A Trane Engineered Conversion is a comprehensive refrigerant compatibility service consisting of Trane materials, engineering analysis and technical support for the retrofit of Trane CenTraVac chillers. When upgraded, each CenTraVac chiller is optimized for its new operating conditions. Impellers and orifice plates are resized based on the new refrigerant pressures, temperatures, densities and mass flow rates calculated for the application. This assures that the upgraded chiller will continue to provide the best possible efficiency and capacity. To ensure chiller reliability, Trane developed new materials and rigorously tested them for compatibility with HCFC-123. These materials are used in components such as gaskets, O-rings, hermetic motors and vendor provided components.

Because of the configured nature of the retrofit package, this manual is not intended to give step by step instructions. Instead, use this manual as a guide when performing an HCFC-123 Engineered Conversion on a Trane CenTraVac.

Retrofit Responsibility

The purpose of Table 1 is to aid coordination of the machine's retrofit. Use the table to indicate the responsibilities of the contractor and those of the Trane Company.

Table 1 - Contractor's List

	Contractors Reference List	Material by		Installation by	
	Item	Trane	Other	Trane	Other
1	Run unit and log pre-retrofit operating data				
2	Verify machine is properly grounded.				
3	Remove required electrical connections.				
4	Drain water boxes.				
5	Remove required insulation.				
6	Install dowel pins, if required.				
7	Evacuate refrigerant.				
8	Secure lifting equipment and rigging.				
9	Perform retrofit - replace motor, impellers, orifice plates, etc.				
10	Reassemble using new gaskets, O-rings, etc.				
11	Pressure test and repair all leaks.				
12	Evacuate chiller and perform a standing vacuum rise test.				
13	Refill system with water.				
14	Charge chiller with new refrigerant.				
15	If input current requirements have changed, verify that branch circuit requirements are in accordance with NEC and the authority having jurisdiction.				
16	Make electrical connection.				
17	Spot paint the chiller as necessary.				
18	Replace/repair insulation.				
19	Change compressor oil after reassembly.				
20	Run unit and log for proper operation.				
21	Install new nameplate.				
22	Clean up jobsite.				
23	Inspect equipment room to ensure requirements of ASHRAE Standard 15 have been met.				
24	Instruct facility personnel on operation, safety requirements and maintenance.				

Prior to Retrofit

Log Pre-Retrofit Operating Data

Prior to performing the conversion, run the unit and log operating data. See Retrofit Log Sheet on page 26. This data will be used as a baseline and compared to operating data obtained after the retrofit.

⚠ WARNING!
To prevent injury or death due to electrical shock or contact with moving parts, lock unit disconnect switch in open position.

Close all chilled water and condenser water supply and return valves and drain the water boxes. Open all electrical disconnects and verify the power has been removed.

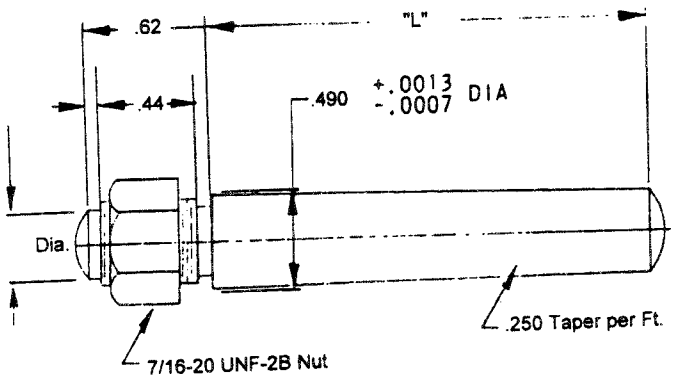
CVHE Doweling Procedure

If the CVHE volute was not factory doweled, doweling must be performed before proceeding.

The alignment of the compressor/motor assembly is determined by the position of the discharge volute. A shift in volute position at either the discharge flange or the compressor foot can change the suction elbow to compressor alignment. When the suction elbow is tightened to final torque, the compressor/motor assembly can shift from its original position. The resulting interference between seals and rotating components can adversely affect machine performance.

