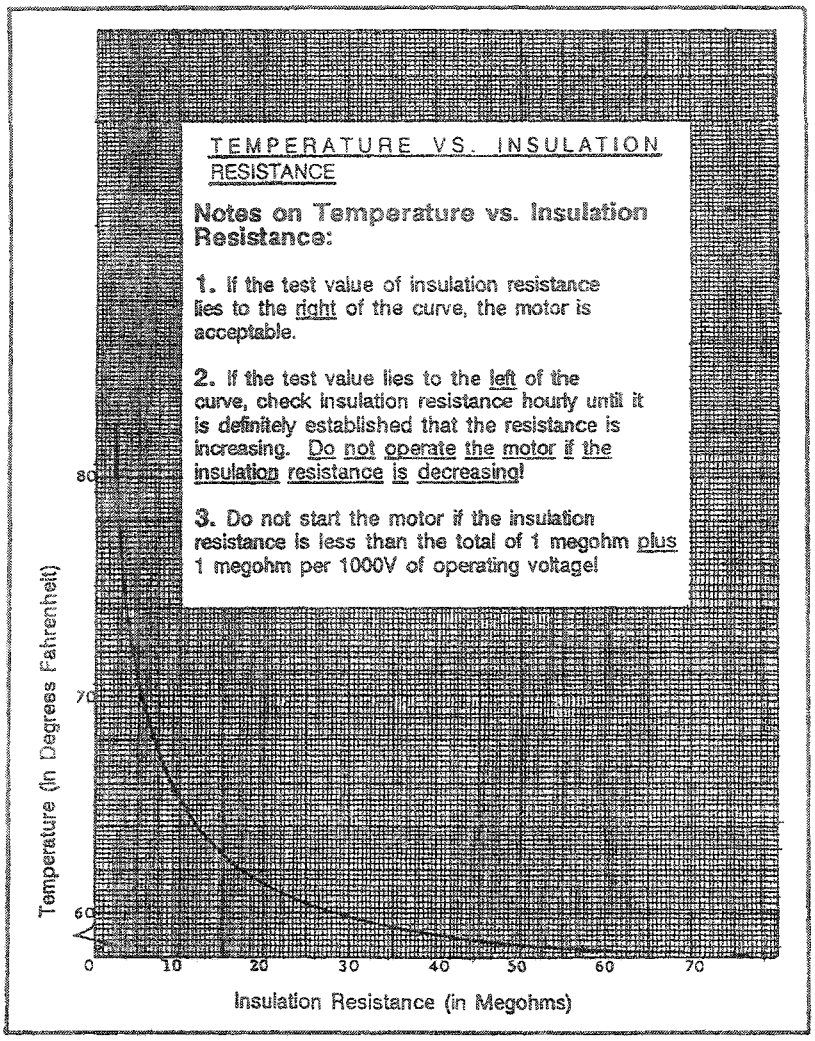

Figure 10
Temperature vs. Insulation Resistance

Caution: Do not "high potential" test! Repeated "high potential" tests drastically reduce motor life. (All motors are factory "high potential" tested at twice the rated voltage plus 1,000 volts, per NEMA MG1.

Caution: To avoid serious motor damage, never perform any of these operations while motor is under vacuum:
a. "high potential" test;
b. "megger" test (insulation resistance test);
c. dry windings by applying single-phase voltage to motor; or,
d. apply 3-phase line voltage to motor.

Motor Installation

1. Measure motor winding insulation resistance; follow the recommended procedure just described under "Electrical Test".

2. If you are replacing the old motor with a new one, remove all lubrication supply and drain line fittings from the old motor and install them on the new motor. Use Teflon tape on all threaded-connection fittings.

Note: When an "A" or "B"-design motor is replaced by one of "C" or later design, notice that the oil feed orifices change. The inboard bearing's oil feed orifice is built into the bearing on "C" and later design motors; discard the external orifice from the old motor. However, an external orifice is required for the outboard bearings of "C" and later design motors; see Table 2 to determine proper orifice size.

Before proceeding, review the bearing-related characteristics that distinguish CVHE motors of "A" or "B" design from those of "C" or later design:

a. CVHEs of "A" or "B" Design. Bearings are provided on both the inboard ("drive end") and outboard ("opposite drive-end") ends of the motor. A roller bearing supports the inboard end of the motor, while the outboard end of the motor is supported by a matched pair of tapered roller bearings that carry the thrust load. Bearing size varies with the frame size of the motor; Table 1 indicates the appropriate bearing and orifice sizes for each compressor motor size.

b. CVHEs of "C" and Subsequent Design. Again, bearings are provided on both the inboard and outboard ends of the motor. However, the inboard end of motors of "C" and later design is supported by a babbitted journal bearing, while a matched set of ball bearings carries the thrust load and supports the outboard end of the motor. Table 2 indicates the appropriate bearing and orifice sizes for each compressor motor frame size.

3. Install the motor on the third-stage volute by completing the disassembly instructions in reverse order.

Note: Connect only the bearing oil supply lines at this time.

4. Measure the oil flow rate through the motor bearings; to do this:

a. Remove the old oil from the sump; then recharge the sump with the proper amount of new oil (i.e., not mixed with refrigerant).

b. Energize the oil sump heater to raise the oil temperature to 140 F.

c. Once the oil is properly heated, energize the oil pump; use the oil pump switch on the unit control panel.

Note: An oil pump switch was not provided on some early versions of the unit control panel. In these instances, it is necessary to install a jumper wire to energize the oil pump. Be sure to remove this jumper wire as soon as you've determined the oil flow rate!

d. Set the oil pressure regulating valve to maintain a constant net oil pressure of 18 to 20 psid.

e. Monitor the quantity of oil leaving the motor bearings. Use Table 1 or 2, as appropriate, to determine the correct oil flow rate while the motor is running.

Note: Oil pressure may change when the motor is started; readjust as required.

5. After verifying that the oil flow rates through the motor bearings are acceptable, reconnect the oil drain lines; use slip couplings and silver solder to rejoin the lines.

Note: Be sure to purge both the oil and refrigerant lines with dry nitrogen while applying the silver solder.

6. Reconnect the motor cooling refrigerant supply and drain lines at the motor.

7. Reassemble the compressor; follow the instructions provided in Section 8.3 of this service guide.

8. Reconnect the temperature sensor leads of the motor winding thermostat.

9. Reconnect the motor power supply when ready, and restart the chiller; follow the start-up instructions provided in Section 4.0 or 4.1, as appropriate.

Table 1
Bearing Orifice Requirements for CVHE Compressor Motors of "A" or "B" Design

Compressor Motor Frame Size	Compressor Motor Bearing Characteristics				
	Type	Location	Correct Oil Flow Rate (See Note)	Approx. Inside Diam	Orifice Size (ID Stamp)
360, 400, 1500 and 1700	Inboard Bearing (Roller Bearing)	"Drive" End of Motor	0.9 gpm ± 15%	5"	0.067" ("01")
	Outboard Bearing (Matched Pair of Tapered Roller Bearings)	"Opposite Drive-End" of Motor	0.5 gpm ± 15%	2"	0.0935" ("03")
440, All 1800 & Larger, and Some 1700	Inboard Bearing (Roller Bearing)	"Drive" End of Motor	1.2 gpm ± 15%	6"	0.082" ("02")
	Outboard Bearing (Matched Pair of Tapered Roller Bearings)	"Opposite Drive-End" of Motor	0.8 gpm ± 15%	3"	0.116" ("04")

Note: Flow rates shown are while the motor is running.

Table 2.
Bearing Orifice Requirements for CVHE Compressor Motors of "C" and Subsequent Design

Compressor Motor Frame Size	Compressor Motor Bearing Characteristics				
	Type	Location	Correct Oil Flow Rate (See Note 1)	Approx. Inside Diam.	Orifice Size (ID Stamp)
360, 400, 1500 and 1700	Inboard Bearing (Babbitted Journal Bearing)	"Drive" End of Motor	1.27 gpm ± 15%	5-1/2"	See Note 2
	Outboard Bearing (Matched Set of Ball Bearings)	"Opposite Drive-End" of Motor	0.5 gpm ± 15%	2"	0.067" ("01")
440, All 1900 & Larger, and Some 1700	Inboard Bearing (Babbitted Journal Bearing)	"Drive" End of Motor	1.70 gpm ± 15%	6-1/2"	See Note 2
	Outboard Bearing (Matched Set of Ball Bearings)	"Opposite Drive-End" of Motor	0.8 gpm ± 15%	3-1/2"	0.082" ("02")

Notes:
1. Flow rates shown are while the motor is running.
2. When replacing an "A"- or "B"-design compressor motor with one of "C" or later design, discard the external inboard bearing orifice from the old motor.

BB/LW

COMPRESSOR MOTOR DISASSEMBLY AND REASSEMBLY A AND B DESIGN SEQUENCE

LITERATURE FILE NO. CTV-SG-2

SECTION 8.5

JULY 1984

This section describes the disassembly and reassembly of the model CVHE CenTraVac compressor motor design sequence A and B. Before the complete motor is disassembled it is necessary to disassemble the compressor. Refer to Section 8.2.

NOTE: Figures 91 and 92, found on pages 25 and 26, are cutaway and exploded views of the motor. Refer to these during disassembly and reassembly of the motor.

NOTE: The following instructions identify motor orientation for the procedures. DRIVE END refers to the shaft extension end or compressor end of the motor. OPPOSITE DRIVE refers to the electrical terminal end of the motor. The compressor drive end of the motor must be disassembled first if the entire motor is to be disassembled. The thrust bearing assembly can be replaced from the opposite drive end of the motor without affecting the compressor.

NOTE: The motor bearings and rotor can be changed without removing the entire motor. The following section describes motor disassembly with the motor mounted on the chiller.

WARNING: Before working on this or any electrical equipment, always disconnect all electrical power. Failure to do so may result in serious personal injury or death caused by electric shock or becoming entangled in rotating equipment.

DISASSEMBLY

1. Disconnect the drive end motor bearing supply line. Unsweat the ¼-inch line near the volute casting as shown in Figure 1.
2. Using large snap ring pliers, remove the bearing snap ring shown in Figure 2.
3. Remove all bolts securing the inner seal and back bearing race retaining ring. See Figures 3 and 4. Remove the retaining ring by carefully sliding it off the shaft.
4. Remove the drive end motor bearing bracket. The entire drive end bearing will also be removed. The procedure is as follows (Refer to Figure 5):
   a. Remove two bolts 180 degrees apart on the horizontal centerline and then insert two guide rods approximately 12 inches long.
   b. Remove the remaining bearing bracket bolts.
   c. Insert four 6 inch bolts into the jack-out bolt holes in the bearing bracket.
   d. Tighten the bolts evenly to push the bearing bracket squarely away from the motor until the bearing and spacer are past the pressed-on area of the shaft. See Figure 6. The bearing bracket can rest on the guide rods. Remove the bearing and spacer assembly. Refer to Figure 7.

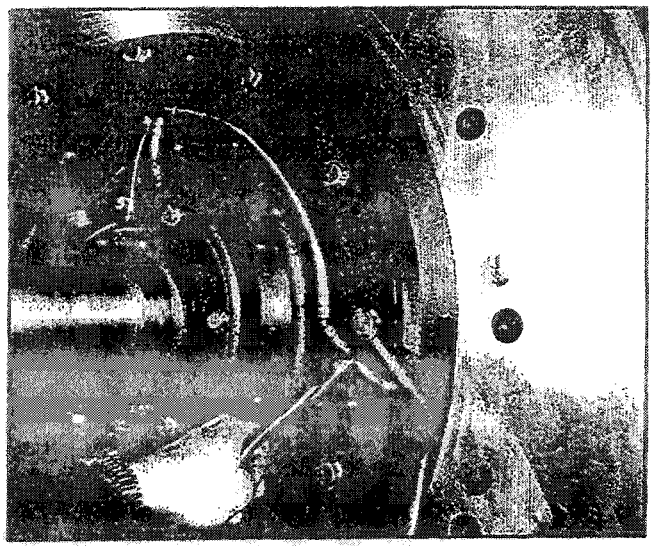

FIGURE 1 — Unsweating the Internal Oil Supply Line

PRINTED IN U.S.A.

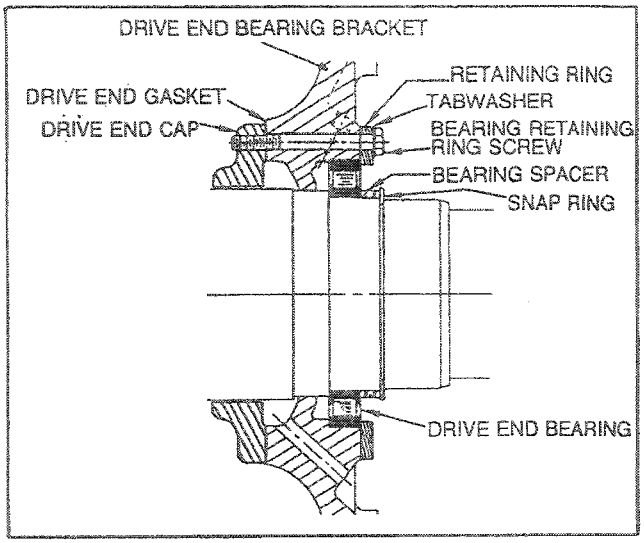

FIGURE 3 — Drive End Bearing Assembly

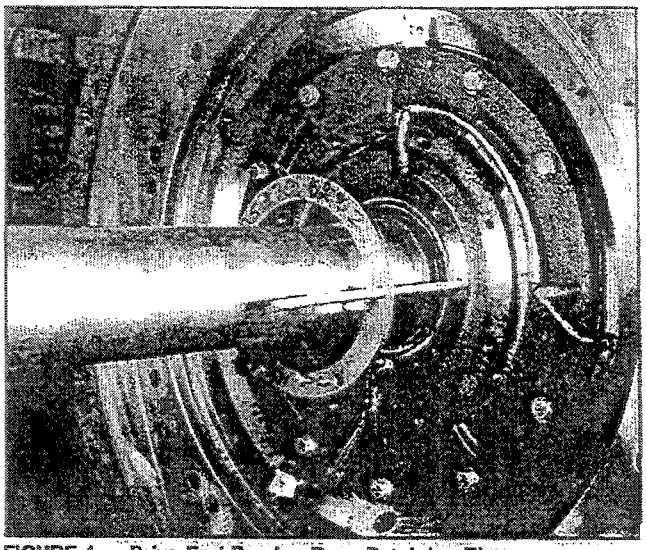

FIGURE 4 — Drive End Bearing Race Retaining Ring

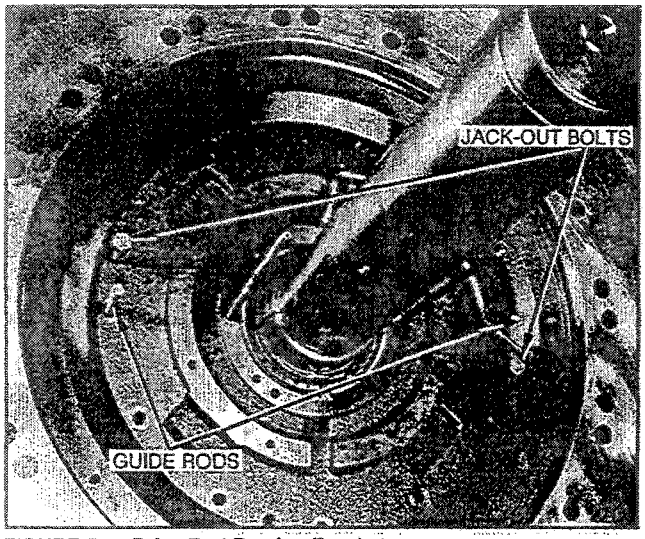

FIGURE 5 — Drive End Bearing Bracket

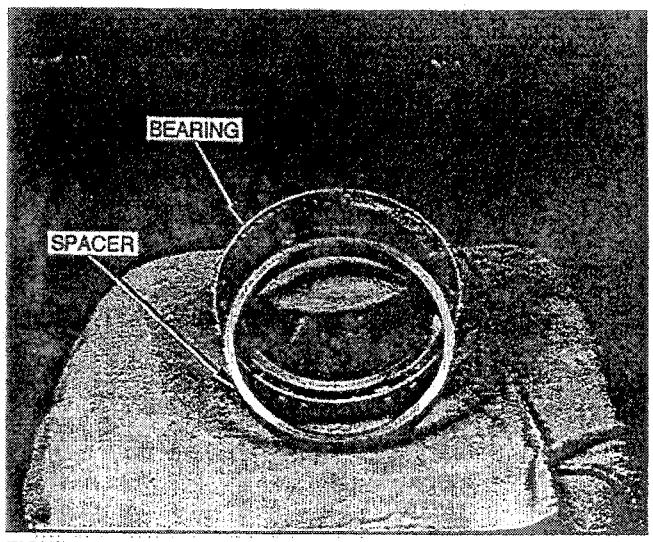

FIGURE 6 — Drive End Bearing and Spacer

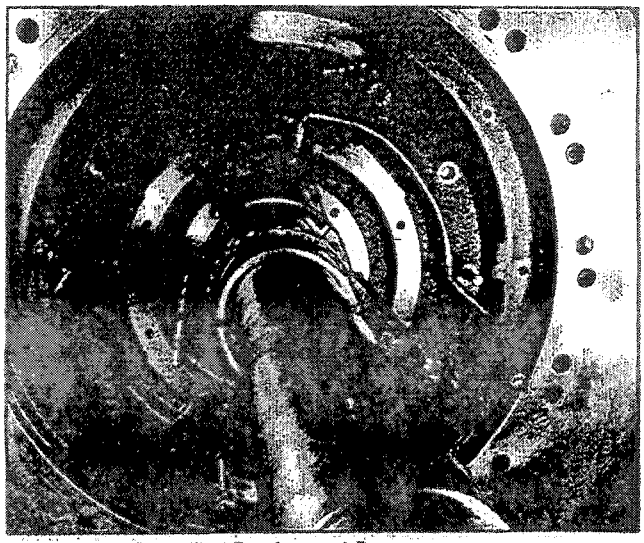

FIGURE 7 — Drive End Bearing and Spacer

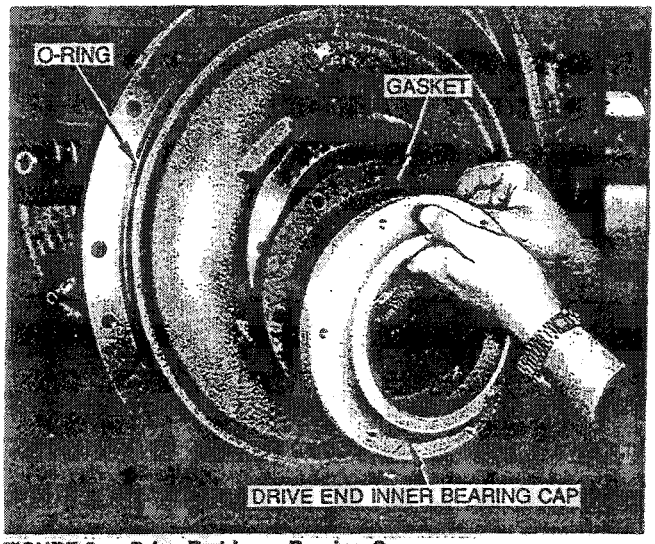
e. Attach an overhead lifting rig to the bearing bracket. Attach with a clevis pin to the bracket and remove slowly from the shaft. Remove the O-ring and bearing cap. The rotor will rest on the stator. Figure 8 illustrates the bracket and bearing cap with gasket.

f. Protect the rotor shaft to prevent damage while the bearing bracket is removed.

g. Remove the outer bearing race by carefully prying it from the bearing bracket. This is not a pressed fit, however, care must be taken so as not to damage the race. Replace the bearing if the race is damaged. Figures 9 and 10 illustrate the bearing parts.

h. Remove the inner bearing cap and gasket from the shaft.



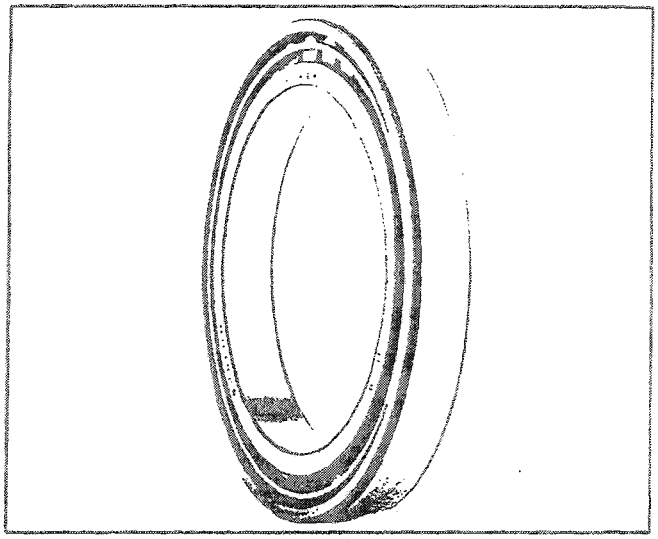


FIGURE 8 — Drive End Inner Bearing Cap

FIGURE 9 — Assembled Drive End Bearing

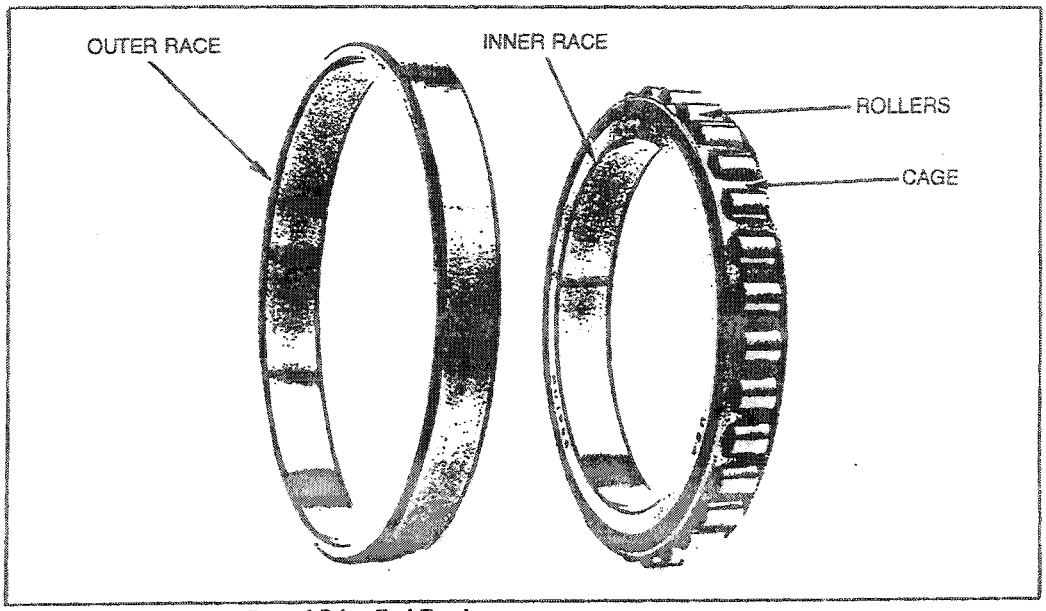

FIGURE 10 — Exploded View of Drive End Bearing

5. Using a tubing cutter, cut the oil supply and drain lines on the opposite drive end of the motor. Before cutting the lines, sand all paint from the area where the cut is to be made. This will allow brazing the lines together during reassembly. Be sure to sand the paint off before making the cut to prevent the entry of dust into the oil lines. Cover the open pipe ends to prevent the entry of dirt, debris and moisture. Refer to Figure 11.
6. Remove the bearing cover with the sight glass. See Figure 12.
7. Release the bearing cap by removing the outer diameter bolts. See Figure 13.
8. Remove the bearing race retaining ring bolts (inner diameter) and remove the retaining ring. Refer to Figure 14.
9. Remove the opposite drive end bearing bracket. Refer to Figures 15, 16, 17 and the following procedure:
   a. Before the opposite drive end bearing bracket retaining bolts are loosened and the bracket removed, its position must be precisely located so that when the motor is reassembled the bearing bracket is returned to its original position. This is accomplished by drilling two ¼-inch holes in the circumference of the bracket and motor flanges. This allows the installation of ¼-inch roll pins during reassembly which precisely locates the bearing bracket in its original position. Drill the ¼-inch holes in the circumference of the flange bolts as shown in Figure 15. The holes are drilled in the seven o'clock and one o'clock positions. Do not drill any holes in the motor terminal box area. Drill the holes all the way through the bracket and motor flanges. When the roll pin holes have been drilled, proceed with Step b.
   b. Remove two bolts, 180 degrees apart on the horizontal centerline and insert two guide rods approximately 6 inches long.
   c. Remove the remaining bearing bracket bolts.

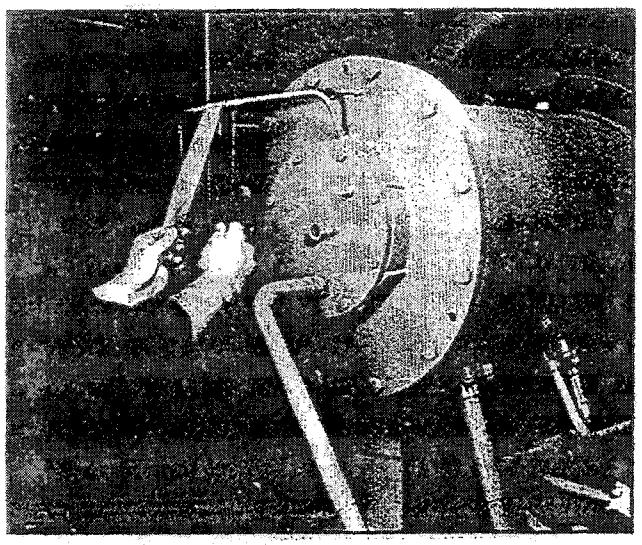

FIGURE 11 — Removing Paint from Oil Supply Line at Opposite Drive End Bearing

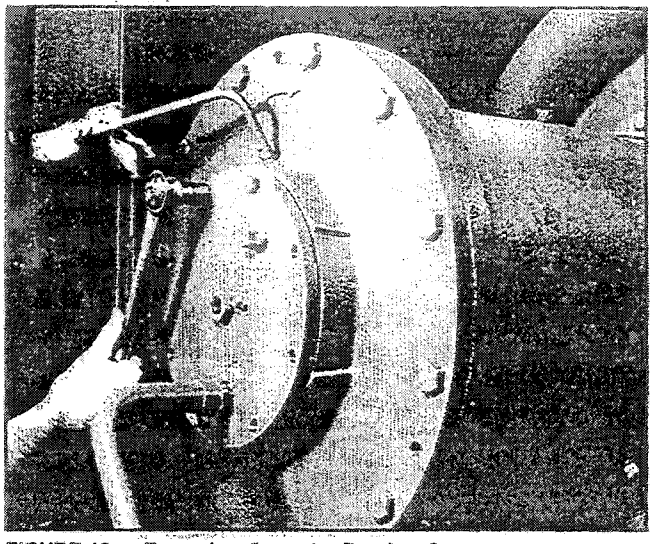

FIGURE 12 — Removing Opposite Bearing Cover

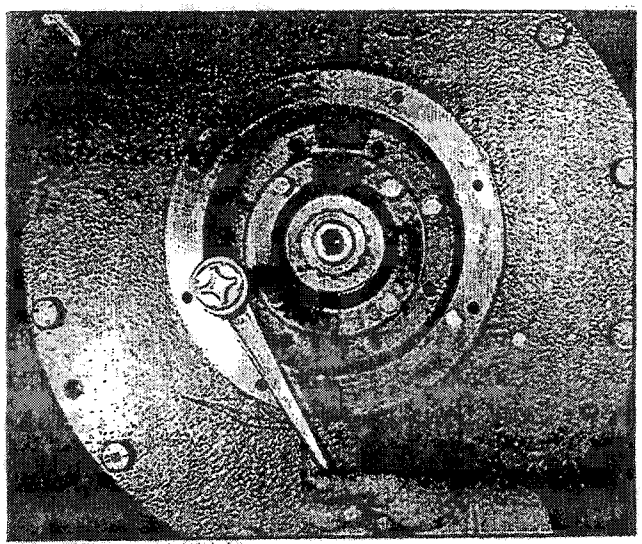

FIGURE 13 — Removing Inside Bearing Cap

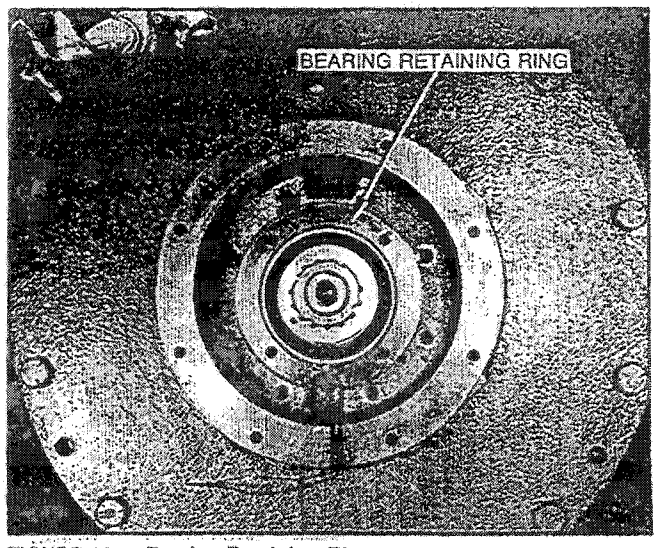

FIGURE 14 — Bearing Retaining Ring

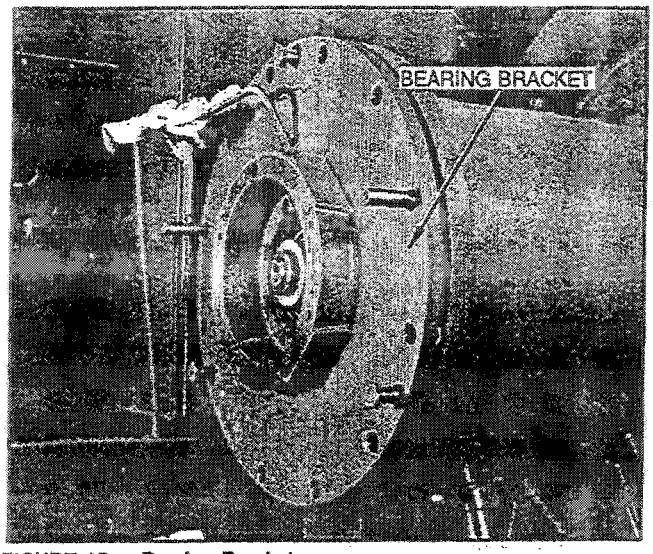

FIGURE 15 — Bearing Bracket

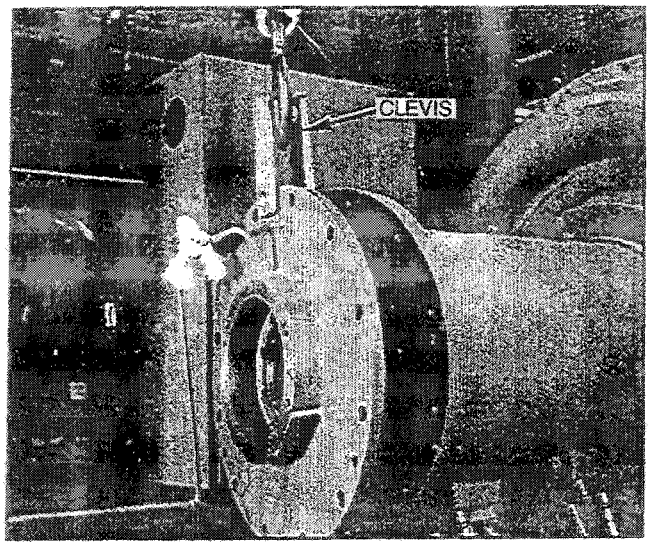

FIGURE 16 — Bearing Bracket Removal

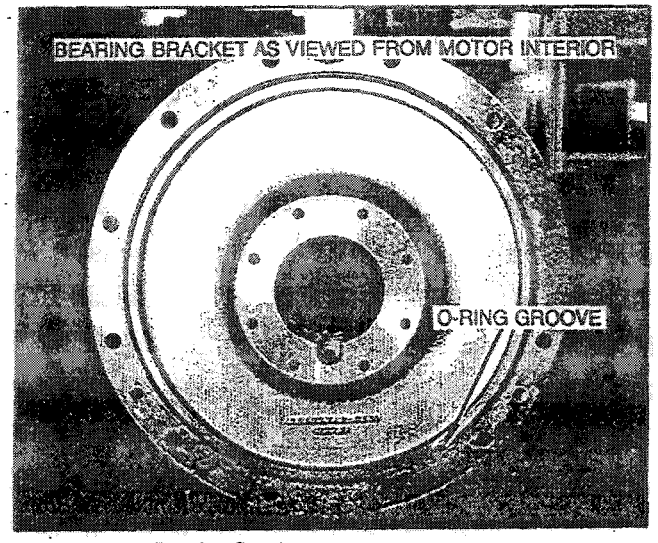

FIGURE 17 — Bearing Bracket

d. Insert three bolts in the jack-out holes to pull the bearing bracket evenly away from the motor.

e. Move the bracket out far enough so that a clevis can be attached. Support and remove the bracket from the motor.

10. Remove the thrust bearing shaft locknut. See Figures 18 and 19. Bend the lockwasher tab back, then loosen the locknut with a spanner and unscrew from the shaft. The threads are right-hand.

11. Remove the spacer — this is not a keyed or press fit. See Figure 18, page 8.5-6.

12. Remove the front end thrust bearing using a puller. The following combination of tools may be used for pulling the thrust bearing:
Owatonna Tool Company, Inc.
Model PP30 manual bearing pull (PPH30 Hydraulic)
Model AP13 jaws
Model KSP150 shaft protector adaptor

Attach the puller with bevelled edge of the jaws against the backside of the inner thrust bearing cone. See Figures 20, 21 and 22.

CAUTION: (1) Do not put the straight side of the puller jaws against the bearing – this will score the motor shaft. (2) Do not attempt to pull the thrust bearing assembly from the shaft by pulling on the rollers, roller cage assembly, or the tapered cup. This will result in bearing or shaft damage. (3) Examine the puller carefully during removal to insure that the puller is lined up squarely with the motor shaft. Failure to do so may result in injury to personnel and damage to the puller, bearing or shaft. (4) Always use shaft protector insert on the end of the puller as a bearing surface to avoid damage to the motor shaft. (5) Never attempt to heat the bearings while installed on the motor shaft as an aid to removal. Machine damage may result.

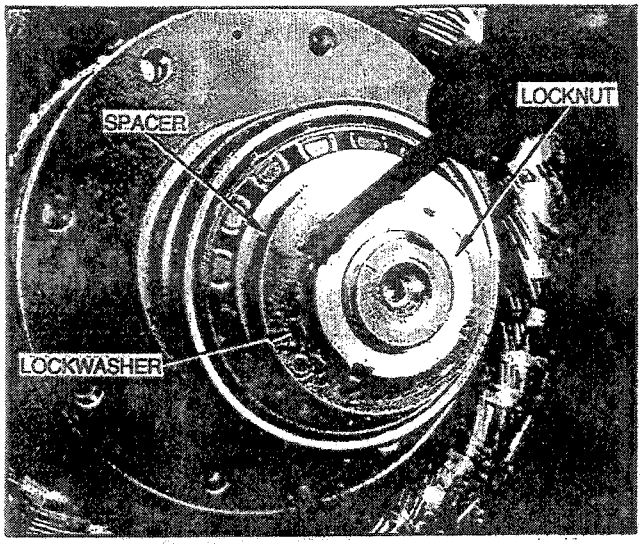

FIGURE 18 — Thrust Bearing Locknut

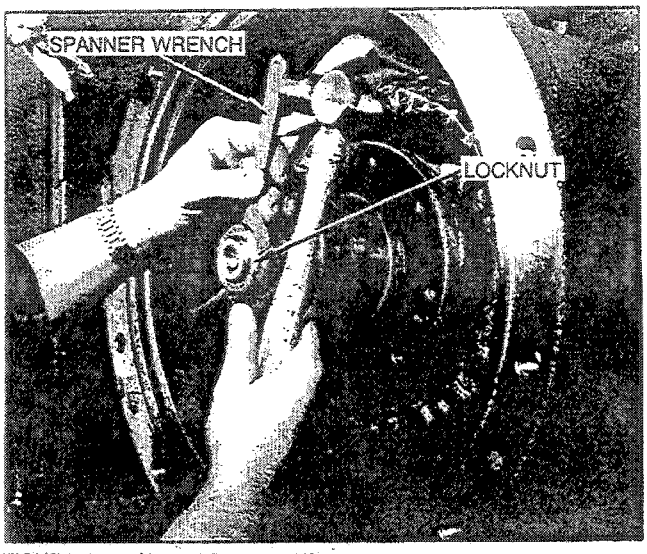

FIGURE 19 — Use of Spanner Wrench

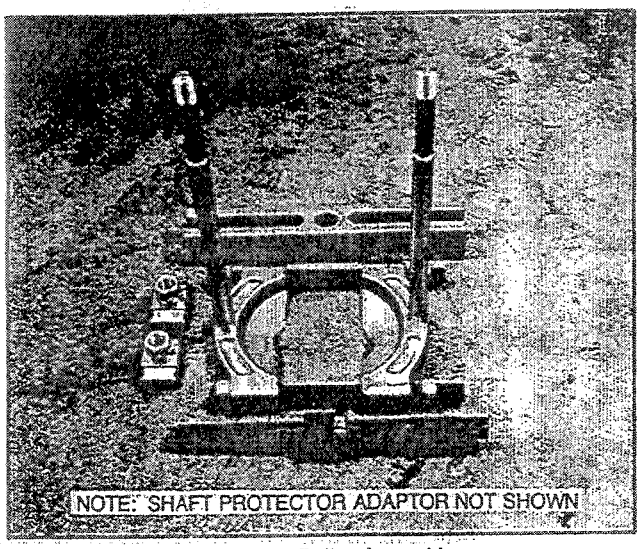

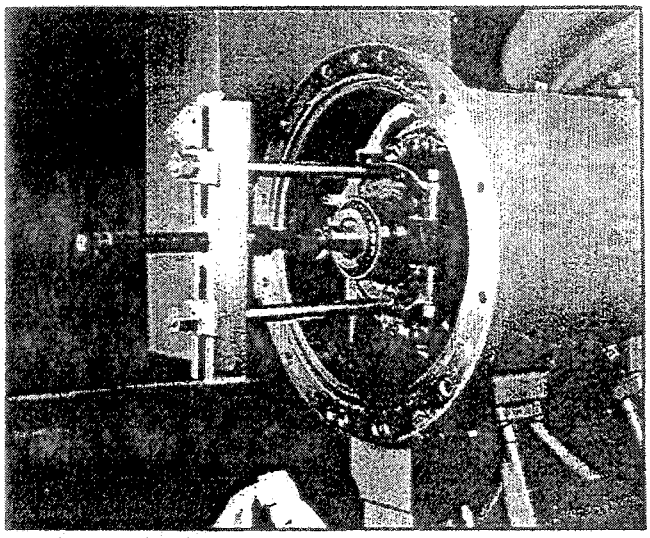

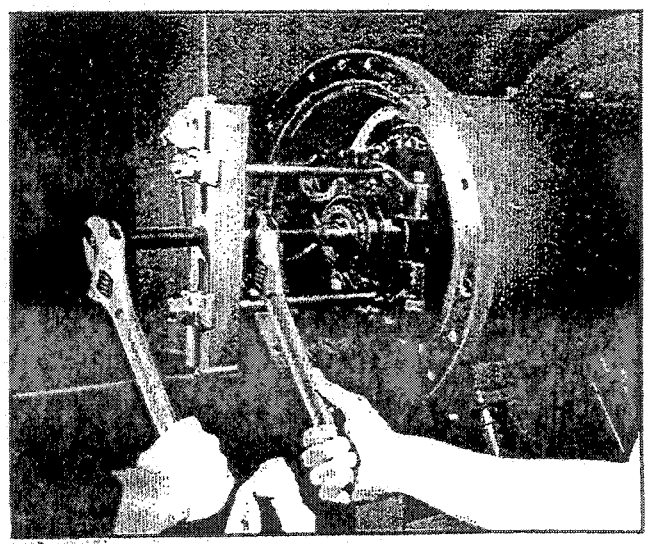

FIGURE 20 — Manual Bearing Puller Assembly

FIGURE 21 — Puller Assembly in Place

FIGURE 22 — Pulling Bearing Assembly

13. Insure that the puller assembly is lined up squarely on the motor shaft while removing the bearings. This should be checked several times. Cover the puller shaft with rags to prevent bearing damage when the bearing cones pull free of the motor shaft. Continue pulling the bearing off the shaft until the outer bearing assembly is free. The bearing will "pop" off the shaft. Place the bearing and roller assembly on the protected portion of the puller shaft. See Figure 23. Continue pulling the inner bearing and roller assembly off the shaft. It will also "pop" off the shaft when free. Remove the puller from the shaft.

CAUTION: WHEN THE INNER BEARING AND ROLLER ASSEMBLY PULL FREE FROM THE SHAFT, THE PULLER WILL FALL. HAVE PERSONNEL READY TO SUPPORT THE PULLER AND BEARINGS TO AVOID DAMAGE TO THE SHAFT AND BEARINGS.

14. Remove the inner bearing cap and gasket from the motor shaft. Notice the position of the oil drain hole at the bottom of the bearing cap. See Figures 24 and 25.

15. Use the following procedure and Figure 26 to remove the rotor assembly.

    a. Protect the rotor shaft while removing the assembly. Cover the shaft with brass pipe or other suitable material to prevent damage during removal.

    b. Place a sling around the pipe as near to the rotor as possible. See Figure 26.

    c. Raise the chain hoist to support the full weight of the rotor and withdraw the rotor from the stator. Withdraw the rotor from the drive end of the motor.

CAUTION: USE EXTREME CARE WHEN REMOVING THE ROTOR TO NOT STRIKE OR DAMAGE THE MOTOR WINDINGS IN ANY WAY.

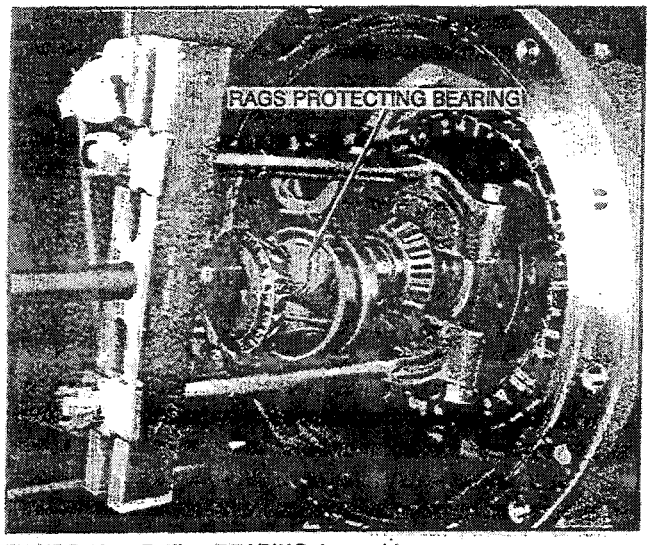

FIGURE 23 — Pulling BEARING Assembly

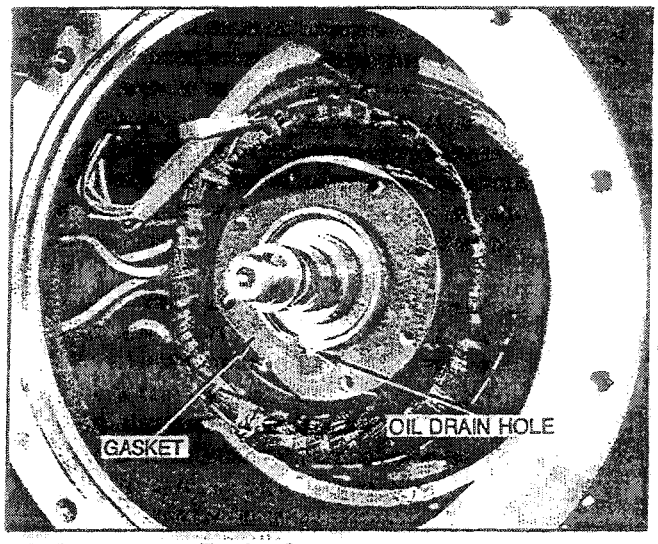

FIGURE 24 — Inner Bearing Cap

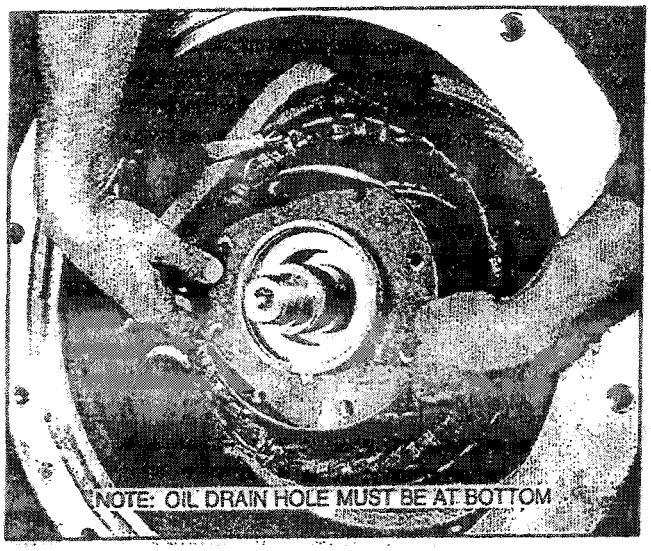

FIGURE 25 — Removing Bearing Cap

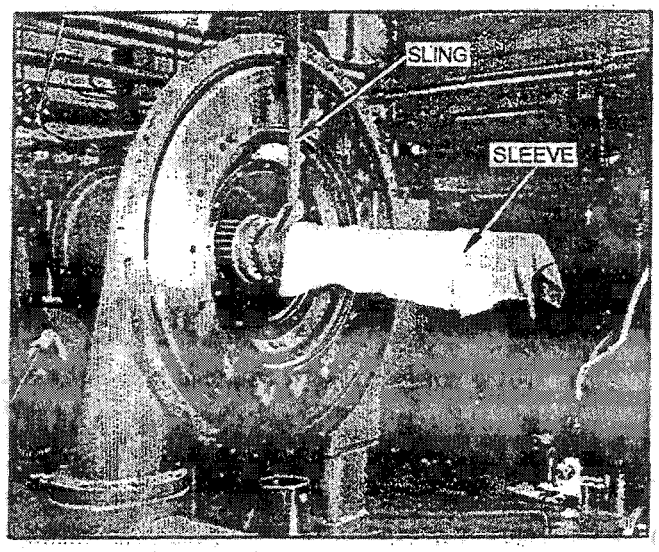

FIGURE 26 — Removing Rotor

MAIN TERMINAL BOARD DISASSEMBLY

This portion describes the disassembly of the main terminal board. Refer to Figure 27 which is a cutaway view of the terminal board when disassembling.

1. Disconnect all electrical power to the unit before proceeding. Verify that there is no power applied by checking with a voltmeter.

   WARNING: BEFORE WORKING ON THIS OR ANY ELECTRICAL EQUIPMENT, ALWAYS DISCONNECT ALL ELECTRICAL POWER. FAILURE TO DO SO MAY RESULT IN SERIOUS PERSONAL INJURY OR DEATH FROM ELECTRIC SHOCK.

2. Remove all refrigerant from the chiller and then evacuate the chiller to 5mm Hg. Then, pressurize the chiller to 0 psig using dry nitrogen.

   WARNING: USE ONLY DRY NITROGEN TO PRESSURIZE THE CHILLER. THE USE OF OXYGEN OR ACETYLENE MAY CAUSE A VIOLENT EXPLOSION RESULTING IN SERIOUS PERSONAL INJURY OR DEATH.

   NOTE: If the chiller is equipped with a factory mounted starter, remove the starter. This must be accomplished before work may proceed.

3. Disconnect the power leads at the motor terminals.

   NOTE: It is necessary to completely remove the conduit box or the factory mounted starter, depending upon the chiller. Also, mark the motor power leads to insure that the motor is wired properly upon reassembly.

4. Loosen and remove all hex head brass jam nuts and spring washers from the terminals. See Figures 28, 29 and 30.

5. Loosen the terminals from the terminal board either by hand or by using a wood mallet to tap the terminals and break the O-ring seal. See Figure 31.