The third stage volute must be doweled at the discharge flange and at the compressor foot.

The dowel pins, see Figure 1, are Trane part number PIN0084. The Trane dowel pins have a threaded end so a nut can be used to pull them off easily for future service. Three pins are required to dowel the volute.



The following tools will be required:

- Drill bit for 7/16" or 29/64" diameter
- Tapered reamer for 0.25" per foot (or No. 8 dowel)
- No. 8 dowel pins (threaded end for easy removal)
- Various hand tools

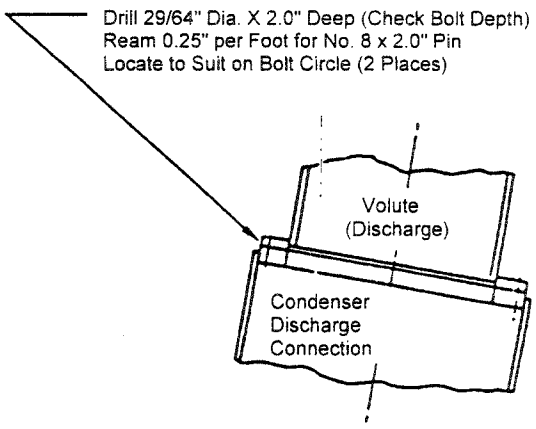
Dowel the condenser discharge flange at **two** locations and the compressor foot at **one** point. **The drilled holes into the discharge flange of the condenser should be no deeper than the existing bolt holes.** Deeper holes will penetrate the flange and cause refrigerant leakage. The same size dowel pins can be used in all locations.

Use the 29/64" drill bit and tapered reamer at the locations indicated in Figures 2 and 3. The pilot area of the reamer must be removed to ream those holes that are blind. The holes should not penetrate the flange. Install the dowel pins.

Figure 1 - Dowel Pin

Prior to Retrofit

Figure 2 - Discharge Flange



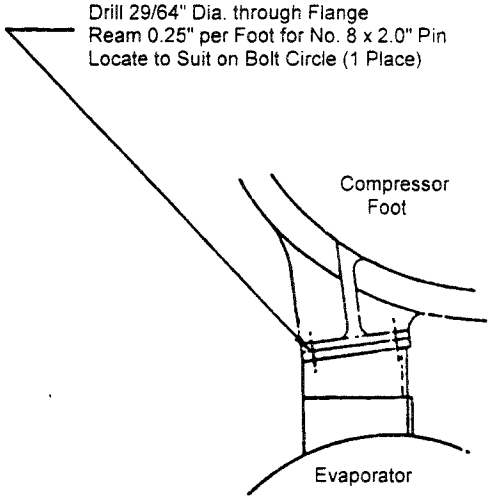


Figure 3 - Compressor Foot Doweling

Evacuate Refrigerant

⚠ WARNING!
To avoid injury or death due to inhalation of, or skin exposure to refrigerant, closely follow all safety procedures described in the Material Safety Data Sheet for the refrigerant and to all labels on refrigerant containers. Certain procedures common to refrigeration system service may expose operating and/or servicing personnel to liquid and/or vaporous refrigerant.

Remove all of the refrigerant charge using UL approved recycling equipment and follow proper handling procedures.

Evacuation should be done with a vacuum pump capable of pulling a vacuum of 1.0mm of mercury or less.

Bring unit pressure back to atmosphere using dry nitrogen to prevent rusting.

Scribing

The casing parts (suction cover, interstage casings and volute flanges) on CVHE units should be scribed on both sides so they can be realigned properly during reassembly. This will insure the suction elbow will fit properly without causing misalignment of the compressor.

Performing the Retrofit

Disassembly

Set up proper rigging and begin unit disassembly. As components are being removed, record all tolerances and match mark components so they may be reassembled in their original position. Make sure all items removed from the unit are properly covered and protected from rusting.