6. Loosen and remove all terminal board bolts. Refer to Figure 32.

7. Remove the terminal board and gasket by slipping it over the studs.

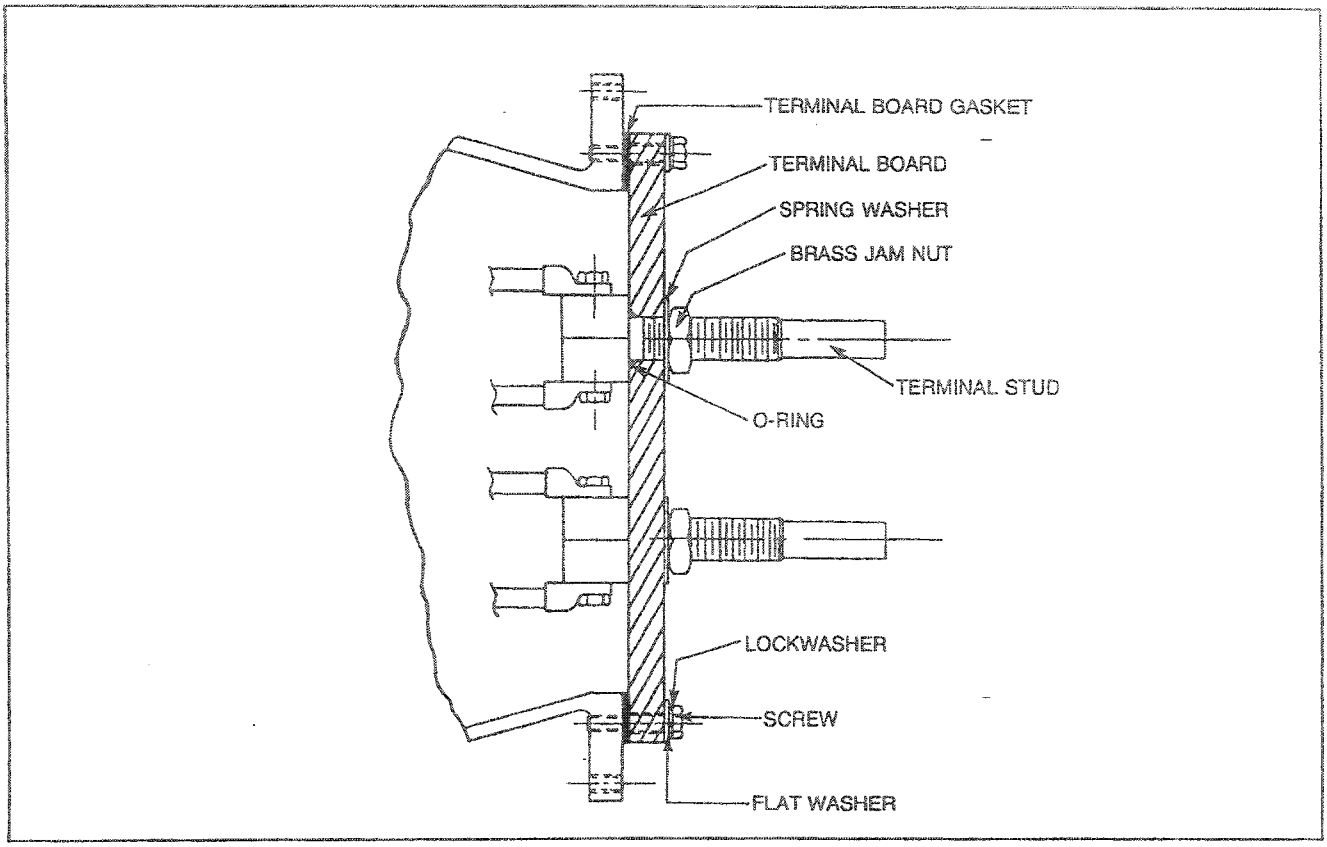

FIGURE 27 — Main Terminal Board Assembly

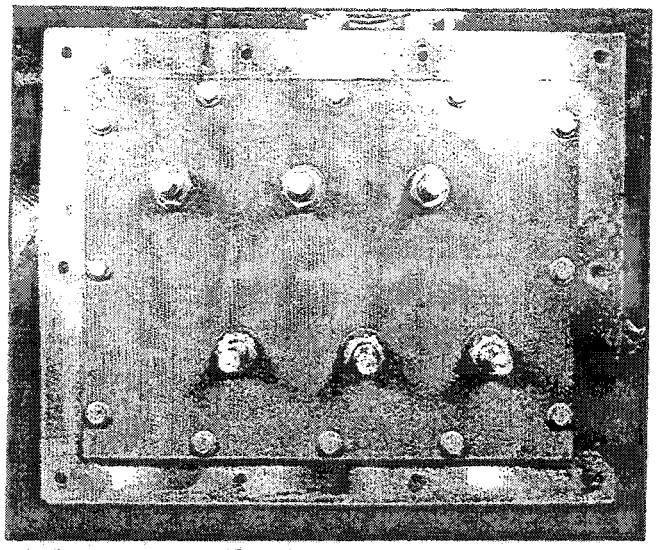

FIGURE 28 — Terminal Board

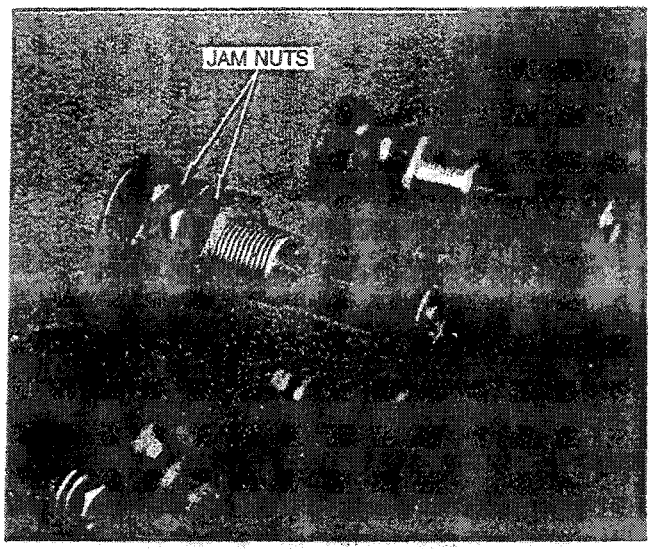

FIGURE 29 — Terminal Stud

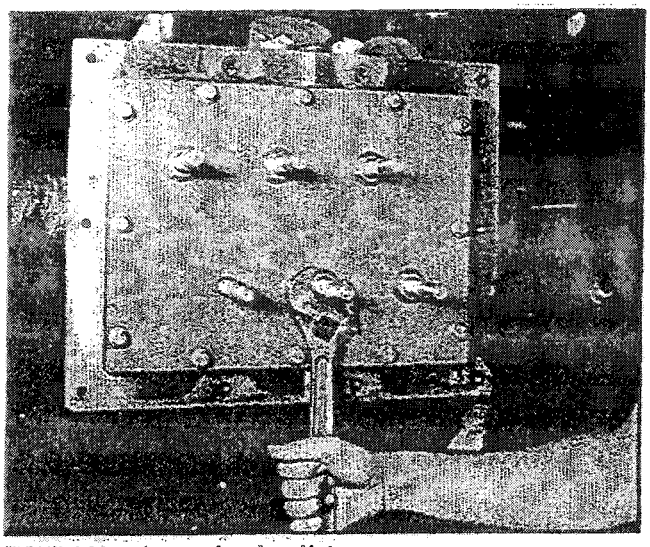

FIGURE 30 — Loosening Jam Nuts

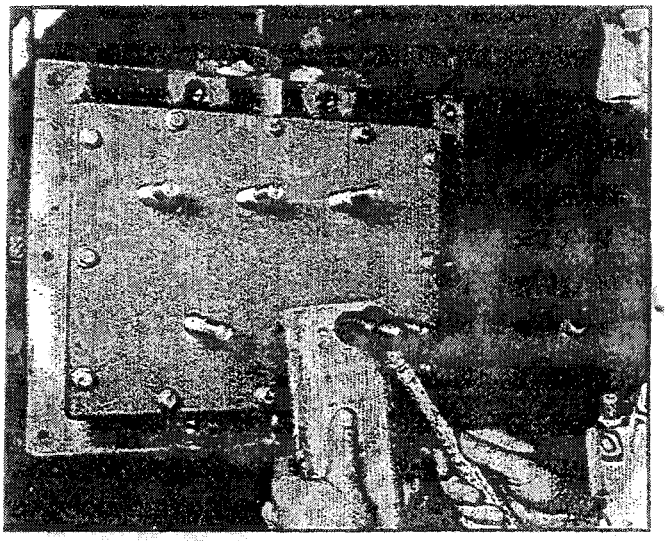

FIGURE 31 — Pushing Studs Through Terminal Board

FIGURE 32 — Removing Terminal Board Retaining Bolts

Terminal Stud Removal

With the entire terminal board removed from the chiller, loosen and remove the brass bolts securing the motor leads to the terminal. See Figures 33 and 34.

NOTE: Although all terminals and motor leads are marked, it is recommended that they be marked again.

R.T.D. (Resistive Temperature Detector) Terminal Board Disassembly

1. Remove the screws securing the conduit box cover. See Figure 35.
2. Disconnect the RTD leads from the stab-on connector.
3. Remove the screws securing the conduit box and remove box. See Figure 36.
4. Remove the four screws securing the temperature detector terminal block. Refer to Figures 37 and 38.
5. Disconnect the motor RTD leads by removing the stab-on connections and remove th terminal O-ring. See Figure 39.

NOTE: Motor-side RTD leads are marked to coincide with the embossed numbers on the terminal. Number 4 terminal is common.

NOTE: The stator assembly of the compressor cannot be removed and no attempt should be made to do so. The stator is welded in place, making field removal inadvisable.

RTD Terminal Board Reassembly

1. Feed the motor RTD lead wires through the hole in the motor barrel.
2. Slip the motor temperature detector terminal board O-rings over the RTD lead wires.
3. Attach the RTD leads to the temperature detector terminals by pressing the stab-on connectors on wires leads on to the terminals. See Figure 39.

   NOTE: All RTD lead wires are marked to coincide with embossed numbers on terminal. Number 4 is common.
4. Place O-ring in groove on temperature detector terminal board. See Figure 39. Coat the O-ring with Loctite 515 "Gasket Eliminator."
5. Secure the motor temperature detector board to the motor barrel with screws and lockwashers. See Figure 37.
6. Install the conduit box with screws and lockwashers. See Figure 36.
7. Reconnect the external RTD leads and conduit.
8. Install the conduit box cover.

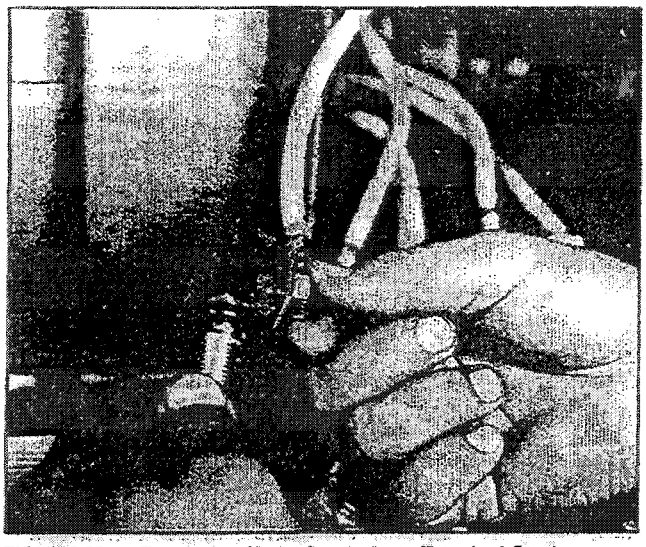

FIGURE 33 — Removing Motor Leads from Terminal Stud

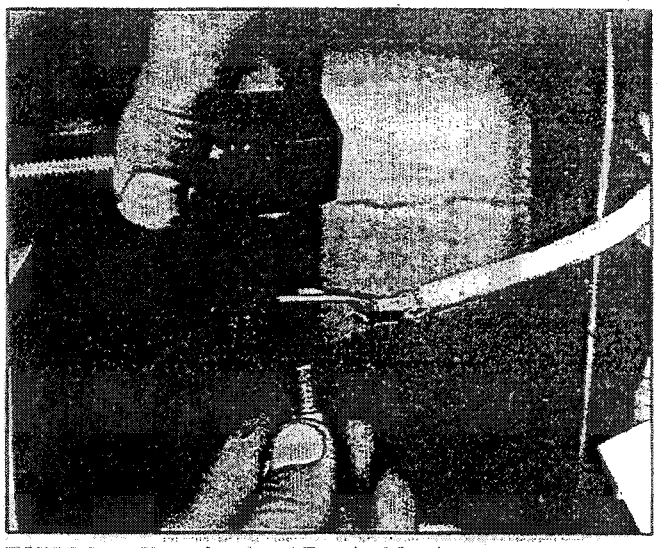

FIGURE 34 — Motor Lead and Terminal Stud

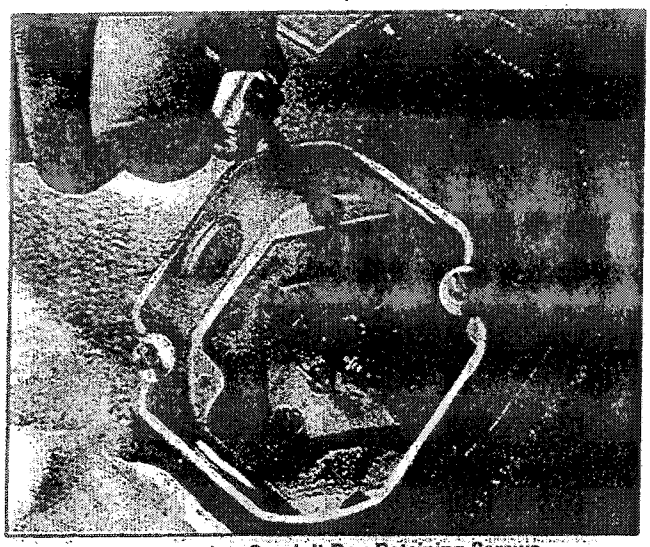

FIGURE 36 — Removing Conduit Box Retaining Screws

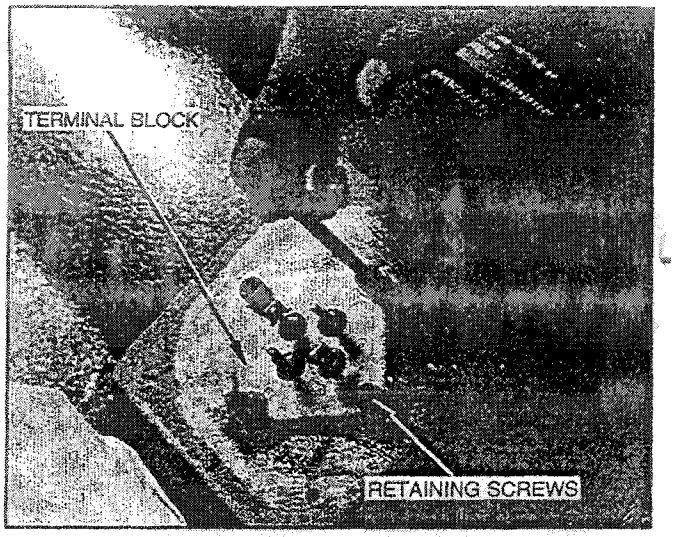

FIGURE 37 — Removing Temperature Detector Terminal Block Retaining Screws

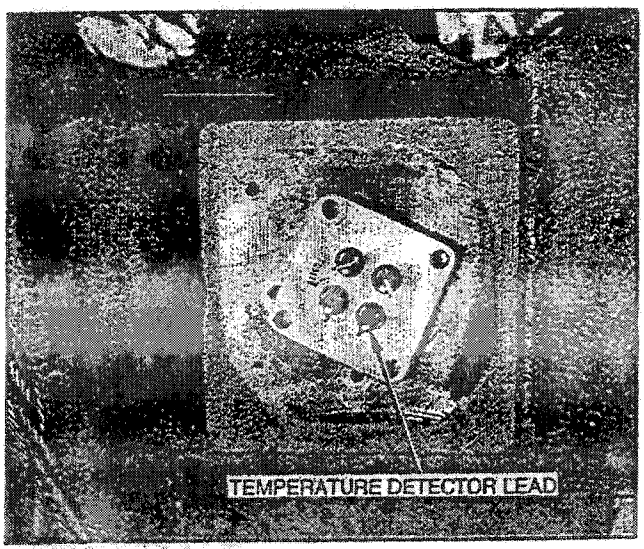

FIGURE 38 — Terminal Block

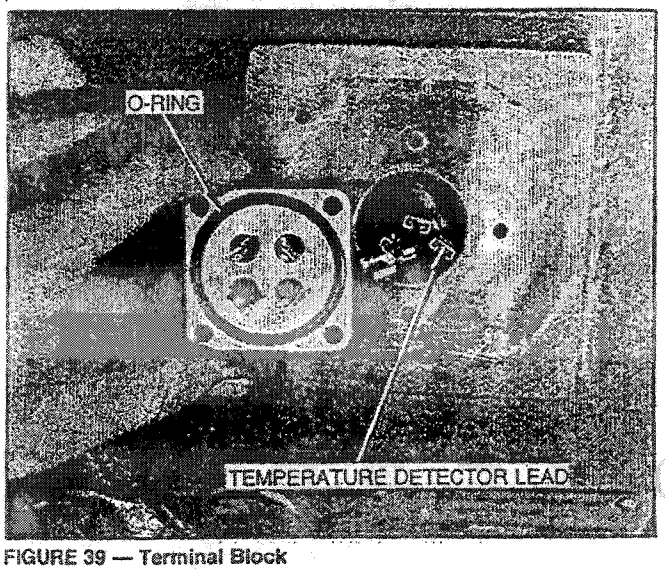

FIGURE 39 — Terminal Block

Main Terminal and Terminal Board Assembly

1. Attach motor leads to terminal studs. If terminal studs are to be reused, each stud has a number on it to coincide with the motor lead. If replacement terminal studs are used, number them appropriately. Motor leads also have an embossed number to coincide with the terminals. See Figure 40. Use brass bolts to attach motor leads to terminal studs. Figure 41 illustrates terminal stud components. Tighten to 10 ft.-lbs.
2. Insert new o-rings over terminal studs and lightly lubricate with Lubriplate.
3. Install the terminal board and a new gasket.
   a. Insert the motor terminals through the holes in the terminal board. The terminal board holes are labelled to coincide with embossed numbers on the terminal studs and motor leads. See Figure 42.
   b. Install spring washers and brass jam nuts over studs. Seat the studs in slot on inside of terminal board to prevent stud rotation, and hand tighten the jam nuts. See Figures 43 and 44.
   c. Position the terminal board gasket — do not lubricate this gasket, the terminal board or the motor casting. THE GASKET AND SEALING SURFACES SHOULD BE CLEAN AND DRY.
   d. Position the terminal board and gasket using the terminal board bolts. Tighten the terminal board bolts to approximately 25 ft.-lbs. torque or until gasket begins to extrude. See Figure 45.
   e. Tighten the brass jam nuts on terminals until the spring washers are completely compressed. See Figure 46.

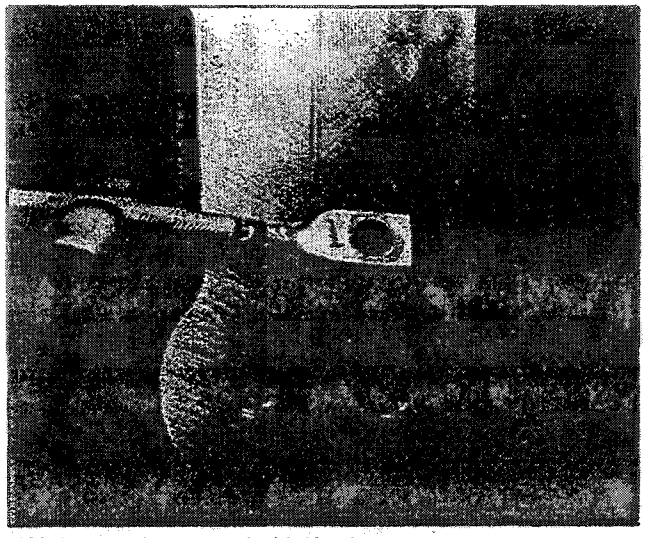

FIGURE 40 — Motor Lead with Number

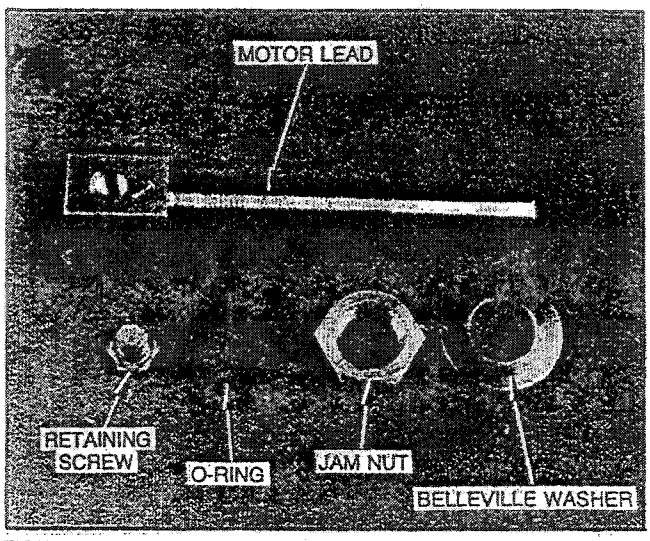

FIGURE 41 — Motor Terminal Stud

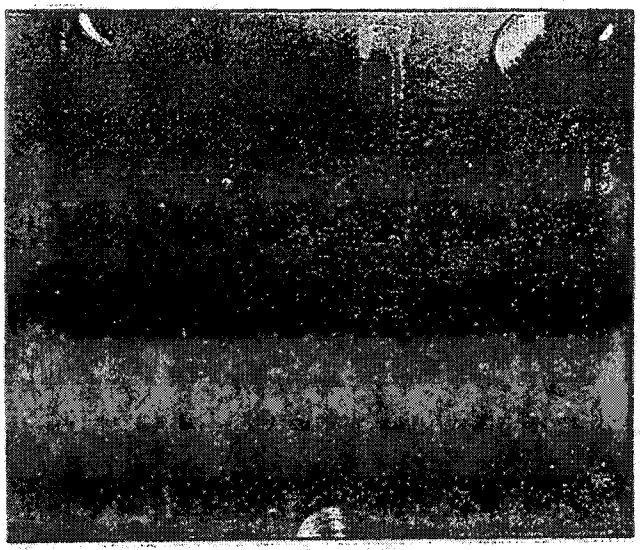

FIGURE 42 — Terminal Board Embossed Numbers

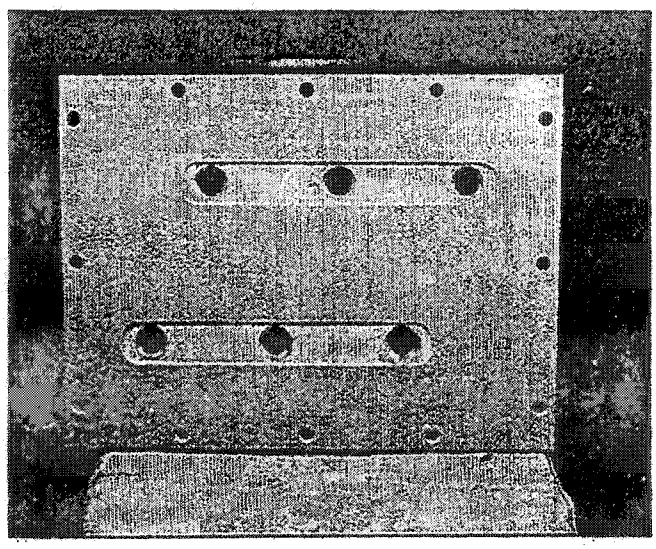

FIGURE 43 — Terminal Board

MOTOR ASSEMBLY

1. Rig and position the rotor in the stator.
   a. Take appropriate precautions to protect the rotor shaft during insertion into the stator. Use a length of brass pipe or similar to cover the rotor shaft.
   b. Put a sling around the pipe near the rotor and lift into position.
   c. Carefully move the rotor into position in the stator. See Figure 47.

      CAUTION: USE EXTREME CARE NOT TO STRIKE THE STATOR WINDINGS WITH THE ROTOR.

   d. Use the protective pipe to balance the rotor as it is moved into the stator. The ends of the laminated steel rotor core must be aligned with the ends of the laminated steel stator core. See Figures 48, 49 and 50.
   e. Lower the rotor assembly to rest on the stator core.
2. Install the opposite drive end inner bearing cap and new gasket on the shaft. Thoroughly clean the seal. See Figures 51, 52, 53 and 54. Inspect the seal grooves for scratches or damage, replace if necessary. (Install seal with oil drain at bottom. Make sure drain is clear.)

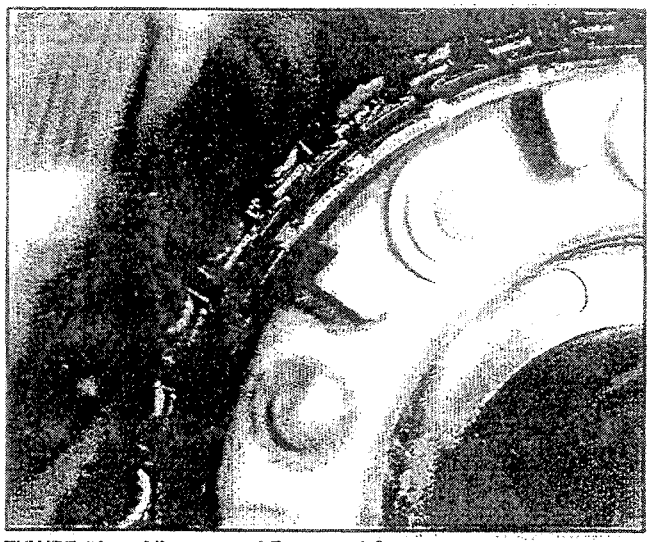

FIGURE 50 — Alignment of Rotor and Stator

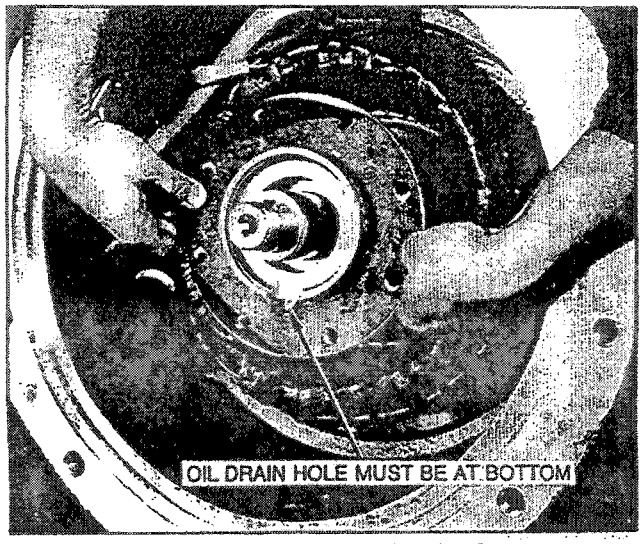

FIGURE 51 — Opposite Drive End Inner Bearing Cap

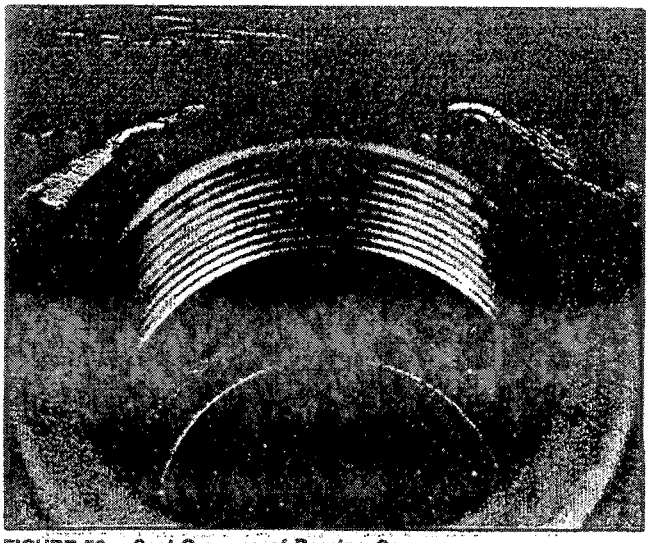

FIGURE 52 —Seal Grooves of Bearing Cap

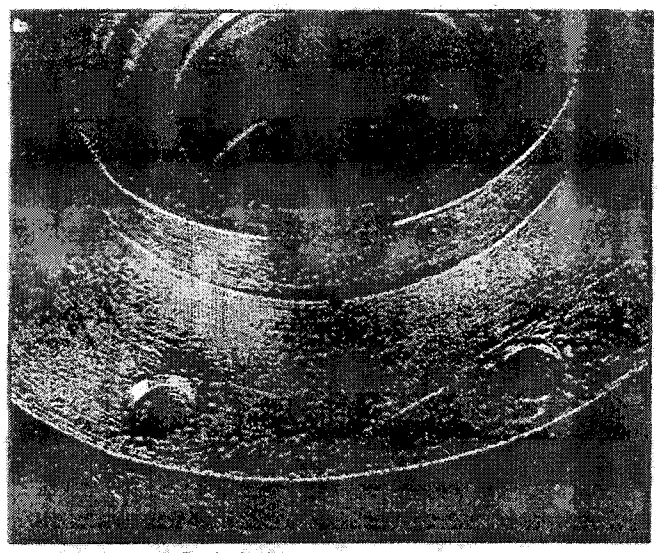

FIGURE 53 — Oil Drain Hole

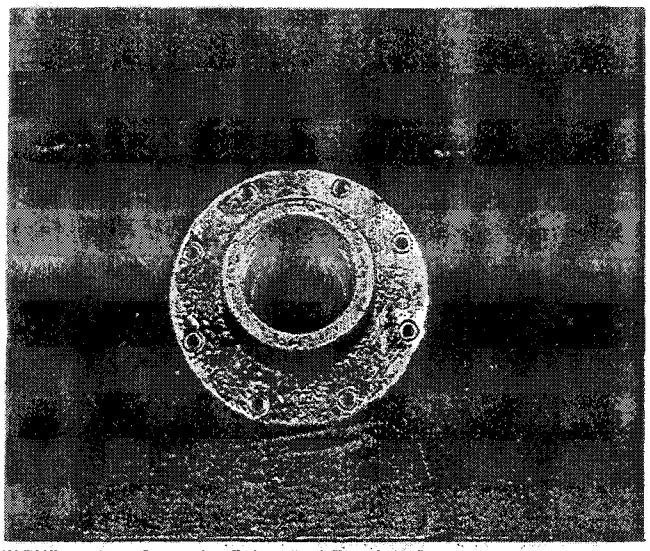

FIGURE 54 — Opposite Drive End Bearing Cap

3. Install the thrust bearing assembly. See Figure 55.

NOTE: The thrust bearing assembly is a matched set. Do not mix parts with another thrust bearing assembly. All mating bearing parts have a serial number inscribed on them to identify the assembly. (See Figures 58 and 59). The thrust bearing can be installed on the shaft in either direction, but it must be assembled properly. For example; one roller assembly will have a matching letter scribed after the serial number. This is to indicate that the bearing must be installed with the lettered roller on the lettered side of the tapered cup. It is recommended that the lettered components face outward from the motor to avoid confusion.

a. Examine the shaft for scratches or burrs and remove with a fine tooth file. See Figures 56 and 57.

NOTE: This is extremely important on the shaft O.D. where the thrust bearing cones are installed. If a scratch is present on the shaft O.D. carefully file it out. Polish it out with crocus cloth and check for high spots with a micrometer. All scratches must be removed or thrust bearing assembly will be extremely difficult.

b. Thoroughly clean the bearing components and shaft using Virginia 10 or an equivalent solvent. Do not use solvent which may leave residue. Remove all oil and debris. Heat the inner bearing assembly to approximately 250-275 F.

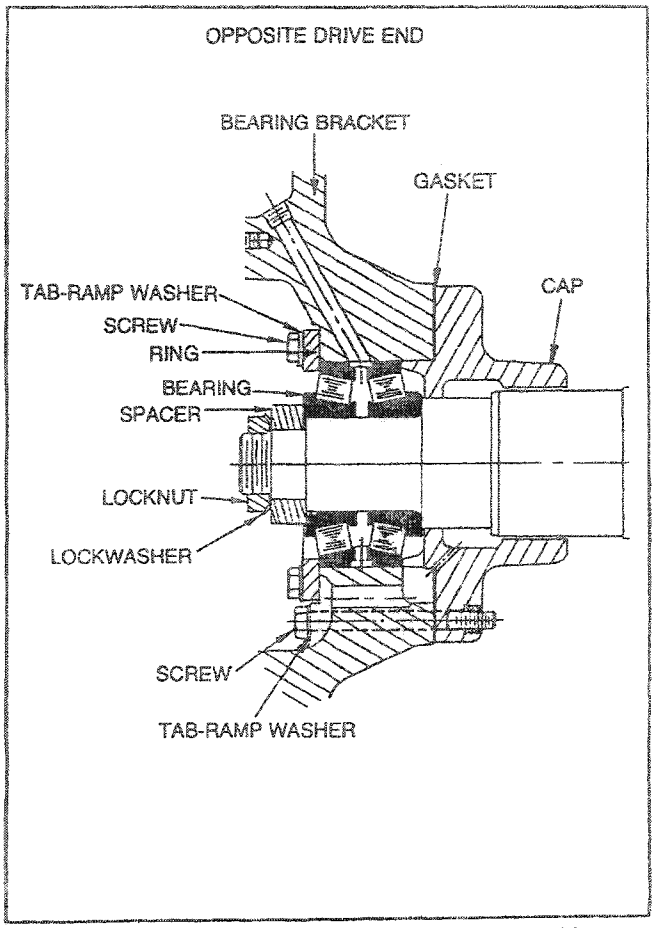

FIGURE 55 — Opposite Drive End Thrust Bearing Assembly Cross-Section

FIGURE 56 — Examining Shaft for Scratches and Burrs

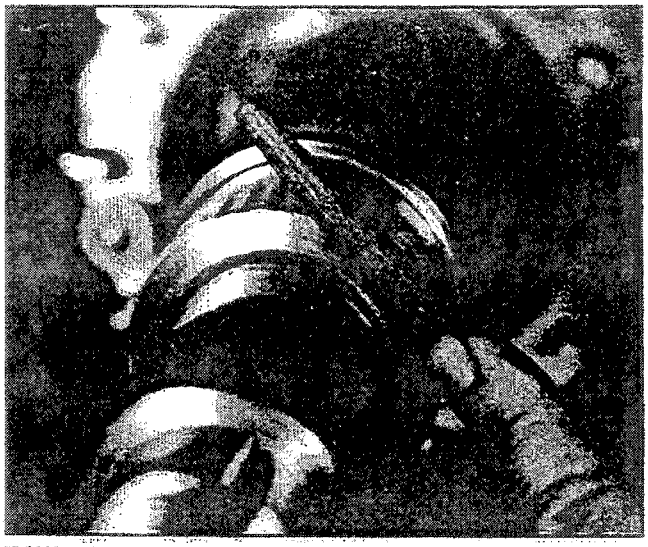

FIGURE 57 — Filing Scratch Out of Shaft

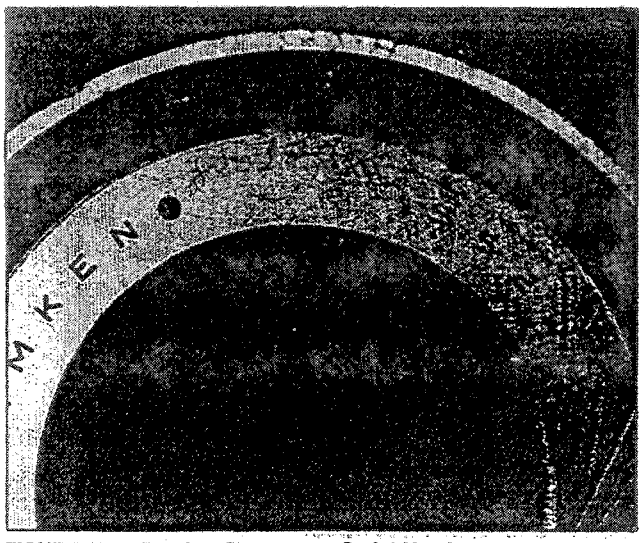

FIGURE 58 — Bearing Component Serial Numbers

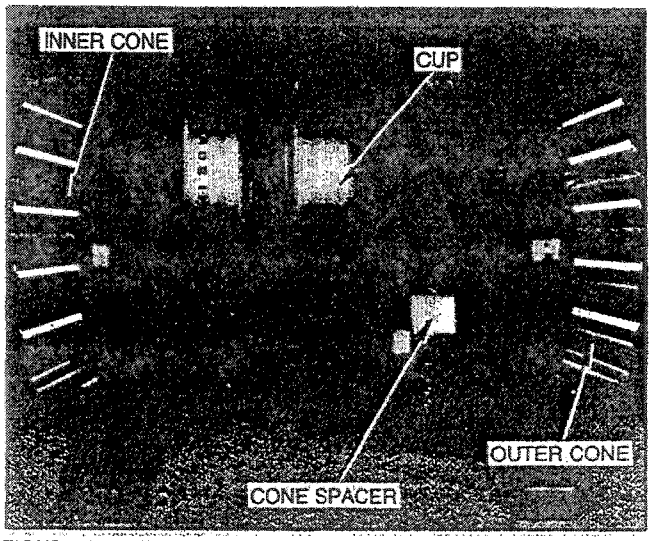

FIGURE 59 — Bearing Components

WARNING: USE WELDER'S GLOVES TO PROTECT THE HANDS AND PREVENT PERSONAL INJURY. HEAT THE BEARINGS DRY, USING A PORTABLE OVEN OR INDUCTION HEATER. DO NOT HEAT THE BEARINGS IN OIL. USE A SURFACE THERMOMETER TO MEASURE THE TEMPERATURE. DO NOT EXCEED 275 F.

c. Install the inner bearing assembly onto the shaft against the shaft shoulder. Hold in place for approximately 30 seconds. See Figure 60.

CAUTION: BEARING ROLLER INSTALLATION MUST BE ACCOMPLISHED QUICKLY BUT CAREFULLY WHILE BEARING IS HOT TO PROPERLY POSITION THE BEARING BEFORE THE BEARING COOLS AND SEIZES ONTO THE SHAFT. IF THE BEARING IS NOT PROPERLY POSITIONED, PULL IT OFF THE SHAFT AND START OVER.

d. After the bearing cools try to insert a 0.002 inch or 0.003 inch feeler gauge between the bearing and shaft shoulder. Figure 61 illustrates this procedure. If a 0.003 inch feeler gauge will fit, the bearing is not properly positioned. Pull it off, and start over.

e. Allow the shaft and inner bearing cone to cool for at least 15 minutes before the outer bearing cone is installed.

f. Install the spacer on the shaft. This is not a shrink fit and does not require heating. The spacer may be installed in either direction. See Figures 62 and 63.

g. Install the tapered cup. Double check for proper match marks with the outer bearing cone. See Figure 64.

h. Heat (as before) and install the outer bearing cone. Insert the bearing cone squarely on the shaft to prevent binding and seizure on the shaft. One person must hold and rotate the cup while another positions the hot bearing cone on the shaft. Push the roller assembly firmly against the cup until it cools while rotating the double cup. See Figure 65.

4. While the assembly is still warm, use a machined piece of pipe (see enclosed figures) to tap the outer bearing cone onto the shaft. See Figures 66. Figure 67 provides dimensions and construction of the pipe. If this is not done, excessive end float and resultant machine vibration will occur.

5. Insert a stiff wire into one of the oil inlet holes of the tapered cup and while observing through another oil inlet hole with a light, try to turn the inner spacer. See Figure 68. If the spacer rotates, the motor shaft will have too much end float and will vibrate. Using the machined pipe and hammer, tap the outer bearing and move it farther onto the shaft to take up the end float. Recheck the spacer for movement as previously described while the bearing is cooling.

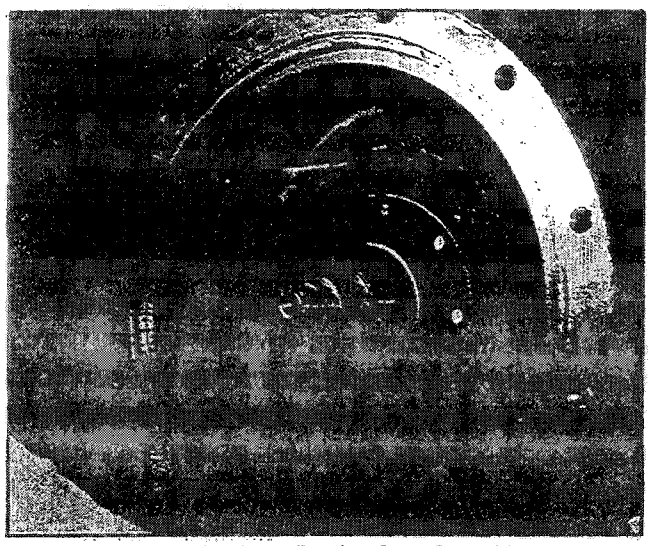

FIGURE 60 — Installing Inner Bearing Cone Assembly

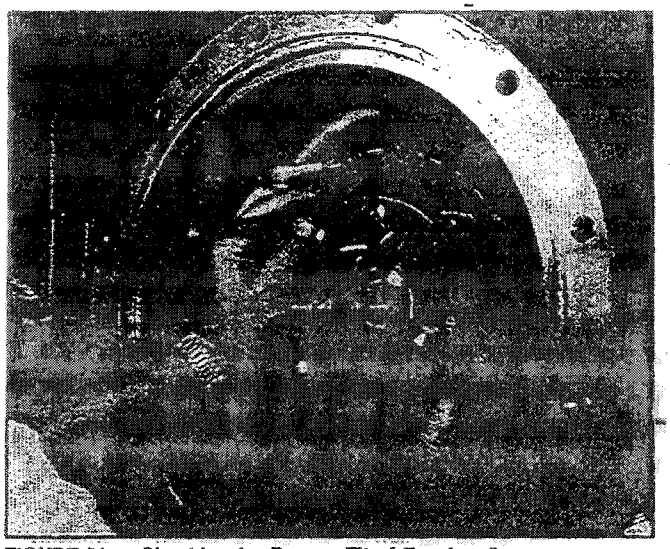

FIGURE 61 — Checking for Proper Fit of Bearing Cone

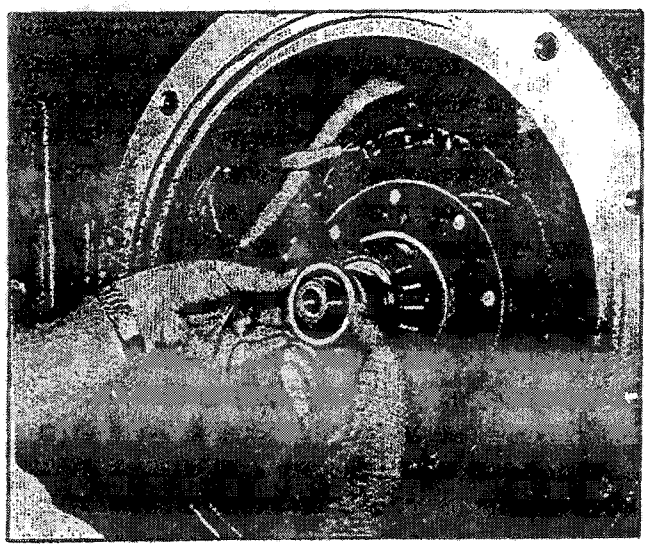

FIGURE 62 — Installing Bearing Cone Spacer

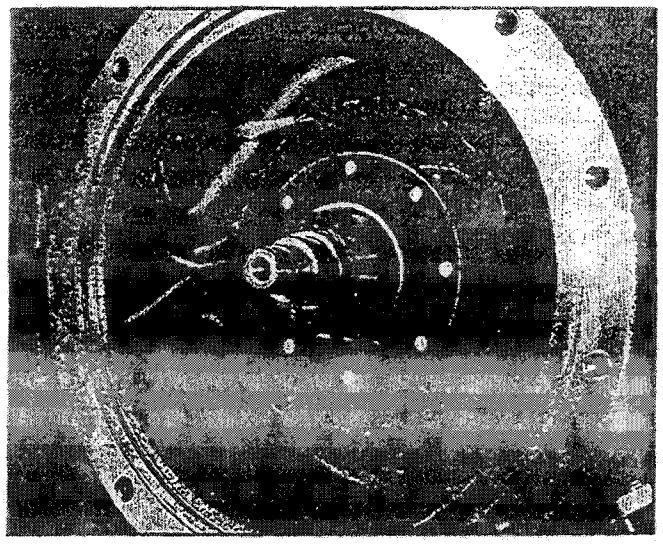

FIGURE 63 — Cone Spacer Installed

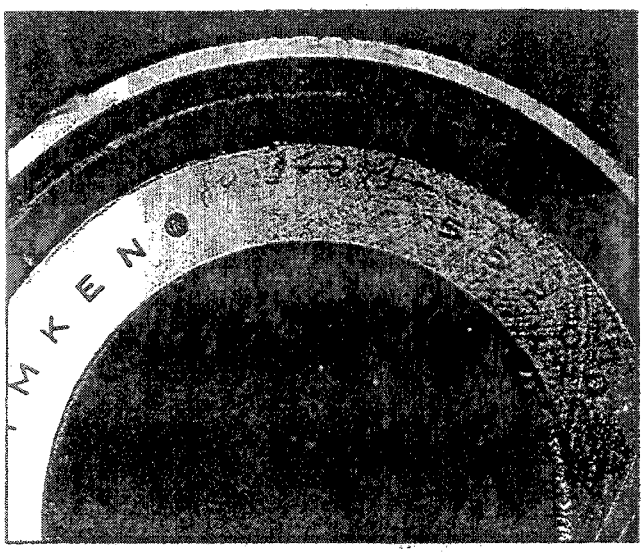

FIGURE 64 — Outer Bearing Cone Assembly

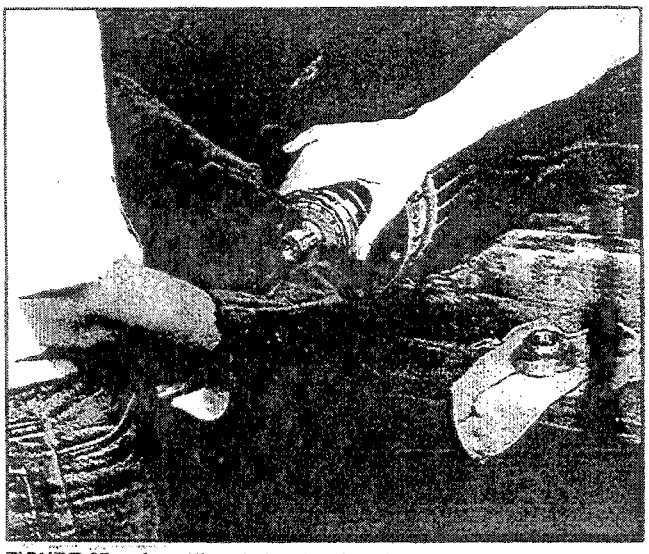

FIGURE 65 — Installing Outer Bearing Cone

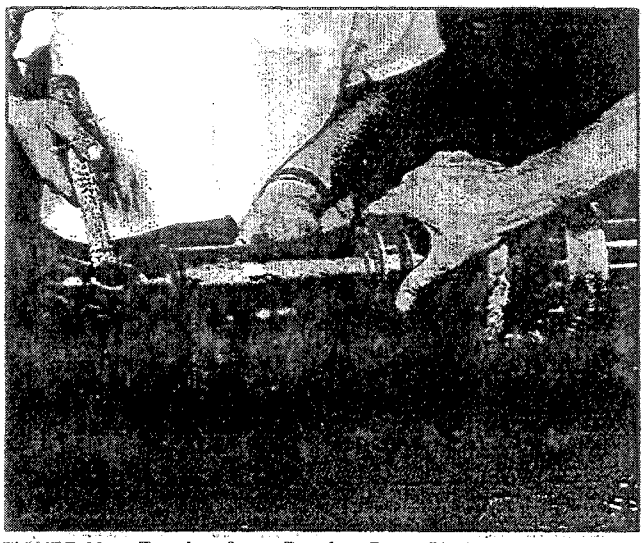

FIGURE 66 — Tapping Outer Bearing On to Shaft

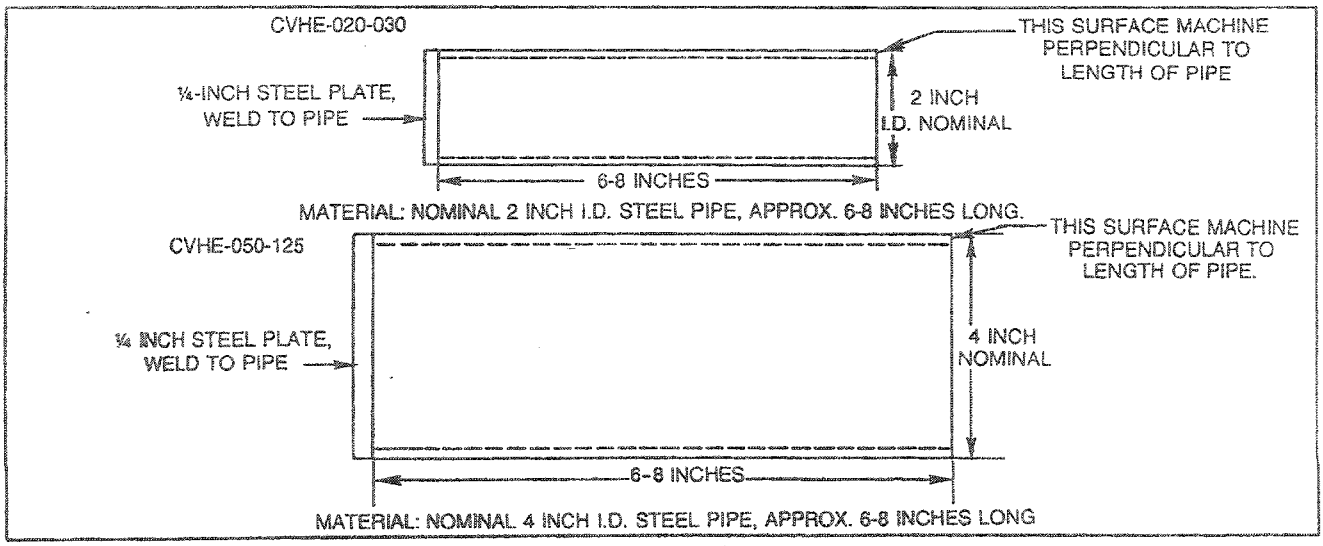

FIGURE 67 — Machined Pipe Dimensions

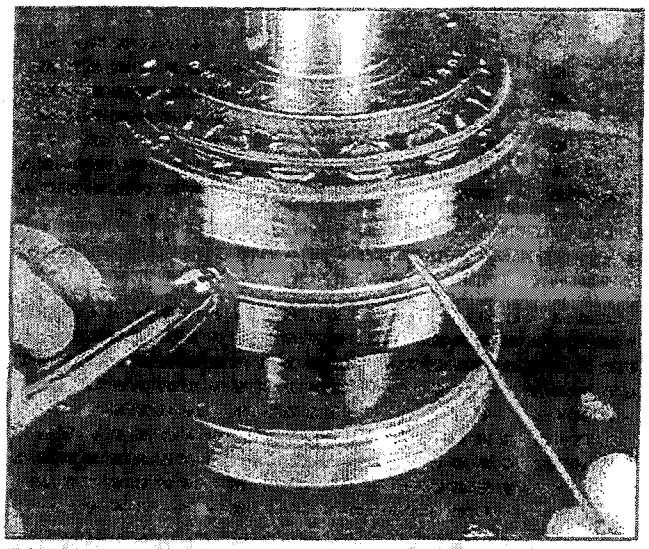

FIGURE 68 — Checking for Cone Spacer Rotation

6. Install the spacer, lockwasher and locknut on the shaft. See Figure 69. The lockwasher has a tab that fits into the keyway on the motor shaft. Tighten the locknut to 250 ft.-lbs. torque. Line up one tab of the lockwasher with a slot in the locknut and bend tab over to secure. See Figure 70. Oil the thrust bearing thoroughly using compressor oil.
7. Install two 6 inch or 8 inch guide rods through gasket into two random holes in the inner bearing cap. See Figure 71. The guide rods serve to align the bearing cap with the bearing bracket. Be sure the small oil drain hole in the seal and gasket are on the bottom. See Figure 72.
8. Install the opposite drive end bearing bracket. Use the following procedure.
   a. Thoroughly clean the bearing bracket and o-ring groove.
   b. Coat the bearing bracket and motor flange o-ring grooves with a ¼-inch bead of Loctite 515 "Gasket Eliminator" sealant. Place the new o-ring in the bearing bracket o-ring groove. Lubricate the outside of the bearing cap with the proper compressor oil to ease bearing bracket insertion on the bearing. See Figure 73.
   c. Hoist the bearing bracket into position.
   d. Install two guide rods on the motor barrel to line up the bearing bracket.
   e. Insert the bearing cap guide rods into proper holes in the bearing bracket and slide the bracket into position. Again verify the bearing cap is positioned w/oil drain hole down.
   f. Remove the lifting clevis and push the bracket firmly against the motor barrel. Bolt in position. See Figures 74 and 75.
   g. Loosely bolt the inner bearing seal to the bearing bracket. Do not tighten at this time. Use the bolts with the tab-ramp washers. Use guide rods to line up the seal and inner bearing cap. See Figure 76. Remove when finished. The drive end bearing bracket must be in place before the seal bolts are tightened.