The internal condition of the chiller at the time of disassembly is an important factor to the success of a retrofit. Problems identified during disassembly with the inlet vanes, impellers, eliminators, or rust in the shells should be immediately brought to the attention of the customer.

Compressor

Note: If a CVHE style unit was originally built using a trim balance nut, the weights should be removed from the nut. A standard nut (supplied in the package) should be used when rebuilding the compressor.

Complete the compressor tear down. During the tear down process, be sure to mark each component to indicate its relative position on the shaft.

Motor Replacement

Meggar test the new motor, check shaft runout and end play (if appropriate) before proceeding with the compressor rebuild. Any concealed shipping damage should be immediately brought to the attention of the shipper.

On CVHE units, particular attention should be given to the original tolerance of the oil seal assembly. The allowable (total) clearance between the shaft and the oil seal should be between 0.004" to 0.007". The clearance radially should be no more than 0.002 to 0.0035". Clearance in excess of this may lead to oil loss problems. If the seal is beyond the allowable clearance it must be replaced.

In general, the conversion package will be provided with a like motor wherever possible. When it becomes necessary to provide a different style motor, there will likely be some piping modifications required. When this is required, a piping modification kit will be provided for PCV units with the retrofit package. When necessary, a new conduit box and cover will be included in the package.

When retrofitting a PCV or CV unit from an old style motor to the newer liquid cooled rotor designs, it will be necessary to make piping modifications. This applies when changing from an RCS style motor to an RPS or RVS style (see Appendix A) or from an RCC to the RVX style (see Appendix B).

In addition, the excess refrigerant drain line on the RPS and RVS style motors should have a filter screen installed as explained in Appendix C.

Performing the Retrofit

Oil

Drain the oil sump thoroughly and dispose of the waste oil in a manner consistent with all state, federal and local regulations for disposal of oil. Disassemble the oil sump head and clean the inside of the sump. The oil sump at this point should be modified to provide the necessary fittings to add an ejector assembly if necessary to insure proper oil return. See Appendix D. If required, replace the oil pump motor. Replace the oil regulating valve and reassemble the oil sump.

Drain oil from the oil filter assembly and remove the filter. Place the used oil filter in a resealable container. Follow all state, federal and local regulations for disposal of filter. Clean the filter holder and install a new filter or element. At this point you may want to install ball valves similar to the current CVHE's to help facilitate future oil filter changes. See Appendix E. Charge the oil sump with OIL22 to the appropriate level.

Oil Drain Hoses

Always replace the existing oil drain hoses with the new ones provided in the retrofit package. It is recommended that the hose clamps be inspected and new ones used when necessary. Using two clamps for the bottom connection on the oil drain line is advised. The oil drain pipe should be checked to ensure it is round, so the hose will seal properly.

Air Run

The motor should be air run without impellers to measure oil flows. Refer to Appendix F for a discussion on oil flow measurement.

⚠ Caution: To prevent possible equipment damage when the compressor is air-run (with or without the suction elbow), exercise these precautions:
[ ] Disable the transition circuit so that the starter cannot transition.
[ ] Isolate the water flows through the chiller to prevent condensate from forming on the tubes.
[ ] Do not start the compressor motor more than five times (three times for across-the-line starters) without refrigerant cooling. After the fifth start (third start for across-the-line starters), allow the motor to cool down for at least 24 hours.

⚠ WARNING!
Disconnect electrical power supply to prevent injury death due to electrical shock.

Performing the Retrofit

To deactivate the transition circuit on a CVHE with a "Classic" Control Panel in the "Wye" configuration:

1. Deactivate the starter panel's "transition circuit". To do this, locate SSOL module A1 in the starter panel and remove Wire No. 125 from Terminal D1 (**or** remove Wire No. 127 from Terminal D2). Insulate the end of the disconnected wire with black electrician's tape.
2. Deactivate the "distribution fault signal" circuit breaker (CB15) at the SSOL (A1). To do this, disconnect Wire No. 133 from Terminal E4 (**or** remove Wire No. 132 from Terminal E3). Insulate the end of the disconnected wire with black electrician's tape.