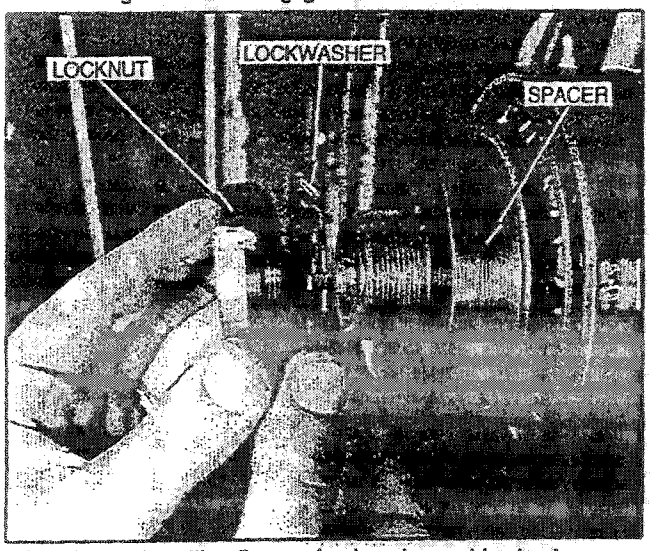

FIGURE 69 — Installing Spacer, Lockwasher and Locknut

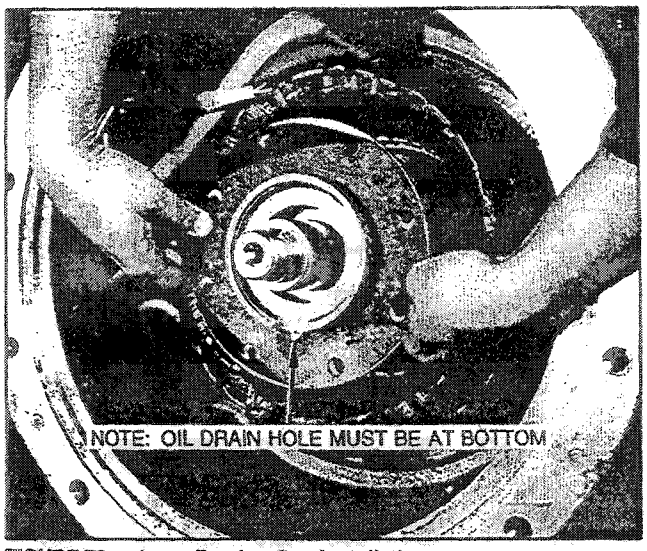

FIGURE 72 — Inner Bearing Cap Installation

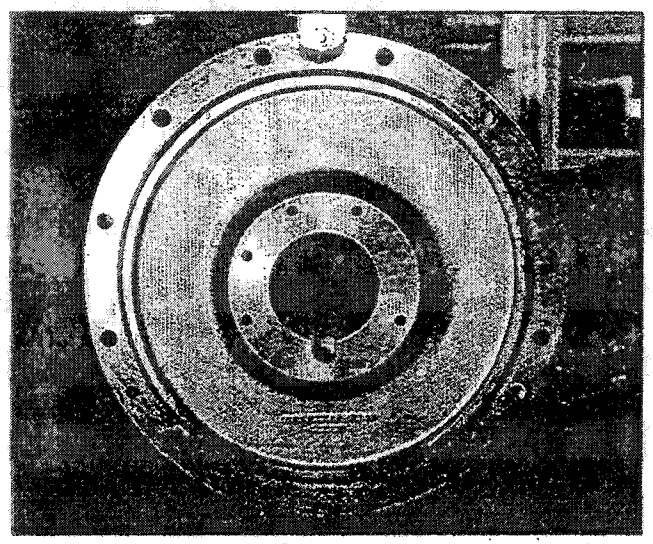

FIGURE 73 — Inner Bearing Cap as Viewed from Motor Interior

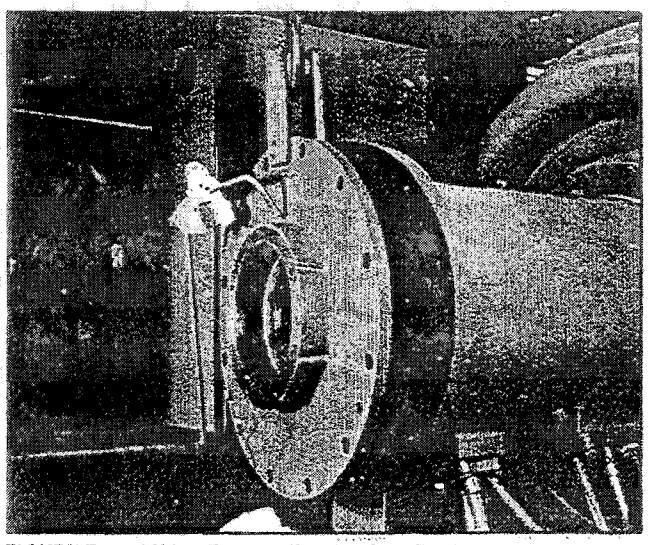

FIGURE 74 — Lifting Bearing Bracket into Position

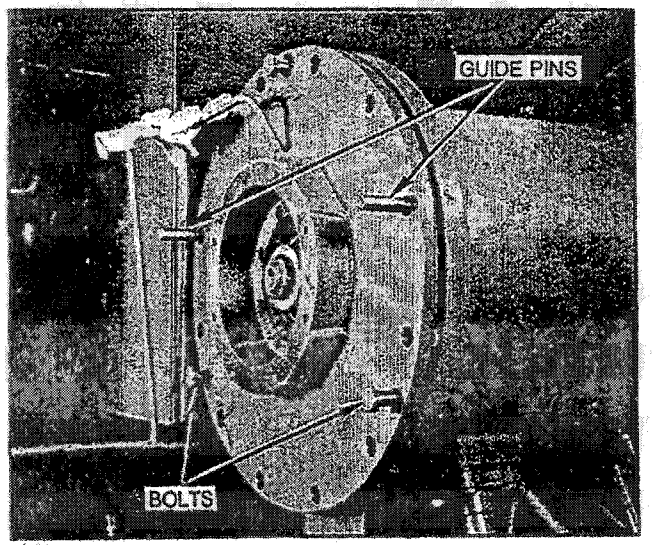

FIGURE 75 — Bearing Bracket in Position

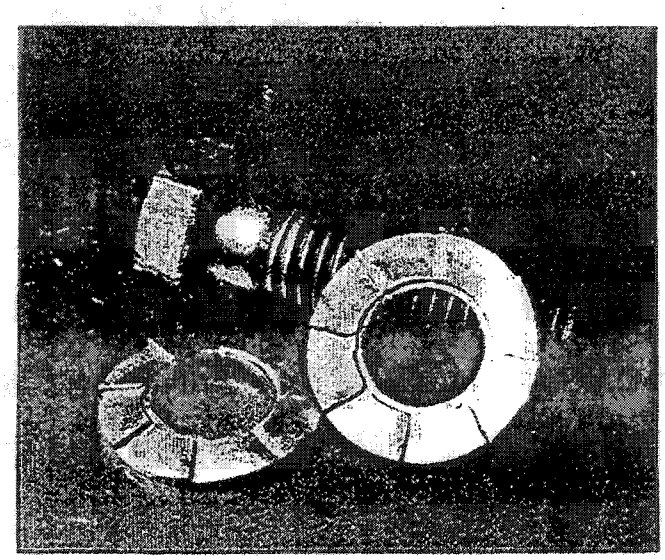

FIGURE 76 — Bolt and Tab-Ramp Washer

9. Place the inner bearing cap over the drive end of the motor shaft. Use the following procedure. See Figure 77.
   a. Clean the drive end seal thoroughly. Replace if worn excessively.
   b. Install two 6 inch or 8 inch guide rods in any two holes in seal.
   c. Install gasket on seal and position on shaft.
10. Install the drive end bearing bracket.
   a. Clean the bracket thoroughly, especially the o-ring groove.
   b. Coat the bearing bracket o-ring groove with a ⅛-inch bead of Loctite 515 "Gasket Eliminator." Place the new o-ring in the bearing bracket groove. Apply a ⅛-inch bead of the same sealant to the mating surface.
   c. Insert two guide rods, 180 degrees apart on the horizontal centerline, into the motor barrel to align the bearing bracket. See Figure 78.
   d. Attach a hoist to bearing bracket with a clevis and lift into position. Align the seal rods and bearing bracket, verify the seal oil drain is on the bottom and move into position. See Figure 79.
   e. Remove the clevis and install the bearing bracket bolts with tab-ramp washers. Tighten the bolts.
   f. Insert two bolts into the inner seal to hold in place and then remove the guide rods. This allows clearance for bearing installation.

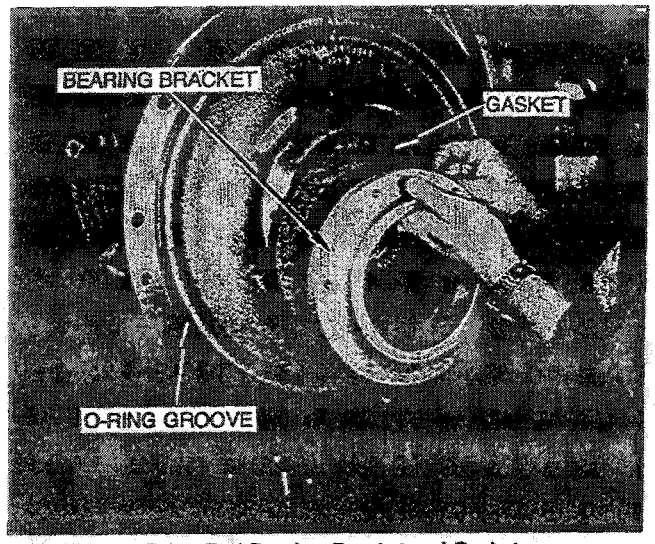

FIGURE 77 — Drive End Bearing Bracket and Gasket

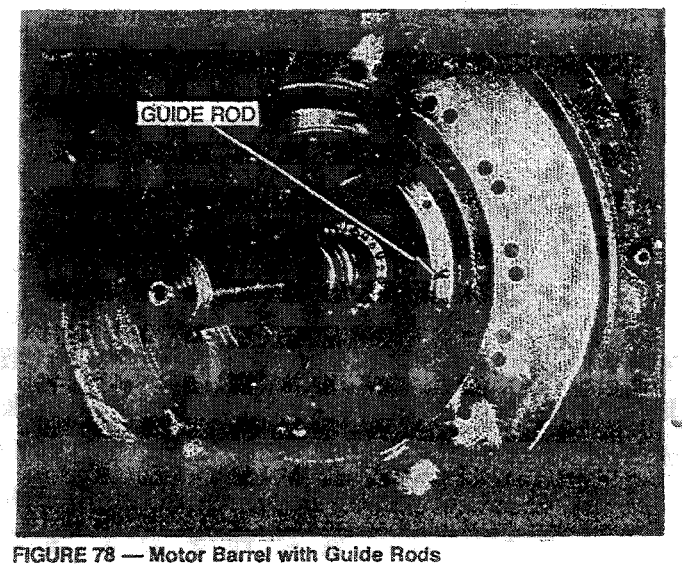

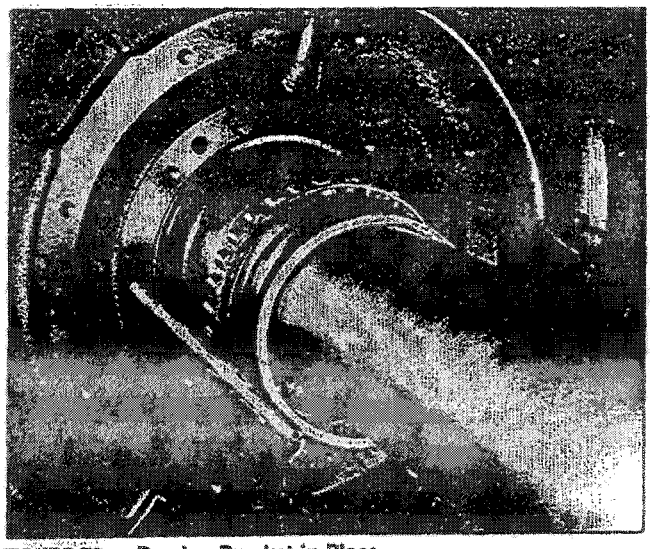

FIGURE 78 — Motor Barrel with Guide Rods

FIGURE 79 — Bearing Bracket in Place

11. Install the roller bearing on the shaft.

a. Thoroughly clean all oil and dirt off the bearing.

b. Heat the bearing dry — do not use oil — to approximately 250-275 F.

CAUTION: EXAMINE THE DRIVE END ROLLER BEARING. THE INNER RACE EDGE WITH THE LARGE RADIUS MACHINED ON IT MUST FACE TOWARDS THE SHAFT SHOULDER. SMALL CHAMFERED EDGE MUST FACE TOWARDS THE OUTSIDE OF THE MOTOR. SEE FIGURE 80.

c. Insert the hot bearing onto the shaft with the more rounded bearing towards the motor as described in the CAUTION above. See Figure 81. Insert the bearing squarely on the shaft to avoid binding and seizure on the shaft. Push the bearing against the motor shaft shoulder and hold in this position for approximately 30 seconds until the bearing cools and binds to the shaft.

d. Slide the drive end bearing spacer against the bearing and lock into place with large snap ring. See Figure 82.

NOTE: This spacer does not require heating to install on shaft.

e. Install the outer race in the bearing bracket. Clean thoroughly and lubricate with WF-68 oil. It may be necessary to lift the shaft to insert the race in the bearing bracket. It may also be necessary to lightly tap the race into position. See Figures 83 and 84.

f. Install the outer race retaining ring. Use bolts with tab-ramp washers. See Figure 85.

NOTE: These bolts also secure the inner bearing cap seal. Install two guide rods in the seal to aid in centering the inner seal and tighten the bolts. Remove the guide rods and insert and tighten the remaining bolts to 24 ft.-lbs. torque. Lightly oil both bearings. Rotate the shaft by hand. If the shaft does not rotate smoothly it may be necessary to readjust the drive end inner seal. Install the remaining bolts to secure the opposite drive end inner bearing cap. Center the seal and check to see that the shaft rotates freely. Readjust the seal location if necessary. Secure the opposite drive end outer bearing race retaining ring. Bolt into position using bolts with tab-ramp washers.

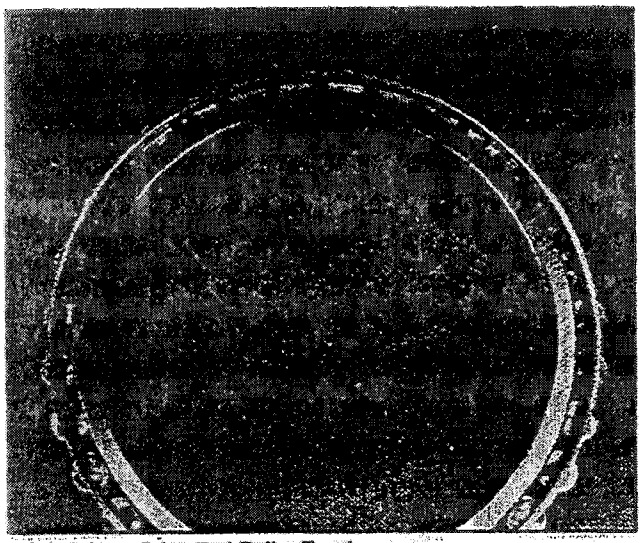

FIGURE 80 — Drive End Roller Bearing

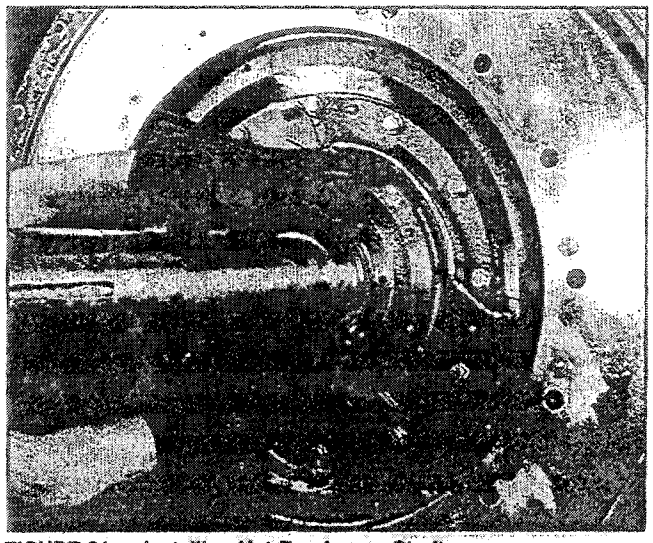

FIGURE 81 — Installing Hot Bearing on Shaft

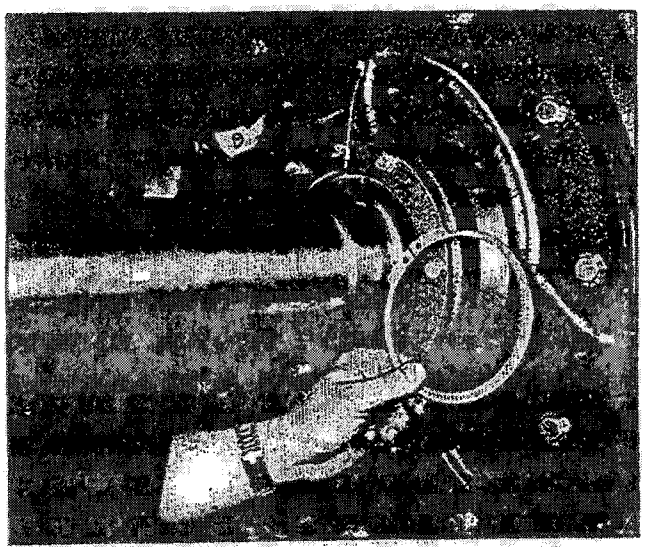

FIGURE 82 — Drive End Bearing Spacer Retaining Snap Ring

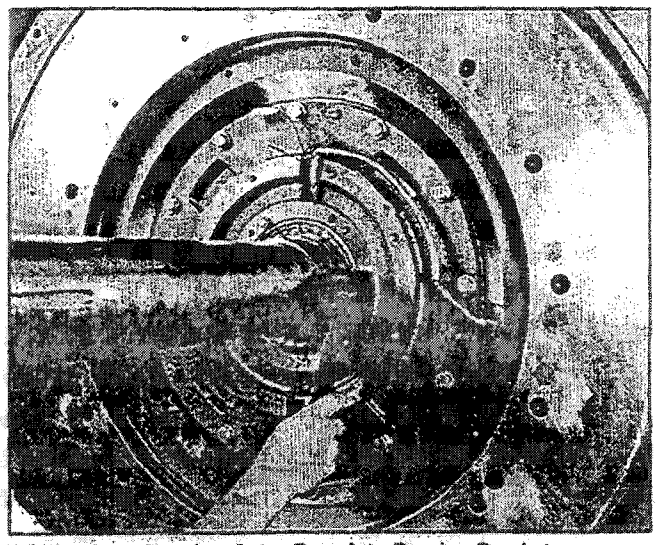

FIGURE 83 — Tapping Outer Race into Bearing Bracket

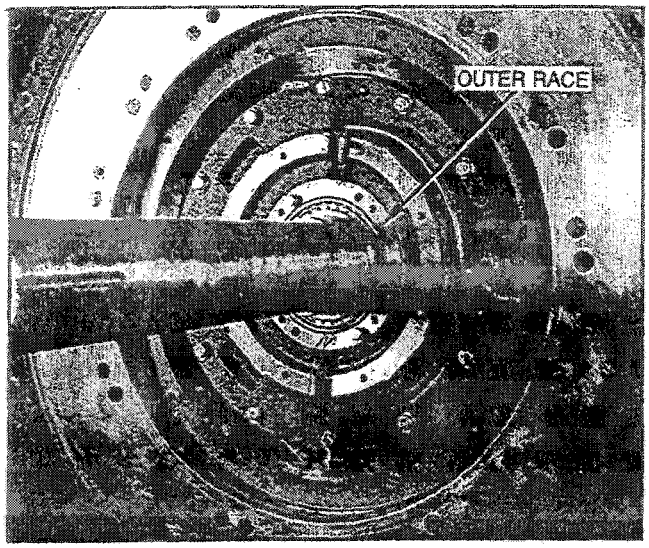

FIGURE 84 — Outer Race Installed

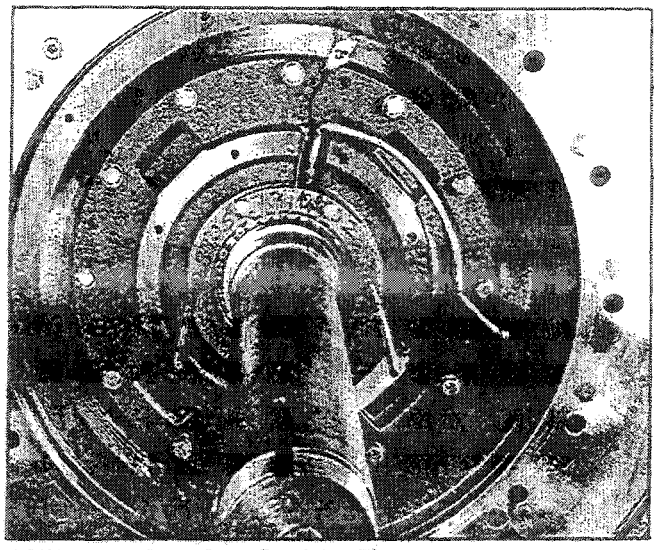

FIGURE 85 — Outer Race Retaining Ring

12. Check the motor shaft end float.

    a. Mount a dial indicator with the dial stem on the shaft shoulder to read the shaft end float. See Figure 86.

    b. Mount a 1 inch × 1 inch steel bar and 1 inch diameter ball bearing on opposite drive end of motor as shown in Figures 87 and 88 to push the motor shaft towards the compressor end. Rock the shaft back and forth to load the roller bearing while tightening the steel bar. Tighten the bar only enough to take up all the end play. Zero the dial indicator. Figure 89 provides dimensions for fabricating the bar.

    c. Remove the steel bar and ball bearing from the opposite drive end of the motor.

    d. Using long threaded rods inserted in the bearing bracket to attach the steel bar and ball bearing to the drive end of the motor. See Figure 90.

    e. Slowly tighten the bar and rock the shaft to take up end float in the opposite direction to that previously indicated. Read the dial indicator to determine the total end float. Total end float is 0.004 inch maximum, 0.002 inch minimum.

    f. If the end float is excessive, remove the thrust locknut, lockwasher, and spacer. Tap the outer bearing towards the inner cone. Reinstall locknut, lockwasher, and spacer. Recheck the end float. Use the machined pipe as previously used to tap the outer bearing towards the inner cone. Recheck the end float.

13. Reconnect the oil supply lines on the drive end bearing bracket.

14. Install the opposite drive end cover plate with a new o-ring. Apply a ⅛-inch bead of Loctite 515 "Gasket Eliminator" to the cover plate o-ring groove. Place the new o-ring in the cover plate groove. Apply a ⅛-inch bead of the same sealant to the mating surface and install the cover plate.

15. Reconnect the oil supply and drain lines on the opposite drive end of the motor.

Centravac General Service Literature

Centravac General Service Literature CTVH-GCO-01-EN

CVHE/CVHG Compressor Disassembly (Including):

- Economizer Removal
- Suction Elbow Removal
- Compressor Disassembly
- Unit Mounted Starter Removal
- Motor Removal
- Discharge Volute Removal

CVHE (E-Design And Later), CVHG And CDHG Duplex Unit Compressor Sizes 013-140 and 350-1280 Ton

This section describes disassembly (including economizer, suction elbow, unit mounted starter, motor, and discharge volute removal) procedures for the model CVHE AND CVHG CenTraVac compressor assemblies. The same information applies to the compressors for the CDHG duplex units. For disassembly and re-assembly procedures for the motor, see Centravac Service Literature Section *CTVH-GMO-01*. The procedures covered in this section may be used for the CVHE (E design sequence and later) and all CVHG compressor sizes (013 through 140) and (130 through 1250) tons. For information on the CVHF compressors, see Centravac Literature Sections *CTVH-GCO-03, 04* for compressor sizes (350 through 1280) and *CTVH-GCO-05 & 06* for the extended capacity compressor sizes 1470 and 1720.

The CVHE AND CVHG compressors are similar in construction. Always check the appropriate table to obtain weights and tolerances for a particular type or size compressor.

Warning and Cautions

WARNINGs and CAUTIONs appear at appropriate sections throughout this manual. Read these carefully.

⚠ WARNING: indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

⚠ CAUTION: indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury.

CAUTION: may also be used to alert the reader to a situation that could result in equipment or property-only damage.

Centravac General Service Literature

Disassembly.

Refer to CenTraVac General Literature Section CTVH-GMS-01 for details on the special lifting fixtures for removing the first stage inlet vane assembly and handling the compressor suction cover and casing components. The tools shown can be fabricated locally using the drawings found in the special tools section. The Trane Company assumes no responsibility for the use of materials that do not meet the required specifications, or for improper or faulty manufacturing, assembly or use of these lifting fixtures. Never exceed the maximum safe lifting capacity of the fixture.

IMPORTANT: Some of the lifting tools built for the CVHE compressor components have a maximum lifting capacity of 1300 lb. The tool maximum weight capacity is stamped on the tool. Some CVHG castings exceed this rating and the lifting tool given in Literature Section CTVH-GMS-01 must be used.

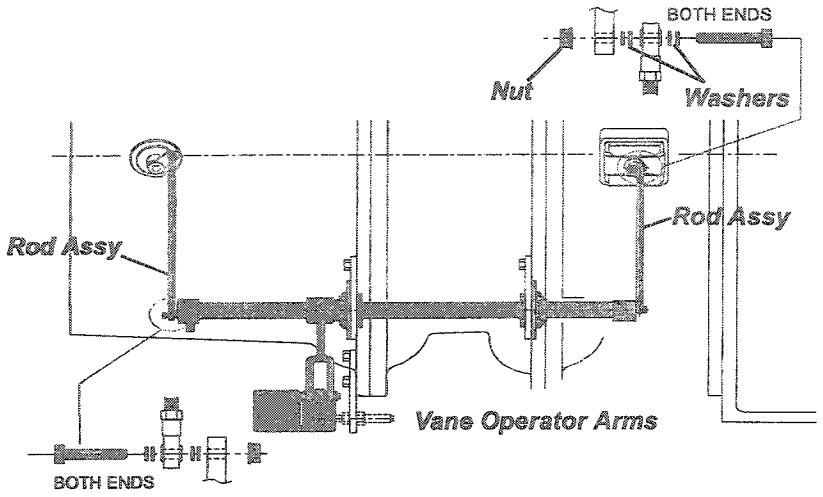
⚠ WARNING
HEAVY OBJECTS!
Use lifting and rigging equipment that is rated to handle the maximum weights. Improper use of lifting fixtures may result in death or serious injury.

Follow all proper procedures when handling large compressor components. Use lifting and rigging equipment that is rated to handle the maximum weights of the pieces found in Table 2 in the back of this literature section. It is recommended that all lifting devices have a capacity rating no less than 100% of the weights shown. Carefully inspect lifting equipment to ensure it is in good condition and has been certified for continued use at proper intervals.

1 It may be advisable to obtain vibration readings for reference purposes prior to disassembly. See General Service Bulletin *CVHE-SB-18* (latest revision) for information on allowable vibration limits.

⚠ WARNING
HAZARDOUS VOLTAGE!
Disconnect all electrical power, including remote disconnects, before servicing. Follow proper lockout/tagout procedures to ensure the power cannot be inadvertently energized. Failure to disconnect power before servicing could result in death or serious injury.

IMPORTANT: Be sure to properly lock out ALL potentially hazardous energy sources before servicing is done on the equipment. Follow all proper refrigerant handling procedures. Before disassembly, evacuate the unit to 2.5 mm vacuum and bring the unit back up to atmospheric pressure using dry nitrogen.



2 Mark and disconnect all power leads to the inlet vane actuator motor. Remove the conduit assembly from the actuator motor.

3 Remove the inlet vane actuator linkages.

(a) Disconnect the universal joints at the inlet vane operator levers.

(b) Remove the 5/8" - 11 x 2" hex head bolts securing the vane drive support assemblies to the compressor castings. Before removing them, mark the compressor castings by scribing a line around the brackets so they may be reassembled in the same relative positions. This will help ensure that the inlet vane linkages maintain their proper coordination between the stages. See Figure 1

Figure 1

(c) Remove the cotter pin securing the vane operator stud.

(d) Slide the vane motor off the stud and remove the entire vane linkage assembly and vane motor from the unit.

(e) Remove the linkage assembly from the vane motor by removing the cotter pin or bolt and nut. The vane motor is now free and can be removed.

CAUTION

COMPONENT ALIGNMENT!

Before disassembling the compressor, scribe lines across the flanges on the exterior edges of all compressor castings in two locations, 180 degrees apart. This must be done so that all components can be re-aligned during re-assembly. Failure to complete this step may result in misalignment of the suction elbow upon re-assembly and possible distortion of the compressor. This can cause vibration problems or seal-to-impeller interference

and possible damage to the impellers and compressor.

CAUTION

COMPONENT ALIGNMENT!

The following two paragraphs provide instructions to maintain proper component alignment and fit. Make sure the compressor casings are dowelled or scribed and the discharge volute is dowelled. Failure to maintain proper alignment may result in compressor damage. Failure to maintain proper suction elbow fit up can cause vibration problems or seal-to-impeller interference and possible damage to the impellers and compressor.

4 Before proceeding further, check to make sure the discharge volute has dowel pins in the flange at the condenser and the compressor foot where it mounts on the evaporator support bracket. These pins are standard on all newer units and will be required if the discharge volute or entire compressor will be removed from the shells. The alignment of the compressor/motor assembly is determined by the position of the discharge volute. A shift in volute position at either the discharge flange or the compressor foot can change the suction elbow to compressor alignment. **Failure to maintain proper suction elbow fit up can cause vibration problems or seal-to-impeller interference and possible damage to the impellers and compressor.** Some early vintage CVHE units were built without these two dowel pins. When necessary, dowel pins should be added to the discharge flange and compressor foot. Units ordered for field disassembly (compressor removal) may have the motor, interstage casings and suction cover doweled as well as the discharge flange and foot.
For additional information on compressor doweling see General Service Bulletin CVHE-SB-10 (latest revision).

5 If the entire compressor or the volute will need to be removed from the shells, the dowel pins at the discharge flange and foot will have to be removed. First remove the threaded nut on the exposed end of the dowel pin. Then slip washers or a bushing over the pin. Reinstall the nut. As the nut is tightened, the pin will be pulled out of place. The dowel pins allow for precise assembly of the compressor components in their original position.

Note: It is not necessary to dowel all compressor casings for overhauls when properly scribed as detailed above.

IMPORTANT: Make sure the evaporator and condenser inlet and outlet water valves have been closed (no water flow!) and the evaporator and condenser water boxes have been completely drained. Failure to prevent water flow through the unit during repairs could cause severe rusting inside the shells. In humid environments it may be advisable to place a portable light or trouble light (100 -300 Watt) in the evaporator and condenser if necessary to provide enough heat to prevent moisture from condensing in the unit during repairs. In excessively humid environments, consider the use of a nitrogen purge to help prevent corrosion.

6 Remove the economizer to allow for compressor volute clearance.

(a) Some CVHE and CVHG units will require cutting the drain line that returns motor cooling liquid to the economizer. Sand the line to remove paint then cut with a tubing cutter. Do not use a hacksaw to cut the line. *Always use a tubing cutter to avoid introducing copper chips (debris) into the unit.*

(b) On smaller units, a floor jack may be placed under the economizer sump.

(c) For larger units it may be advisable to block the economizer and piping when the bolts are removed and then use slings (in the choke configuration) at each end to lift the economizer. See Table 2 for weights of economizers. Make sure the proper balance point of the economizer is found, to prevent it from rotating as it is lifted. See Figure 2 for proper sling use.

Note: The lifting capacity of a sling is reduced when the load angle is less than 90°. See Table 1 for load factor values. For angles less than 90°, multiply the load factor by the nominal sling lifting capacity to determine the allowed lift weight.

Figure 2
Typical Choke Sling Cable Arrangement

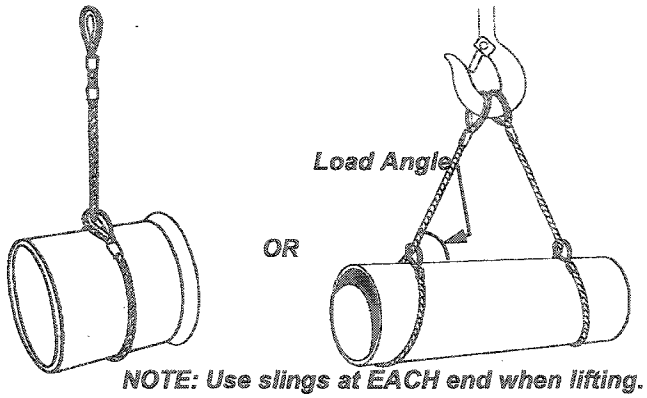


Table 1

Load Angle (°)	Factor	Load Angle (°)	Factor
90	1.000	50	0.7660
85	0.9962	45	0.7071
80	0.9848	40	0.6428
75	0.9659	35	0.5736
70	0.9397	30	0.5000
65	0.9063	25	0.4226
60	0.8660	20	0.3420
55	0.8192	15	0.2589

(d) Carefully slide the economizer away from the shells.

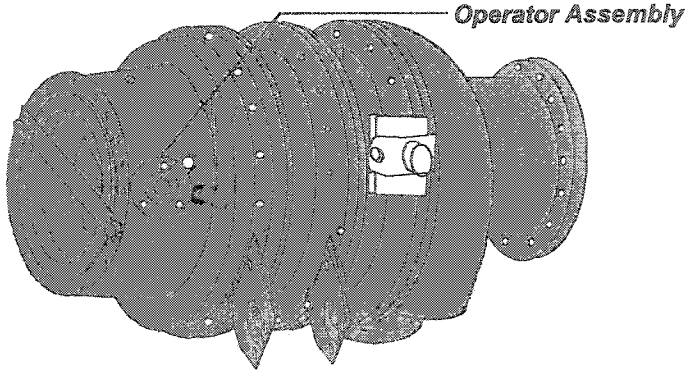
(e) Lightly oil all flanges with compressor oil. Cover all openings with plastic and seal with duct tape to prevent debris from entering the economizer.

(f) Remove the orifice assemblies and mark them properly. Oil the flanges on the condenser liquid line and the evaporator liquid inlet to prevent rusting. Cover the openings with plastic and duct tape to prevent entry of debris.

7 Remove the Suction Elbow.

(a) Remove the bolts from the suction elbow flanges at the evaporator and compressor.

(b) Place a sling in the choke configuration around the suction elbow. Position the sling so the elbow balances properly as it is lifted. *Do NOT use the weld nut on the suction elbow for lifting.* See Table 2 for the weight of the suction elbow.



(c) Clean and lightly oil the suction elbow flanges to prevent rusting and place the elbow on wooden blocks to protect the face of flange. Remove the o-ring, then thoroughly clean the groove in the flange on the evaporator. Lightly oil the flange on the evaporator. Cover the opening with plywood to protect the flange and prevent debris from entering the evaporator during repairs.

IMPORTANT: Mark all components before removing them. Mark the face of components with a description or location (e.g. 1st stage impeller seal) and the top (12 o'clock) mounting position of all seals, impellers, spacers, casings, plates etc. so they may be re-installed in the same position. This will be important in maintaining the proper balance and alignment of the rotating components during re-assembly.

8 Remove the first stage inlet vane assembly.

(a) Loosen and remove the 5/16" - 18 x 1" hex head bolts and lockwashers securing the first stage vane operator assembly to the suction cover. See Figure 3. Mark the operator lever and the suction cover casing with the vanes in the closed position. Remove the vane operator assembly.

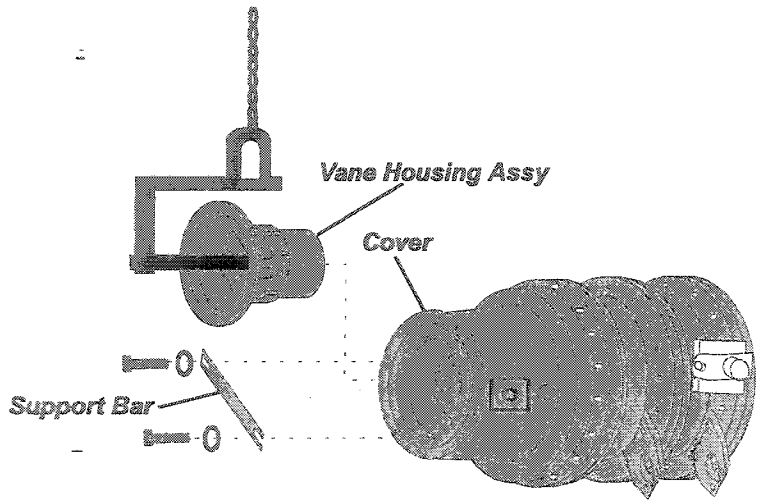


Figure 3

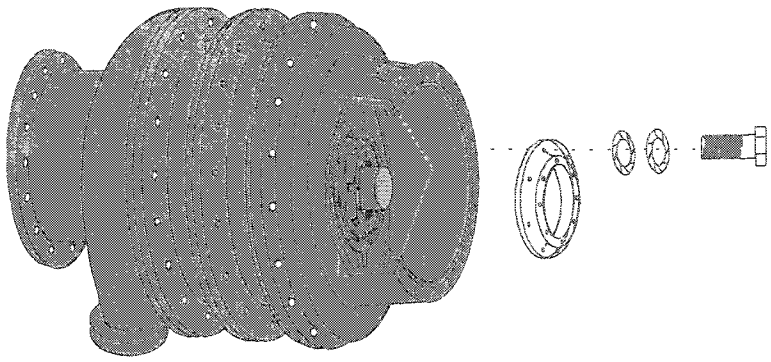
(b) Use a length of L-channel extending across the width of the inlet vanes and two bolts with washers in the suction cover flange to hold the inlet vane assembly in the cover.

Remove the three 5/16" - 18 x 3/8" countersunk set screws in the suction cover holding the inlet vane assembly in place. See Figure 3.

Figure 4

(c) Using the vane lifting tool shown in Figure 4, lift up slightly on the vane assembly. Remove the L-channel holding it in place and pull the vane assembly away from the suction cover. The weight of the vane assembly is given in Table 2.



IMPORTANT: Immediately spray a rust-preventive penetrating oil into the needle bearings in the inlet vane housing, while manually opening and closing the vanes. Thoroughly oil the bearings to minimize the risk of rust forming in the bearings, which could lead to vane binding. Anytime a unit will be open for major repairs, it is recommended the needle bearings in the vane assembly be replaced.

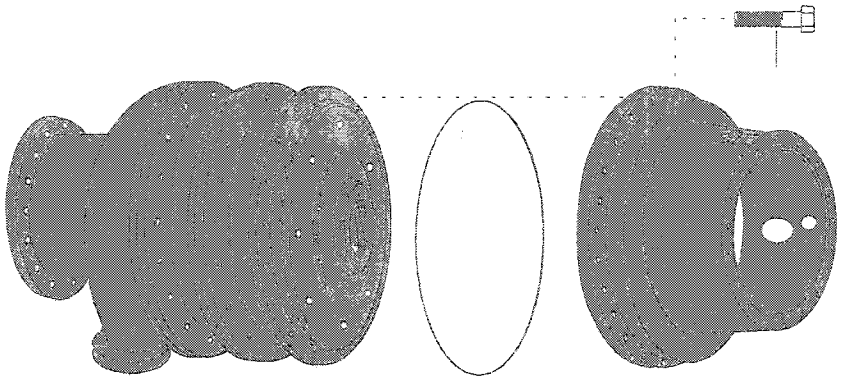
9 When applicable, sand the paint from the oil sump vent line to the suction cover and cut the pipe using a tubing cutter. Do not use a hacksaw to cut the line. Always use a tubing cutter to avoid introducing copper chips (debris) into the unit.

10 Remove the 1/4" oil drain line at the bottom of the suction cover.

11 Measure and record the clearance between the 1st stage seal impeller labyrinth and impeller nose using a feeler gauge. If so equipped, bend the tabwasher tab back allowing the hex head bolts that secure the seal to be removed. The tabwashers are no longer used in production and should be replaced by ramp washers during re-assembly. Remove the seal and store properly along with the retaining bolts. See Figure 5.

Figure 5

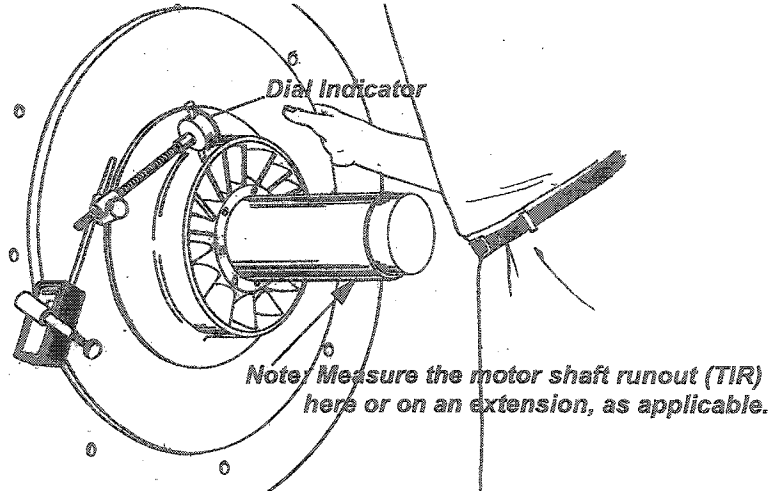
IMPORTANT: Mark this seal carefully. On some size units this seal is mounted in a reverse position. Installing it incorrectly could result in improper venting of the suction cover and may lead to oil loss. Do not mix the bolts with those of other seals, as the bolt lengths may vary.



12 Remove the suction cover and suction cover o-ring.

(a) Remove two of the 5/8" bolts from the suction cover, 180 degrees apart on the horizontal centerline (3 and 9 o'clock position) and insert 6" long guide pins.

(b) Attach a casting lifting fixture to the face of the suction cover flange.



(c) Remove a bolt near the bottom of the suction cover and one to the side of the lifting fixture and insert 6" long 5/8" stop bolts with heads to limit movement of the cover until a proper balance point is obtained. Attach an overhead hoist of sufficient lifting capacity to the lifting plate. See Table 2 for the weight of the suction cover. Remove the remaining bolts (leaving in place the 6" long guide pins and 6" long stop bolts) and pick up slightly on cover. It may be necessary to use jacking bolts to push the cover away from the casing. If necessary, move the pick-up point on the lifting tool until the cover is balanced. Once the cover is balanced properly with the lifting tool, remove the stop bolts at the top and bottom of the cover and remove the suction cover. Oil the cover flanges lightly and store it properly to prevent rust or damage to the sealing surfaces. See Figure 6. Remove the guide pins.