Likewise to deactivate the transition circuit on a CVHE with a UCP1 Control Panel in the "Wye" configuration:

1. Disconnect Wires 131B and 132B from micro module Terminals 1TB4-5 and -6 respectively. Wrap the exposed end of each lead with electrician's tape.
2. Disconnect Wires 10C and 12A from micro module Terminals 1TB2-5 and -6 in the UCP. Insulate the free end of each lead with electrician's tape.
3. Connect Terminals 1TB4-5 to 1TB2-5, and 1TB4-6 to 1TB2-6. Use #14 AWG, 600V copper wire.

Note: These connections prevent the starter from "transitioning" the compressor motor into the "delta" configuration.

⚠ Caution:
Exercise extreme care when connecting the 1TB4 terminals in the low-voltage (<30V) section of the UCP to the 1TB2 terminals in the 115V section. Improper connections in these temporary circuits can result in fatal damage to micro module 1U3.

Compressor Reassembly

Reassemble the compressor making sure all components are installed properly. Record all tolerances. Clean all casing parts thoroughly to remove the previous O-ring compound. The compressor O-rings should be coated with Loctite 515 gasket eliminator. See Appendix G for information on using and applying the sealant.

Note: Gortex joint sealant (1/8" width) should be used for the elbow to compressor joint.

Before tightening any bolts, the locating dowel pins must be installed. Tighten all bolts to a snug tightness, following the appropriate numerical sequence for the flange. Repeat this sequence to apply the final torque to each bolt. Flange bolt torque requirements are given in Table 2.

Table 2 - Flange Bolt Torque Recommendations for O-Ring and Flat-Gasket Piping Connections (See Note).

Bolt Size (In.)	Gasket Type	
	O-Ring	Flat
3/8	25 (34)	12-18 (16-24)
1/2	70 (95)	33-50 (45-68)
5/8	150 (203)	70-90 (95-122)
3/4	250 (339)	105-155 (142-210)

Note: Torques provided in ft./lbs (Newton/meters).

Continue the standard rebuild procedure, including reinstallation of the inlet guide vanes. After the vanes are installed, lock the vanes in the closed position and again air-run the compressor and monitor its vibration levels.

Vibration Monitoring

Following the air-run procedure documented previously, start the chiller and run it for five minutes before recording any vibration readings. During this "warm-up" period, monitor the unit's vibration level with a vibration analyzer set-up for running speed (i.e. 60hz or 3600 RPM).

Once the five minute "warm-up" expires, take a complete set of vibration readings. The horizontal and vertical vibration measurements should not exceed 0.10 in/sec peak for CVHE units. Vibration levels for units other than CVHE's should not exceed 1.0 mil displacement or 0.19 in/sec at shaft operating speed (nominally 3575 cpm).

If the levels of vibration are acceptable, continue rebuilding the unit.

When vibration levels on CVHE chillers exceed 0.10 in/sec, a trim balance will need to be performed. See Appendix H. For other style units it may be necessary to have the impellers and motor rotor assembly rechecked to insure they are within factory specifications.

Performing the Retrofit

Threaded Pipe Joints

It is advisable to disassemble all threaded pipe joints while doing a major overhaul or retrofit on an older chiller. The joints should be cleaned and resealed using a thread sealing compound compatible with both refrigerant CFC-11 and HCFC-123. Threaded pipe joints on current production chiller units use either Loctite 277 or La-Co Slic-Tite paste with Teflon, except where the joint is close to a braze connection and may be subjected to extreme heat. Where heat is a major concern, Teflon tape should be used. The Loctite 277 thread locker compound has been approved for use as a pipe sealer in this application and requires approximately 24 hours set time before being exposed to refrigerants. Set time before exposure will likely be a requirement for most of the pipe sealing compounds available today. There are undoubtedly many other pipe sealing compounds that are compatible in this type of application with refrigerants CFC-11 and HCFC-123. Before using other thread sealers check with the manufacturer of the compound to verify compatibility and reliability through laboratory testing and field experience in use.