Figure 6

13 Measure and record the total indicated runout (TIR) on the nose of the 1st stage impeller. Use a dial indicator with a magnetic base for measuring runout. See Figure 7.

Figure 7

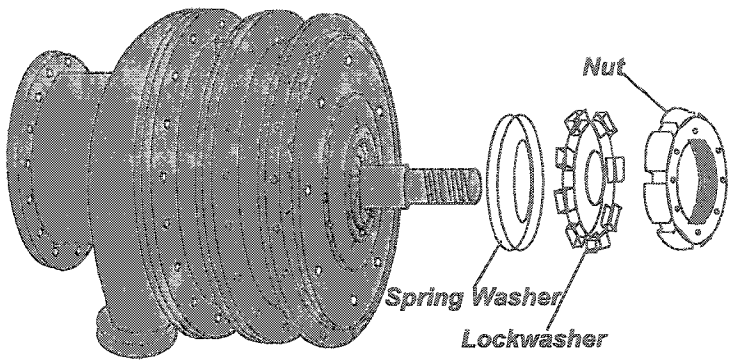
14 Measure and record the total indicated runout (TIR) at the end of the shaft. Some motor sizes have an extension on the end of the shaft where the runout can be measured without having to remove the impeller locknut. Many motors will require removal of the locknut and 1st stage impeller to provide a surface for measuring runout. The allowable TIR is .0012". See note in Figure 7.

15 If it is anticipated that the present compressor seals along with other components will be used during re-assembly, it is advisable to record clearances and runout measurements. The form at the back of this section can be used to record the tolerances. The recommended tolerances can be found in Table 3.

16 Remove the impeller locknut.

Note: Some units are equipped with a standard locknut, while some units have a balance style locknut. The balance style locknut has small tapped holes in the face for the purpose of installing balancing screws and weights.

IMPORTANT: When the unit has a balance style locknut with weights attached, and the motor and all rotating compressor components will be re-used, it is necessary to mark all rotating components such as the locknut, spacers, impellers and motor shaft. This is required to ensure the components can be re-assembled in the exact position as they were removed. Failure to mark all components and reassemble properly could lead to an out of balance condition and require the assembly to be trim balanced. If the motor/rotor or other rotating components located on the shaft will be replaced, it is not necessary to mark all components. Whenever replacing individual rotating components with new ones, the balance weights from the locknut should be removed.



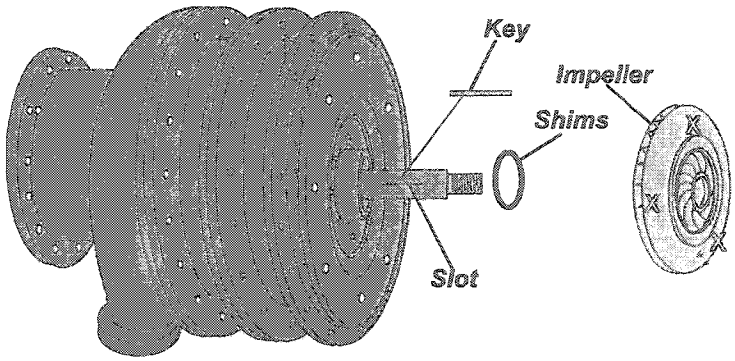
All major rotating components are individually balanced to specification before the compressor is assembled. Even though each major rotating component in the compressor is individually balanced, a small percentage of the compressors assembled in the factory and in the field may be beyond the allowable limit for unbalance. When this occurs, the compressor will need to be trim balanced in the field after re-assembly, using a balance style locknut and weights. Refer to Service Bulletin *CVHE-SB-18* (latest revision) for information on allowable vibration limits.

IMPORTANT: When all components will be re-used during re-assembly, mark the position of the locknut relative to the end of the motor shaft. It is best to mark these at the location of the keyway for the 1st stage impeller. A small center punch can be used to place a mark on the locknut and the end of the shaft. ***Do not remove the balance screws or weights from the balance locknut when all components will be re-used!***

(a) Bend the lockwasher tab back from the slot on the impeller locknut.

(b) Remove the impeller locknut, lockwasher, spring washer, and steel spacer as applicable. Use a spanner wrench to remove the locknut. See Figure 8. The locknut has right hand threads. To loosen impeller locknut, turn it counter clockwise. Use a wire cable tie or tape to keep the items together. Tape the end of the shaft to prevent damage to the threads. Note: It is recommended that the lockwasher be discarded and replaced with a new lockwasher during re-assembly.

Figure 8



CAUTION

POSSIBLE COMPRESSOR FAILURE!

Use undamaged or new lockwashers for re-assembly. Once a locking tab has been bent over on a lockwasher it may become weak and break off if re-used. This could cause the impeller locknut to loosen and come off during operation, causing major damage to the compressor and motor.

(c) Note: Discard old or damaged lockwashers. Save the conical spring washer for re-use.

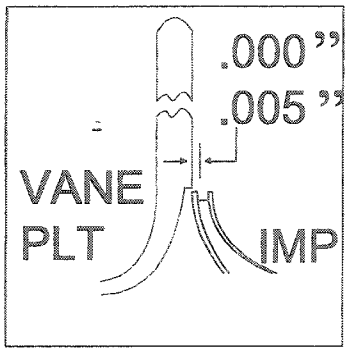


Figure 9

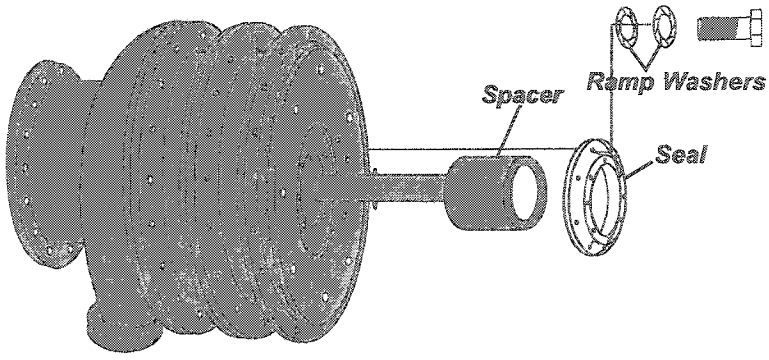
17 Remove the impeller. (See Figure 9.)

(a) Before removing the impeller, check the alignment of the impeller inside back discharge surface to the diffuser plate. The impeller surface should be aligned as shown in Figure 10. When reusing all rotating components and the alignment is not as specified above, measure and record the amount of shim(s) that may need to be added or removed during re-assembly.

Figure 10

(b) It may be necessary to use a puller to remove the impeller. When using a puller, make sure the face of the puller is parallel to the face of the impeller hub to ensure a straight pull. Take care not to damage the machining center in the end of the shaft. If necessary, a small amount of heat may be required to loosen the impeller on the shaft. When heating impeller, use a large (Rosebud) tip with a soft gentle flame. Do not overheat the impeller. The impeller should be heated so that it is warm to the touch. Do not exceed 120° F.



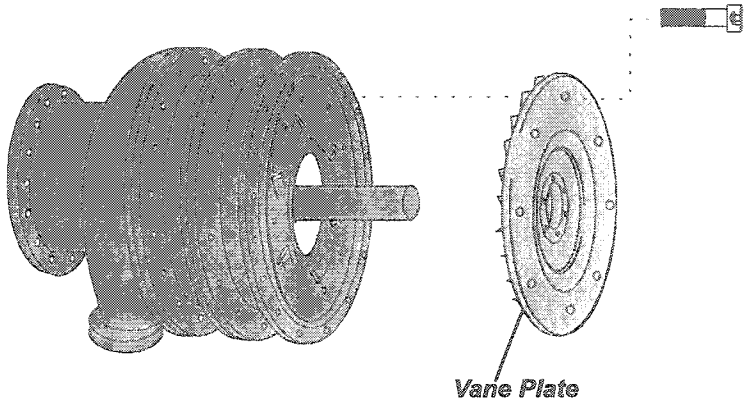
(c) Mark the impeller 1st STAGE.

18 Remove the impeller key and shims from behind the impeller. Tape the shims together and secure them to the impeller along with the key. Keep the parts for each stage separate.

19 Measure and record the clearance between the 1st stage shaft seal and spacer. If the shaft seal has the lockwashers with bent over tab, bend them over using a screw driver. It is recommended the tab type lock washers be discarded and replaced by the ramp type washers shown in Figure 11. Remove the hex head bolts and ramp washers and remove the seal and mark it properly.

20 Remove the 1st stage spacer and spacer tube (some CVHG compressors).

Figure 11



(a) Mark the spacer and spacer tube with its position on the shaft with the first stage impeller keyway at the 12 o'clock position. The shaft spacer has tapped pull-off holes that can be used to pull the spacer if needed. Using the pull-off holes may be required on units where corrosion has occurred due to leaks and moisture or other causes.

(b) Mark the spacer and spacer tube for TOP and 1st STAGE.

21 Remove the 1st stage vane plate. See Figure 12. Refer to Table 2 for the weight of the vane plate.

Figure 12

(a) Remove four 3/8"- 16 socket head cap screws.

(b) Mark the vane plate for TOP and 1st STAGE.

(c) Install two 3/8"- 16 x 6" stop bolts with heads in two of the bolt holes. Install two 3/8"- 16 x 6" guide pins (may be threaded rod, no heads) in the remaining two bolt holes.

(d) Remove the remaining socket head screws holding the vane plate to the interstage casing.

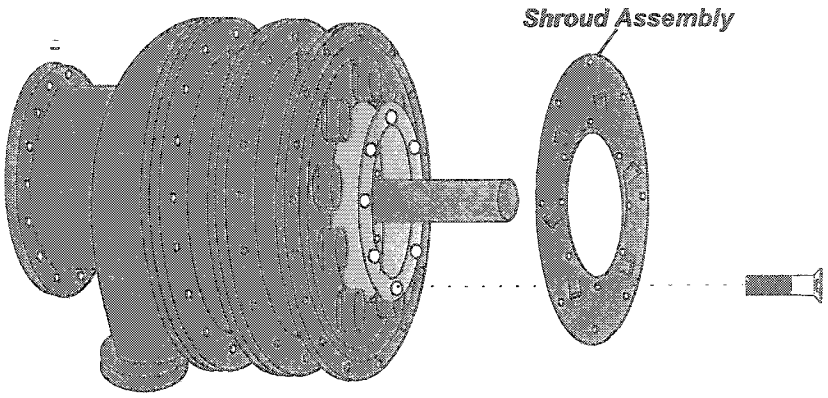
(e) Back the vane plate away from the interstage casing on the guide and stop bolts as far as the bolt heads will allow (approximately 6").

(f) Place a nylon sling through the center of the vane plate in the choke configuration.

(g) Lift the plate slightly with the nylon sling and remove the two remaining stop bolts with heads.

(h) Remove the vane plate, being careful not to damage the rotor shaft.

22 Remove the 2nd stage steel shroud assembly. See Figure 13.



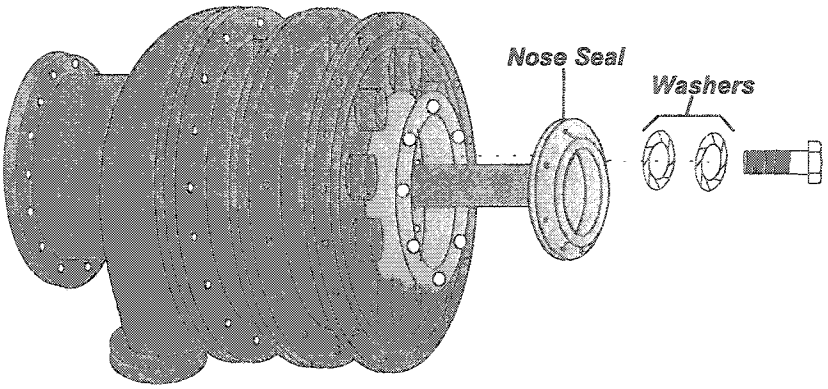
(a) Leave the guide pins in place as installed in Step 21 above.

(b) Mark the TOP of the shroud assembly.

(c) Remove the 1/4"-20 x 3/4" flathead screws that secure the shroud assembly. These screws use a a thread locking compound and may be difficult to remove. Use an allen

head socket for removal. Make sure the allen head socket does not have rounded edges. A hand impact driver may be helpful in removing screws. See Figure 13.

Figure 13



(d) Slide the vane shroud assembly out on the guide pins and attach a lifting sling.

(e) Remove the shroud, guiding it clear with the guide pins. Lightly coat the shroud with compressor oil and store properly.

23 Remove the shims from in front of the 2nd stage impeller. Tape them together and secure them to the back of the spacer removed in Step 20.

24 Remove the 2nd stage impeller nose seal. Refer to Figure 14.

Figure 14

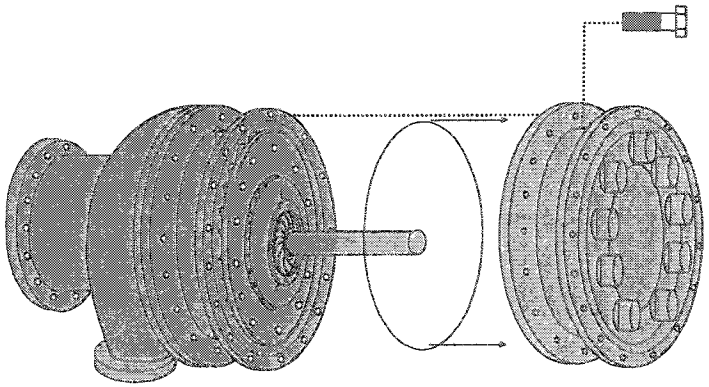
(a) Measure and record the seal clearance. Table 3 provides proper clearances.

(b) Mark the seal for TOP and 2nd STAGE. *IMPORTANT: Mark this seal carefully. On some size units this seal is mounted in a reverse position.*

(c) Remove the 3/8" - 16 x 1" hex head screws and tab or ramp washers.

(d) Remove the seal. See Figure 14.

25 Measure and record the total indicated runout (TIR) on the nose of the 2nd stage impeller.



26 Remove the 2nd stage suction cover and o-ring. See Table 2 for the weight of the intermediate stage suction cover.

(a) Remove two bolts from the suction cover, 180 degrees apart on the horizontal centerline (3 and 9 o'clock positions) and insert 6" long guide pins.

(b) Remove a bolt near the bottom of the suction cover and one to the side of the lifting fixture and insert 6" long stop bolts (with heads) to limit movement of the cover until a proper balance point with the lifting fixture is obtained. Attach the lifting plate. Remove the remaining bolts (leaving in place the guide pins and stop bolts) and pick up slightly on the cover. It may be necessary to use jacking bolts to push the cover away from the casing. If necessary, move the pick up point on the lifting tool until the cover is balanced.

(c) Once the cover is balanced properly with the lifting tool, remove the stop bolts at the top and bottom of the cover and remove the suction cover. Lightly oil the cover flanges and store it properly to prevent rust or damage to the flange sealing surfaces. See Figure 15.

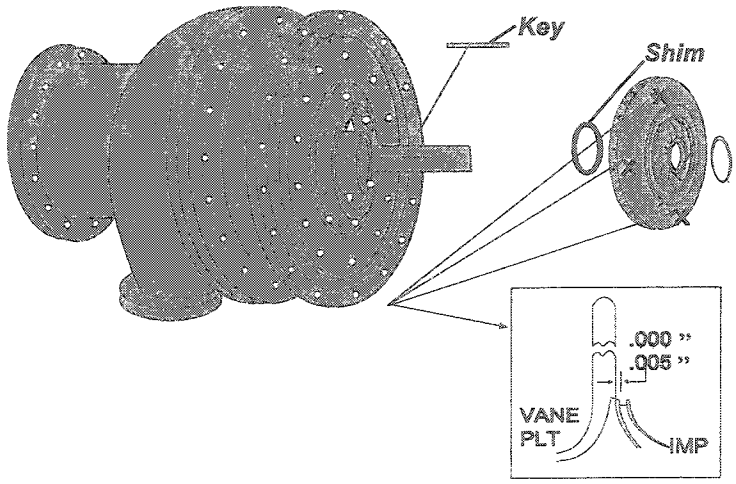


Figure 15

27 Remove the 2nd stage impeller.

(a) Before removing the impeller, check the alignment of the impeller inside the back discharge surface to the diffuser plate. The impeller surface should be aligned as shown in Figure 16. When re-using all rotating components and the alignment is not as specified above, measure and record the amount of shims that may need to be added or removed during re-assembly.

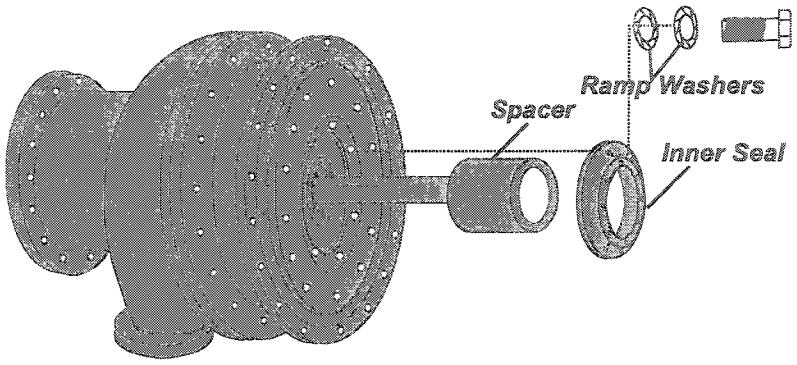
Figure 16

(b) It may be necessary to use a puller to remove the impeller. When using a puller, make sure the face of the puller is parallel to the face of the impeller hub to ensure a straight pull. Take care not to damage the machining center in the end of the shaft. If necessary, a small amount of heat may be required to loosen the impeller on the shaft. When heating impeller, use a large (Rosebud) tip with a soft gentle flame. Do not overheat the impeller. The impeller should be heated so that it is warm to the touch. Do not exceed 120° F.

(c) Mark the impeller 2nd STAGE.

28 Remove the impeller key and shims from behind the impeller. Tape the shims together and secure them to the impeller along with the key. Keep the parts for each stage together. See Figure 16.

29 Mark and remove the 2nd stage shaft seal.



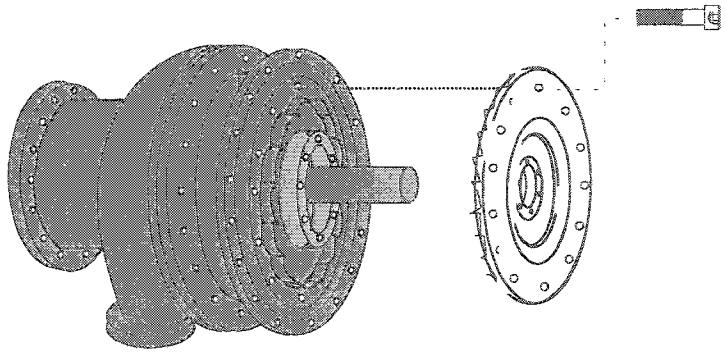
(a) Measure and record the seal clearance. Proper clearances are given in Table 3.

(b) Mark the seal for TOP and second stage.

(c) Remove the 3/8" - 16 x 1" bolts and tab or ramp washers that secure the seal to the vane plate.

(d) Remove the seal. See Figure 17.

Figure 17



30 Remove the 2nd stage shaft spacer.

(a) Mark spacer position on the shaft with the 1st stage impeller keyway at the 12 o'clock position.

(b) Mark the seal for TOP and 2nd STAGE.

31 Remove the aluminum vane plate. See Figure 18. Refer to Table 2 for the weight of the vane plate.

Figure 18

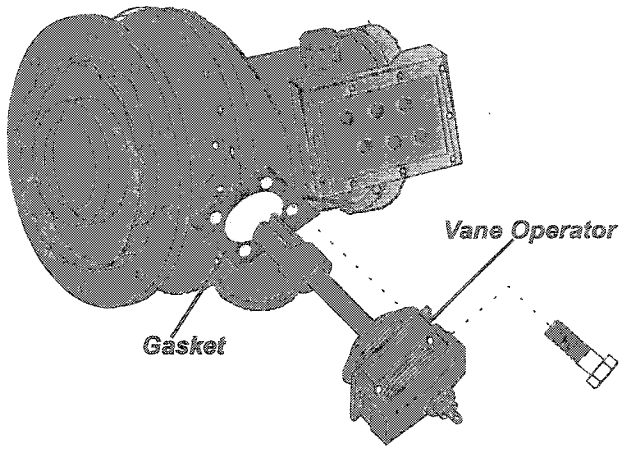
(a) Remove four 3/8"-16 socket head screws.

(b) Mark the vane plate for TOP and 2nd STAGE.

(c) Install two 3/8"-16 x 6" stop bolts with heads in two of the bolt holes. See Figure 12. Install two 3/8"-16 x 6" guide pins (can be threaded rod, no heads) in the remaining two bolt holes.

(d) Remove the remaining socket head screws holding the vane plate to the interstage casing.

(e) Back the vane plate away from the interstage casing on the bolts as far as the bolt heads will allow.



(f) Place a nylon sling through the center of the vane plate in the choke configuration.

(g) Lift the plate slightly with the nylon sling until the two stop bolts (with heads) can be removed.

(h) Remove the vane plate, being careful not to damage the rotor shaft.

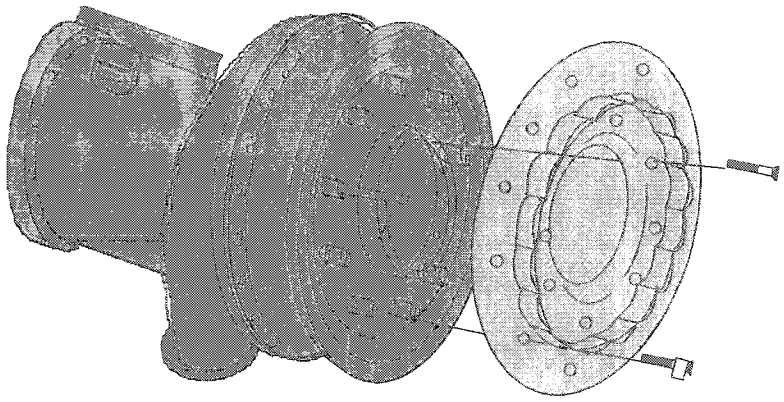
32 Remove the 3rd stage vane operator assembly. See Figure 19.

Figure 19

(a) Remove the 1/2" - 13 x 1-3/4" hex head screws that secure the vane operator assembly.

(b) Remove the vane operator and gasket. Lightly coat all bare metal surfaces with compressor oil.

33 Remove the shroud and 3rd stage inlet vane assembly.



(a) Mark the assembly for TOP.

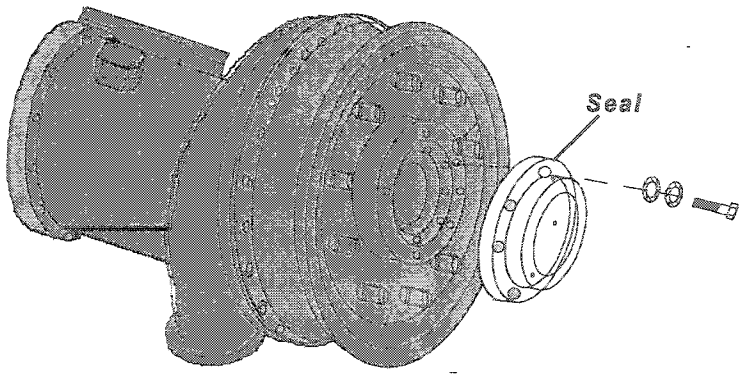
(b) Leave the guide pins installed in Step 32 in place. See Figure 20.

(c) Remove the 1/4" - 20 x 3/4" flathead screws that secure the shroud. These screws use a thread locking compound and may be difficult to remove. Use an allen head socket for removal. Make sure the allen head socket does not have rounded edges. A hand impact driver may be helpful in removing screws.

(d) Attach a sling or cable to the shroud and remove the shroud and vane assembly. See Figure 20. For weights, see Table 2. Immediately coat the vane assembly shroud, pins, levers etc. with compressor oil or rust preventive oil to stop corrosion or rust.

Figure 20

34 Remove the 3rd stage impeller nose seal. Refer to Figure 21.



(a) Measure and record the seal clearance. Table 3 provides proper clearances.

(b) Mark the seal for TOP and 3rd STAGE.

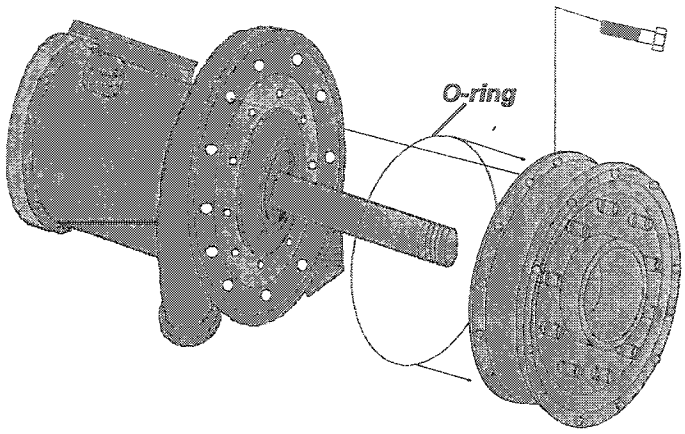
(c) Remove the 3/8" - 16 x 1" hex head screws and tab or ramp washers.

(d) Remove the seal.

Figure 21

35 Measure and record the total indicated runout (TIR) on the nose of the 3rd stage impeller.

36 Remove the 3rd stage suction cover and o-ring. See Table 2 for the weight of the intermediate stage suction cover.



(a) Remove two bolts from the suction cover, 180 degrees apart on the horizontal centerline (3 and 9 o'clock positions) and insert 6" long guide pins.

(b) Remove a bolt near the bottom of the suction cover and one to the side of the lifting fixture and insert 6" long stop bolts (with heads) to limit movement of the cover until a proper balance point with the lifting fixture is obtained. Attach the lifting plate. Remove the remaining bolts (leaving in place the guide pins and stop bolts) and pick up slightly on the cover. It may be necessary to use jacking bolts to push the cover away from the casing. If necessary, move the pick-up point on the lifting tool until the cover is balanced.

(c) Once the cover is balanced properly with the lifting tool, remove the stop bolts at the top and bottom of the cover and remove the suction cover. Lightly oil the cover flanges and store it properly to prevent rust or damage to the flange sealing surfaces. See Figure 22.

37 Remove the 3rd stage impeller and the shim(s) in front of impeller. Tape the shims to the spacer removed earlier.

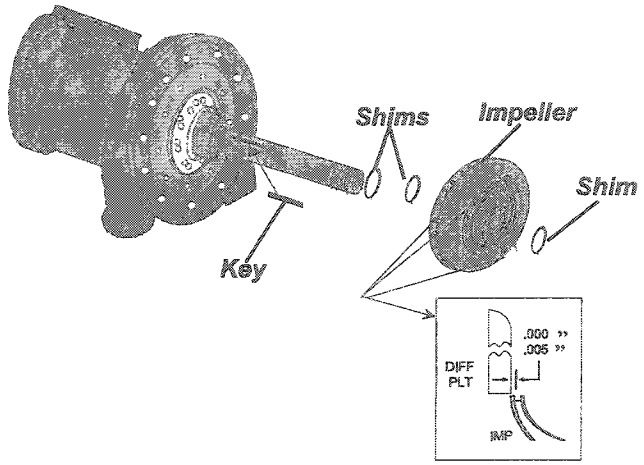


Figure 22

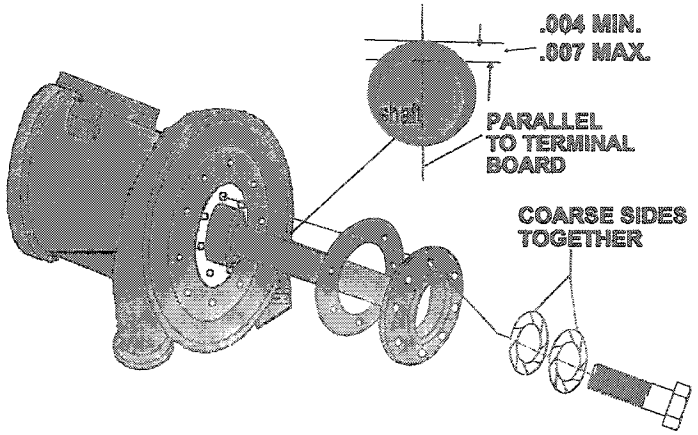
(a) Before removing the impeller, check the alignment of the impeller inside the back discharge surface to the diffuser plate. The impeller surface should be aligned as shown in Figure 23. When re-using all rotating components and the alignment is not as specified, measure and record the amount of shims that may need to be added or removed during re-assembly.

(b) A puller may be necessary to remove the impeller. When using a puller, make sure the face of the puller is parallel to the face of the impeller hub to ensure a straight pull. Take care not to damage the machining center in the end of the shaft. If necessary, a small amount of heat may be required to loosen the impeller on the shaft. When applying heat, use a torch with a large (Rosebud) tip and a soft gentle flame. Do not overheat the impeller. The impeller should be heated so that it is warm to the touch. Do not exceed 120° F. See Figure 23.

Figure 23



(c) Mark the impeller 3rd STAGE.

38 Remove the impeller key and shims from behind the impeller. Tape the shims together and secure them to the impeller along with the key. *Note: It is important that the thicker steel spacer be installed against the shaft shoulder with the chamfer facing the shaft shoulder.*

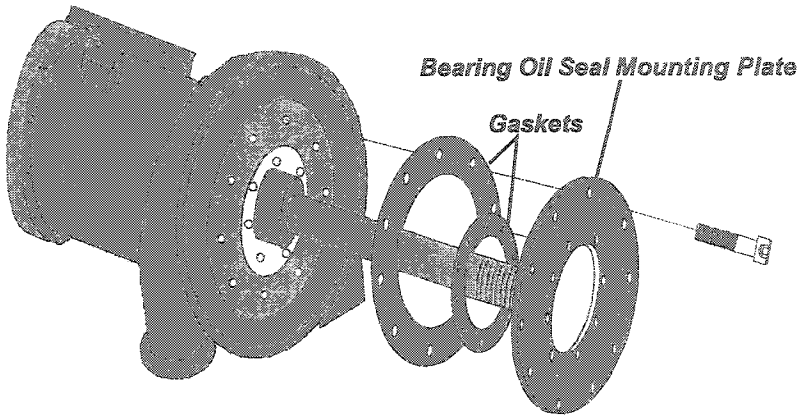
39 Remove the bearing oil seal and gasket.

(a) Measure and record the seal clearance. *IMPORTANT: Excessive clearance of this seal will cause oil loss.* Measure the seal clearance all the way around as shown. The total clearance between the shaft OD and seal ID will be 0.0040" to 0.0070". This seal is set in the factory with the bottom of the seal brought up to the bottom of the shaft and all the clearance (.004"-.007" total) at the top. The clearance between shaft and seal at the sides (3 and 9 o'clock positions) should be equal. See Figure 24.

Figure 24

(b) Mark the seal for TOP. *IMPORTANT: The seal has a small oil drain hole in the back which must be correctly aligned during re-assembly. The drain hole must be at the 6 o'clock position.*

(c) Remove the hex head screws and tab or ramp washers securing the seal and gasket.



40 Remove the bearing oil seal mounting plate and gasket.

(a) Mark the plate for TOP.

(b) Remove two 3/8" - 16 x 1" socket head screws and insert two stop bolts approximately 6" in length and two 6" long guide pins.

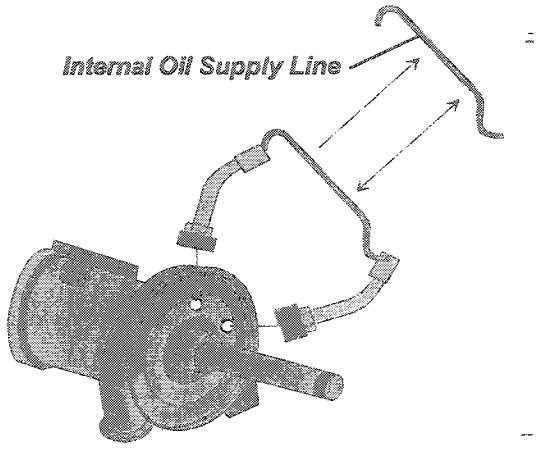
(c) Remove the remaining screws and then remove the plate and gasket. See Figure 25. Use a nylon sling or rope to lift the plate. See Table 2 for the weight of the plate. Place a container under the plate since some oil will drain out when the plate is removed. Lightly coat the plate with compressor oil to prevent rust.

Figure 25

41 Unit mounted starter removal (when applicable).

(a) Attach a small chain to the lifting eye bolts on top of the starter. Pick up slightly on the chain to take up slack.

(b) Remove the motor leads from the motor terminal studs. Mark each lead carefully with the corresponding motor terminal number stamped on the motor terminal board. Remove other electrical connections as necessary to allow enough room to remove the starter and mark them carefully.



(c) Remove the bolts holding the starter to the motor housing and the bolts (when applicable) on the lower support bracket and move the starter away from the motor, being careful not to damage the motor terminals.

42 Motor removal.

(a) Sand the external oil supply and drain lines to remove paint, then cut them with a tubing cutter. Do not use a hacksaw to cut the lines. Always use a tubing cutter to avoid introducing copper chips (debris) into the unit.

(b) Heat the internal oil supply line to loosen and remove line. Bleed nitrogen through the line when heating to prevent build up of copper oxides inside the line. Use a wet rag to protect the threaded connections from excessive heat. See Figure 26.

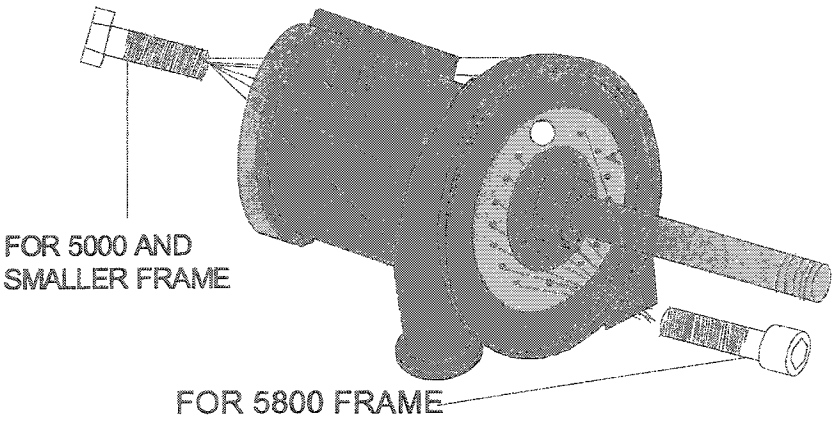
Figure 26

(c) If the motor is to be replaced or remanufactured, remove the bearing oil supply orifice on the thrust (ball) bearing end of the motor. The orifice threads into the motor bearing housing.

IMPORTANT: Save the orifice for re-use.

IMPORTANT: Failure to use a properly sized orifice on the ball bearing supply line could result in excessive oil flow and possible oil loss problems.

(d) Remove the flange bolts for the motor cooling refrigerant supply line and drain lines. In some instances, the drain lines may need to be cut to provide enough clearance for motor removal. Sand the drain line to remove paint then cut it with a tubing cutter. Do not use a hacksaw to cut the line. Always use a tubing cutter to avoid introducing copper chips (debris) into the unit.



IMPORTANT: Remove the motor cooling orifice located between the motor housing and the motor cooling supply line flange. Save the orifice for re-use.

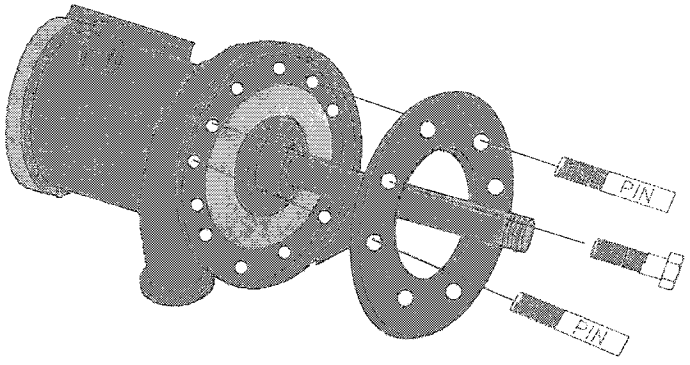
(e) Using two slings in the choke configuration, position them at each end of the motor housing. Refer to Table 4 for motor weights.

(f) Remove two of the bolts holding the motor assembly in the volute and install 5/8" guide pins (2-3" in length) so they are 180 degrees across from each other.

Note: On some units with large frame motors (>5000 frame), the bolts securing the motor to the discharge volute must be accessed from the compressor side. See Figure 27. This will require removing the volute diffuser plate as detailed in step 43.

Figure 27

(g) Pick up on the slings to take up slack and remove the remaining bolts that secure the motor to the volute. Lift the motor slightly and move away from the volute being careful not to damage the motor shaft.



(h) Oil the shaft and cover all openings to prevent debris from entering the motor.

43 Volute diffuser plate removal.

(a) Remove four 1/2" allen head cap screws and insert two 6" long guide pins and two 4" long stop bolts.

(b) Remove the remaining allen head cap screws and slide the diffuser plate away from the volute. See Figure 28.

Figure 28

(c) Place a sling or cable in the choke configuration through to the center of the diffuser plate. See Table 2 for the weight of the diffuser plate.

(d) Lift the diffuser plate and remove the stop bolts.

(e) Slide the diffuser plate away from the volute. Oil the diffuser to prevent rusting.

44 Discharge volute removal.

(a) Remove the dowel pins on the discharge flange at the condenser and on the foot of the volute. First remove the threaded nut on the exposed end of the dowel pin. Then slip washers or a bushing over the pin and reinstall the nut. As the nut is tightened, the pin will be pulled out of place. The dowel pins allow for precise assembly of the compressor components in their original position.

(b) Place a sling in the choke configuration through the center of the volute. Take up the slack in the sling.

(c) Remove the bolts at the discharge flange and the compressor foot and then lift the volute. See Table 2 for volute weights.

(d) Clean and oil the discharge flange on the condenser and cover the opening to prevent entry of debris

Inspect all components for damage or excessive wear. Do not re-assemble the compressor using faulty components. Clean each component and apply a light coat of compressor oil to protect it from moisture and corrosion (especially o-ring and gasket surfaces).

Note: Refer to Centravac Literature Section CTVH-GCO-02 for the compressor re-assembly procedures.

Centravac General Service Literature

Centravac General Service Literature Section CTVH-GCO-02-EN

CVHE/CVHG Compressor Assembly (Including)

- Discharge Volute Installation
- Motor Installation
- Unit Mounted Starter Installation
- Compressor Assembly
- Suction Elbow Installation
- Economizer Installation

CVHE (E-Design And Later), CVHG AND CDHG Duplex Unit: Compressor Sizes 013-140 and 350-1280 Ton

This section describes assembly (including discharge volute, motor, unit mounted starter, suction cover and economizer installation) procedures for the model CVHE AND CVHG CenTraVac 3 stage compressor assemblies. The same information applies to the compressors for the CDHG duplex units. For disassembly and re-assembly procedures for the motor see Centravac Service Literature Section CTVH-GMO-01. The procedures covered in this section may be used for the CVHE (E design sequence and later) and all CVHG compressor sizes (013 through 140) and (130 through 1250) tons. For information on the CVHF compressors see Centravac Literature Sections CTVH-GCO-03 & 04 for compressor sizes (350 through 1280), and CTVH-GCO-05 & 06 for the extended capacity compressor sizes 1470 and 1720.

Warning and Cautions

WARNINGs and CAUTIONs appear at appropriate sections throughout this manual. Read these carefully.

⚠ WARNING: indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

⚠ CAUTION: indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury.

CAUTION: may also be used to alert the reader to a situation that could result in equipment or property-only damage.

Centravac General Service Literature

IMPORTANT: Before beginning re-assembly of the compressor, it is important to check all pieces for damage, rust, or worn parts that could result in leaks or problems with unit operation or reliability. Clean all gasket and o-ring surfaces thoroughly. All traces of previous sealants must be completely removed and the surfaces wiped with a suitable solvent such as industrial grade isopropyl alcohol to remove all traces of oil and other contaminants. When using Loctitè between flanges do not touch the flanges after cleaning and before application of Loctite. The oils left from fingerprints can affect the sealing ability of the Loctite. Check flange surfaces for high spots left around bolt holes and at jack bolt locations. These high spots can cause flange separation and may result in leaks. If necessary use a flat file to remove high spots.

⚠ WARNING
Hazardous Chemicals!
Always use proper protection when handling solvents and other potentially harmful chemicals. Use rubber gloves, clothing and eye protection and avoid prolonged inhalation of vapors. Failure to do so can result in death or serious injury.

IMPORTANT: See the chemicals MSDS (Material Safety Data Sheet) for additional precautions and warnings on use.

The procedures for using an o-ring sealant can be found in General Service Bulletin CTV-SB-66 (latest revision).

⚠ WARNING
Heavy Objects!
Use lifting and rigging equipment that is rated to handle the maximum weights. Improper use of lifting fixtures may result in death or serious injury.

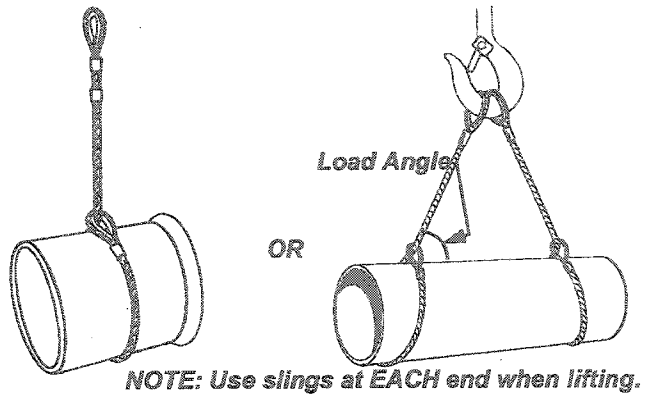
Follow all proper procedures when handling large compressor components. Use lifting and rigging equipment that is rated to handle the maximum weights of the pieces found in Table 2 in the back of this literature section. It is recommended that all lifting devices have a capacity rating no less than 100% of the weights shown. Carefully inspect lifting equipment to ensure it is in good condition and has been inspected and certified for continued use at proper intervals as appropriate.

For larger units it may be advisable to block larger components like the economizer and piping when the bolts are removed and then use slings (in the choke configuration) at each end to lift the part. See Table 2 for weights of components. Make sure the proper balance point of the load is found, to prevent it from rotating as it is lifted. See Figure 1 for proper sling use.

Centravac General Service Literature

Note: The lifting capacity of a sling is reduced when the load angle is less than 90°. See Table 1 for load factor values. For angles less than 90°, multiply the load factor by the nominal sling lifting capacity to determine the allowed lift weight.

Figure 1
Typical Choke Sling Cable Arrangement



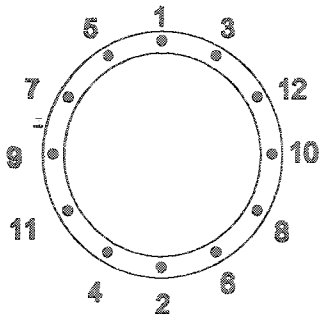


Table 1

Load Angle (°)	Factor	Load Angle (°)	Factor
90	1.000	50	0.7660
85	0.9962	45	0.7071
80	0.9848	40	0.6428
75	0.9659	35	0.5736
70	0.9397	30	0.5000
65	0.9063	25	0.4226
60	0.8660	20	0.3420
55	0.8192	15	0.2589

Before proceeding with compressor re-assembly review the procedures in General Literature Section CTVH-GCO-01EN containing information and details on compressor disassembly.

Unless otherwise specified, the bolt torques required on all flange joints with o-rings or joints where only Loctite 515 is used, can be found in Table 3 in the back of this section. The bolt torques listed in Table 3 are for Grade 5 bolts. *Use only grade 5 bolts or better.* Tighten bolts to final torque in incremental steps. Unless otherwise specified follow a crossing pattern when tightening bolts. See Figure 2 for a typical recommended bolt tightening sequence. The recommended bolt torque values in Table 3 do not apply to bolts used with flat gaskets. Bolt torques for flat gaskets will be provided in the sections covering their installation.

Figure 2

⚠ WARNING
Hazardous Voltage!
Before working on this or any electrical equipment, always disconnect the electric power supply. Follow proper lockout/tagout procedures to ensure the power cannot be applied during repairs. Failure to do so may result in death or serious injury.

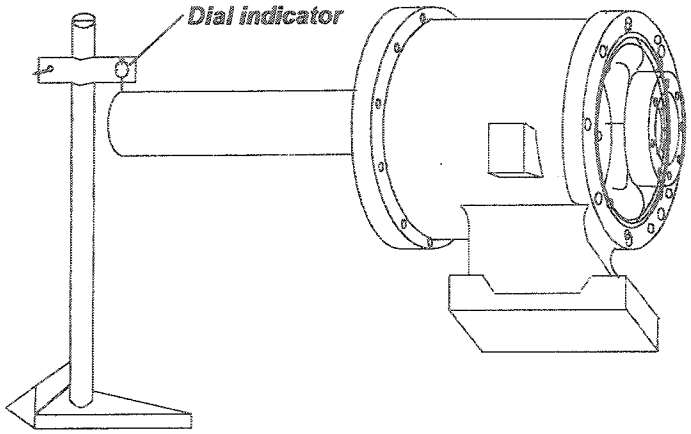
Re-assembly

1 Discharge Volute Installation

(a) Clean the dowel pins and the dowel pin holes in the condenser discharge flange and evaporator mounting base to remove rust or other debris. Lightly coat the pins with a petroleum jelly or anti-seize compound.

(b) Clean the flanges and apply Loctite 515 and o-ring (when applicable) as recommended.

IMPORTANT: See Service Bulletin CTV-SB-66 (latest revision) for procedures for using Loctite 515. Always check the date on the Loctite tube to ensure the sealant use time has not expired.



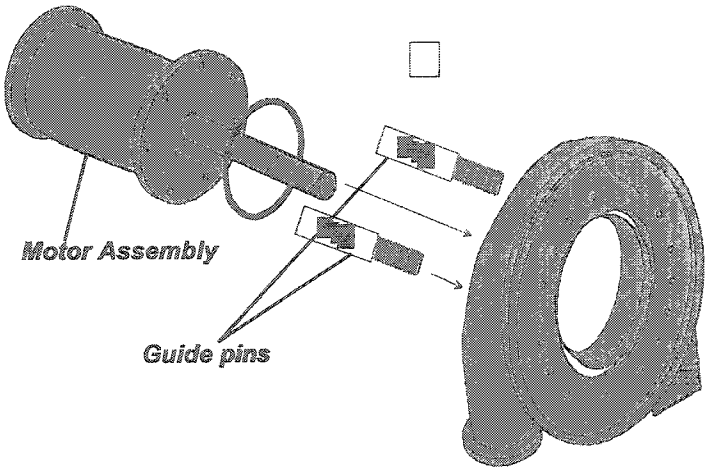
(c) Using a sling or cable in the choke configuration through the center of the volute for lifting. Be sure to protect the flange surfaces when using a cable. Place the volute on the condenser and line up the dowel holes.

(d) Tap the dowels in place as the bolts in the foot and discharge flange are tightened. Torque the bolts per Table 3 in the back of this section.

2 Motor Installation.

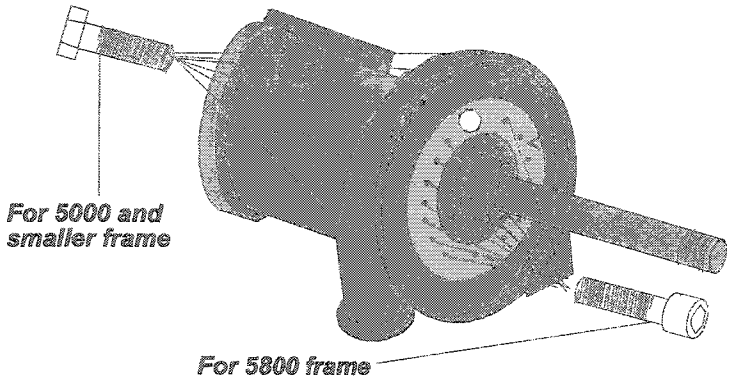
(a) Before installing the motor, check shaft runout (TIR) as shown in Figure 3. Using a dial indicator turn the shaft and measure the runout at the end of the shaft. The maximum allowable runout is .0012" TIR. Make sure the end of the shaft is wrapped with tape for protection during assembly.