Valves

Units with factory or field installed electrically actuated hot gas bypass or free cooling valves may require rebuild or replacement. Prior to 1994, the Trane Company used four different valve manufacturers.

- Valves manufactured by **Posi-Seal**, will in most cases require rebuild kits in order to be made compatible. There were a few Posi-Seal valves manufactured with resilient internal seats that will require complete valve replacement since new seats are not available in a compatible material.
- Valves manufactured by **Keystone** and **Jamesbury** are compatible.
- In a very limited number of units **Dover-Norris** valves were also used. The Dover-Norris valves are not compatible and must be replaced since rebuild kits are not available.

In all cases, the unit should be inspected to determine the valve manufacturer and their model numbers. This information is necessary in order to insure the correct material or valves are furnished and to determine what work will be required.

Note: Units with pnuematically actuated hot gas valves have stem seals and other internal components that are compatible. In all cases we recommend new flange gaskets be used.

Performing the Retrofit

Orifice Replacement

- **PCV,CVHA,CV,CVHB**

When a new set of orifices are required for these model units, the retrofit package will include a new set of distributor plates for installation in the condenser and evaporator liquid lines. The package also includes a drawing that highlights the new well rounded orifice diameter that will be required. The well rounded orifice (both) should be enlarged by using a proper diameter steel Hawg cutter, a tapered reamer or a die grinder with carbide bur to increase the size to the new specified diameter. Discard the old distributor plates and install the new ones provided.

- **CVHE**

When orifices are required, new orifice assemblies will be provided for the condenser liquid line, evaporator liquid line and the economizer. For units which do not have the removable orifice option, it will be necessary to remove the entire liquid sump from the bottom of the economizer.

After the sump is removed, the orifice welds must be ground away so the new orifice can be installed. Make sure the new orifice is welded into the economizer at the same depth as the original to insure there will be no restrictions to flow. The sump should be welded back onto the economizer.

Performing the Retrofit

Additional Unit Modifications and Enhancements

- **All Units**

It is advisable to add the necessary fittings so that an InterClean™ system can be added to the chiller to remove any small amounts of debris (typically rust) or old compressor oil etc., that may still be left in the unit after the retrofit is completed. The fittings that are added for connection of an InterClean system can also be used as access points for future use of recovery equipment etc. when servicing the chiller.

- **CVHE**

Older style CVHE's that had the oil sump vent line connected to the suction elbow should be repiped, see Appendix I, to include a vent line solenoid valve, timer and a larger 1-1/8" line. The larger vent line, solenoid valve, and timer should be installed on all units. CVHE units should be modified to have two eductors similar to new production units. One is used to return oil from the suction cover and the other returns oil directly from the evaporator. Make sure that the system is clean so that debris does not get into the sump as indicated above.

- **CV, CVHB**

The oil sump vent line valve should be located on the suction elbow. An oil return line from the suction cover to the oil sump should also be added. See Appendix J.

- **CVHE035-050 with Louis Allis DRV5-1740 Motor**

When a DRV5-1740 Louis Allis motor is replaced or is used as a replacement for a Reliance motor, replace the motor liquid feed line orifice with a number three or enlarge the existing number two orifice to a 0.390 inch diameter. The enlarged orifiice will provide improved liquid refrigerant flow to the motor.

- **CVHE022 - 032 units with DRV3-1500 motors**

Some of the earlier units of this size with nominal 1500 frame motors used a number one motor cooling orifice (0.250" dia.). If the unit is determined to have a number one orifice, it should be increased to a diameter of 0.312".

Completing the Retrofit

After the unit has been reassembled, do the following to complete the retrofit job.