Figure 3



(b) Place two slings or cables in the choke configuration around the motor. Place them at each end of the motor near the flanges and lift the motor slightly to get the proper balance point. See Table 4 for maximum motor weights.

(c) Apply Loctite 515 and o-ring (when applicable) around the motor (shaft end) end bell.

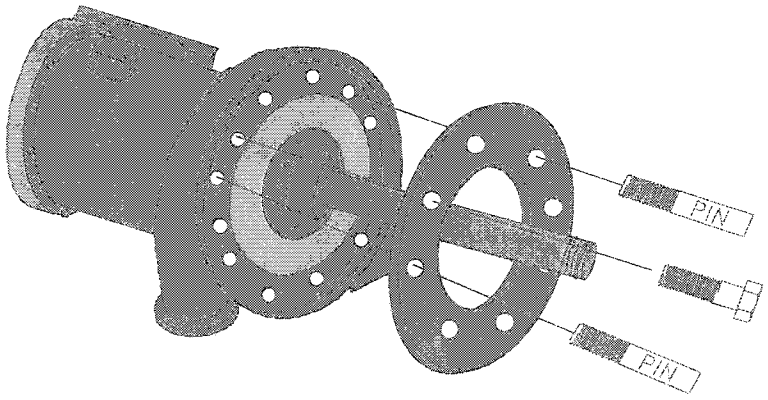


(d) Install two guide pins in the volute or motor flange (large frame) to help guide the motor in place. See Figure 4.

Figure 4

(e) Lift the motor in place and hand tighten the bolts holding the motor to the volute (Figure 5). Snug the bolts and remove the guide pins. Note on some large frame motors, the bolts (allen head) that hold the motor to the volute are located on the compressor side of the volute. The proper torque for both styles of bolts is 120-165 lb-ft.

Figure 5



3 Volute Diffuser Plate Installation.

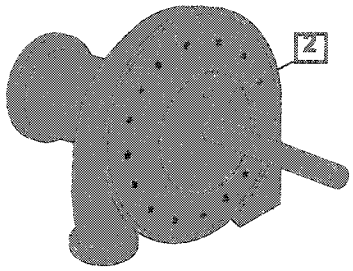
(a) Install two pins in the volute to guide the diffuser in place.

(b) Place a sling or cable in the choke configuration through the center of the diffuser.

(c) Lift the diffuser and slide it over the guide pins. Install countersunk screws and torque them to 55-75 lb-ft. Make sure the screws in the counterbore area behind impeller do not protrude more than .060" above the surface.

Figure 6

4 Oil Feed Tube Installation.



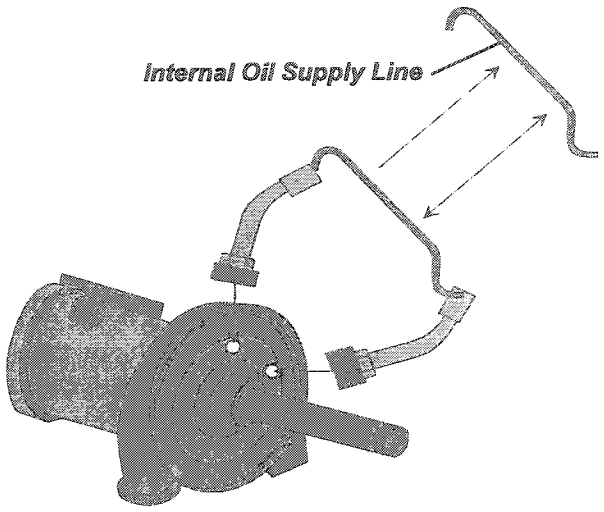
(a) Clean the ends of the lines thoroughly using a scotch bright pad or equivalent for metal. See Figure 7. Remove as much of the old brazing material as possible. Clean the inside of the couplings using a steel tubing brush. Use Loctite 277 Sealant on the threads.

Figure 7

1 *Cover holes to prevent water from collecting in the oil drain tube*

2 *Cool joints with wet rag*

3 *Apply air pressure and leak test*



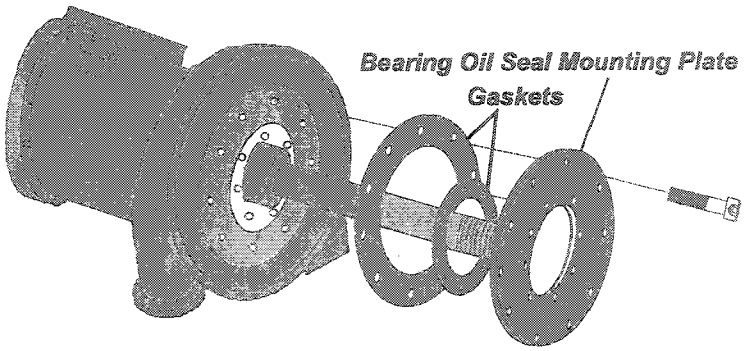
(b) Wrap a wet rag around both ends of the line to prevent overheating the threaded joints.

(c) Using a regulator, allow a slight purge of dry nitrogen to flow through the volute threaded fitting and oil supply line to prevent a buildup of oxidation when brazing.

(d) Braze the lines as shown in Figure 8 using a good Sil-Fos material with 5-15% (Ag) silver.

Figure 8

(e) After brazing, allow the lines to cool. Increase the nitrogen pressure and check the line and threaded fittings for a leak using a soap solution.



5 Bearing Cover Plate Installation

(a) Install two guide pins in both the inner and outer bolt centers to help hold the gaskets in place and to align the cover plate.

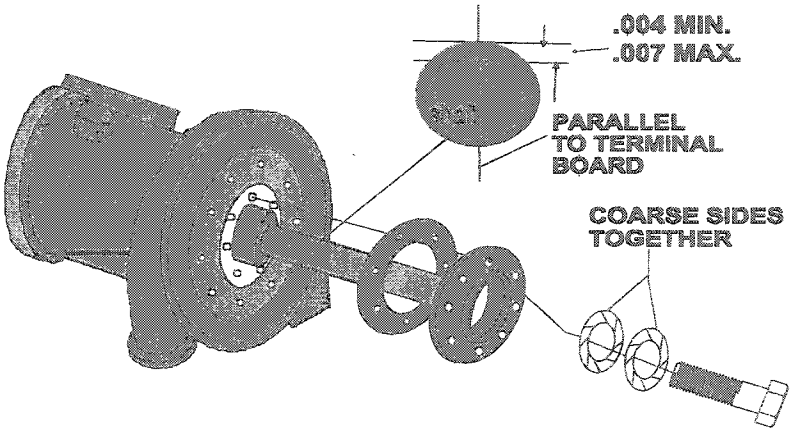
(b) Lightly coat both the inner and outer gaskets with a small amount of petroleum jelly to help hold them in place.

(c) Using a sling or cable in the choke configuration, slide the bearing cover plate in place while observing the gaskets to make sure they do not move out of position. See Figure 9.

Figure 9

(d) Install the outer mounting bolts. Remove the outer guide pins and torque the bolts to 20-27 lb-ft.

6 Bearing Oil Seal Installation.



(a) Lightly coat the bearing oil seal gasket (between the bearing cover plate and oil seal) with a small amount of petroleum jelly to help hold it in place. Make sure the gasket behind the bearing cover plate is still in its proper position.

(b) Slide the bearing oil seal over the guide pins. **IMPORTANT: The oil seal has a drain hole between the teeth of the seal that must be installed at the 6 o'clock position.** Install the mounting bolts with ramp washers and hand tighten. Remove the guide pins.

*NOTE: Check the clearance between the bearing oil seal and the shaft outside diameter at the seal location. The maximum allowable total clearance is .0040-.0070". **IMPORTANT:** Clearances in excess of this amount will lead to oil loss.*

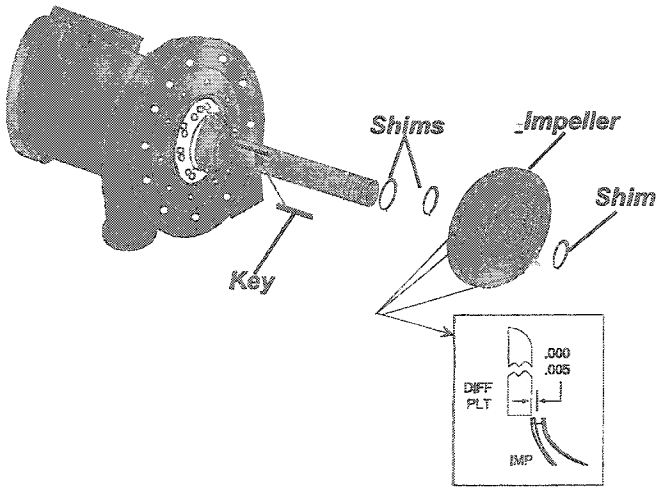
(c) Push up on or lightly tap the seal until the bottom of the seal touches the bottom of the shaft. Position the seal so the clearances on each side of the seal (3 and 9 o'clock) are equal. Using a feeler gauge, measure the total clearance at the 12 o'clock position and the clearances at the sides. It is recommended that a new oil seal be used if there is any question about the total clearance of the existing seal.

Figure 10

(d) With all the clearance at the top of the seal, tighten the bolts to 20-27 lb-ft. Recheck the clearance and rotate the shaft to ensure it turns freely. See Figure 10.

(e) At this point you may want to run only the motor to check for balance. This is desirable if a replacement motor is being installed or if the rotor was changed or repaired. See *General Service Bulletin CVHE-SB-18* (latest revision) for the procedures when air running motors.

7 3rd Stage Impeller Installation.



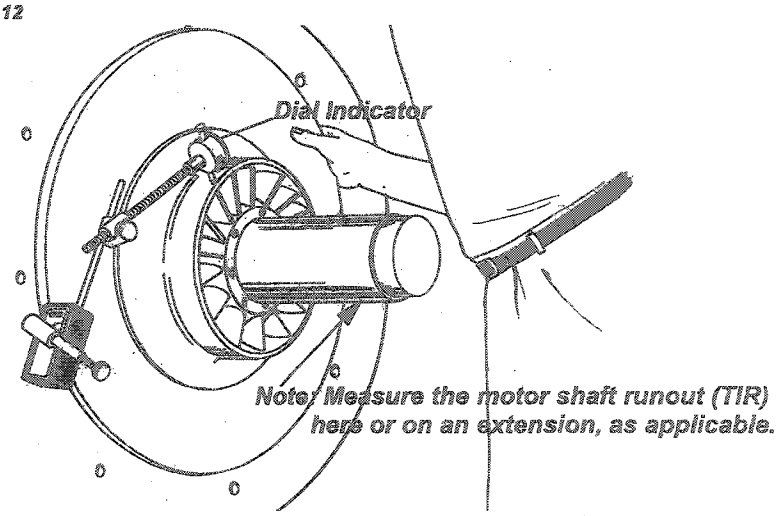
(a) Clean the impeller shims. Slide the impeller shims with the thicker steel shim against the shaft shoulder. *Note: The chamfer on the thicker steel shim should be facing the shaft shoulder.* Impeller alignment should have been checked during disassembly and any adjustments to the shim(s) thickness necessary to get proper impeller alignment can be made at this time. If the impeller or motor shaft has been replaced, then you may want to use only the steel spacer for an initial alignment to determine how many additional shims may be required.

(b) Thoroughly clean the impeller, key and shaft. Check the impeller bore for cracks. This can be done using a dye penetrant flaw detection kit. These kits are available through most weld supply or large industrial supply companies. The kits usually consist of a penetrant, developer, and cleaner and include instructions on their use. Replace the impeller if cracked. Some types of damage to the impeller bore or nose seal area on impellers can be repaired by The Trane Company.

(c) Check the impeller key and keyway in the impeller bore for damage. Check to ensure the sides of the keyway in the impeller bore are square.

(d) Coat the impeller bore and shaft with compressor oil. Install the key in the shaft. Slide the impeller on the shaft until it contacts the shims. Check the alignment of the impeller. The back inside discharge surface of the impeller should be flush to no more than a .0050" set out beyond the face of the diffuser plate. See Figure 11.

Figure 11



If the impeller does not slide easily on the shaft, it may be necessary to heat the impeller slightly to allow it to slide on the shaft. Before heating the impeller, inspect the impeller bore for debris or a dent (high spot) that could be causing interference. When heating the impeller, use a large (Rosebud) tip with a soft gentle flame. The impeller should be heated so that it is warm to the touch. Do not exceed 120° F. *The impeller bore (ID) to shaft diameter (OD) total clearance should be .0000 - .0015" maximum.*

(e) When required, remove the impeller and add shims to obtain the proper alignment. Slide the impeller on the shaft and recheck the alignment.

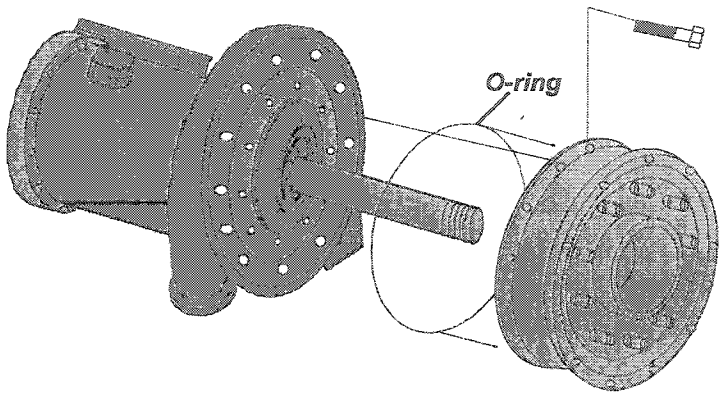
(f) Check the radial clearance between the impeller OD and the vane plate ID The minimum clearance around the entire circumference is .0220" minimum. If necessary loosen the diffuser plate and reposition it to obtain proper clearance.

(g) Check the impeller nose runout using a dial indicator with a magnetic base. Rotate the impeller and measure the maximum runout (see Figure 12). The allowable maximum runout for fabricated (welded) impellers is .0050" and .0035" for cast style impellers.

Figure 12

(h) Install the shim(s) removed during disassembly in front of the 3rd stage impeller.

8 3rd Stage Suction Cover Installation.



(a) Clean the cover and discharge volute.

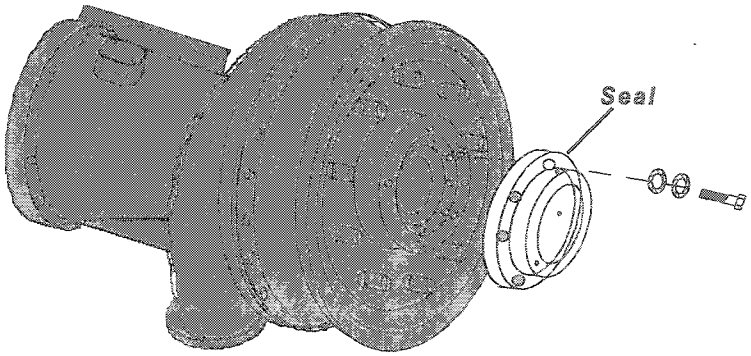
(b) Attach the lifting fixture to the suction cover and find the proper balance point.

(c) Apply Loctite 515 and an o-ring (when applicable) per recommended procedures.

(d) Install four guide pins to help align the suction cover as shown in Figure 13. Make sure the scribe marks between the volute and the suction cover are lined up before final tightening of the bolts.

Figure 13

(e) Install bolts and torque to 120-165 lb-ft.



9 Impeller Nose Seal Installation.

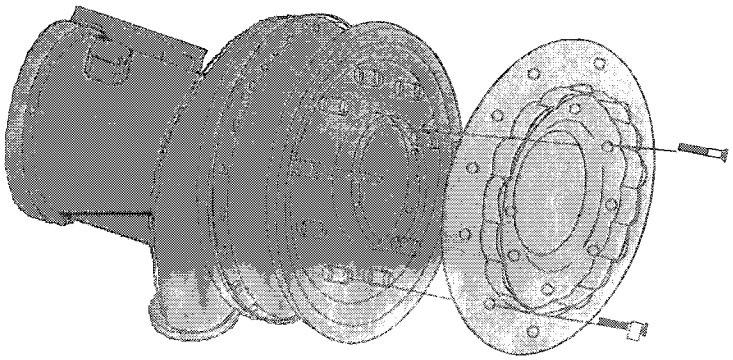
(a) Thoroughly clean the nose seal to remove any debris or loose chips from the labyrinth teeth.

(b) Use the original bolts and new locking tab washers.

(c) Using a feeler gauge, center the seal around the nose of the impeller. The proper clearance can be found in Table 5.

Figure 14

(d) With the seal set properly, tighten the bolts to 20-27 lb-ft. Recheck seal clearance.



(e) Rotate the shaft to ensure it turns freely.

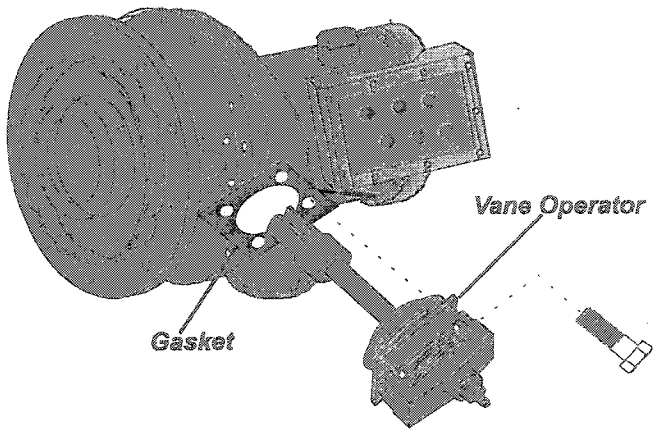
10 3rd Stage Vanes Assembly Installation.

(a) Install two guide pins in the suction cover to help align the shroud and vane assembly.

(b) Use a sling to lift the vane assembly in place. It is recommended that new screws be used. If reusing the original screws, coat the threads with a thread locking compound. New screws will have a nylon locking insert. It is recommended the new screws also be coated with a thread locking compound. See Figure 15.

Figure 15

(c) Tighten the allen head screws to 5-7 lb-ft.



11 3rd Stage Vane Operator Assembly Installation.

(a) Clean the flange on the suction cover and vane operator assembly.

(b) Clean any powder residue from the new gasket. The gasket should be installed dry. Slide the fork of the vane operator lever over the pin in the vane drive ring pin assembly.

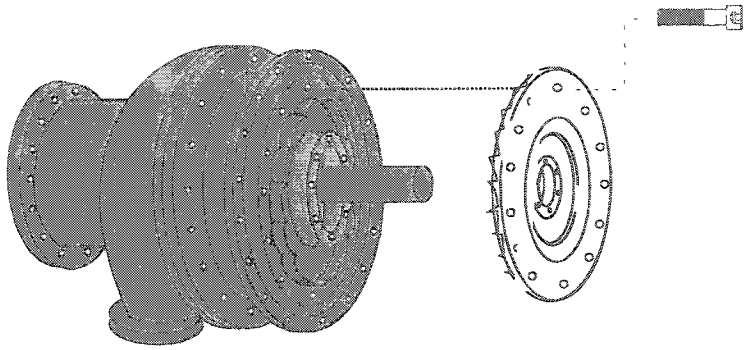
(c) Tighten bolts to 33-50 lb-ft. See Figure 16.

Figure 16

(d) Open and close the vane assembly to ensure it operates freely. Check to make sure the vanes close completely and open fully.

12 3rd Stage Aluminum Vane Plate Installation.

(a) Before installing the vane plate, make sure the shim in front of the impeller has been installed.



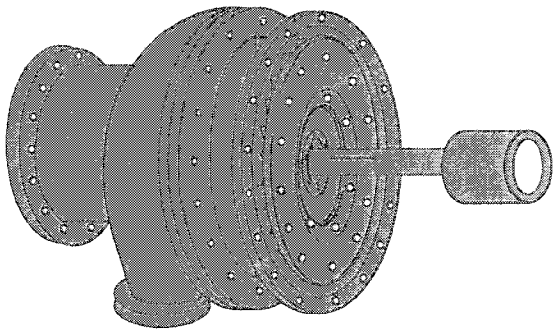
(b) Clean the aluminum plate.

(c) Insert the four guide pins to help align and hold the vane plate during installation.

(d) Lift the plate through the center using a sling in the choke configuration.

(e) It is recommended that new bolts be used. If reusing the original bolts, coat the threads with a thread locking compound. New bolts have a nylon locking insert. See Figure 17.

Figure 17

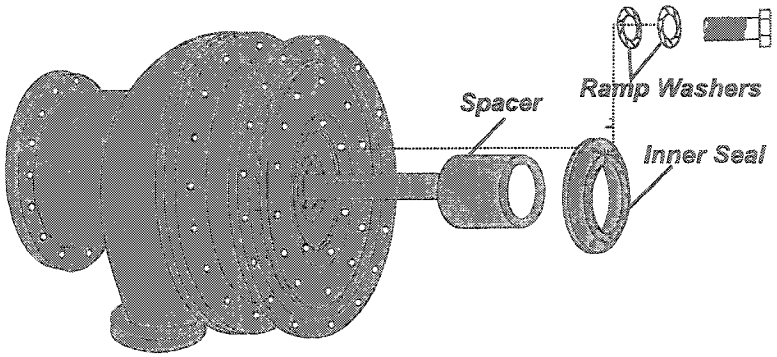


(f) Tighten the bolts to 20-27 lb-ft.

13 Interstage Spacer Installation.

(a) Slide the spacer and shims on the shaft. Make sure the spacer, which was marked during disassembly, is placed back on the shaft in the proper position. This will help maintain proper balance if all the rotating components are being re-used.

Figure 18



14 Interstage Spacer Seal installation.

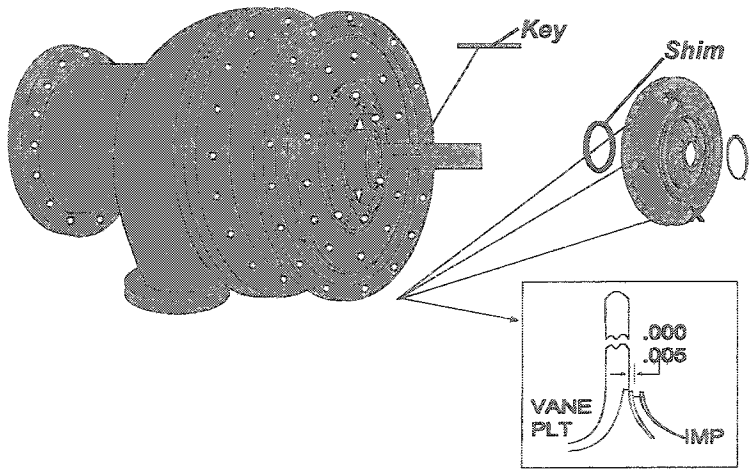
(a) Install the seal and bolts with a ramp washer over the interstage spacer.

(b) Center the seal using a feeler gauge. The allowable tolerance can be found in Table 5.

(c) Tighten the bolts to 20-27 lb-ft. See Figure 19

Figure 19

15 2nd Stage Impeller Installation.



(a) Clean the impeller shims and slide them up against the interstage spacer. Impeller alignment should have been checked during disassembly and any adjustments to the shim(s) thickness necessary to get proper impeller alignment can be made at this time. If the impeller or motor shaft has been replaced, then you may want to use only a portion of the original shims for an initial alignment to determine how many additional shims may be required.

(b) Thoroughly clean the impeller, key and shaft. Check the impeller bore for cracks. This can be done using a dye penetrant flaw detection kit. (These kits are available through most weld supply or large industrial supply companies. The kits consist of a penetrant, developer and cleaner and include instructions on their use.) Replace the impeller if cracked. Some types of damage to the impeller bore or nose seal area on impellers can be repaired by The Trane Company.

(c) Check the impeller key and keyway in the impeller bore for damage. Check to ensure the sides of the keyway in the impeller bore are square.

(d) Coat the impeller bore and shaft with compressor oil. Install the key in the shaft. Slide the impeller on the shaft until it contacts the shims. Check alignment of the impeller. The back inside discharge surface of the impeller should be flush to no more than a .0050" set out beyond the face of the vane plate. See Figure 20. The back plate on welded impellers may have some distortion due to the weld process. Locate the impeller back inside edge (lowest point) so it is flush with the vane plate.

Figure 20

If the impeller does not slide easily on the shaft, it may be necessary to heat the impeller slightly to allow it to slide on the shaft. Before heating the impeller, inspect the impeller bore for debris or a dent (high spot) that could be causing interference. When heating the impeller, use a large (Rosebud) tip with a soft gentle flame. The impeller should be heated so that it is warm to the touch. Do not exceed 120° F. The impeller bore (ID) to shaft diameter (OD) total clearance should be .0000 - .0015" maximum.

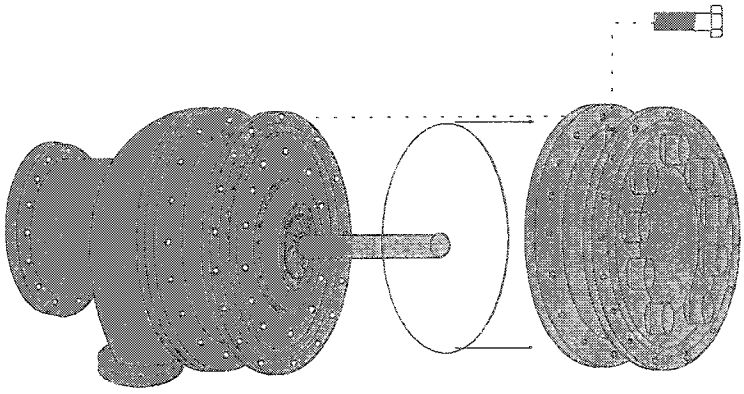
(e) When required, remove the impeller and add shims to obtain the proper alignment. Slide the impeller on the shaft and recheck alignment.

(f) Check the radial clearance between the impeller OD and the diffuser ID The minimum clearance around the entire circumference is .0220". If necessary, loosen the vane plate and reposition it to obtain proper clearance.

(g) Check the impeller nose runout using a dial indicator with a magnetic base. Rotate impeller and measure the maximum runout. The allowable maximum runout for fabricated (welded) impellers is .0050" and .0035" for cast style impellers.

(h) Install the shim removed during disassembly in front of the 2nd stage impeller.

16 2nd Stage Suction Cover Installation.



(a) Clean the cover and mating surface on the 2nd stage cover. Remove any old sealing compound and wipe surfaces with a suitable solvent to remove oil or grease.

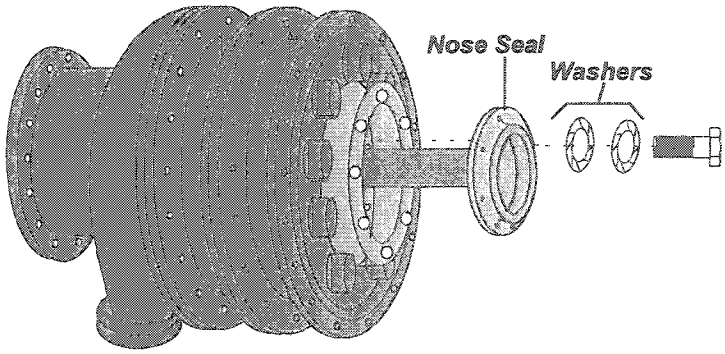
(b) Attach the lifting fixture to the suction cover and find the proper balance point.

(c) Apply Loctite 515 and an o-ring (when applicable) per recommended procedures.

(d) Install four guide pins to help align the suction cover as shown in Figure 21. Make sure the scribe marks between the 3rd stage cover and 2nd stage cover are lined up before final tightening of bolts.

Figure 21

(e) Install the bolts and torque to 120-165 lb-ft.



17 Impeller Nose Seal Installation. (See Figure 22)

(a) Thoroughly clean the nose seal to remove any debris or loose chips from the labyrinth teeth.

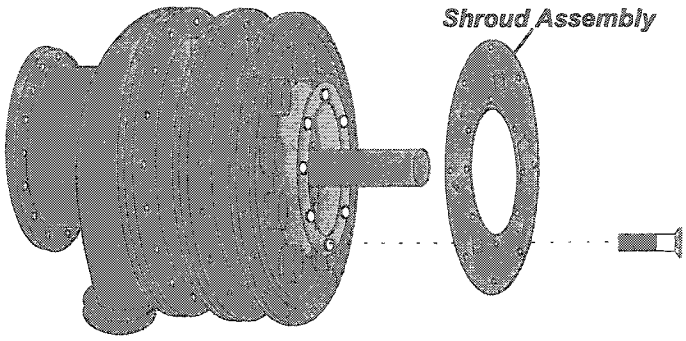
(b) Use the original bolts and new locking tab washers.

(c) Using a feeler gauge, center the seal around the nose of the impeller. The proper clearance can be found in Table 5.

Figure 22

(d) With the seal set properly, tighten the bolts to 20-27 lb-ft. Recheck the seal clearance.

(e) Rotate the shaft to ensure it turns freely.



18 2nd Stage Vane Shroud Installation.

(a) Install two guide pins in the suction cover to help align the shroud assembly.

(b) Lift the shroud assembly in place. It is recommended that new screws be used. If reusing the original screws, coat the threads with a thread locking compound. New screws will have a nylon locking insert. It is recommended that new screws also be coated with a thread locking compound. See Figure 23.

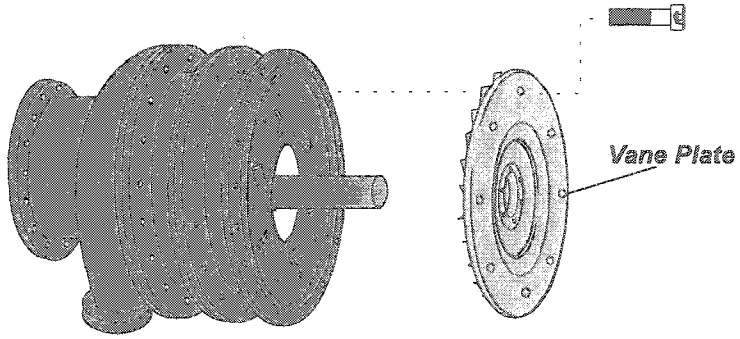
(c) Tighten the allen head screws to 5-7 lb-ft.

Figure 23

19 2nd Stage Aluminum Vane Plate Installation.

(a) Before installing the vane plate, make sure the shim in front of the impeller has been installed.

(b) Clean the aluminum plate.



(c) Insert four guide pins to help align and hold the vane plate during installation.

(d) Lift the plate through the center using a sling in the choke configuration.

(e) It is recommended that new bolts be used. If reusing original bolts, coat the threads with a thread locking compound. New bolts have a nylon locking insert. See Figure 24.

(f) Tighten the bolts to 20-27 lb-ft.

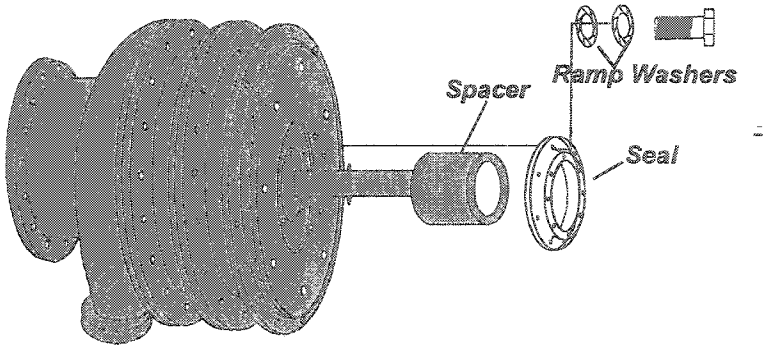


Figure 24

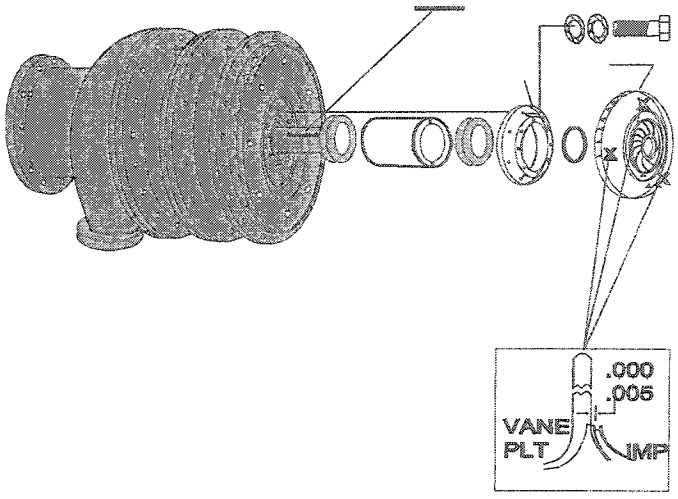
20 Interstage Spacer Installation.

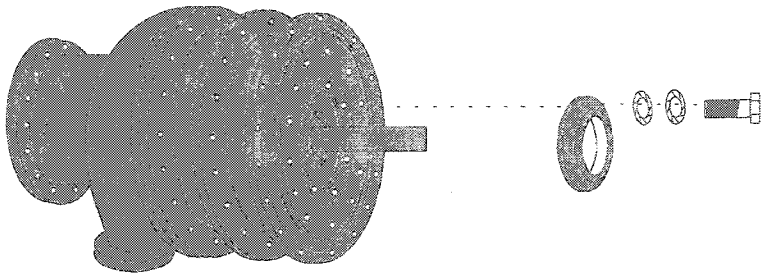


(a) For units with a the large diameter (straight) shaft at the 1st stage impeller location, slide the shim and spacer on the shaft that was removed during disassembly (see Figure 25). Make sure the spacer, which was marked during disassembly, is placed back on the shaft in the proper position. This will help maintain proper balance if all the rotating components are being re-used.

Figure 25

(b) Some units have a step shaft, where the shaft diameter for the 1st stage impeller is smaller than the remainder of the shaft. Depending on unit size and design sequence, there may be a .500" aluminum spacer mounted against the 2nd stage impeller hub and then a longer aluminum spacer that steps down to the smaller shaft diameter. Some units will have a thin shim against the 2nd stage impeller, a long aluminum spacer tube, and then an end spacer that fits inside the tube. Make sure the spacer tube and end spacer (when used), which were marked during disassembly, are placed back on the shaft in the proper position. (See Figure 26.) This will help maintain proper balance if all the rotating components are being re-used.

Figure 26



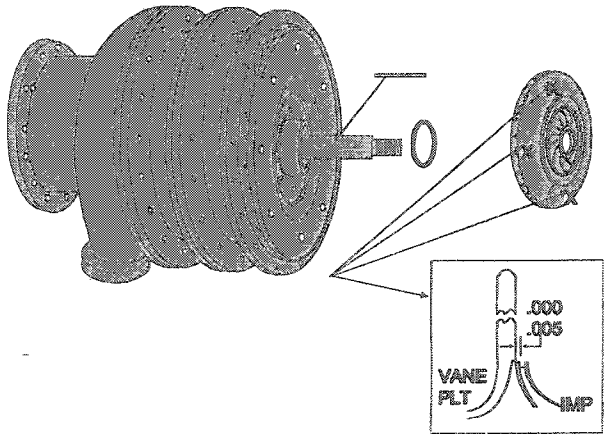
21 Interstage Spacer Seal installation.

(a) Install the seal with bolts and ramp washers over the interstage spacer.

(b) Hand tighten the bolts and center the seal using a feeler gauge. The allowable tolerance can be found in Table 5.

(c) Tighten the bolts to 20-27 lb-ft.

Figure 27



22 1st Stage Impeller & Impeller Locknut Installation.

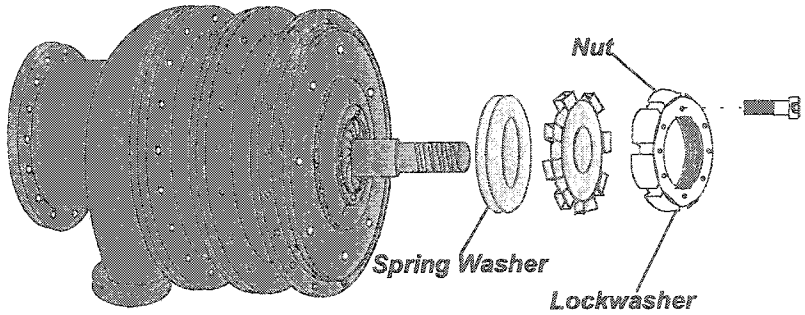
(a) Clean the impeller shims. Slide the impeller shims against the interstage spacer. Impeller alignment should have been checked during disassembly and any adjustments to the shim(s) thickness necessary to get proper impeller alignment can be made at this time. If the impeller or motor shaft has been replaced, then you may want to use only a portion of the original shims for an initial alignment to determine how many additional shims may be required.

(b) Thoroughly clean the impeller, key, and shaft. Check the impeller bore for cracks. This can be done using a dye penetrant flaw detection kit. Replace the impeller if cracked. Some types of damage to the impeller bore or nose seal area on impellers can be repaired by The Trane Company.

Figure 28

(c) Check the impeller key and keyway in the impeller bore for damage. Check to ensure that the sides of the keyway in the impeller bore are square.

(d) Coat the impeller bore and shaft with compressor oil. Install the key in the shaft. Slide the impeller on the shaft until it contacts the shims. Check the alignment of the impeller. The back inside discharge surface of the impeller should be flush to no more than a .0050" set out beyond the face of the diffuser plate. See Figure 28.



If the impeller does not slide easily on the shaft, it may be necessary to heat the impeller slightly to allow it to slide on the shaft. Before heating the impeller inspect the impeller bore for debris or a dent (high spot) that could be causing interference. When heating the impeller, use a large (Rosebud) tip with a soft gentle flame. The impeller should be heated so that it is warm to the touch. Do not exceed 120°F. The impeller bore (ID) to shaft.

(e) When required, remove the impeller and add shims to obtain the proper alignment. Slide the impeller on the shaft and recheck the alignment.

(f) Check the radial clearance between the impeller OD and the vane plate ID The minimum clearance around the entire circumference is .0220" minimum. If necessary, loosen the diffuser plate and reposition it to obtain proper clearance.

(g) Before installing the spacer, conical (spring) washer, and lockwasher on the shaft, (Figure 29) thread the locknut on by hand to ensure there are no burrs or damaged threads etc. The locknut thread fit should be snug but may be turned by hand without use of a spanner wrench. Install the spacer, spring (conical shaped) washer, lockwasher, and impeller locknut on the shaft and tighten by hand until all clearance has been taken up in the assembly. Make sure the spring washer is installed so the concave side is toward the impeller as shown in Figure 29.

Figure 29

(h) Rotate the shaft so that the 1st stage impeller key is at the 12 o'clock position.

(i) Some compressors have a balance/locknut with weights. If all original compressor components (motor/rotor, impellers, spacers etc.) are being re-used, then the weights may be left on the balance nut. Once the locknut has been hand tightened, place a mark on the locknut and the impeller hub. Tighten the locknut the required rotation as described below.

Small Locknut:

Once hand tightened, the small locknut (less than 2.500") should be rotated another 360-390 degrees using a spanner wrench and brass hammer or special socket and impact wrench. Use the marks described above to determine the rotation of the nut compared to the impeller. Once reaching 360 degrees of rotation, look for the next

locking tab on the lockwasher that will fit into a notch in the locknut. Do not overtighten the locknut as it is possible to cause shaft bending and runout, which could result in vibration problems.

Large Locknut:

Once hand tightened, the large locknut (greater than 4.000") should be rotated 170-180 degrees. Use the marks to determine the rotation of the nut compared to the impeller. Once reaching 170 degrees of rotation, look for the next locking tab on the lockwasher that will fit into a notch in the locknut. Do not overtighten the locknut as it is possible to cause shaft bending and runout, which could result in vibration problems.

When reusing a locknut with balance weights, make sure the match marks made during disassembly are aligned in their original position after the nut is tightened properly. See the Disassembly section.

IMPORTANT: If the rotating components have been reused and the balance weights do not line up as originally marked, the balance weights should be removed.

IMPORTANT: If the rotating components have been replaced or were not marked during disassembly or do not line up as originally marked, the balance weights should be removed.

(j) Once the locknut has been properly tightened, bend over a tab on the locking washer. It is recommended that a new lockwasher be used during re-assembly.

CAUTION

Compressor Damage!

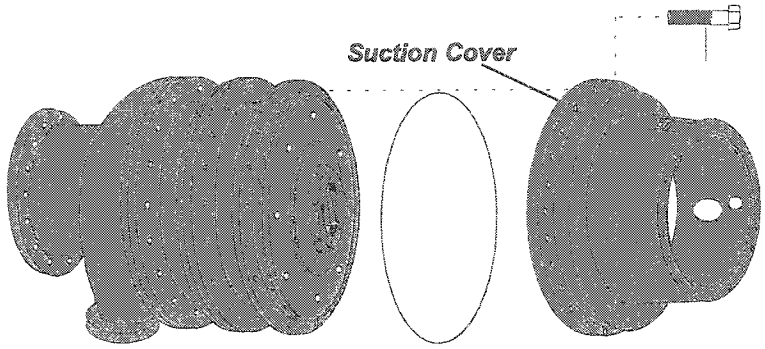
Once a locking tab has been bent over on a lockwasher it may become weak and break off if the same tab is re-used. This could cause the impeller locknut to loosen and come off during operation, causing major damage to the compressor and motor.

(k) Check the impeller nose runout using a dial indicator with a magnetic base. Rotate the impeller and measure the maximum runout. The allowable maximum runout for fabricated (welded) impellers is .0050" and .0035" for cast style impellers.

(l) For shafts with the extension beyond the locknut or units with balance nuts, check the shaft runout after the locknut is tightened. Checking shaft runout on units without the balance nut or shaft extension will be difficult since the standard locknut does not have a smooth machined surface where the indicator can be used. Rotate the shaft and measure the maximum shaft runout. The allowable maximum shaft runout is .0012"

23 1st Stage Suction Cover Installation.

(a) Clean the cover and mating surface.



(b) Attach the lifting fixture to the suction cover and find the proper balance point.

(c) Apply Loctite 515 and an o-ring (when applicable) per recommended procedures.

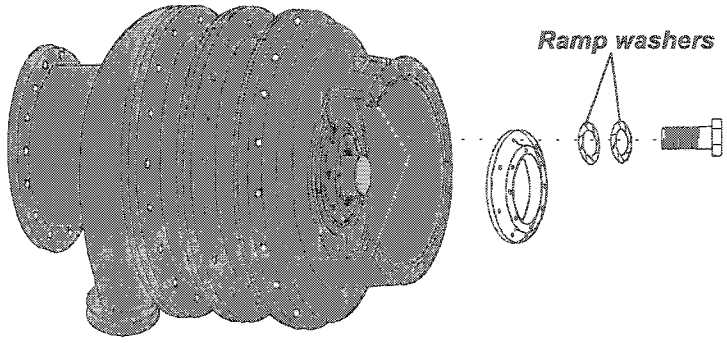
(d) Install four guide pins to help align the suction cover. Make sure the scribe marks between the 2nd stage cover and 1st stage cover are lined up before final tightening of bolts.

(e) Install bolts and torque to 120-165 lb-ft.

Figure 30

24 Impeller Nose Seal Installation. (see Figure 31)

(a) Thoroughly clean the nose seal to remove any debris or loose chips from the labyrinth teeth.



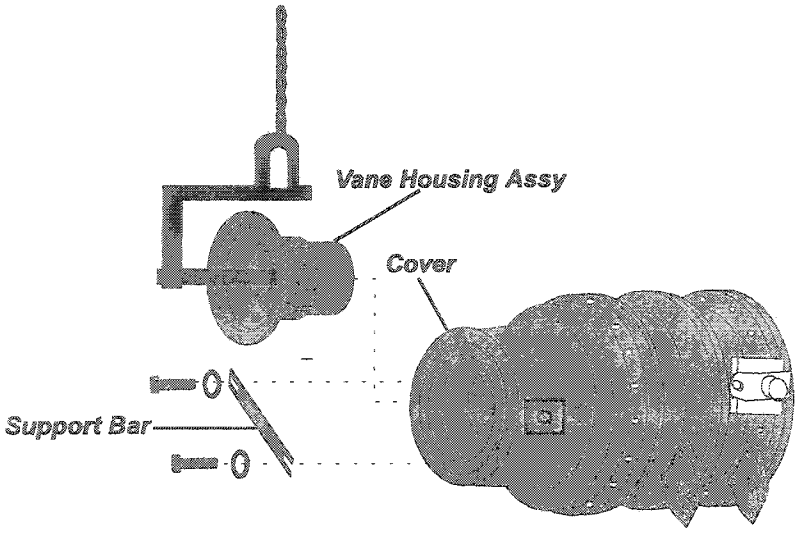
(b) Use the original bolts and new locking tab washers.

(c) Using a feeler gauge, center the seal around the nose of the impeller. The proper clearance can be found in Table 5.

(d) With the seal set properly, tighten the bolts to 20-27 lb-ft. Recheck the seal clearance.

(e) Rotate the shaft to ensure it rotates freely.

Figure 31



25 1st Stage Vane Assembly Installation.

(a) Thoroughly clean the vane assembly and check to ensure that the vanes move freely. Oil the vane bearings before installing.

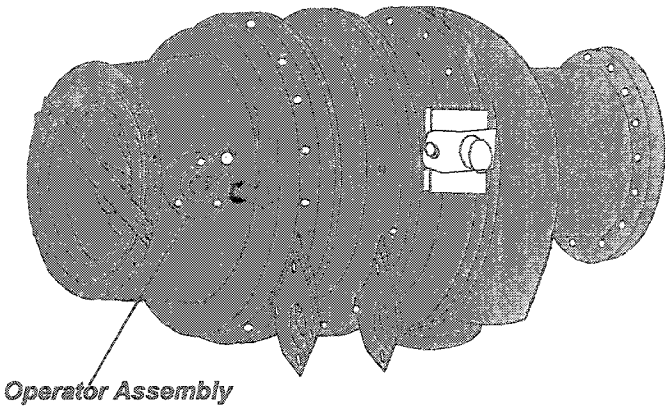
(b) Use the special lifting tool described in the disassembly section to lift the vane assembly. Once the vanes are positioned in the housing, secure the vane assembly using a piece of L-angle and two bolts with washers. See Figure 32.

Figure 32

(c) Use three allen head setscrews to secure the inlet vane in the housing. Tighten the setscrews. See Figure 33.

(d) Install the 1st stage vane operator tang assembly using the marks placed on the operator lever and suction cover (with vanes closed) during disassembly to position the tang assembly (see Figure 33). It may be advisable to consider rebuilding of the operator using new o-rings, nylon bushings, and lip seal if applicable to eliminate a leak potential. The 1/8" NPT pipe plug should be removed and compressor oil poured into the area between the two internal o-rings to lubricate them. Replace the plug (see Figure 34.

Figure 33



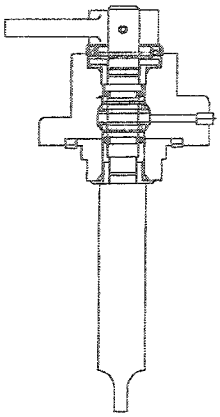


Figure 34

(e) Torque the tang operator mounting bolts to 14 lb-ft.

(f) Remove the L-angle and bolts holding the vane assembly in the suction cover.

26 Air Run of Compressor For Balance.

(a) Run the compressor on air with the suction elbow off.

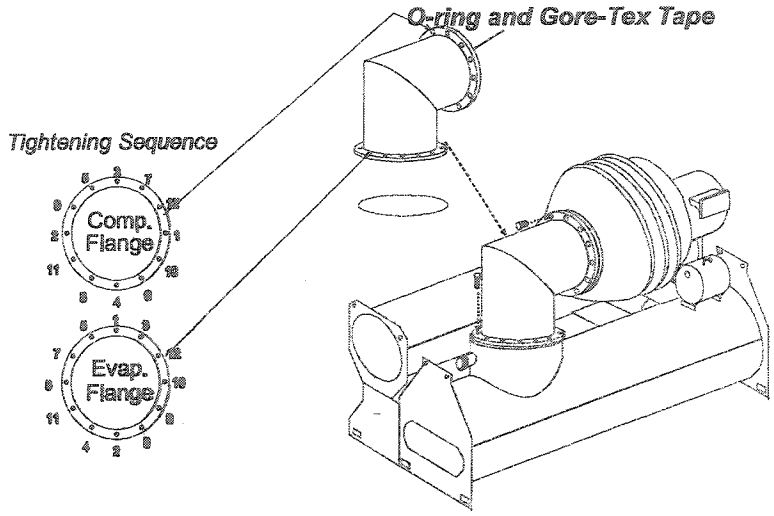
(b) Measure the vibration levels as indicated in *CVHE-SB-18* (latest revision) and, when required, trim balance the compressor to ensure proper balance.

27 Suction Elbow Installation.

(a) Clean the sealing surfaces on the suction elbow, evaporator, and suction cover flanges. The suction elbow must be properly insulated to prevent moisture from condensing. Insulation that was improperly applied or damaged may allow moisture to collect between the flanges and in the bolt holes. It may be necessary to use a bottoming tap to clean up the bolt holes before installing the elbow.

(b) Apply Loctite 515 and o-ring (when applicable) per recommended procedures. The lower flange at the evaporator requires Loctite. The upper suction elbow connection at the compressor suction cover should be installed with *no* sealant on the o-ring and a back-up Gore-Tex tape installed between the o-ring groove and the inner suction connection opening in the elbow. After installing the Gore-Tex tape, apply a small amount of petroleum jelly to the o-ring to help hold it in place while installing the suction elbow. See General Service Bulletin *CTV-SB-66* (latest revision).

(c) Using a sling lift the suction elbow into position. Install bolts by hand making sure the flanges at the suction cover are square with the cover. ***NOTE:*** *All bolts should be coated with an anti-seize compound to help prevent rust.* Snug up the bolts slightly.



(d) Torque the bolts in the elbow to 120-165 lb-ft following the pattern shown in Figure 35. Ensure the elbow flange pulls up square to the suction cover and does not place a strain on the cover.

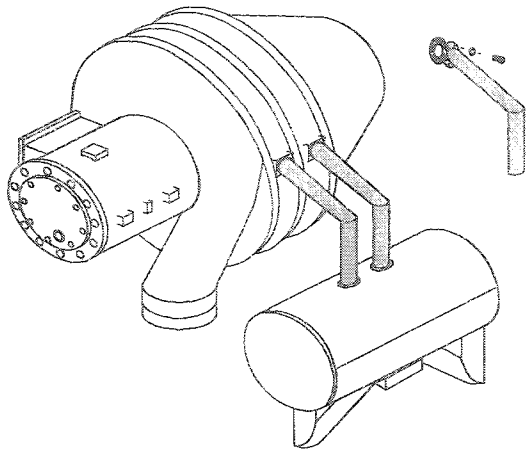
⚠ CAUTION

Compressor Damage!

Verify proper elbow flange fit. Failure to maintain proper suction elbow fit up can cause vibration problems or seal-to-impeller interference and possible damage to the impellers and compressor.

Figure 35

(e) The compressor should be run on air with the suction elbow installed. Refer to General Service Bulletin *CVHE-SB-18 (latest revision).*



(f) See Step 30 when the unit-mounted starter is used.

28 Economizer Installation.

(a) Clean the flanges on the economizer, evaporator, and the condenser outlet pipe. The bolts holes on the evaporator flange may need to be cleaned up using a bottoming tap to remove rust. Some of the early vintage CVHEs with unit sizes larger than CVHE056 used a four bolt flange at the evaporator for the larger size units. This was changed on later designs to eight bolts to ensure a better seal. It may be advisable to drill and tap the four additional holes in the evaporator flanges of early-production chillers to prevent leaks. The replacement gasket will have the four additional holes.

(b) Using a sling on either end of the economizer, move the economizer into position. See Figure 36.

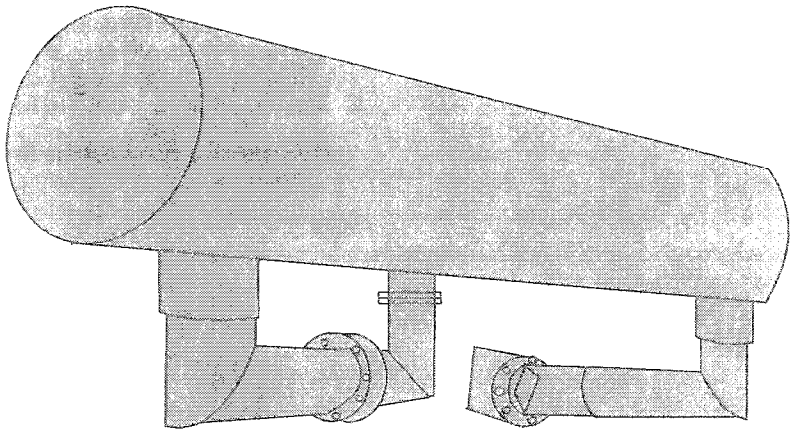


Figure 36

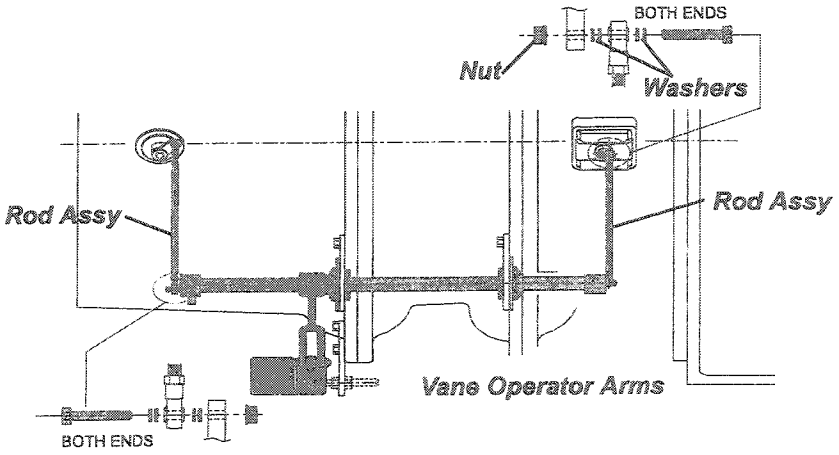
(c) Coat the threads of the bolts for the evaporator flange with an anti-seize compound.

(d) Tighten the bolts to 14 -16 lb-ft. See Figure 37.

Figure 37



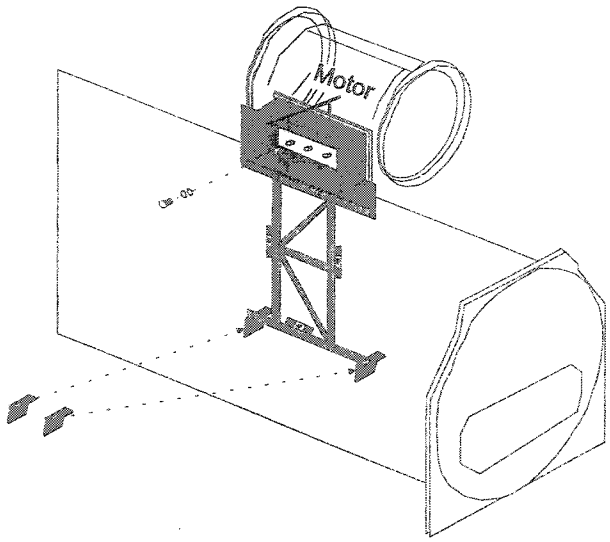
29 Inlet Vane Linkage Installation.

(a) Attach the linkage assembly brackets to the compressor casings. The outline of the mounting brackets should have been scribed on the casings to align the brackets in their original position.

IMPORTANT! Maintaining the proper vane schedule between stages is important. Misadjustment of the vanes can cause gas flow turbulence at certain compressor load points resulting in noise and vibration. This problem is usually an indication that the final stage vane assembly has lagged behind the 1st stage vane position. Adjustment of the vane assembly brackets on the compressor casings or length of linkage rods may resolve this condition.

(b) Reconnect the drive rods to the vane operator arms. See Figure 38.

Figure 38



(c) Open and close the vanes to ensure they operate freely.

30 Unit Mounted Starter Installation.

(a) Clean off the flange on the motor housing and transition piece between the starter and motor housing.

(b) Use a new gasket between the transition piece that bolts to the motor terminal board casting flange. See Figure 39.

Figure 39

(c) Lift the unit mounted starter into position using the eye bolts in top of starter.

(d) Bolt the starter to the motor housing flange and the lower evaporator mounting brackets.

(e) Re-attach the motor leads to the motor terminal studs. The leads and motor studs should have been marked during disassembly. Torque clamp connectors to 27 lb-ft.

31 Motor Cooling Lines.

(a) Clean the motor cooling line flanges and motor housing.

(b) Install the motor cooling orifice between the flange and motor housing with a gasket on either side of the orifice. The motor cooling orifice is a flat piece of steel with a stamped hole in the center of a specific diameter matching the motor size and horsepower.

(c) Install the drain lines using new gaskets.

(d) Tighten the bolts.

32 Oil Supply Line Orifice.

(a) The oil supply line for the ball bearing end has an orifice at the motor housing. The orifice is threaded into the motor end bell. The orifice limits the amount of oil that is supplied to the ball bearing. Installing the oil supply line without the proper orifice may lead to excessive oil flow through the bearing cavity and possible oil loss.

CTVH-GCO-03-EN

CVHF Compressor Disassembly (Including):

- Economizer Removal
- Suction Elbow Removal
- Compressor Disassembly
- Unit Mounted Starter Removal
- Motor Removal
- Discharge Volute Removal

CVHF and CDHF Duplex Unit

Compressor Sizes 350 through 1280 Ton

This section describes disassembly (including economizer, suction elbow, unit mounted starter, motor, and discharge volute removal) procedures for the model CVHF CenTraVac compressor assemblies. The same information applies to the compressors for the CDHF duplex units. For disassembly and re-assembly procedures for the motor, see CenTraVac Service Literature Section *CTVH-GMO-01*.The procedures covered in this section may be used for the CVHF and CDHF compressor sizes 350 through 1280 tons. For information on the CVHE and CVHG compressors, see CenTraVac Literature Sections *CTVH-GCO-01& 02.*

For information on the extended capacity compressor sizes CVHF 1470 and 1720 see CenTraVac literature sections *CTVH-GCO-05 &06.* Always check the appropriate table to obtain weights and tolerances for a particular type or size of compressor.

Warning and Cautions

WARNINGs and CAUTIONs appear at appropriate sections throughout this manual. Read these carefully.

WARNING: indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

CAUTION: indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury.

CAUTION: may also be used to alert the reader to a situation that could result in equipment or property-only damage.

Disassembly.

Refer to CenTraVac General Literature Section CTVH-GMS-01 for details on the special lifting fixtures for removing the first stage inlet vane assembly and handling the compressor suction cover and casing components. The tools shown can be fabricated locally using the drawings found in the special tools section. The Trane Company assumes no responsibility for the use of materials that do not meet the required specifications, or for improper or faulty manufacturing, assembly or use of these lifting fixtures. Never exceed the maximum safe lifting capacity of the fixture.

IMPORTANT!: Some of the lifting tools built for the CVHF compressor components have a maximum lifting capacity of 1300 lb. The tool maximum weight capacity is stamped on the tool. Some CVHF castings exceed this rating and the lifting tool given in Literature Section CTVH-GMS-01 must be used.

⚠ WARNING
Heavy Objects!
Use lifting and rigging equipment that is rated to handle the maximum weights. Improper use of lifting fixtures may result in death or serious injury.

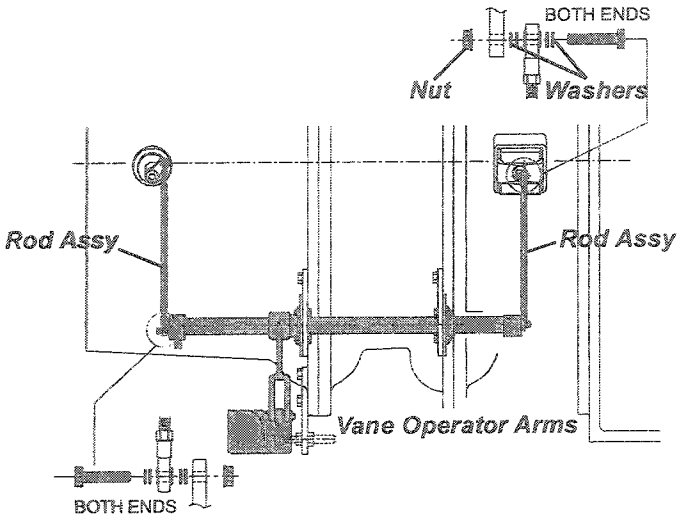
Follow all proper procedures when handling large compressor components. Use lifting and rigging equipment that is rated to handle the maximum weights of the pieces found inTable 2 in the back of this literature section. It is recommended that all lifting devices have a capacity rating no less than 100% of the weights shown. Carefully inspect lifting equipment to ensure it is in good condition and has been certified for continued use at proper intervals.

1. It may be advisable to obtain vibration readings for reference purposes prior to disassembly. See General Service Bulletin *CVHE-SB-18* (latest revision) for information on allowable vibration limits.

⚠ WARNING
Hazardous Voltage!
Disconnect all electrical power, including remote disconnects, before servicing. Follow proper lockout/tagout procedures to ensure the power cannot be inadvertently energized. Failure to disconnect power before servicing could result in death or serious injury.

IMPORTANT!: Be sure to properly lock out ALL potentially hazardous energy sources before servicing is done on the equipment. Follow all proper refrigerant handling procedures. Before disassembly, evacuate the unit to 2.5 mm vacuum and bring the unit back up to atmospheric pressure using dry nitrogen.

2 Mark and disconnect all power leads to the inlet vane actuator motor. Remove the conduit assembly from the actuator motor.



3 Remove the inlet vane actuator linkages.

(a) Disconnect the universal joints at the inlet vane operator levers.

(b) Before removing the vane drive support assemblies, mark the compressor castings by scribing a line around the brackets so they may be reassembled in the same relative positions. This will help ensure that the inlet vane linkages maintain their proper coordination between the stages.

(c) Remove the 5/8"-11 x 2"hex head bolts securing the vane drive support assemblies to the compressor castings. See Figure 1.

Figure 1

(d) Remove the cotter pin securing the vane operator stud.

(e) Slide the vane motor off the stud and remove the entire vane linkage assembly and vane motor from the unit.

(f) Remove the linkage assembly from the vane motor by removing the cotter pin or bolt and nut. The vane motor is now free and can be removed.

⚠ CAUTION

Component Alignment!

Before disassembling the compressor, scribe lines across the flanges on the exterior edges of all compressor castings in two locations, 180 degrees apart. This must be done so

that all components can be re-aligned during re-assembly. Failure to complete this step may result in misalignment of the suction elbow upon re-assembly and possible distortion of the compressor. This can cause vibration problems or seal-to-impeller interference and possible damage to the impellers and compressor.

⚠ CAUTION

Component Alignment!

The following two paragraphs provide instructions to maintain proper component alignment and fit. Make sure the compressor casings are doweled or scribed and the discharge volute is doweled. Failure to maintain proper alignment may result in compressor damage. Failure to maintain proper suction elbow fit up can cause vibration problems or seal-to-impeller interference and possible damage to the impellers and compressor.

4 Before proceeding further, check to make sure the discharge volute has dowel pins in the flange at the condenser and the compressor foot where it mounts on the evaporator support bracket. These pins are standard on all newer units and will be required if the discharge volute or entire compressor will be removed from the shells. The alignment of the compressor/motor assembly is determined by the position of the discharge volute. A shift in volute position at either the discharge flange or the compressor foot can change the suction elbow to compressor alignment. **Failure to maintain proper suction elbow fit up** can cause vibration problems or seal-to-impeller interference and possible damage to**the impellers and compressor.** Dowel pins should be present in the discharge flange and compressor foot. Units ordered for field disassembly (compressor removal) may have the motor, interstage casings and suction cover doweled as well as the discharge flange and foot.

For additional information on compressor doweling see *General Service Bulletin CVHE-SB-10* (latest revision).

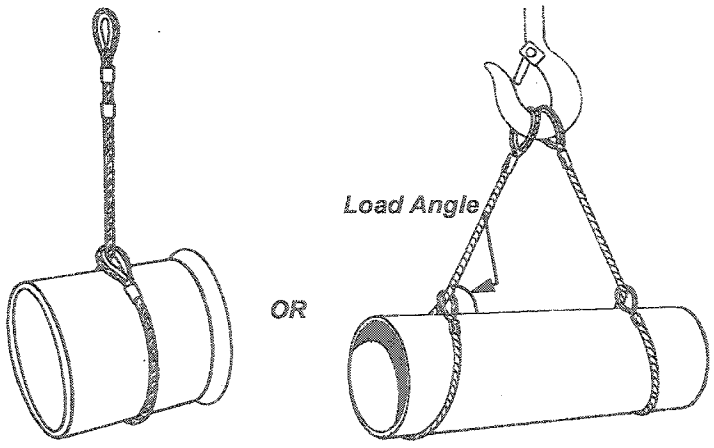
5 If the entire compressor or the volute will need to be removed from the shells, the dowel pins at the discharge flange and foot will have to be removed. First remove the threaded nut on the exposed end of the dowel pin. Then slip washers or a bushing over the pin. Reinstall the nut. As the nut is tightened, the pin will be pulled out of place. The dowel pins allow for precise assembly of the compressor components in their original position.

Note: It is not necessary to dowel all compressor casings for overhauls when properly scribed as detailed above.

IMPORTANT!: Make sure the evaporator and condenser inlet and outlet water valves have been closed (no water flow!) and the evaporator and condenser water

boxes have been completely drained. Failure to prevent water flow through the unit during repairs could cause severe rusting inside the shells. In humid environments it may be advisable to place a portable light or trouble light (100 -300 Watt) in the evaporator and condenser if necessary to provide enough heat to prevent moisture from condensing in the unit during repairs. In excessively humid environments, consider the use of a nitrogen purge to help prevent corrosion.

6 Remove the economizer to allow for compressor volute clearance.



(a) Some CVHE and CVHG units will require cutting the drain line that returns motor cooling liquid to the economizer. Sand the line to remove paint then cut with a tubing cutter. Do not use a hacksaw to cut the line. *Always use a tubing cutter to avoid* introducing copper chips (debris) into the unit.

(b) On smaller units, a floor jack may be placed under the economizer sump.

(c) For larger units it may be advisable to block the economizer and piping when the bolts are removed and then use slings (in the choke configuration) at each end to lift the economizer. See Table 2 for weights of economizers. Make sure the proper balance point of the economizer is found, to prevent it from rotating as it is lifted. See Figure 2 for proper sling use.

Note: The lifting capacity of a sling is reduced when the load angle is less than 90 °. See Table 1 for load factor values. For angles less than 90°, multiply the load factor by the nominal sling lifting capacity to determine the allowed lift weight.

Figure 2

NOTE: Use slings at EACH end when lifting.

Table 1

Load Angle (°)	Factor	Load Angle (°)	Factor
90	1.000	50	0.7660
85	0.9962	45	0.7071
80	0.9848	40	0.6428
75	0.9659	35	0.5736
70	0.9397	30	0.5000
65	0.9063	25	0.4226
60	0.8660	20	0.3420
55	0.8192	15	0.2589

(d) Carefully slide the economizer away from the shells.

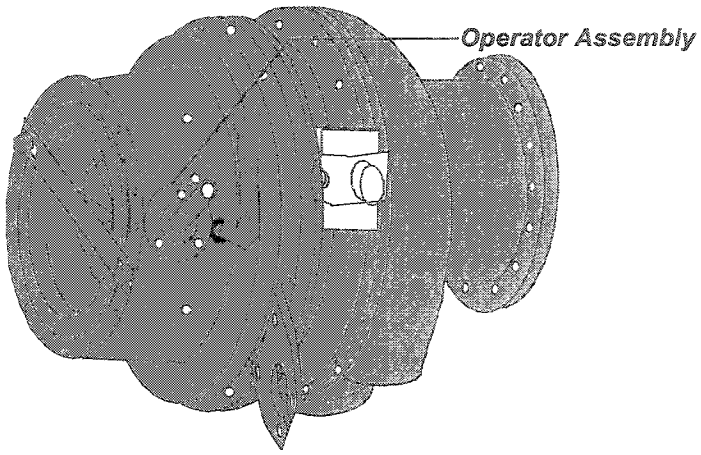
(e) Lightly oil all flanges with compressor oil. Cover all openings with plastic and seal with duct tape to prevent debris from entering the economizer.

(f) Remove the orifice assemblies and mark them properly. Oil the flanges on the condenser liquid line and the evaporator liquid inlet to prevent rusting. Cover the openings with plastic and duct tape to prevent entry of debris.

7 Remove the Suction Elbow.

(a) Remove the bolts from the suction elbow flanges at the evaporator and compressor.

(b) Place a sling in the choke configuration around the suction elbow. Position the sling so the elbow balances properly as it is lifted. *Do NOT use the weld nut on the suction elbow for lifting.* See Table 2 for the weight of the suction elbow.



(c) Clean and lightly oil the suction elbow flanges to prevent rusting and place the elbow on wooden blocks to protect the face of flange. Remove the o-ring, then thoroughly clean the groove in the flange on the evaporator. Lightly oil the flange on the evaporator. Cover the opening with plywood to protect the flange and prevent debris from entering the evaporator during repairs.

IMPORTANT!: During the compressor disassembly process, you must mark all components before removing them. Mark the face of components with a description or location (e.g.1st stage impeller seal) and the top(12 o'clock) mounting position of all seals, impellers, spacers, casings, plates etc. so they may be re-installed in the same position. This will be important in maintaining the proper balance and alignment of the rotating components during re-assembly. A permanent ink marker or a scribe may be used to mark the components.

8 Remove the first stage inlet vane assembly.

(a) Loosen and remove the 5/16"-18 x 1"hex head bolts and lockwashers securing the first stage vane operator assembly to the suction cover. See Figure 3. Mark the operator lever and the suction cover casing with the vanes in the closed position. Remove the vane operator assembly.

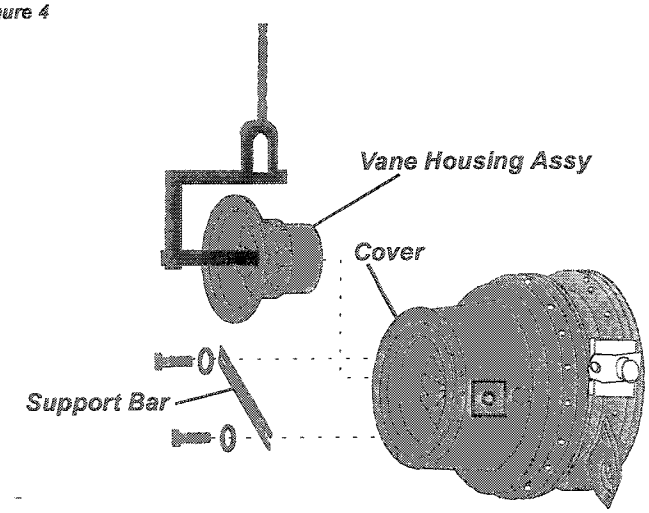


Figure 3

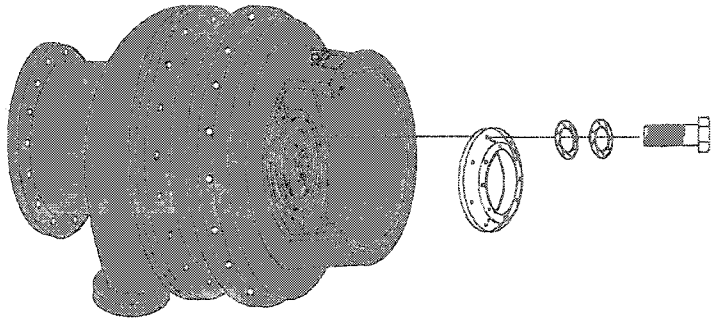
(b) Use a length of L-channel extending across the width of the inlet vanes and two bolts with washers in the suction cover flange to hold the inlet vane assembly in the cover.

– Remove the three 5/16"-18 x 3/8" countersunk set screws in the suction cover holding the inlet vane assembly in place. See Figure 4.

Figure 4

(c) Using the vane lifting tool shown in Figure 4, lift up slightly on the vane assembly. Remove the L-channel holding it in place and pull the vane assembly away from the suction cover. The weight of the vane assembly is given in Table 2.



*IMPORTANT!: Immediately spray a rust-preventive penetrating oil into the needle bearings in the inlet vane housing, while manually opening and closing the vanes. Thoroughly oil the bearings to minimize the risk of rust forming in the bearings, which could lead to vane binding. **Anytime a unit will be open for major repairs, it** is recommended the needle bearings in the vane assembly be replaced.*

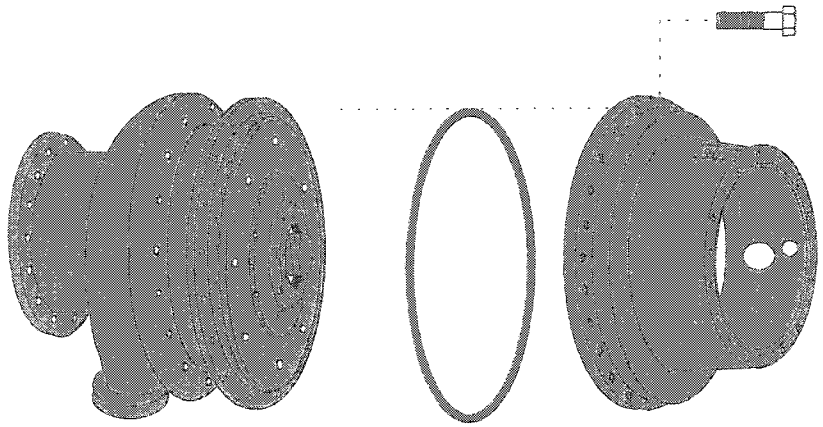
9 When applicable, sand the paint from the oil sump vent line to the suction cover and cut the pipe using a tubing cutter. Do not use a hacksaw to cut the line. Always use a tubing cutter to avoid introducing copper chips (debris) into the unit.

10 Remove the 1/4" oil drain line at the bottom of the suction cover.

11 Measure and record the clearance between the 1st stage seal impeller labyrinth and impeller nose using a feeler gauge. If so equipped, bend the tabwasher tab back allowing the hex head bolts that secure the seal to be removed. The tabwashers are no longer used in production and should be replaced by ramp washers during re-assembly. Remove the seal and store properly along with the retaining bolts. See Figure 5.

Figure 5

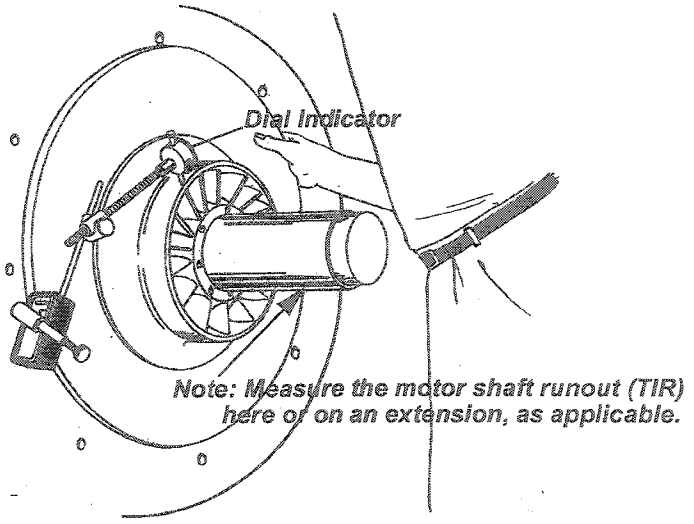
IMPORTANT: Mark this seal carefully. On some size units this seal is mounted in a reverse position. Installing it incorrectly could result in improper venting of the suction cover and may lead to oil loss. Do not mix the bolts with those of other seals, as the bolt lengths may vary.



12 Remove the suction cover and suction cover o-ring.

(a) Remove two of the 5/8" bolts from the suction cover, 180 degrees apart on the horizontal centerline (3 and 9 o'clock position) and insert 6" long guide pins.

(b) Attach a casting lifting fixture to the face of the suction cover flange.



(c) Remove a bolt near the bottom of the suction cover and one to the side of the lifting fixture and insert 6" long 5/8" stop bolts with heads to limit movement of the cover until a proper balance point is obtained. Attach an overhead hoist of sufficient lifting capacity to the lifting plate. See Table 2 for the weight of the suction cover. Remove the remaining bolts (leaving in place the 6" long guide pins and 6" long stop bolts) and pick up slightly on cover. It may be necessary to use jacking bolts to push the cover away from the casing. If necessary, move the pick-up point on the lifting tool until the cover is balanced. Once the cover is balanced properly with the lifting tool, remove the stop bolts at the top and bottom of the cover and remove the suction cover. Oil the cover flanges lightly and store it properly to prevent rust or damage to the sealing surfaces. See Figure 6. Remove the guide pins.

Figure 6

13 Measure and record the total indicated runout (TIR) on the nose of the 1st stage impeller. Use a dial indicator with a magnetic base for measuring runout. See Figure 7.

Figure 7

14 Measure and record the total indicated runout (TIR) at the end of the shaft. Some motor sizes have an extension on the end of the shaft where the runout can be measured without having to remove the impeller locknut. Many motors will require removal of the locknut and 1st stage impeller to provide a surface for measuring runout. The allowable TIR is .0012".See note in Figure 7.

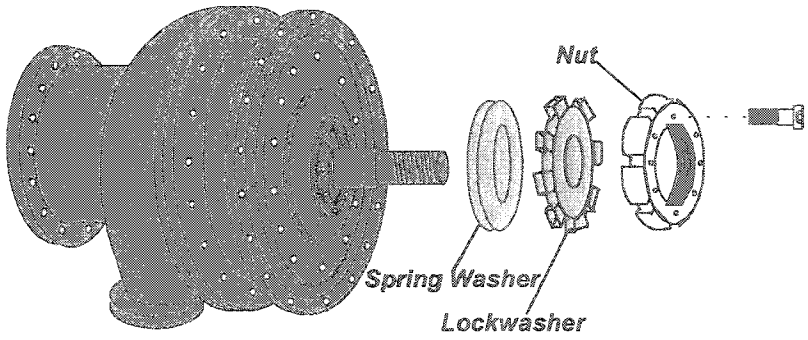
15 If it is anticipated that the present compressor seals along with other components will be used during re-assembly, it is advisable to record clearances and runout measurements.

The form at the back of this section can be used to record the tolerances. The recommended tolerances can be found in Table 3.

16 Remove the impeller locknut.

Note: Some units are equipped with a standard locknut, while some units have a balance style locknut. The balance style locknut has small tapped holes in the face for the purpose of installing balancing screws and weights.

IMPORTANT!: When the unit has a balance style locknut with weights attached, and the motor and all rotating compressor components will be re-used, it is necessary to mark all rotating components such as the locknut, spacers, impellers and motor shaft. This is required to ensure the components can be re-assembled in the exact position as they were removed. Failure to mark all components and reassemble them properly could lead to an out of balance condition and require the assembly to be trim balanced. If the motor/rotor or other rotating components located on the shaft will be replaced, it is not necessary to mark all components. Whenever replacing individual rotating components with new ones, the balance weights from the locknut should be removed.



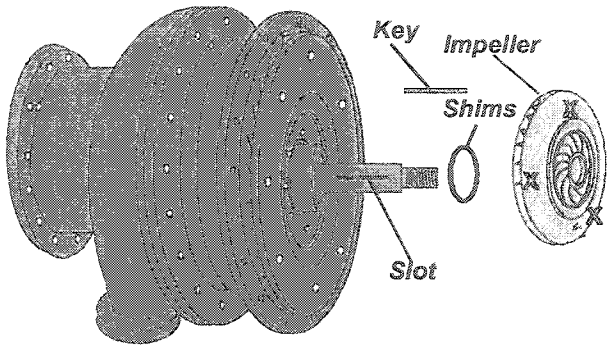
All major rotating components are individually balanced to specification before the compressor is assembled. Even though each major rotating component in the compressor is individually balanced, a small percentage of the compressors assembled in the factory and in the field may be beyond the allowable limit for unbalance. When this occurs, the compressor will need to be trim balanced in the field after re-assembly, using a balance style locknut and weights. Refer to Service Bulletin *CVHE-SB-18* (latest revision) for information on allowable vibration limits.

IMPORTANT!: When all components will be re-used during re-assembly, mark the position of the locknut relative to the end of the motor shaft. It is best to mark these at the location of the keyway for the 1st stage impeller. A small center punch can be used to place a mark on the locknut and the end of the shaft. Do not remove the balance screws or weights from the balance locknut when all components will be re-used!

(a) Bend the lockwasher tab back from the slot on the impeller locknut.

(b) Remove the impeller locknut, lockwasher, spring washer, and steel spacer as applicable. Use a spanner wrench to remove the locknut. SeeFigure 8. The locknut has right hand threads. To loosen impeller locknut, turn it counter clockwise. Use a wire cable tie or tape to keep the items together. Tape the end of the shaft to prevent damage to the threads. Note: It is recommended that the lockwasher be discarded and replaced with a new lockwasher during re-assembly.

Figure 8



⚠ CAUTION

Possible Compressor Failure!

Use undamaged or new lockwashers for re-assembly. Once a locking tab has been bent over on a lockwasher it may become weak and break off if re-used. This could cause the impeller locknut to loosen and come off during operation, causing major damage to the compressor and motor.

(c) Note: Discard old or damaged lockwashers. Save the conical spring washer for re-use.

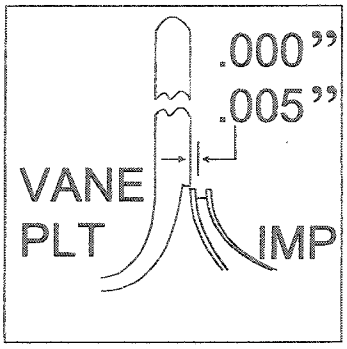


Figure 9

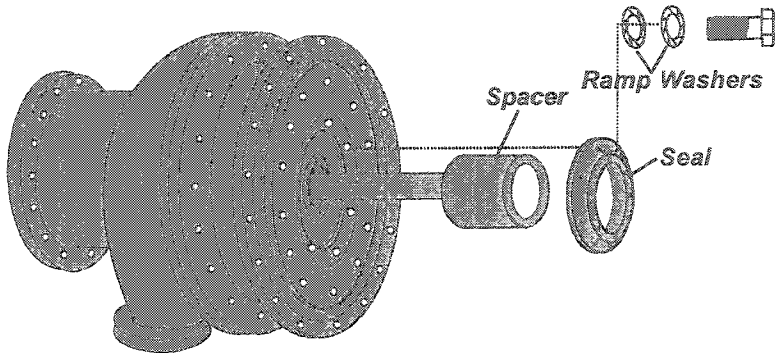
17 Remove the impeller (see Figure 9).

(a) Before removing the impeller, check the alignment of the impeller inside back discharge surface to the diffuser plate. The impeller surface should be aligned as shown in Figure 10. When reusing all rotating components and the alignment is not as specified above, measure and record the amount of shim(s) that may need to be added or removed during re-assembly.

Figure 10

(b) It may be necessary to use a puller to remove the impeller. When using a puller, make sure the face of the puller is parallel to the face of the impeller hub to ensure a straight pull. Take care not to damage the machining center in the end of the shaft. If necessary, a small amount of heat may be required to loosen the impeller on the shaft.

When heating impeller, use a large (Rosebud) tip with a soft gentle flame. Do not overheat the impeller. The impeller should be heated so that it is warm to the touch. Do not exceed 120°F.



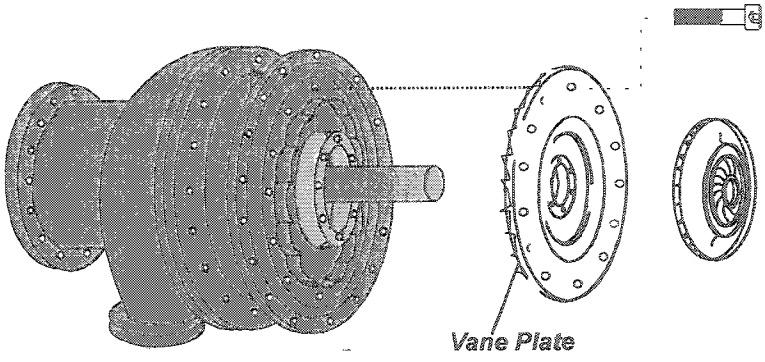
(c) Mark the impeller 1st STAGE.

18 Remove the impeller key and shims from behind the impeller. Clean the impeller, key and shaft. Tape the shims together and secure them to the impeller along with the key. Keep the parts for each stage together, and keep them separate from the other stage.

19 Measure and record the clearance between the 1st stage shaft seal and spacer. If the shaft seal has the lockwashers with bent over tab, bend them over using a screw driver. It is recommended the tab type lock washers be discarded and replaced by the ramp type washers shown in Figure 11. Remove the hex head bolts and ramp washers and remove the seal and mark it properly.

20 Remove the 1st stage spacer and spacer tube (some compressors).

Figure 11



(a) Mark the spacer and spacer tube with its position on the shaft with the first stage impeller keyway at the 12 o'clock position. The shaft spacer has tapped pull-off holes that can be used to pull the spacer if needed. Using the pull-off holes may be required on units where corrosion has occurred due to leaks and moisture or other causes.

(b) Mark the spacer and spacer tube for TOP and 1st STAGE.

21 Remove the 1st stage vane plate. See Figure 12. Refer to Table 2 for the weight of the vane plate.

Figure 12

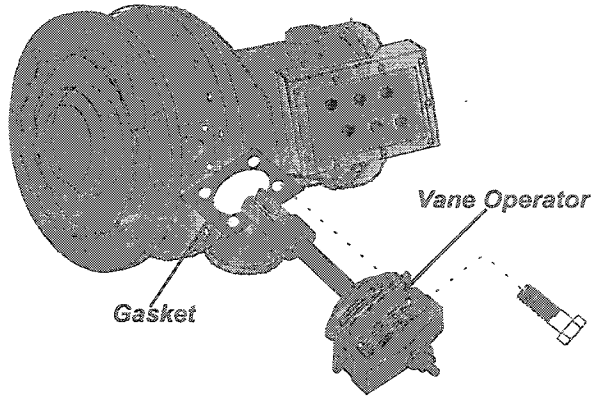
(a) Remove four 3/8" -16 socket head cap screws.

(b) Mark the vane plate for TOP and 1st STAGE.

(c) Install two 3/8" -16 x 6"stop bolts with heads in two of the bolt holes. Install two 3/8" - 16 x 6"guide pins (may be threaded rod, no heads) in the remaining two bolt holes.

(d) Remove the remaining socket head screws holding the vane plate to the interstage casing.

(e) Back the vane plate away from the interstage casing on the guide and stop bolts as far as the bolt heads will allow (approximately 6").



(f) Place a nylon sling through the center of the vane plate in the choke configuration.

(g) Lift the plate slightly with the nylon sling and remove the two remaining stop bolts with heads.

(h) Remove the vane plate, being careful not to damage the rotor shaft.

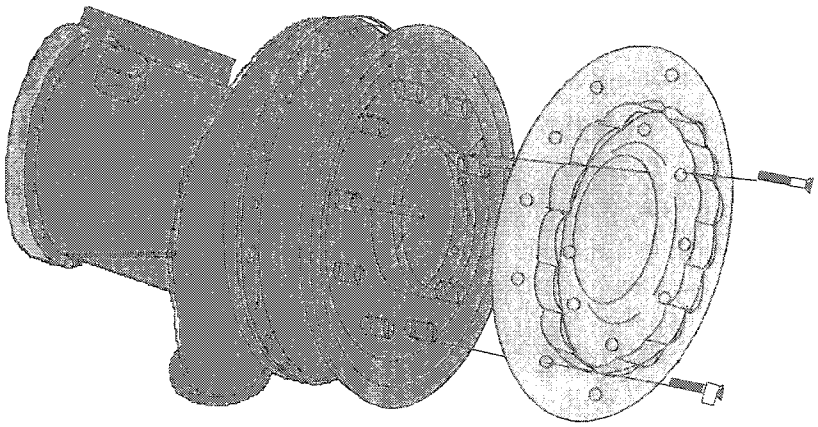
22 Remove the 2nd stage vane operator assembly. See Figure 13.

Figure 13

(a) Remove the 1/2" -13 x 1-3/4" hex head screws that secure the vane operator assembly.

(b) Remove the vane operator and gasket. Lightly coat all bare metal surfaces with compressor oil.

23 Remove the shroud and 2nd stage inlet vane assembly.



(a) Mark the assembly for TOP.

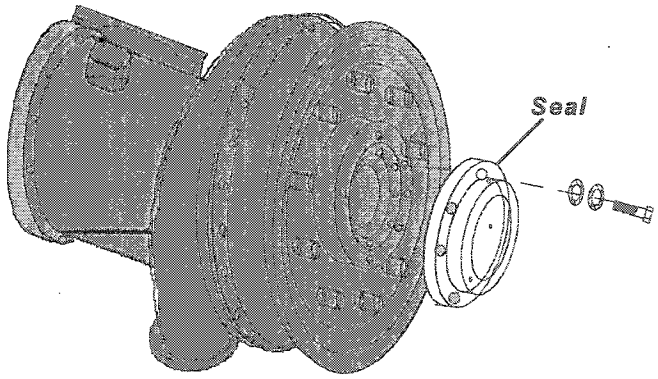
(b) Leave the guide pins installed in Step 32 in place. See Figure 14.

(c) Remove the 1/4" -20 x 3/4" flathead screws that secure the shroud. These screws use a thread locking compound and may be difficult to remove. Use an allen head socket for removal. Make sure the allen head socket does not have rounded edges. A hand impact driver may be helpful in removing screws.

(d) Attach a sling or cable to the shroud and remove the shroud and vane assembly. See Figure 14. For weights, see Table 2. Immediately coat the vane assembly shroud, pins, levers etc. with compressor oil or rust preventive oil to stop corrosion or rust.

Figure 14

24 Remove the 2nd stage impeller nose seal. Refer to Figure 15.



(a) Measure and record the seal clearance. Table 3 provides proper clearances.

(b) Mark the seal for TOP and 2nd STAGE.

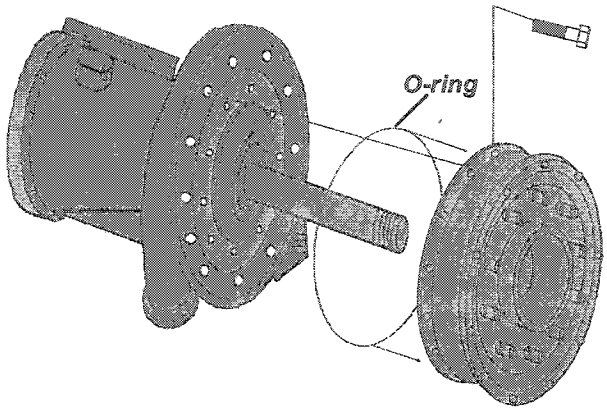
(c) Remove the 3/8" -16 x 1" hex head screws and tab or ramp washers.

(d) Remove the seal.

Figure 15

25 Measure and record the total indicated runout (TIR) on the nose of the 2nd stage impeller.

26 Remove the 2nd stage suction cover and o-ring. See Table 2 for the weight of the intermediate stage suction cover.



(a) Remove two bolts from the suction cover, 180 degrees apart on the horizontal centerline (3 and 9 o'clock positions) and insert 6" long guide pins.

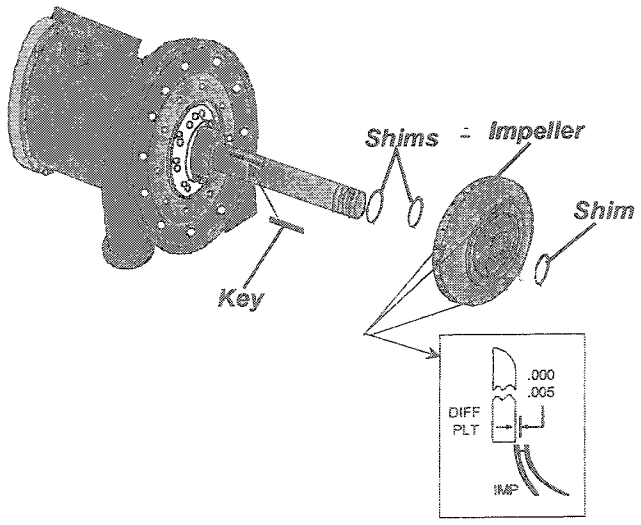
(b) Remove a bolt near the bottom of the suction cover and one to the side of the lifting fixture and insert 6" long stop bolts (with heads) to limit movement of the cover until a

proper balance point with the lifting fixture is obtained. Attach the lifting plate. Remove the remaining bolts (leaving in place the guide pins and stop bolts) and pick up slightly on the cover. It may be necessary to use jacking bolts to push the cover away from the casing. If necessary, move the pick-up point on the lifting tool until the cover is balanced.

(c) Once the cover is balanced properly with the lifting tool, remove the stop bolts at the top and bottom of the cover and remove the suction cover. Lightly oil the cover flanges and store it properly to prevent rust or damage to the flange sealing surfaces. See Figure 16.

Figure 16

27 Remove the 2nd stage impeller and the shim(s) in front of impeller. Tape the shims to the spacer removed earlier.



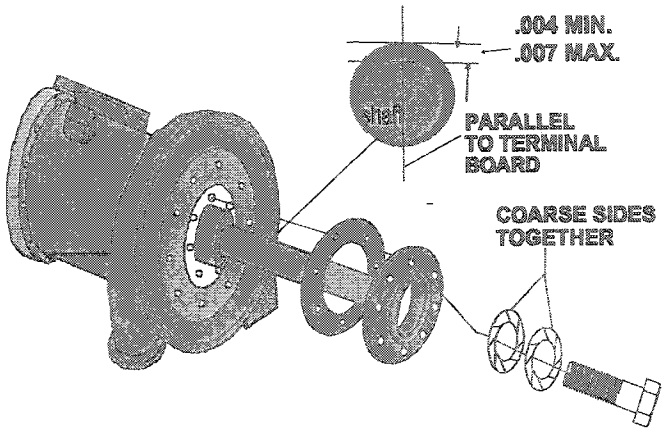
(a) Before removing the impeller, check the alignment of the impeller inside the back discharge surface to the diffuser plate. The impeller surface should be aligned as shown in Figure 17. When re-using all rotating components and the alignment is not as specified, measure and record the amount of shims that may need to be added or removed during re-assembly.

(b) A puller may be necessary to remove the impeller. When using a puller, make sure the face of the puller is parallel to the face of the impeller hub to ensure a straight pull. Take care not to damage the machining center in the end of the shaft. If necessary, a small amount of heat may be required to loosen the impeller on the shaft. When applying heat, use a torch with a large (Rosebud) tip and a soft gentle flame. Do not overheat the impeller. The impeller should be heated so that it is warm to the touch. Do not exceed 120°F. See Figure 17.

(c) Mark the impeller 2nd STAGE.

CenTraVac General Service Literature

Figure 17



28 Remove the impeller key and shims from behind the impeller. Tape the shims together and secure them to the impeller along with the key. *Note: It is important that the thicker steel* spacer be installed against the shaft shoulder with the chamfer facing the shaft shoulder.

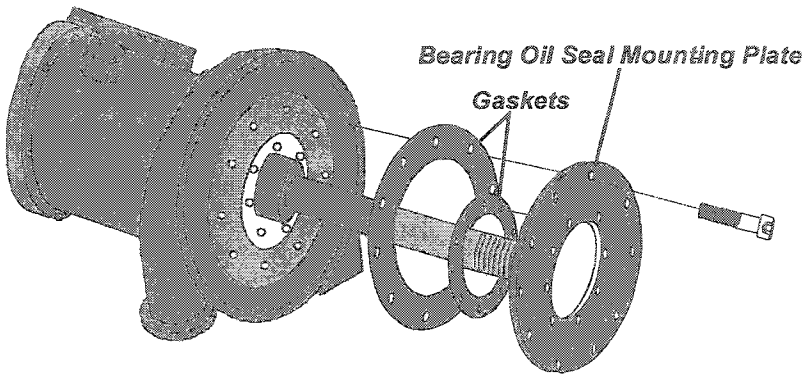
29 Remove the bearing oil seal and gasket.