- Make sure that all other field added components such as liquid level indicators, head pressure controls, etc. have been reviewed for compatibility.
- After the unit has been reassembled, it should be pressure tested using dry nitrogen and soap solution. Repair all leaks and evacuate the unit to 1.0 millimeters. Once evacuated the chiller will be required to pass a standing vacuum rise test.
- Inspect the equipment room to insure the requirements of ASHRAE Standard 15 have been met. This will require:
  - — A refrigerant monitor
  - — Self Contained Breathing Apparatus (SCBA)
  - — Ventilation
  - — The purge relief is piped into the rupture relief vent line to outside the building.
- Refill the chilled and condenser water systems.
- Charge the chiller with the new refrigerant. Refer to Appendix K for proper refrigerant charge. Make sure vapor only is charged until the unit pressure is above the vapor pressure equivalent to the freezing point of water. Always run the evaporator pump while charging the unit to prevent freeze-ups from occurring. Charge the new refrigerant through a filter drier and moisture indicating sight glass.
- Change compressor oil after reassembly. Use only Trane approved oil.
- Run the unit and log it for proper operation. If an InterClean™ has been installed, the refrigerant angle valve on the liquid supply line should be adjusted to maintain a proper level in the tank. If an eductor has been connected directly to the oil sump, it may be necessary to adjust the volume of flow to insure the oil sump temperature does not drop too low from excessive refrigerant flow. After cleanup, the InterClean or the eductor system can be turned off and only used if future oil migration occurs due to unusual operating conditions etc.
- Spot paint the chiller as necessary and repair or replace all insulation.
- Install the new nameplate and the R123 label on the unit control panel. **Do not** remove the existing nameplate.
- Instruct the facilities operating personnel on proper procedures to follow when operating the chiller, the requirements for safely handling refrigerants, and the maintenance of the chiller and ancillary equipment such as the monitor etc.

After the Retrofit

After a few weeks of operation, the following is advisable:

- Recheck bolt torques. This is especially critical in gasketed joints such as terminal boards, liquid lines, suction and discharge pipes etc.
- Take a refrigerant and oil sample and have it analyzed.

CenTraVac® Engineered Conversion Retrofit / Commissioning Checklist and Test Log

Job Name _____ **Location** _____

Model # _____ **Serial #** _____

Sales Order # _____ **Conversion Date** _____

NOTE: The Unit Installation, Operation and Maintenance Manuals, Submittals, and Design Specifications must be used in conjunction with this checklist.

I. PRE-RETROFIT PROCEDURE

☐ **A. Run unit and log pre-retrofit operating data on the Retrofit Log Sheet.**

☐ **B. Electrical Connections**

Verify machine is properly grounded. Open disconnects and remove required electrical connections.

☐ **C. Drain Water Boxes**

☐ **D. Remove Required Insulation**

☐ **E. Install Dowel Pins, if required.**

II. RETROFIT PROCEDURES

A. Evacuate Refrigerant

B. Disassemble Unit

- ☐ 1. Record tolerances
- ☐ 2. Match mark/scribe components
- ☐ 3. Inspect internal condition of chiller

C. Motor Replacement

- ☐ 1. Meggar the new motor.
- ☐ 2. Check runout and end play.
- ☐ 3. Check oil seal assembly (CVHE)
- ☐ 4. Piping modifications (PCV or CV, if required)
- ☐ 5. Filter screen installation (PCV/CVHA, if required)

D. Compressor

- ☐ 1. Remove elbow and IGVs
- ☐ 2. Record location of balance weights on trim balance nut (if required)
- ☐ 3. Mark each component to indicate relative position on shaft

E. Oil

- ☐ 1. Drain/dispose oil
- ☐ 2. Modify oil sump to add eductor assembly (if required)
- ☐ 3. Replace oil pump motor (if required)
- ☐ 4. Replace oil regulating valve.
- ☐ 5. Replace/dispose oil filter
- ☐ 6. Modify piping/install ball valves (if desired)
- ☐ 7. Replace existing drain hoses

F. Air Run

- ☐ 1. Measure oil flows

G. Reassemble Compressor

- ☐ 1. Record all tolerances
- ☐ 2. Install impellers, gaskets, O-rings, bolts, nuts, washers, etc.
- ☐ 3. Reinstall inlet guide vanes
- ☐ 4. Air run and monitor vibration
- ☐ 5. Install suction elbow
- ☐ 6. Tighten all bolts to recommended bolt torques.