(a) Measure and record the seal clearance. *IMPORTANT: Excessive clearance of this seal will cause oil loss.* Measure the seal clearance all the way around as shown. The total clearance between the shaft OD and seal ID will be 0.0040" to 0.0070". This seal is set in the factory with the bottom of the seal brought up to the bottom of the shaft and all the clearance (.004"-.007" total) at the top. The clearance between shaft and seal at the sides (3 and 9 o'clock positions) should be equal. See Figure 18.

Figure 18

(b) Mark the seal for TOP. *IMPORTANT: The seal has a small oil drain hole in the back* which must be correctly aligned during re-assembly. The drain hole must be at the 6 o'clock position.

(c) Remove the hex head screws and tab or ramp washers securing the seal and gasket.



30 Remove the bearing oil seal mounting plate and gasket.

(a) Mark the plate for TOP.

(b) Remove two 3/8" -16 x 1" socket head screws and insert two stop bolts approximately 6"in length and two 6" long guide pins.

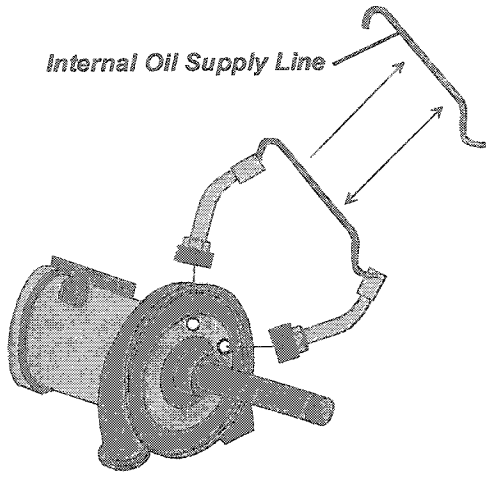
(c) Remove the remaining screws and then remove the plate and gasket. See Figure 19. Use a nylon sling or rope to lift the plate. See Table 2 for the weight of the plate. Place a container under the plate since some oil will drain out when the plate is removed. Lightly coat the plate with compressor oil to prevent rust.

Figure 19

31 Unit mounted starter removal (when applicable).

(a) Attach a small chain to the lifting eye bolts on top of the starter. Pick up slightly on the chain to take up slack.

(b) (Remove the motor leads from the motor terminal studs. Mark each lead carefully with the corresponding motor terminal number stamped on the motor terminal board. Remove other electrical connections as necessary to allow enough room to remove the starter and mark them carefully.



(c) (Remove the bolts holding the starter to the motor housing and the bolts (when applicable) on the lower support bracket and move the starter away from the motor, being careful not to damage the motor terminals.

32 Motor removal.

(a) Sand the external oil supply and drain lines to remove paint, then cut them with a tubing cutter. Do not use a hacksaw to cut the lines. Always use a tubing cutter to avoid introducing copper chips (debris) into the unit.

(b) Heat the internal oil supply line to loosen and remove line. Bleed nitrogen through the line when heating to prevent build up of copper oxides inside the line. Use a wet rag to protect the threaded connections from excessive heat. See Figure 20.

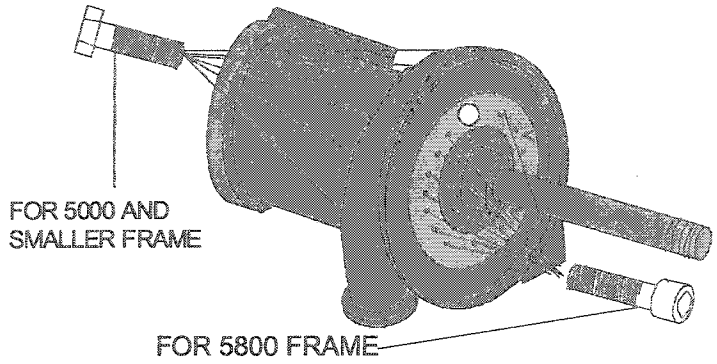
Figure 20

(c) If the motor is to be replaced or remanufactured, remove the bearing oil supply orifice on the thrust (ball) bearing end of the motor. The orifice threads into the motor bearing housing.

IMPORTANT!: Save the orifice for re-use.

IMPORTANT!: Failure to use a properly sized orifice on the ball bearing supply line could result in excessive oil flow and possible oil loss problems.

(d) Remove the flange bolts for the motor cooling refrigerant supply line and drain lines. In some instances, the drain lines may need to be cut to provide enough clearance for motor removal. Sand the drain line to remove paint then cut it with a tubing cutter. Do not use a hacksaw to cut the line. Always use a tubing cutter to avoid introducing copper chips (debris) into the unit.



IMPORTANT!: Remove the motor cooling orifice located between the motor housing and the motor cooling supply line flange. Save the orifice for re-use.

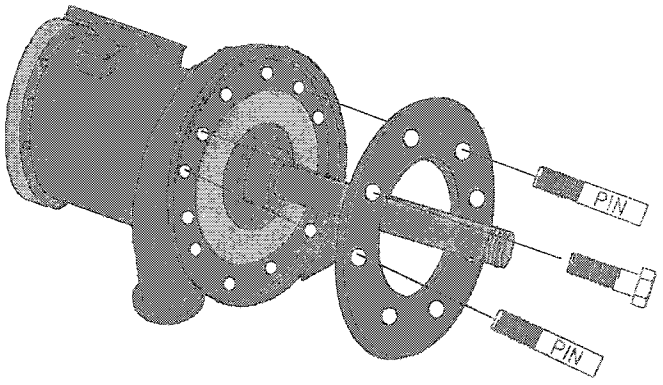
(e) Using two slings in the choke configuration, position them at each end of the motor housing. Refer to Table 4 for motor weights.

(f) Remove two of the bolts holding the motor assembly in the volute and install 5/8" guide pins (2-3" in length) so they are 180 degrees across from each other.

Note: On some units with large frame motors (>5000 frame), the bolts securing the motor to the discharge volute must be accessed from the compressor side. This will require removing the volute diffuser plate as detailed in step 33.

Figure 21

(g) Pick up on the slings to take up slack and remove the remaining bolts that secure the motor to the volute. Lift the motor slightly and move away from the volute being careful not to damage the motor shaft.



(h) Oil the shaft and cover all openings to prevent debris from entering the motor.

33 Volute diffuser plate removal.

(a) Remove four 1/2" allen head cap screws and insert two 6"long guide pins and two 4" long stop bolts.

(b) Remove the remaining allen head cap screws and slide the diffuser plate away from the volute. See Figure 22.

Figure 22

(c) Place a sling or cable in the choke configuration through to the center of the diffuser plate. See Table 2 for the weight of the diffuser plate.

(d) Lift the diffuser plate and remove the stop bolts.

(e) Slide the diffuser plate away from the volute. Oil the diffuser to prevent rusting.

34 Discharge volute removal.

(a) Remove the dowel pins on the discharge flange at the condenser and on the foot of the volute. First remove the threaded nut on the exposed end of the dowel pin. Then slip washers or a bushing over the pin and reinstall the nut. As the nut is tightened, the pin will be pulled out of place. The dowel pins allow for precise assembly of the compressor components in their original position.

(b) Place a sling in the choke configuration through the center of the volute. Take up the slack in the sling.

(c) Remove the bolts at the discharge flange and the compressor foot and then lift the volute. See Table 2 for volute weights.

(d) Clean and oil the discharge flange on the condenser and cover the opening to prevent entry of debris

Inspect all components for damage or excessive wear. Do not re-assemble the compressor using faulty components. Clean each component and apply a light coat of compressor oil to protect it from moisture and corrosion (especially o-ring and gasket surfaces).

This is a good opportunity to closely check the impeller bores for cracks. This can be done using a dye penetrant flaw detection kit. These kits are available through most weld supply or large industrial supply companies. The kits usually consist of a penetrant, developer, and cleaner, and include instructions on their use. Replace the impeller if cracked. Some types of damage to the impeller bore or nose seal area on impellers can be repaired by The Trane Company.

Note: Refer to Centravac Literature Section CTVH-XXXXXX for the CVHF compressor re- Assembly procedures.

Table 2
CVHF/CVDF Compressor Component Weights

Unit Type	Unit/Comp Size	Economizer (std, less free cooling)	Suction Elbow	1st Stage Inlet Vane	1st Stage Suction Cover	Impellers All Stages	2nd Stage Alum Vane Plate	2nd Stage Casing	2nd Stage Inlet Vanes and Plate	Steel Volute Diffuser Plate	Discharge Volute	Complete Compressor Including Motor
CVHF	350-485	700 lb. (318 kg.)	494 lb. (224 kg.)	295 lb. (134 kg.)	1400 lb. (635 kg.)	64 lb. (29 kg.)	190 lb. (86 kg.)	1400 lb. (635 kg.)	82 lb. (37 kg.)	289 lb (131 kg.)	1336 lb. (606 kg.)	7610 lb. (3452 kg.)

CVHF Compressor Assembly (Including)

- Discharge Volute Installation
- Motor Installation
- Unit Mounted Starter Installation
- Compressor Assembly
- Suction Elbow Installation
- Economizer Installation

CVHF and CDHF Unit:

Compressor Sizes 350-1280 Ton

This section describes re-assembly (including discharge volute, motor, unit mounted starter, suction cover and economizer installation) procedures for the model CVHF CenTraVac compressor assemblies. The same information applies to the compressors for the CDHF duplex units. For disassembly and re-assembly procedures for the motor, see CenTraVac Service Literature Section *CTVH-GMO-01*.The procedures covered in this section may be used for the CVHF and CDHF compressor sizes 350 thru 1280 tons. For information on the CVHE and CVHG compressors, see Centravac Literature Sections *CTVH-GCO-01& 02.*

See *CTVH-GCO-05 & 06* for the extended capacity compressor sizes 1470 and 1720.

Always check the appropriate table to obtain weights and tolerances for a particular type or size compressor.

Warning and Cautions

WARNINGs and CAUTIONs appear at appropriate sections through out this manual. Read these carefully.

WARNI NG: indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

CAUTION: indicates a potentially hazard us situation which, if not avoided, may result in minor or moderate injury.

CAUTION: may also be used to alert the reader to a situation that could result in equipment or property-only damage.

Centravac General Service Literature

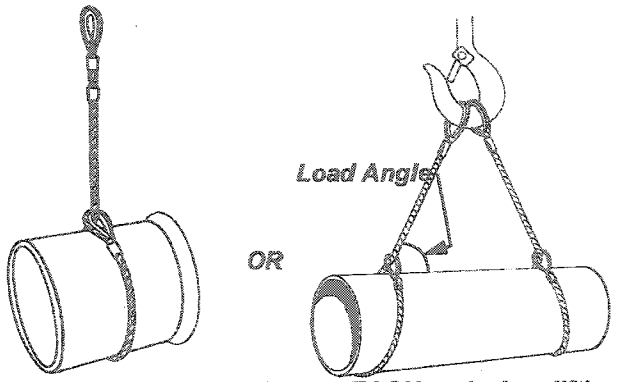
IMPORTANT!: Before beginning re-assembly o the compressor, it is important to check all pieces for damage, rust, or worn parts that could result in leaks or problems with unit operation or reliability. Clean all gasket and o-ring surfaces thoroughly. All traces of previous sealants must be completely removed and the surfaces wiped with a suitable solvent such as industrial grade isopropyl alcohol to remove all traces of oil and other contaminants. When using Loctite between flanges do not touch the flanges after cleaning and before application of Loctite. The oils left from fingerprints can affect the sealing ability of the Loctite. Check flange surfaces or high spots left around bolt holes and at jack bolt locations. These high spots can cause flange separation and may result in leaks. If necessary use a flat file to remove high spots.

⚠ WARNING
Hazardous Chemicals!
Always use proper protection when handling solvents and other potentially harmful chemicals. Use rubber gloves, clothing and eye protection and avoid prolonged inhalation of vapors. Failure to do so can result in death or serious injury.

IMPORTANT!: See the chemicals MSDS (Material Safety Data Sheet) for additional precautions and warnings on use.

The procedures for using an o-ring sealant can be found in *General Service Bulletin CTV-SB-66* (latest revision).

⚠ WARNING
Heavy Objects!
Use lifting and rigging equipment that is rated to handle the maximum weights. Improper use of lifting fixtures may result in death or serious injury.



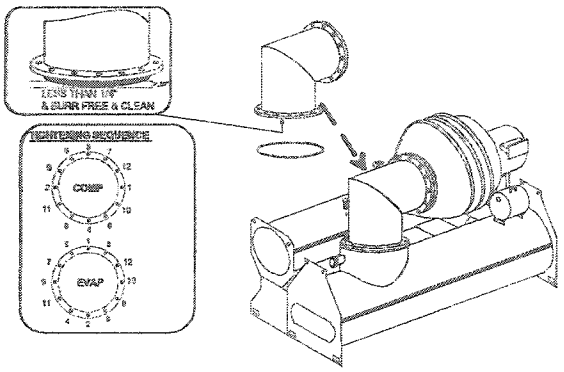
Follow all proper procedures when handling large compressor components. Use lifting and rigging equipment that is rated to handle the maximum weights of the pieces found in Table 2 in the back f this literature section. It is recommended that all lifting devices have a capacity rating no less than 100%of the weights shown. Carefully inspect lifting equipment to ensure it is in good condition and has been inspected and certified for continued use at proper intervals as appropriate.

For larger units it may be advisable to block larger components like the economizer and piping when the bolts are removed and then use slings (in the choke configuration) at each end to lift the part. See Table 2 for weights of components. Make sure the proper balance point of the load is found, to prevent it from rotating as it is lifted. See Figure 1 for proper sling use.

Centravac General Service Literature

Note: The lifting capacity of a sling is reduced when the load angle is less than 90°. See Table 1 or load actor values. For angles less than 90°, multiply the load actor by the nominal sling lifting capacity to determine the allowed lift weight.

Figure 1
Typical Choke Sling Cable Arrangement



NOTE: Use slings at EACH end when lifting.

Table 1

Load Angle (°)	Factor	Load Angle (°)	Factor
90	1.000	50	0.7660
85	0.9962	45	0.7071
80	0.9848	40	0.6428
75	0.9659	35	0.5736
70	0.9397	30	0.5000
65	0.9063	25	0.4226
60	0.8660	20	0.3420
55	0.8192	15	0.2589

Centravac General Service Literature

Figure 2

Before proceeding with compressor re-assembly review the procedures in General Literature Section CTVH-GCO-03EN containing information and details on CVHF compressor disassembly.

Unless otherwise specified, the bolt torques required on all flange joints with o-rings or joints where only Loctite 515 is used, can be found in Table 3 in the back of this section. The bolt torques listed in Table 3 are for Grade 5 bolts. *Use only grade 5 bolts or better.* Tighten bolts to final torque in incremental steps. Unless otherwise specified follow a crossing pattern when tightening bolts. See Figure 2 for a typical recommended bolt tightening sequence. The recommended bolt torque values in Table 3 do not apply to bolts used with flat gaskets. Bolt torques for flat gaskets will be provided in the sections covering their installation.

⚠ WARNING
Hazardous Voltage!

Before working on this or any electrical equipment, always disconnect the electric power supply. Follow proper lockout/tagout procedures to ensure the power cannot be applied during repairs. Failure to do so may result in death or serious injury.

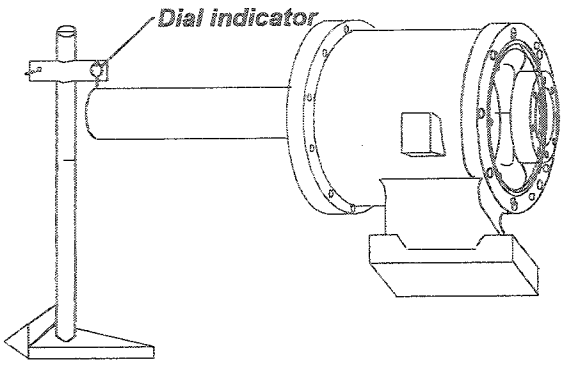
Re-assembly

1 Discharge Volute Installation

(a) Clean the dowel pins and the dowel pin holes in the condenser discharge flange and evaporator mounting base to remove rust or other debris. Lightly coat the pins with a petroleum jelly or anti-seize compound.

(b) Clean the flanges and apply Loctite 515 and o-ring (when applicable) as recommended.

IMPORTANT!: See Service Bulletin CTV-SB-66 (latest revision) or procedures for using Loctite 515.Always check the date on the Loctite tube to ensure the sealant use time has not expired.



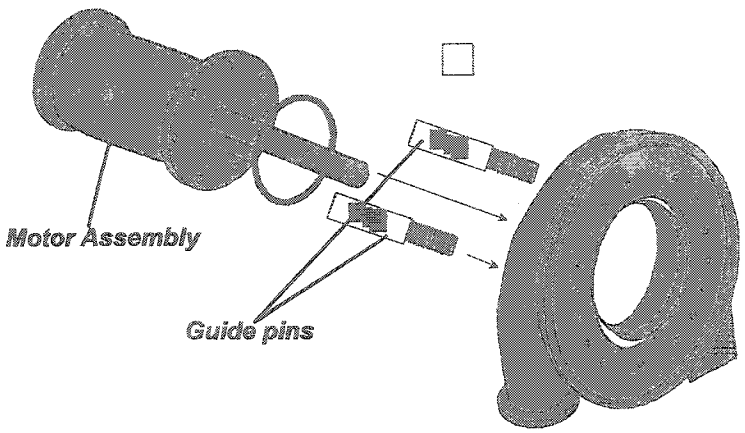
(c) Use a sling or cable in the choke configuration through the center of the volute for lifting. Be sure to protect the flange surfaces when using a cable. Place the volute on the condenser and line up the dowel holes.

(d) Tap the dowels in place as the bolts in the foot and discharge flange are tightened. Torque the bolts per Table 3 in the back of this section.

2 Motor Installation.

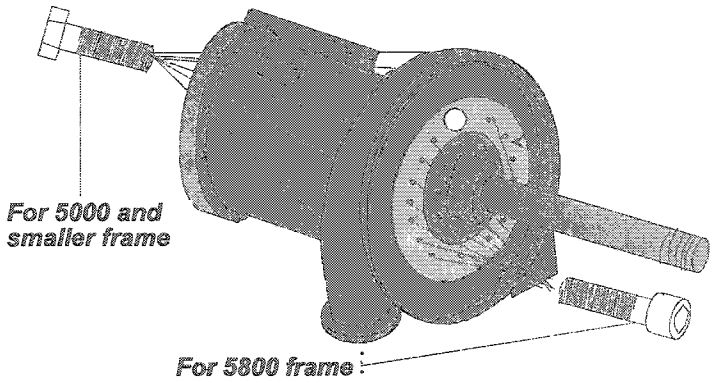
(a) Before installing the motor, check shaft run out (TIR) as shown in Figure 3. Using a dial indicator turn the shaft and measure the runout at the end f the shaft. The maximum allowable runout is .0012"TIR. Make sure the end of the shaft is wrapped with tape for protection during assembly.

Figure 3



(b) Place two slings or cables in the choke configuration around the motor. Place them at each end of the motor near the flanges and lift the motor slightly to get the proper balance point. See Table 4 for maximum motor weights.

(c) Apply Loctite 515 and -ring (when applicable) around the motor (shaft end) end bell.



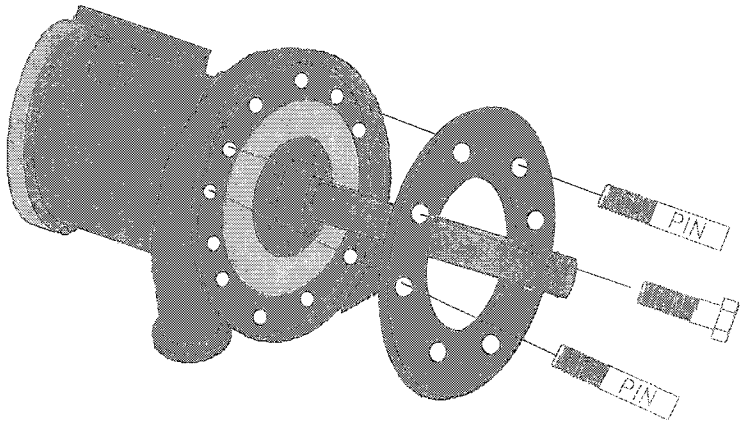
(d) Install two guide pins in the volute r motor flange (large frame) to help guide the motor in place. See Figure 4.

Figure 4

(e) Lift the motor in place and hand tighten the bolts holding the motor to the volute Snug the bolts and remove the guide pins. Note on some large frame motors, the bolts (allen head) that hold the motor to the volute are located on the compressor side of the volute. The proper torque for both styles of bolts is 120-165 lb- ft.

Figure 5

3 Volute Diffuser Plate Installation.



(a) Install two pins in the volute to guide the diffuser in place.

(b) Place a sling r cable in the choke configuration through the center of the diffuser.

(c) Lift the diffuser and slide it over the guide pins. Install countersunk screws and torque them to 55-75 lb-ft. Make sure the screws in the counterbore area behind impeller do not protrude more than .060"above the surface.

Centravac General Service Literature

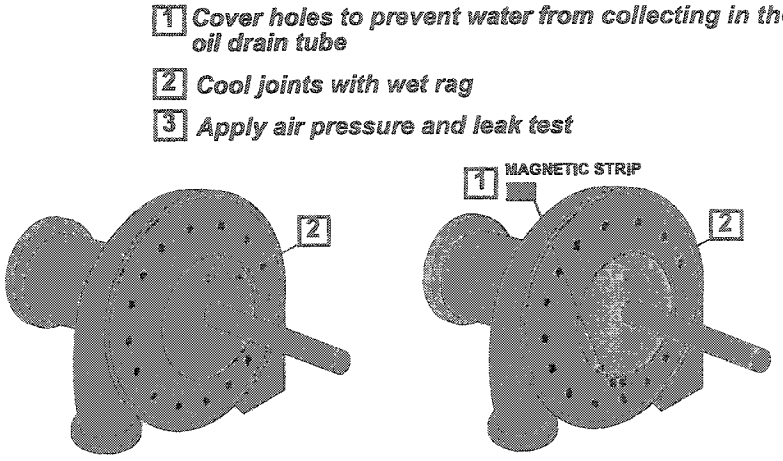


Figure 6

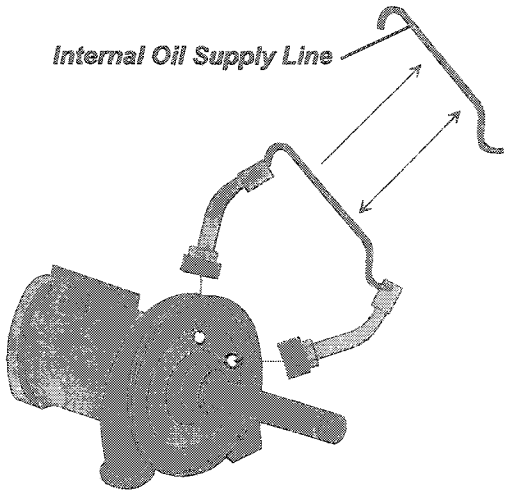
4 Oil Feed Tube Installation.

(a) Clean the ends of the lines thoroughly using a scotch bright pad or equivalent for metal. See Figure 7. Remove as much of the old brazing material as possible. Clean the inside of the couplings using a steel tubing brush. Use Loctite 277 Sealant on the threads.

Figure 7



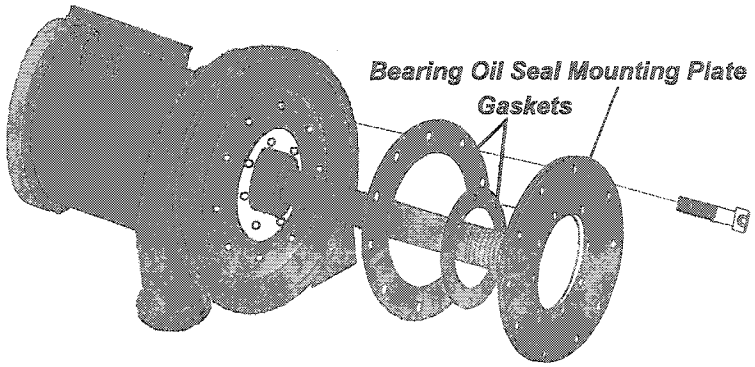
(b) Wrap a wet rag around both ends f the line t prevent overheating the threaded joints.

(c) Using a regulator, allow a slight purge of dry nitrogen to flow through the volute threaded fitting and oil supply line to prevent a buildup of oxidation when brazing.

(d) Braze the lines as shown in Figure 8 using a good Sil-Fos material with 5-15%(Ag) silver.

Figure 8

(e) After brazing, allow the lines to cool. Increase the nitrogen pressure and check the line and threaded fittings for a leak using a soap solution.



5 Bearing Cover Plate Installation

(a) Install two guide pins in both the inner and outer bolt centers to help hold the gaskets in place and to align the cover plate.

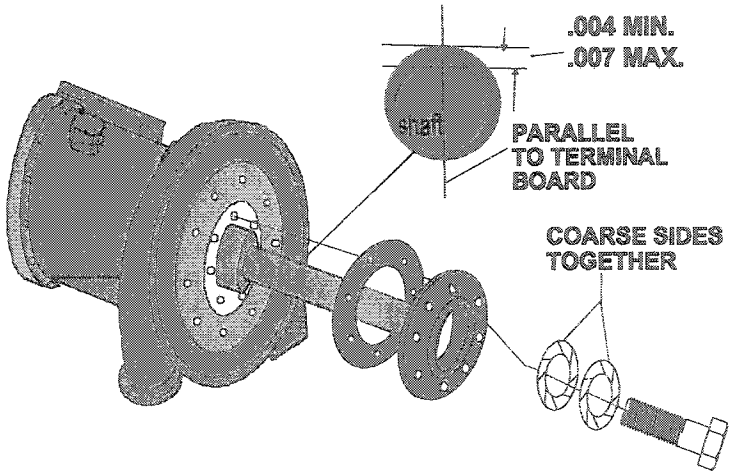
(b) Lightly coat both the inner and outer gaskets with a small amount of petroleum jelly to help hold them in place.

(c) Using a sling or cable in the choke configuration, slide the bearing cover plate in place while observing the gaskets to make sure they don't move out of position. See Figure 9.

Figure 9

(d) Install the outer mounting bolts. Remove the outer guide pins and torque the bolts to 20-27 lb-ft.

6 Bearing Oil Seal Installation.



(a) Lightly coat the bearing oil seal gasket (between the bearing cover plate and oil seal) with a small amount of petroleum jelly to help hold it in place. Make sure the gasket behind the bearing cover plate is still in its proper position.

(b) Slide the bearing oil seal over the guide pins. IMPORTANT: The oil seal has a drain *hole between the teeth of the seal that must be installed at the 6 o'clock position.* Install the mounting bolts with ramp washers and hand tighten. Remove the guide pins.

NOTE: Check the clearance between the bearing oil seal and the shaft outside diameter at the seal location. The maximum allowable total clearance is .0040- .0070". IMPORTANT: Clearances in excess of this amount will lead to oil loss.

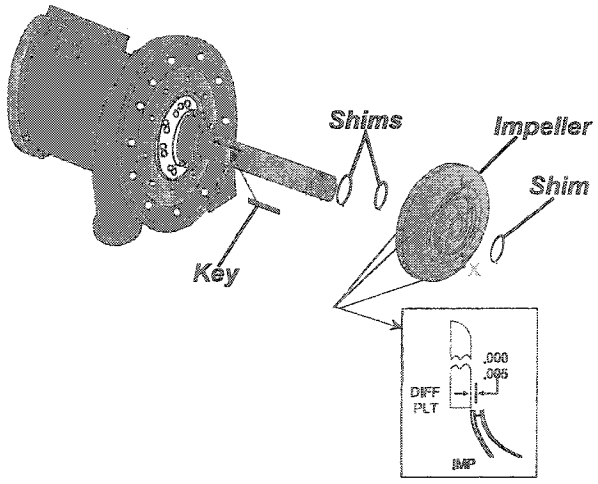
(c) Push up on or lightly tap the seal until the bottom of the seal touches the bottom of the shaft. Position the seal so the clearances on each side of the seal (3 and 9 o'clock) are equal. Using a feeler gauge, measure the total clearance at the 12 o'clock position and the clearances at the sides. It is recommended that a new oil seal be used if there is any question about the total clearance of the existing seal.

Figure 10

(d) With all the clearance at the top of the seal, tighten the bolts to 20-27 lb-ft. Recheck the clearance and rotate the shaft to ensure it turns freely. See Figure 10.

(e) At this point you may want to run only the motor to check for balance. This is desirable if a replacement motor is being installed or if the rotor was changed or repaired. See *General Service Bulletin CVHE-SB-18* (latest revision) for the procedures when air running motors.

7 2nd Stage Impeller Installation.



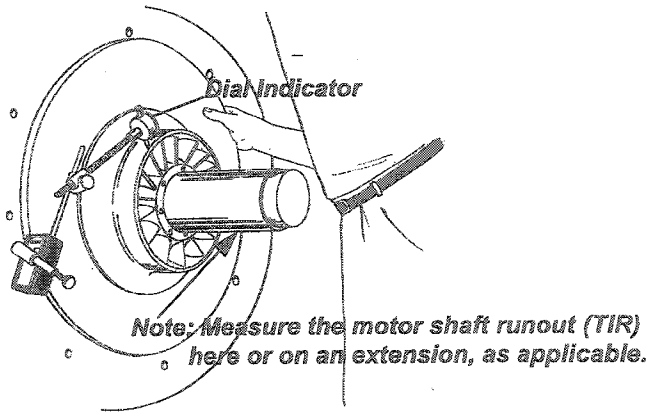
(a) Clean the impeller shims. Slide the impeller shims with the thicker steel shim against the shaft shoulder. *Note: The chamfer on the thicker steel shim should be facing the shaft shoulder.* Impeller alignment should have been checked during disassembly and any adjustments to the shim(s) thickness necessary to get proper impeller alignment can be made at this time. If the impeller or motor shaft has been replaced, then you may want to use only the steel spacer for an initial alignment to determine how many additional shims may be required.

(b) Thoroughly clean the impeller, key and shaft. Check the impeller bore for cracks. This can be done using a dye penetrant flaw detection kit. These kits are available through most weld supply or large industrial supply companies. The kits usually consist of a penetrant, developer, and cleaner and include instructions on their use. Replace the impeller if cracked. Some types of damage to the impeller bore or nose seal area on impellers can be repaired by The Trane Company.

(c) Check the impeller key and keyway in the impeller bore for damage. Check to ensure the sides of the keyway in the impeller bore are square.

(d) Coat the impeller bore and shaft with compressor oil. Install the key in the shaft. Slide the impeller on the shaft until it contacts the shims. Check the alignment of the impeller. The back inside discharge surface of the impeller should be flush to no more than a .0050" set out beyond the face of the diffuser plate. See Figure 11.

Figure 11



If the impeller does not slide easily on the shaft, it may be necessary to heat the impeller slightly to allow it to slide on the shaft. Before heating the impeller, inspect the impeller bore for debris or a dent (high spot) that could be causing interference. When heating the impeller, use a large (Rosebud) tip with a soft gentle flame. The impeller should be heated so that it is warm to the touch. Do not exceed 120° F. *The impeller bore (ID) to shaft* diameter (OD) total clearance should be .0000 -.0015"maximum.

(e) When required, remove the impeller and add shims to obtain the proper alignment. Slide the impeller on the shaft and recheck the alignment.

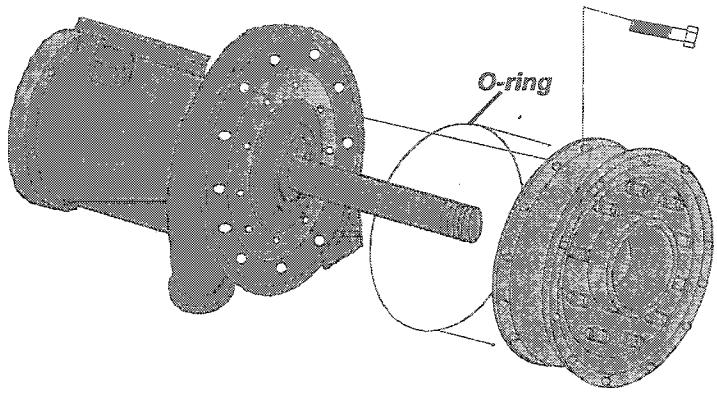
(f) Check the radial clearance between the impeller OD and the vane plate ID The minimum clearance around the entire circumference is .0220"minimum. In the unlikely event that clearance around the impeller is inadequate, it will be necessary to reposition the diffuser plate to obtain proper clearance. To reposition the diffuser plate first remove the impeller, then loosen the diffuser plate mounting bolts just enough to allow diffuser movement. Wrap a pry bar with a rag to prevent scratching the metal, then use the pry bar to shift the diffuser plate in the desired direction. Then retighten the diffuser plate bolts to 55-75 lb-ft. Re-install the impeller and recheck the clearances.

(g) Check the impeller nose run out using a dial indicator with a magnetic base. Rotate the impeller and measure the maximum runout (see Figure 12). The allowable maximum runout for fabricated (welded) impellers is .0050" and .0035" for cast style impellers.

Figure 12

(h) Install any shim(s) removed during disassembly in front of the 2nd stage impeller.

8 2nd Stage Suction Cover Installation.



(a) Clean the cover and discharge volute.

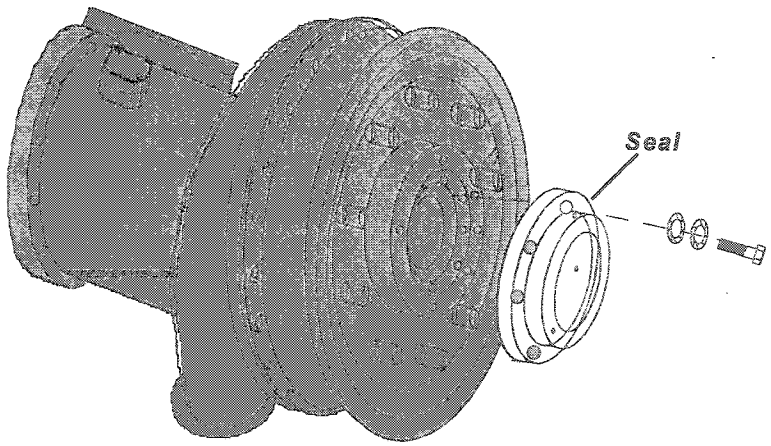
(b) Attach the lifting fixture to the suction cover and find the proper balance point.

(c) Apply Loctite 515 and an o-ring (when applicable) per recommended procedures.

(d) Install four guide pins to help align the suction cover as shown in Figure 13. Make sure the scribe marks between the volute and the suction cover are lined up before final tightening of the bolts.

Figure 13

(e) Install bolts and torque to 120-165 lb-ft.



9 Impeller Nose Seal Installation.

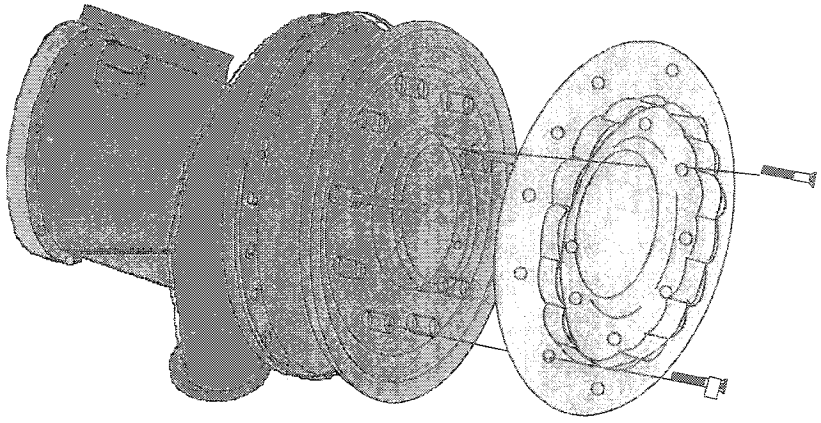
(a) Thoroughly clean the nose seal to remove any debris or loose chips from the labyrinth teeth.

(b) Use the original bolts and new locking tab washers.

(c) Using feeler gauges, center the seal around the nose of the impeller. The proper clearance can be found in Table 5.

Figure 14

(d) With the seal set properly, tighten the seal retaining bolts to 20-27 lb-ft. Recheck seal clearance.



(e) Rotate the shaft to ensure it turns freely.

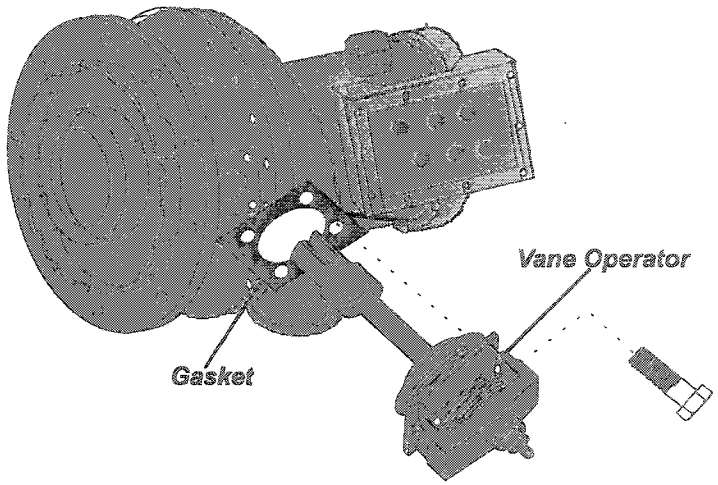
10 2nd Stage Vanes Assembly Installation.

(a) Install two guide pins in the suction cover to help align the shroud and vane assembly.

(b) Use a sling to lift the vane assembly in place. It is recommended that new screws be used. If reusing the original screws, coat the threads with a thread locking compound. New screws will have a nylon locking insert. It is recommended the new screws also be coated with a thread locking compound. See Figure 15.

Figure 15

(c) Tighten the allen head screws to 5-7 lb-ft. The screw heads must be flush or below the surface. Note: if installing a complete new vane/shroud assembly, you will first have to counter-sink the 8 mounting holes to accept the screw heads.



11 2nd Stage Vane Operator Assembly Installation.

(a) Clean the flanges on the suction cover and vane operator assembly.

(b) Clean any powder residue from the new gasket. The gasket should be installed dry. Slide the fork of the vane operator lever over the pin in the vane drive ring pin assembly.

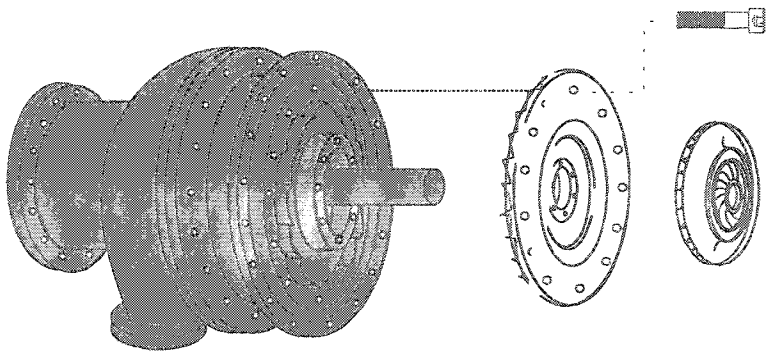
(c) Tighten bolts to 33-50 lb-ft. See Figure 16. Do not over-tighten.

Figure 16

(d) Open and close the vane assembly to ensure it operates freely. Check to make sure the vanes close completely and open fully.

12 2nd Stage Aluminum Vane Plate Installation.

(a) Before installing the vane plate, make sure the shim in front of the impeller has been installed.



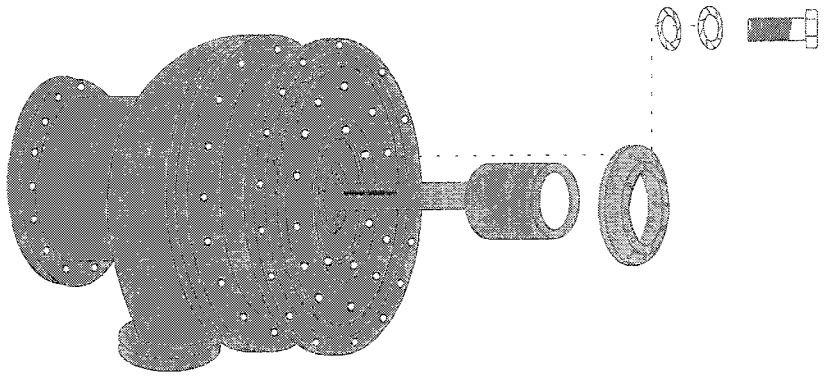
(b) Clean the aluminum plate.

(c) Insert the four guide pins to help align and hold the vane plate during installation.

(d) Lift the plate through the center using a sling in the choke configuration.

(e) It is recommended that new bolts be used. If reusing the original bolts, coat the threads with a thread locking compound. New bolts have a nylon locking insert. See Figure 17.

Figure 17



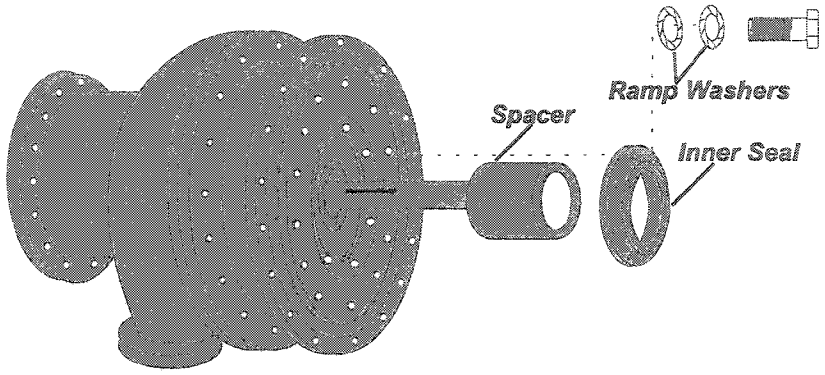
(f) Tighten the bolts to 20-27 lb-ft.

13 Interstage Spacer Installation.

(a) For units with a the large diameter (straight) shaft at the 1st stage impeller location, slide the shim and spacer on the shaft that was removed during disassembly (see Figure 18. Make sure the spacer, which was marked during disassembly, is placed back on the shaft in the proper position. This will help maintain proper balance if all the rotating components are being re-used.

Figure 18

(b) Some units have a step shaft, where the shaft diameter for the 1st stage impeller is smaller than the remainder of the shaft. Depending on unit size and design sequence, there may be a .500"aluminum spacer mounted against the 2nd stage impeller hub and then a longer aluminum spacer that steps down to the smaller shaft diameter. Some units will have a thin shim against the 2nd stage impeller, a long aluminum spacer tube, and then an end spacer that fits inside the tube. Make sure the spacer tube and end spacer (when used), which were marked during disassembly, are placed back on the shaft in the proper position. This will help maintain proper balance if all of the rotating components are being re-used.



14 Interstage Spacer Seal installation.

(a) Install the seal and bolts with a ramp washer over the interstage spacer.

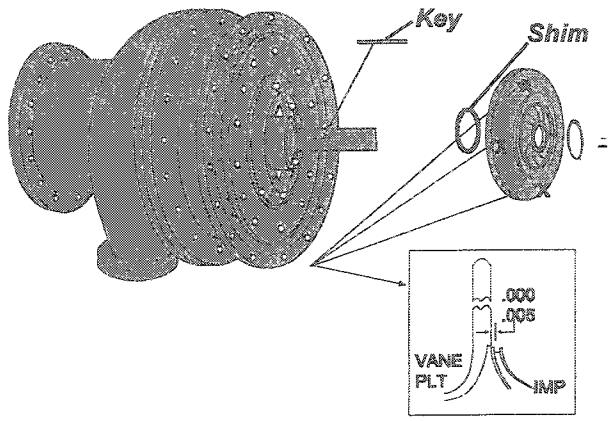
(b) Center the seal using feeler gauges. The allowable tolerance can be found in Table 5.

(c) Tighten the bolts to 20-27 lb-ft. See Figure 19.

Figure 19

15 1st Stage Impeller and Impeller Locknut Installation

(a) If impeller shims were originally installed, clean the impeller shims and slide them up against the interstage spacer. Impeller alignment should have been checked during disassembly and any adjustments to the shim(s) thickness necessary to get proper impeller alignment can be made at this time. If the impeller or motor shaft has been replaced, then you may want to use only a portion of the original shims for an initial alignment to determine how many additional shims may be required.



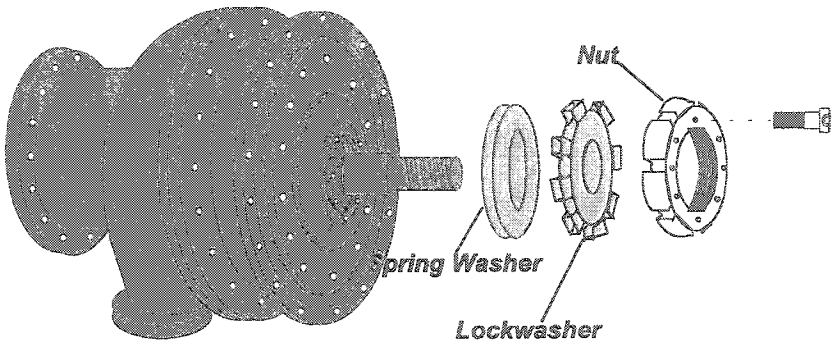
(b) Thoroughly clean the impeller, key and shaft. Check the impeller bore for cracks. This can be done using a dye penetrant flaw detection kit. (These kits are available through most weld supply or large industrial supply companies. The kits consist of a penetrant, developer and cleaner and include instructions on their use.) Replace the impeller if cracked. Some types of damage to the impeller bore or nose seal area on impellers can be repaired by The Trane Company.

(c) Check the impeller key and keyway in the impeller bore for damage. Check to ensure the sides f the keyway in the impeller bore are square.

(d) Coat the impeller bore and shaft with compressor oil. Install the key in the shaft. Slide the impeller on the shaft until it contacts the shims. Check alignment of the impeller.

The back inside discharge surface f the impeller should be flush t no more than a .0050"set out beyond the face of the vane plate. See Figure 20.The back plate on welded impellers may have some distortion due to the weld process. Locate the impeller back inside edge (lowest point) so it is flush with the vane plate.

Figure 20



If the impeller does not slide easily on the shaft, it may be necessary to heat the impeller slightly to allow it to slide n the shaft. Before heating the impeller, inspect the impeller bore for debris or a dent (high spot) that could be causing interference. When heating the impeller, use a large (Rosebud) tip with a soft gentle flame. The impeller should be heated so that it is warm to the touch. Do not exceed 120°F. The impeller bore (ID) to shaft diameter (OD) total clearance should be .0000 -.0015"maximum.

(e) When required, remove the impeller and add shims to obtain the proper alignment. Slide the impeller on the shaft and recheck alignment.

(f) Check the radial clearance between the impeller OD and the vane plate ID The minimum clearance around the entire circumference is .0220"minimum. In the unlikely event that clearance around the impeller is inadequate, it will be necessary to reposition the diffuser plate to obtain proper clearance. To reposition the diffuser plate first remove the impeller, then loosen interstage seal mounting bolts, then loosen the diffuser plate mounting bolts just enough to allow diffuser movement. Wrap a pry bar with a rag to prevent scratching the metal, then use the pry bar to shift the diffuser plate in the desired direction. Then retighten the diffuser plate bolts to 55-75 lb-ft. Re-set the interstage seal clearances as was described in step 14 and tighten the seal retaining bolts to 20-27 lb-ft. Reinstall the impeller and recheck the clearances.

(g) Before installing the spacer, conical (spring) washer, and lockwasher on the shaft, (Figure 29) thread the locknut on by hand to ensure there are no burrs or damaged threads etc. The locknut thread fit should be snug but may be turned by hand without use of a spanner wrench. Install the spacer, spring (conical shaped) washer, lockwasher, and impeller locknut on the shaft and tighten by hand until all clearance has been taken up in the assembly. Make sure the spring washer is installed so the concave side is towards the impeller as shown in Figure 29.

Figure 21

(h) Rotate the shaft so that the 1st stage impeller key is at the 12 o'clock position.

(i) Some compressors have a balance/locknut with weights. If all original compressor components (motor/rotor, impellers, spacers etc.) are being re-used, then the original weights may be left on the balance nut. Once the locknut has been hand tightened, place a mark on the locknut and the impeller hub. Tighten the locknut the required rotation as described below.

Small Locknut:

Once hand tightened, the small locknut (less than 2.500") should be rotated another 360-390 degrees using a spanner wrench and brass hammer or special socket and impact wrench. Use the marks described above to determine the rotation of the nut compared to the impeller. Once reaching 360 degrees of rotation, look for the next locking tab on the lockwasher that will fit into a notch in the locknut. Do not over-tighten the locknut as it is possible to cause shaft bending and run out, which could result in vibration problems.

Large Locknut:

Once hand tightened, the large locknut (greater than 4.000") should be rotated 170-180 degrees. Use the marks to determine the rotation of the nut compared to the impeller. Once reaching 170 degrees of rotation, look for the next locking tab n the lockwasher that will fit into a notch in the locknut. Do not over-tighten the locknut as it is possible to cause shaft bending and run out, which could result in vibration problems.

When reusing a locknut with it's original balance weights, make sure the match marks made during disassembly are aligned in their original position after the nut is tightened properly. See the Disassembly section.

IMPORTANT!: If the rotating components have been reused and the balance weights do not line up as originally marked, the balance weights should be removed.

Centravac General Service Literature

IMPORTANT!: If the rotating components have been replaced or were not marked during disassembly or do not line up as originally marked, the balance weights should be removed.

⚠ CAUTION

Once the locknut has been properly tightened, bend over a tab on the locking washer. It is recommended that a new lockwasher be used during re-assembly.

⚠ CAUTION

Compressor Damage!

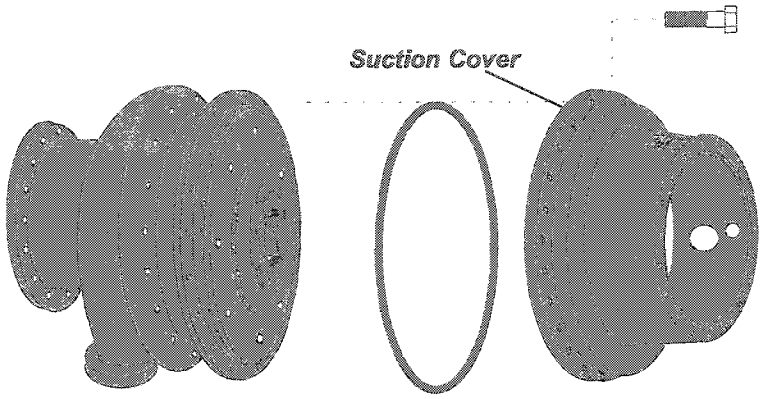
Once a locking tab has been bent over on a lockwasher it may become weak and break off f the same tab is re-used. This could cause the impeller locknut to loosen and come off during operation, causing major damage to the compressor and motor.

(j) Check the impeller nose run out using a dial indicator with a magnetic base. Rotate the impeller and measure the maximum runout. The allowable maximum runout for fabricated (welded) impellers is .0050"and .0035"for cast style impellers.

(k) For shafts with the extension beyond the locknut or units with balance nuts, check the shaft runout after the locknut is tightened. Checking shaft runout on units without the balance nut or shaft extension will be difficult since the standard locknut does not have a smooth machined surface where the indicator can be used. Rotate the shaft and measure the maximum shaft runout. The allowable maximum shaft runout is .0012"

16 1st Stage Suction Cover Installation. (See Figure 22)

(a) Clean the cover and mating surface.



(b) Attach the lifting fixture to the suction cover and find the proper balance point.

(c) Apply Loctite 515 and an o-ring (when applicable) per recommended procedures.

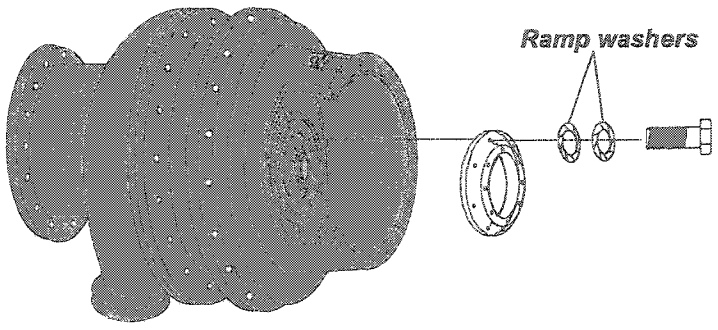
(d) Install four guide pins to help align the suction cover. Make sure the scribe marks between the 2nd stage cover and 1st stage cover are lined up before final tightening of bolts.

(e) Install bolts and torque to 120-165 lb-ft.

Figure 22

17 Impeller Nose Seal Installation (see Figure 23)

(a) Thoroughly clean the nose seal to remove any debris or loose chips from the labyrinth teeth.



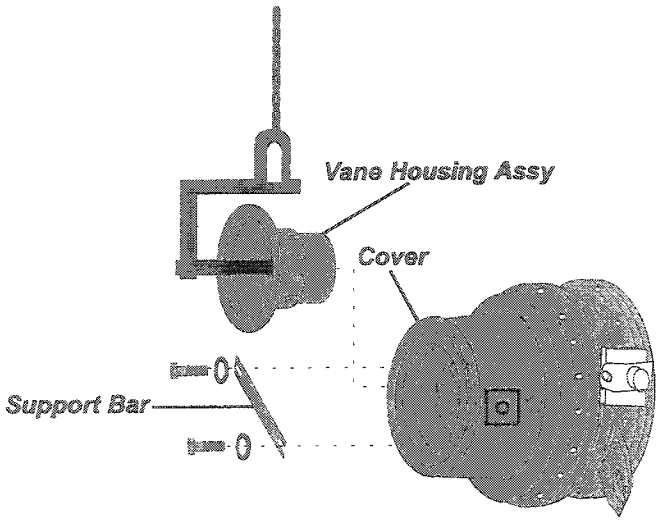
(b) Use the original bolts and new locking tab washers.

(c) Using feeler gauges, center the seal around the nose of the impeller. The proper clearance can be found in Table 5.

(d) With the seal set properly, tighten the bolts to 20-27 lb-ft. Recheck the seal clearance.

(e) Rotate the shaft to ensure it rotates freely.

Figure 23



18 1st Stage Vane Assembly Installation.

(a) Thoroughly clean the vane assembly and check to ensure that the vanes move freely. Oil the vane bearings before installing.

(b) Use the special lifting tool described in the disassembly section to lift the vane assembly. Once the vanes are positioned in the housing, secure the vane assembly using a piece of L-angle and two bolts with washers. See Figure 24.

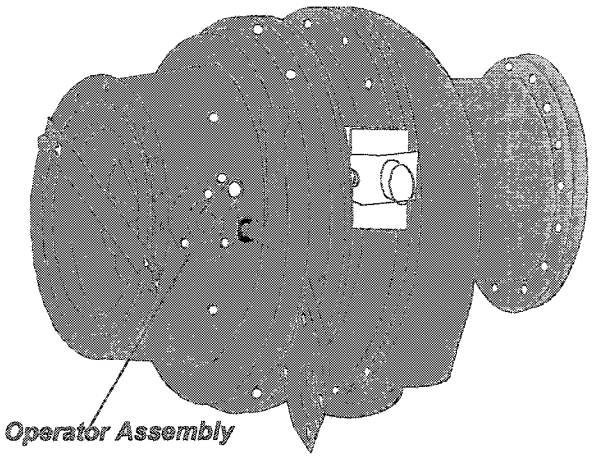
Centravac General Service Literature

Figure 24

(c) Use three allen head setscrews to secure the inlet vane in the housing. Tighten the setscrews. See Figure 25.

(d) Install the 1st stage vane operator tang assembly using the marks placed on the operator lever and suction cover (with vanes closed) during disassembly to position the tang assembly (see Figure 25). It may be advisable to consider rebuilding of the operator using new o-rings, nylon bushings, and lip seal if applicable to eliminate a leak potential. The 1/8" NPT pipe plug should be removed and compressor oil poured into the area between the two internal o-rings to lubricate them. Replace the plug (see Figure 26).

Figure 25



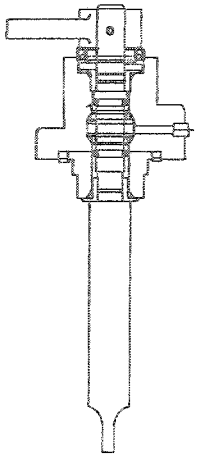


Figure 26

(e) Torque the tang operator mounting bolts to 14 lb-ft.

(f) *(f)*Remove the L-angle and bolts holding the vane assembly in the suction cover.

19 Air Run of Compressor For Balance.

(a) Run the compressor on air with the suction elbow off.

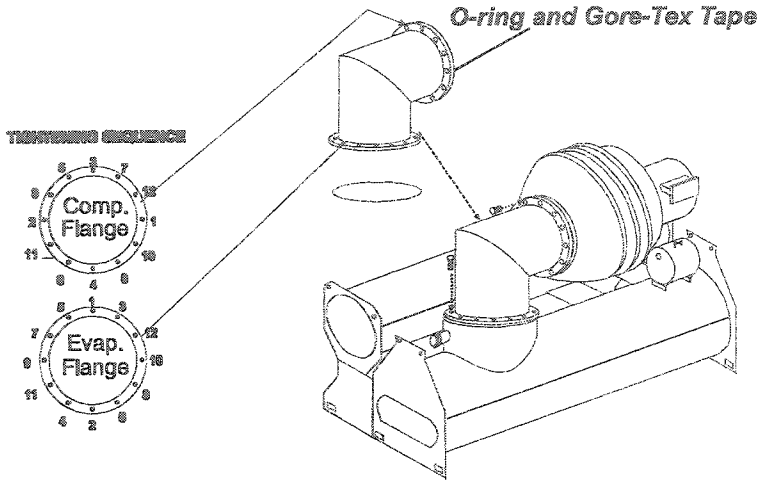
(b) Measure the vibration levels as indicated in *CVHE-SB-18* (latest revision) and, when required, trim balance the compressor to ensure proper balance.

20 Suction Elbow Installation.

(a) Clean the sealing surfaces on the suction elbow, evaporator, and suction cover flanges. The suction elbow must be properly insulated to prevent moisture from condensing. Insulation that was improperly applied or damaged may allow moisture to collect between the flanges and in the bolt holes. It may be necessary to use a bottoming tap to clean up the bolt holes before installing the elbow.

(b) Apply Loctite 515 and o-ring (when applicable) per recommended procedures. The lower flange at the evaporator requires Loctite. The upper suction elbow connection at the compressor suction cover should be installed with *no* sealant on the o-ring and a back-up Gore-Tex tape installed between the o-ring groove and the inner suction connection opening in the elbow. After installing the Gore-Tex tape, apply a small amount of petroleum jelly to the -ring to help hold it in place while installing the suction elbow. See *General Service Bulletin CTV-SB-66* (latest revision).

(c) Using a sling lift the suction elbow into position. Install bolts by hand making sure the flanges at the suction cover are square with the cover. *NOTE: All bolts should be coated with an anti-seize compound to help prevent rust.* Snug up the bolts slightly.



(d) Torque the bolts in the elbow to 120-165 lb-ft following the pattern shown in Figure 27. Ensure the elbow flange pulls up square to the suction cover and does not place a strain on the cover.

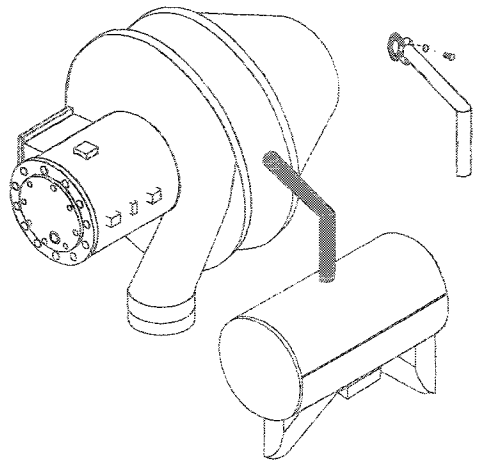
⚠ CAUTION

Compressor Damage!

Verify proper elbow flange fit. Failure to maintain proper suction elbow fit up can cause vibration problems or seal-to-impeller interference and possible damage to the impellers and compressor.

Figure 27

(e) The compressor should be run on air with the suction elbow installed. Refer to *General Service Bulletin CVHE-SB-18* (latest revision).



(f) See Step 23 when the unit-mounted starter is used.

21 Economizer Installation.

(a) Clean the flanges on the economizer, evaporator, and the condenser outlet pipe. The bolts holes on the evaporator flange may need to be cleaned up using a bottoming tap to remove rust. Some of the early vintage CVHF units may have used a four bolt flange at the evaporator for the larger size units. This was changed on later designs to eight bolts to ensure a better seal. It may be advisable to drill and tap the four additional holes in the evaporator flanges of early-production chillers to prevent leaks. The replacement gasket will have the four additional holes.

(b) Using a sling on either end of the economizer, move the economizer into position. See Figure 28.

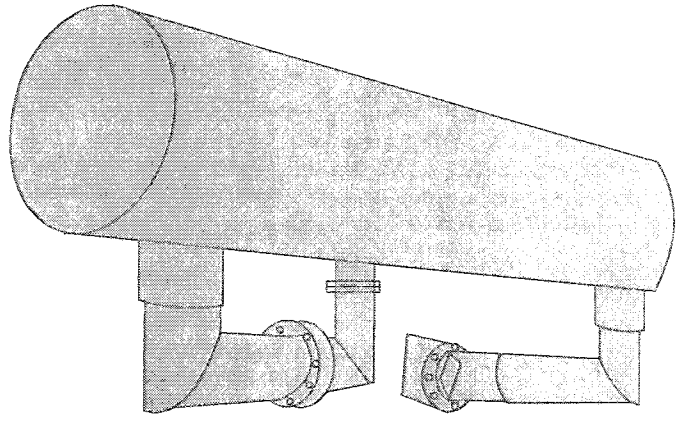


Figure 28

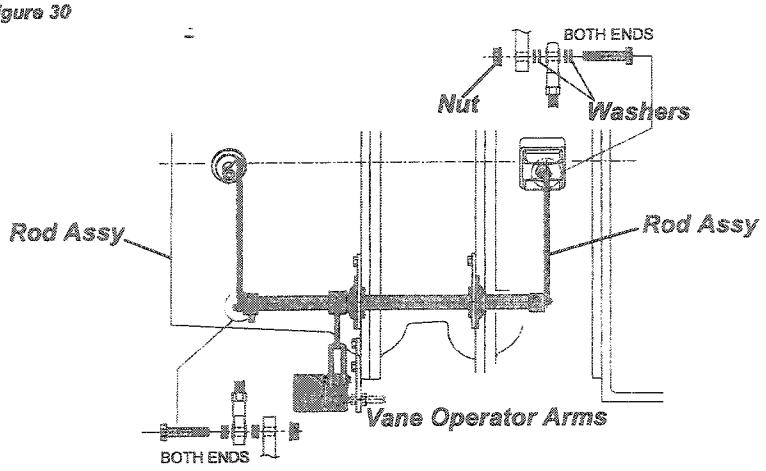
(c) Coat the threads of the bolts for the evaporator flange with an anti-seize compound.

(d) Evenly tighten the bolts to 14 -16 lb-ft. See Figure 29. Do not overtighten or cause the gasket to extrude from between the flanges.

Figure 29

22 Inlet Vane Linkage Installation.

(a) Attach the linkage assembly brackets to the compressor casings. The outline of the mounting brackets should have been scribed on the casings to align the brackets in their original position.



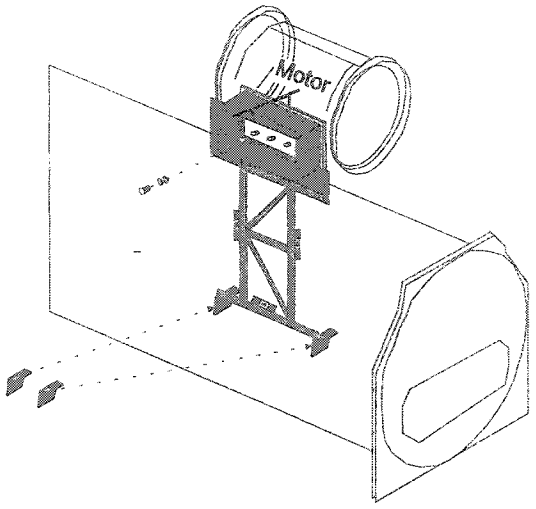
IMPORTANT! Maintaining the proper vane schedule between stages is important. Mis-adjustment of the vanes can cause gas flow turbulence at certain compressor load points resulting in noise and vibration. This problem is usually an indication that the final stage vane assembly has lagged behind the 1st stage vane position.

Centravac General Service Literature

Adjustment of the vane assembly brackets on the compressor casings or length of linkage rods may resolve this condition.

(b) Reconnect the drive rods to the vane operator arms. See Figure 30.

Figure 30



(c) Open and close the vanes to ensure they operate freely.

23 Unit Mounted Starter Installation.

(a) Clean off the flange on the motor housing and transition piece between the starter and motor housing.

(b) Use a new gasket between the transition piece that bolts to the motor terminal board casting flange. See Figure 31.

Figure 31

(c) Lift the unit mounted starter into position using the eye bolts in top of starter.

(d) Bolt the starter to the motor housing flange and the lower evaporator mounting brackets.

(e) Re-attach the motor leads to the motor terminal studs. The leads and motor studs should have been marked during disassembly. Torque clamp connectors to 27 lb-ft.

24 Motor Cooling Lines.

(a) Clean the motor cooling line flanges and motor housing.

(b) Install the motor cooling orifice between the flange and motor housing with a gasket on either side of the orifice. The motor cooling orifice is a flat piece of steel with a stamped hole in the center of a specific diameter matching the motor size and horsepower.

(c) Install the drain lines using new gaskets.

(d) Tighten the bolts.

25 Oil Supply Line Orifice.

(a) The oil supply line for the ball bearing end has an orifice at the motor housing.

The orifice is threaded into the motor end bell. The orifice limits the amount of oil that is supplied to the ball bearing. Installing the oil supply line without the proper orifice may lead to excessive oil flow through the bearing cavity and possible oil loss.

MOTOR/COMPRESSOR TEARDOWN HANDOUT

Objectives:

1. To present the proper sequence and procedures for the teardown of the motor assembly.
2. To provide techniques for unusual installations.
3. Provide a comparison of the various bearing assemblies.
4. Provide a cutaway of the motor/compressor assembly.
5. Miscellaneous assembly - disassembly techniques.

Identification of components can be made by the cutaway drawing shown in Figure 1.

For procedures not covered in this handout, refer to the appropriate service literature.

MOTOR TEARDOWN

This handout describes the changeout of the CVHE motor rotor and/or bearings. This generally can be done without removing the motor from the chiller. The motor orientation in this procedure will be drive end (shaft extension end or compressor end) and opposite drive end, motor terminal end or thrust end. In general, the compressor must be disassembled before any work is done on the motor. The exception to this is the removal of the thrust bearing, which can be done without disassembly of the compressor.

DISASSEMBLY

1. Disconnect 1/4 inch copper bearing supply line on the drive end. Either unsweat the line or cut the line (if cut, a coupling will be needed for reassembly).
2. Check the rotor shaft runout as close to the bearing as possible.
3. Support the rotor shaft approximately 1/2 of the bearing clearance with a jack or other means of support. See Figure 2.
   NOTE: The shaft must never be lifted by a sling or chain ball assembly as this could bend the shaft. The movement of the shaft should be monitored with a dial indicator.
4. Remove the bolts securing the drive end bearing. Refer to Figure 3. Care must be taken to prevent damage to the babbitt bearing as well as the shaft. Remove the bearing using the jack bolt holes. Rest the bearing temporarily on the shaft with the proper shaft and bearing protection. Refer to Figure 4.
5. Remove the six socket head screws that hold the bearing seal in place.
6. Remove the oil supply and drain lines on the opposite drive end of the motor. To aid in reassembly, the paint should be removed prior to cutting.
7. See Figure 5. Remove the opposite drive end bearing inspection plate.
8. See Figure 6. Loosen the retaining bolts holding the motor end bearing bracket. Remove two of the bolts, replace them with guide pins. Guide pins are recommended to help support the weight of the bracket and shaft.
9. Remove bearing retaining ring as indicated in Figure 7.
10. Remove the eight socket head screws holding the opposite drive end bearing seal. Refer to Figure 8.
11. Using the jack bolt holes, remove the opposite end bearing jacket. The bearing bracket will need to be slid over the ball bearings. This will involve a gentle rocking action back and forth to slide the bearing bracket over the outer race of the bearing. Extreme care must be exercised at this point to prevent the bearing bracket from jamming on the bearings and to prevent the moving of the rotor assembly which could damage the stator. Refer to Figure 9. It is also recommended that opposite drive end bearing bracket be supported with the chain fall or crane to support the weight.
12. Remove the thrust bearing lockwasher and locknut. Refer to Figures 10 and 11. This is accomplished by bending back the lockwasher tab using spanner wrench to drive off the locknut.
13. Remove the thrust bearing. Refer to Figure 12. This is done by using a bearing puller. The puller must pull on the inner race of the back bearing. Care must be taken to prevent damage to the shaft and the bearing. Important items to remember are:
    a. The puller must be square with respect to the shaft.
    b. The puller should pull on the inner race. Use .050 shims between the puller and the inner race.
    c. The bearing must be protected from damage.
    d. Never heat the bearing to remove it, as this could cause damage to the bearing or motor.
    e. The weight of the puller should be supported by a sling and chain fall.

14. Remove the inner bearing cap or seal. Care should be taken to prevent damage to the gasket. Note that there is an oil drain hole on the bottom. This should be marked and emphasized that it is installed with the drain hole on the bottom.
15. Remove the drive end seal bolts. Before this is done, the shaft support can be removed.
16. Refer to Figure 13. Once the seal bolts have been removed, remove the bearing bracket. In removal of the drive end bearing bracket guide pins are recommended to support weight of the bracket.
17. To remove the rotor, cover the shaft extension with a pipe (brass or aluminum) to protect the shaft. Sling as close to the rotor as possible. Raise the rigging to support the weight of the rotor. Care must be taken to prevent damage to the motor windings.

ASSEMBLY

1. Install the rotor. Cover the shaft extension with the brass or aluminum pipe to protect the shaft and to balance the motor. Sling the rotor into place.
2. Position the rotor such that the end of the lamination of the motor and stator are aligned. After the rotor is aligned, allow the rotor to rest on the stator. At this point, caution must be taken to prevent any damage to the windings.
3. Refer to Figure 14. Place the opposite drive end inner bearing cap and new gasket on the shaft. During reassembly, all new components should be cleaned and inspected for damage, replace as necessary. The oil drain should be at the bottom.
4. Install the thrust bearings.
   NOTE: Bearings must be installed back to back. This can be determined by looking at the cages of the bearings. It can also be determined by the races. Refer to Figure 15.
   a. Remove any nicks or burrs before installation. Polish the bearing surface on the shaft with crocus cloth. Check for high spots with a micrometer. Then thoroughly clean all components.
   b. Refer to Figures 16, 17 and 18. Heat the bearings to 220° with a convection oven. Do not exceed 250° as this will result in damage to the bearings. Use a "tempil" stick to indicate temperature. Install the bearings on the shaft back to back. (NOTE: If the bearing is marked as having a high spot, align the marks on the inner and outer race with each other. If both bearings have high spots marked, turn the outer bearing so the high spots are 180° from the high spots on the inner bearing.) Install the lockwasher and locknut. Tighten hand tight with a spanner wrench. Allow bearings to cool.
   c. Assemble the alignment sleeve. Tighten sleeve bolts to 14 ft-lbs. if the bearings do not spin freely, remove the sleeve and reposition.
   d. Tighten the locknut to 250 ft-lbs. while turning the bearings with the alignment sleeve.
   e. Check the total indicated runout of the bearings. Maximum TIR is .0015 inches. Compare the runout for each race. The runout for each side of the race should not exceed .0002 inches.
   f. If any test fails, remove the bearings and repeat the bearing alignment procedure. If the test fails a second time, replace the bearings.
5. Install all thread rods or guide pins into the seal. Align the seal so that the drain hole is on the bottom. Refer to Figure 20.
6. Lift the opposite drive end bearing bracket into place. The bearing bracket should be positioned on guide pins to support the weight.
   NOTE: The all-thread rod must go through the bolt holes in the bearing bracket to align the inner seal.
7. Align the edge of the bearing with the edge of the bearing bracket.

8. Mic the drive end of the shaft and surface and the babbitt bearing for proper clearance. Refer to Figures 22 and 23.
9. Install the guide pins to support the drive end bearing bracket.
10. Install the all-thread to hold the inner bearing cap/oil seal in place.
    NOTE: Take note to insure that the oil drain hole is on the bottom.
11. Slide the drive end bearing bracket into place (as indicate in Figure 24).
12. Slide the bearing onto the shaft resting it prior to the bearing surface of the shaft.
13. Support the surface with a jack or similar device until the bearing is aligned and will slide in easily (as shown in Figure 25). At this point, it will be necessary to go to the opposite drive end of the motor to install the thrust bearing bracket.
14. Work the bearing bracket into place and snug down all the bolts.
15. Return to the drive end of the motor and work the babbitt bearing into place. Insert the bolts and tighten (refer to Figure 26). Again support the shaft assembly with a jack prior to installation.
16. Once the drive end bearing is in place, secure the opposite drive end bearing bracket.
17. Set the drive end inner bearing seal in place. This is done by inserting two socket-head capscrews to hold the seal firmly. The seal is then located and adjusted by moving the all-thread up or down (as shown in Figure 27). Once it is located, the seal should be firmly snug.
18. A similar adjustment should be made to the opposite end drive the bearing seal (refer to Figure 28). The remaining cap screws should then be put in place and firmly tightened on both seals (refer to Figure 29).
19. Install the bearing retaining rings and bolts and tighten (as shown in Figure 30).
    NOTE: The inner seal/cap must be aligned and installed before the retaining ring. Replace the inspection cover (as shown in Figure 31).
20. Add oil to the inlet sides of both bearings and rotate the rotor assembly. The oil will help lubricate and prevent corrosion on the bearings.
21. Reassemble the bearing supply and drain lines. At this point, the rotor runout should be checked. There should not be any end play.
22. The assembly is now set for compressor reassembly.

REMOVAL OF MOTOR/COMPRESSOR ASSEMBLY

Many installation sites require the compressor assembly to be removed prior to installation. The following is the recommended procedure for the removal and reassembly of the motor/compressor assembly.

1. It is recommended before removing the assembly to have it dowelled into place. The preferred method is to have the assembly dowelled into place on the production line. If this is not the case, the assembly must be dowelled into place per Figure 32. Refer to Table 1 for dowel sizes.
2. Field dowelling (locations shown in Figure 32) is needed to prevent shifting of the various components as well as alignment for reassembly. Basically the procedure involves two dowels per flange and mounting location.
3. Remove external components. This includes vane linkage, vent lines, motor cooling supply and drain lines, econimizer bolts, etc. Refer to the Service Guide, Section 8, Compressor Disassembly for details.

COMPRESSOR SIZE	MOTOR TO DISCHARGE VOLUTE	VOLUTE TO VOLUTE	DISCHARGE FLANGE	COMPRESSOR FOOT
013-020	(2) No. 8 x 2.50"	(6) No. 8 x 2.0"	(2) No. 8 x 2.0"	(2) No. 8 x 2.0"
022-032	(2) No. 8 x 2.50"	(6) No. 8 x 2.0"	(2) No. 8 x 1.5"	(2) No. 8 x 2.0"
035-050	(2) No. 8 x 2.50"	(6) No. 8 x 2.0"	(2) No. 8 x 2.0"	(2) No. 8 x 2.0"
055-080	(2) No. 8 x 2.50"	(6) No. 8 x 2.0"	(2) No. 8 x 2.0"	(2) No. 8 x 2.0"
089-125	(2) No. 8 x 2.50"	(6) No. 8 x 2.0"	(2) No. 8 x 2.0"	(2) No. 8 x 2.0"

4. Install lifting plates that would bolt to the top 2 or 3 bolts. These plates should be installed on the first and third volute flanges (Refer to Figure 33).
5. Remove the suction elbow. Take note to see if the compressor moves at all. This can be monitored with dial indicators (indicators should be from the condensate shell or floor stand). If the compressor moves, corrective action will be necessary for reassembly (i.e. bolt holes will have to be enlarged).
6. Support the motor/compressor assembly with rigging. This is just to support the assembly and to prevent it from slipping as the compressor foot and discharge flange bolts are removed.
7. Remove motor/compressor assembly. This assembly should be placed on a skid in such a manner as to allow the compressor foot and discharge flange to be bolted down. The terminal end of the motor should be supported as well.
   NOTE: The assembly may shift to one side during lifting. This should not be more than several inches. If the shift is greater, the rigging must be readjusted.

REASSEMBLY

1. Rig the motor/compressor assembly into place. Replace the bolts into compressor foot and discharge flange connections. Before tightening these bolts, the locating dowel pins should be installed.
2. Torque the bolts down on the compressor foot and discharge flange. Then remove the rigging.
3. Install the suction elbow. Use the proper torquing sequence (as shown in Figure 34). Dial indicators should be used on the horizontal and vertical axis to monitor any compressor movement. (NOTE: Support indicators from the floor or condenser shell). This movement must be minimized where installing the suciton elbow. If applicable, tighten support bolts on the motor end of the compressor.
4. Reconnect all external components. This includes vane linkages, vent lines, etc.
   NOTE: New gaskets should be used for reassembly. All gasket surfaces should be clean and dry. At this point, the vibration of the unit should be checked. Refer to the vibration handout for this procedure.

INSTALLATION OF NEW MOTOR

1. Inspect shipping container for any shipping damage. Repair or report any damages as necessary.
2. Disassemble compressor and remove old motor.

3. Checking new motor
   a. Check shaft rotation for T.I.R. The motor may have to be rotated so the terminal board is in the proper position. The shaft can be turned by hand, although it may be easier to use a strap wrench to turn it.
   b. Check for end play. Using a dial indicator, there should not be any play. This is because the ball bearings are pre-loaded.
   c. Check for damage to the terminal board.
      NOTE: The studs should be tight and they should be numbered for proper electrical connections.
4. Install the motor. This should include the oil supply and drain lines, motor cooling supply and return lines, etc.
5. Check the oil flow. The oil flow is minimum of 0.6 gallons/minute for the babbitt bearing and a minimum of 0.2 gallons/minute for the ball bearing.
6. Complete the assembly of the compressor. Refer to the appropriate service literature for this procedure.
   NOTE: Vibration levels should be checked after any teardown. Refer to the vibration analysis handout for more information.

BEARING COMPARISON

Refer to Figures 35 and 36.

The CVHE motors have two bearing designs. The initial "A" design was a roller bearing on the compressor end and a double taper roller thrust bearing on the terminal end. The correct "B" and "C" designs incorporate a babbitt bearing on compressor end and a double (duplex) ball bearing on the thrust end. The comparative cross-sections are shown in Figures 35 and 36.

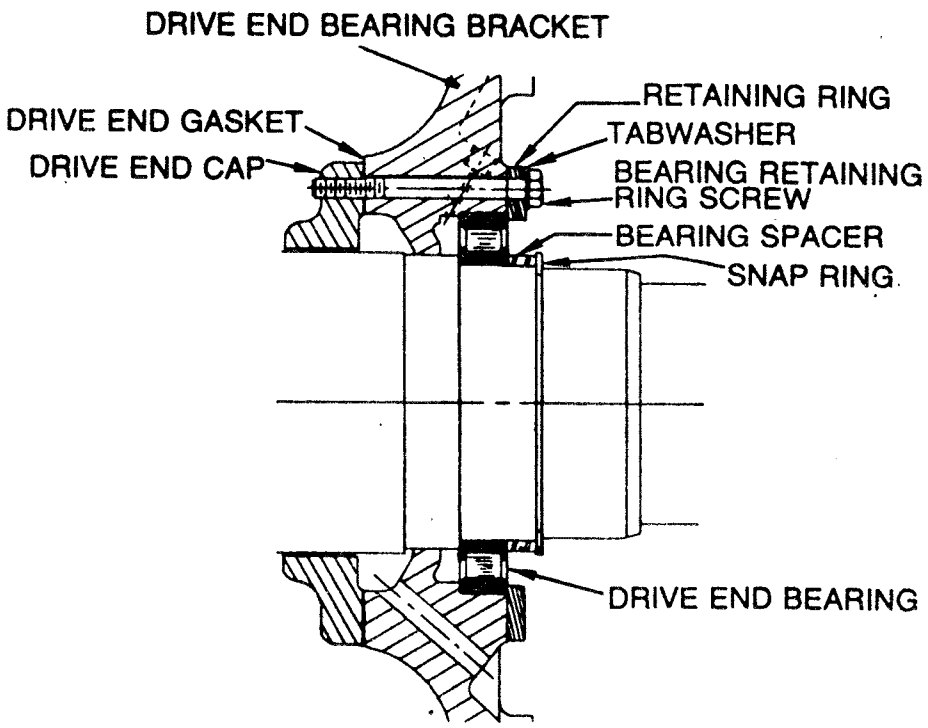
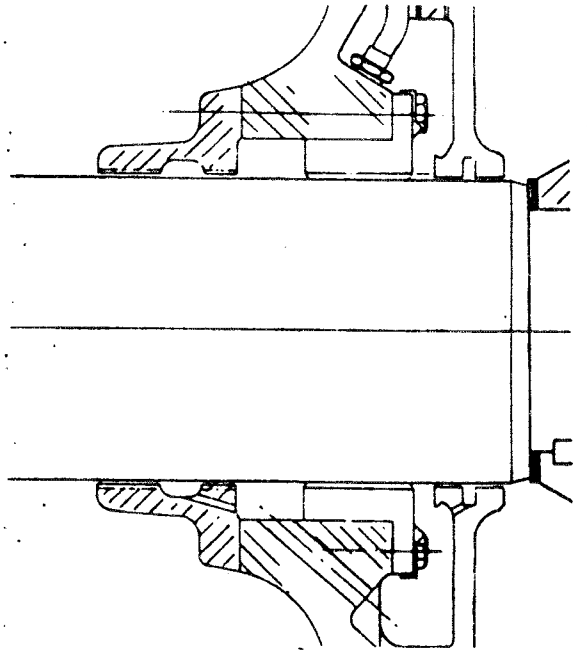
Assemble the elbow to the unit with "O" rings in place. Use the bolting sequence as shown below.



TIGHTENING SEQUENCE



A. Start tightening sequence on bolts #1 and #2 on suction connection. Tighten bolts #1 and #2 on the compressor.

B. Proceed with sequence on suction connection, then on the compressor.

Ordering No.	**CTV-EB-83**

CVHE / CVHF / CVHG / CDHF DISASSEMBLY FOR LIMITED ACCESS INSTALLATION REQUIREMENTS

This engineering bulletin presents the latest information regarding partial disassembly of CenTraVac® chillers for limited access installation requirements. This bulletin outlines the various disassembly options available.

1. **Compressor Removal (Compressor Doweling)**
   To remove the compressor for limited access installation requires ordering "compressor doweling"* which is listed in the CenTraVac Lynx pricing. This feature is standard on CDHF models. Removing the compressor assembly may expose it to unusual forces which could result in misalignment of the compressor castings. To eliminate the potential for misalignment, dowel pins must be factory installed in the compressor casting and mounting flanges.

   — Consult Service Company for field supervision estimate.

   — The Green Sheet shipping cycle for the chiller is not affected.

   *The compressor doweling package includes a set of gaskets and O-rings to be used during reassembly.

©American Standard 1997

2. **Economizer/Purge Removal**
The purge can be easily removed.

The economizer can be removed by unbolting the connecting flanges. For reassembly, use new gaskets and bolt the connecting flanges.

— Consult CVHE-IN-3A (Chiller Jobsite Disassembly/Reassembly Instructions)

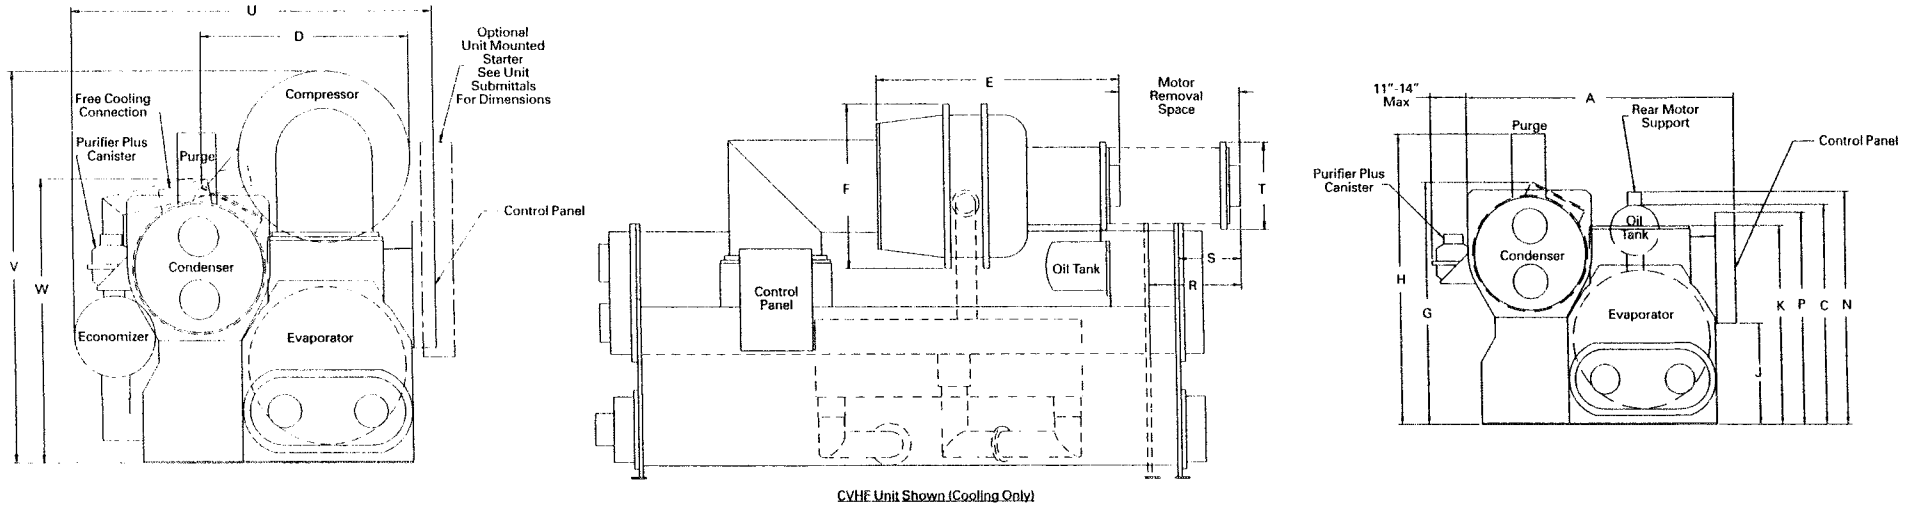
— Consult Service Company for field supervision estimate.

3. **Separable Shells**
The CVHE / CVHF / CVHG / CDHF chiller can be designed and constructed with flanges to allow separation of the condenser and the evaporator shells. The compressor must be removed prior to the separation of the shells. Consequently, the separable shell option must include compressor doweling.

— Order "separable shells and compressor doweling" from Lynx pricing. Standard feature on CDHF models

— Allow for extended shipping cycle.

— Consult Service Company for field supervision estimate.



4. **Disassembled Shipment**
Trane will **not** ship a disassembled unit. Any disassembly must be done at the job site.

5. **Special Rigging**
Rigging the CVHE / CVHF / CVHG / CDHF in a nonhorizontal configuration is not recommended because of possible damage.

Table 1 — Description of Dimensions

Dimension	Description
A	Width of chiller without economizer.
B	Horizontal distance the control panel extends beyond the evaporator tube sheet.
C	Height from the chiller base to the top of the oil tank.
D	Width of the compressor including the inlet guide vane linkage and discharge volute flange.
E	Overall length of the compressor/motor.
F	Height of the compressor.
G	Height from the chiller base to the discharge connection on the condenser.
H	Height from the chiller base to the top of the purge.
J	Height from the chiller base to the bottom of the control panel (not including the gauge bracket).
K	Height from the chiller base to the top edge of the suction connection flange.
L	Width from front of control panel to left edge of connection flange.
M	Width of condenser (this width incorporates the connection flange, etc.)
N	Height from the chiller base to the top of the rear motor support.
P	Height from the chiller base to the top of the control panel.
R	Length from tube sheet of "S,M" length heat exchanger to end of motor removal space.
S	Length from tube sheet of "L" length heat exchanger to end of motor removal space.
T	Diameter of motor end flange.
U	Overall width of chiller.
V	Overall height of chiller.
W	Height from the chiller base to the top of free cooling connection. CVHE / CVHF / CVHG models only.

NOTE: EVAPORATOR AND CONDENSER WEIGHTS DO NOT INCLUDE THE WEIGHTS OF WATERBOXES
WATERBOX WEIGHTS ARE FOR 2 PASS 300 PSI WATERBOXES (EXCEPT FOR CDHF & CDHG 1 PASS EVAP AND COND)

Notes:
1. All weights +/-5%.
2. All dimensions +/-0.5 inch.
3. See Table 1 for a description of each lettered dimension.
4. All weights are without water boxes.

R-11, R-113 and R-123 CenTraVac O-Ring Sealant Instructions

The Trane Company recommends using Loctite 515 Gasket Eliminator on all refrigerant to atmospheric O-ring connections (except CVHE suction elbows) on centrifugal chillers using R-11, R-113 and R-123. Loctite 515 Gasket Eliminator is available from Trane Company in 50 ml tubes (SEL0416) and 300 ml caulking tubes (SEL0376). To ensure leak free joints after rebuild, apply Loctite 515 to grooved O-ring joints as follows:

1. Inspect O-ring groove for nicks and scratches. Minor surface scratches or nicks can be repaired by filling the imperfection with a soft soldering material, then filing or sanding to a smooth finish.
2. Apply a bead of Loctite 515 (1/8" dia. max.) to the entire circumference of the bottom I.D. of the O-ring groove as shown in Figure 1.
3. Place the O-ring into the groove and gently press it into sealant. (Note: O-rings should not be stretched more than 5% of their ID dimension once seated in the groove.)
4. Apply a bead of Loctite 515 (1/8" dia. max.) to the entire circumference between the O-ring and top O.D. of the groove as shown in Figure 2.

For more specific information concerning the use of Loctite 515, refer to Service Bulletin CTV-SB-66 (latest version).

WARNING

This manual, including the warnings and cautions inside, must be carefully read and followed by all persons who use or maintain this product, including those who have any responsibility involving its selection, application, service or repair. This equipment will perform as designed only if used and maintained according to the instructions. Otherwise, it could fail to perform as designed and persons who rely on this product could sustain serious personal injury or death.

Model Number

Unit Model Number

For service and replacement purposes, the Trane Engineered Conversion Retrofit is assigned a multiple-character alphanumeric model number that precisely identifies each unit. The model number keys are shown here.

Use of the model number will enable the owner/operator, installing contractor, and service technician to define the characteristics of any CenTraVac® unit. Be sure to refer to the model number when ordering replacement parts or requesting service.

General Information

About This Manual

The instructions outlined in this booklet describe the recommended procedures to follow when performing an HCFC 123 Engineered Conversion℠ on a Trane CenTraVac®.

There will be certain recommendations made in this installation manual that refer to specific Trane parts that may need to be replaced or added to the unit during retrofit. It will be the Installer's responsibility to provide these parts when required. Many of these parts can be ordered as service parts from the Trane Company.

Environmental Accountability Policy

The Trane Company urges that all HVAC servicers working on Trane equipment, or any manufacturer's products, make every effort to eliminate, if possible, or vigorously reduce the emission of CFC, HCFC and HFC refrigerants to the atmosphere resulting from installation, operation, routine maintenance, or major service on this equipment. Always act in a responsible manner to conserve refrigerants for continued usage even when acceptable alternatives are available.

Recover and Recycle Refrigerants
Refrigerant used in centrifugal water chillers should be recovered and/or recycled for reuse, reprocessed (reclaimed), or properly disposed of, whenever it is removed from the equipment. Never release to atmosphere! Always determine recycle or reclaim requirements of the refrigerant before beginning recover procedure. Obtain a chemical analysis of the refrigerant if necessary. (Questions about recovered refrigerant and acceptable refrigerant quality standards are addressed in ARI Standard 700.)

Refrigerant Handling and Safety
Consult manufacturer's Material Safety Data Sheets (MSDS) on refrigerants being handled to understand health, safety, storage, handling and disposal requirements. Use approved containment vessels and refer to appropriate safety standards. Comply with all applicable transportation standards when shipping refrigerant containers.

Service Equipment and Procedures
To minimize refrigerant emissions while recovering the refrigerant, use recycling equipment such as a Trane recycle/recovery system or equivalent. Use equipment and methods which will pull the lowest possible system vacuum while recovering and condensing refrigerant. Equipment capable of pulling a vacuum of less than 1,000 microns (1.0 mm) of mercury is recommended. Do not open the unit to atmosphere for service work until the refrigerant charge is fully removed/recovered. When leak-testing with trace refrigerant and nitrogen, use HCFC-22 (R-22) rather than CFC-12 (R-12) or any other fully-halogenated refrigerant. Be aware of any new leak test methods which may eliminate refrigerants as a trace gas. Evacuation prior to charging should be done with a vacuum pump capable of pulling a vacuum of 1000 microns (1.0 mm) of mercury or less. The unit should stand for 12 hours and the vacuum should not rise above 2500 microns (2.5 mm) of mercury. A rise above 2500 microns (2.5 mm) of mercury indicates a leak test is required to locate and repair any leaks. A leak test will be required on any repaired area. Charge refrigerant into the machine only when it is determined that the machine does not leak or contain moisture. Charge refrigerant into the machine by weight. A proper charge is required for efficient machine operation. When charging is complete purge or drain charging lines into an approved refrigerant container. Seal all used refrigerant containers with approved closure devices to prevent unused refrigerant from escaping to the atmosphere. Take extra care to properly maintain all service equipment directly. Supporting refrigerant service work such as gauges hoses vacuum pumps and recycling equipment. When cleaning system components or parts avoid using CFC-11 (R-11) or CFC-113 (R-113). Use only cleaning-solvents that do not have ozone depletion factors. Property dispose of used materials. Refrigeration system cleanup methods using filters and driers are preferred. Maintain the purge unit on centrifugal water chillers in proper working condition. An improperly maintained purge unit can cause significant refrigerant emissions to the atmosphere. Consider replacing older operational purge units with the new Trane Purifier Purge unit. Excessive purge operation is an indication of possible refrigerant leakage. Check for leaks when excessive purge operation is observed.

Future Developments
Keep abreast of unit enhancements, conversion refrigerants, compatible parts and manufacturer's recommendations which will reduce refrigerant emissions and increase equipment operating efficiencies. Follow specific manufacturers guidelines for conversion of existing equipment. Use only Trane approved gaskets O-rings, oil filters and other components on Trane centrifugal water chillers or CenTraVacs. In order to assist in reducing power generation requirements always attempt to improve chiller equipment performance with improved maintenance operations which will help conserve energy resources. Items to be considered include tube cleanliness, proper water flows, correct refrigerant charge, cooling tower maintenance and proper operation.

General Information

Literature Change History

CTV-IN-1 (February 1996)

Original issue of manual; specifically intended for use by experienced service technicians.

Warnings and Cautions

Notice that warnings and cautions appear at appropriate intervals throughout this manual.

⚠ WARNINGS!
are provided to alert service technicians and other personnel to potential hazards that could result in serious personal injury or death.

⚠ Cautions:
are provided to alert personnel to conditions which could result in moderate or minor personal injury or damage to equipment or property.

Your personal safety and the proper operation of this machine depend upon precautions. The Trane Company assumes no liability for installation or service procedures performed by unqualified personnel.

Nameplates

Each retrofitted chiller is issued a new Trane nameplate that records the chiller's new Trane serial number, order number and model number. This nameplate facilitates owner service support through parts identification and engineering records retrieval. Install the new nameplate on the unit control panel.

Important: Do not remove the original nameplate.

Contents of Retrofit Package:

Each retrofit package is configured and uniquely different. As such, it is impossible to include a drawing and parts list of the retrofit package in this manual. The package will include gaskets, O-rings, impellers, oil pump motor, nuts, impeller shims, washers and a hermetic motor. When required, a new set of orifices (CVHE units) or distributor plates (other than CVHE) will be provided. When orifices require enlarging, a drawing giving the new dimension and a reaming procedure will be provided.

Included with each retrofit package is a configured drawing and bill of material. Use these items to inventory each part and insure that the retrofit package shipped is complete.