H. Pipe Threads

- ☐ 1. Disassemble and clean threads
- ☐ 2. Reseal and reassemble

I. Valves

- ☐ 1. Replace/rebuild valves (if required)

J. Orifice Replacement

- ☐ 1. Replace orifices (CVHE, if required)
- ☐ 2. Enlarge well rounded orifice (PCV/CVHA/CV/CVHB, if required)

K. Other Modifications/Enhancements

- ☐ 1. Add Interclean™ system (if desired)
- ☐ 2. Repipe oil sump vent line (CVHE)
- ☐ 3. Relocate oil sump vent line (CV, CVHB)
- ☐ 4. Replace motor liquid feed line orifice (CVHE 035-050 with Louis Allis DRV5-1740 motor or CVHE022-032 with DRV3-1500 frame motors)

L. Complete the Retrofit

- ☐ 1. Insure field added components have been reviewed for compatability
- ☐ 2. Pressure test unit and perform standing vacuum rise test
- ☐ 3. Inspect equipment room to insure requirements of ASHRAE Standard 15 have been met
- ☐ 4. Refill water systems
- ☐ 5. Charge chiller with new refrigerant
- ☐ 6. Spot paint and repair or replace insulation
- ☐ 7. Change compressor oil
- ☐ 8. Install new nameplate

III. PRECOMMISSIONING PROCEDURES

☐ **A. Obtain Design (order) Specification Data**

This indicates the design criteria of the particular unit. A unit cannot be properly retrofitted/commissioned unless this data is known. It is the responsibility of the selling office to furnish this data.

☐ **B. Obtain Wiring Diagrams**

The "as-wired" electrical diagram should be compatable with the recommended Trane submittals and diagrams. Are customer added external/remote control circuits compatable? Yes ☐ No ☐

☐ **C. General Installation Observations**

☐ 1. Is the water piping correctly installed? Yes ☐ No ☐
Flow Switches Yes ☐ No ☐ Pressure Gauges Yes ☐ No ☐

Isolation Valves Yes ☐ No ☐ Flow Balancing Valves Yes ☐ No ☐

Thermometer Wells Yes ☐ No ☐ Vent Cocks and Drains Yes ☐ No ☐

☐ 2. Have proper clearances around the unit been maintained? Yes ☐ No ☐

☐ 3. Is power wiring of adequate ampacity and correct voltage? Yes ☐ No ☐

Are fuses or circuit breakers of the correct value or type? Yes ☐ No ☐

☐ 4. Is the unit base acceptable and level and is the unit on isolators (rubber as supplied by Trane or springtype)? Yes ☐ No ☐

☐ 5. Have the Class 2 (less than 30 volts) circuits been properly isolated from the higher voltage control and power circuits? Yes ☐ No ☐

☐ **D. Comments** _____

_____

_____

IV. COMMISSIONING PROCEDURES

A. Pre-start operations

1. Calibration of Controls

☐ Calibrate all controls per original unit specifications shown in the operation and maintenance manual.

2. Condenser

☐ Calibrated thermometers and pressure gauges installed in/out of condenser on machine side of any valve or elbow.

☐ If condenser pump controlled by unit control panel, is field wiring correct and complete?

☐ Condenser pump(s) run, system and strainers properly cleaned and/or flushed.

☐ Condenser water strainer in close proximity to entering connection of condenser.

☐ Provisions installed to properly maintain water treatment additives.

☐ Initial water treatment added to system.

☐ Flow or differential pressure switch installed and wired in series with auxiliary of pump motor starter. Operation of circuit verified.

☐ Condenser water flow balanced. Ft H20 PD design_____ Ft H20 actual_____

GPM design_____ GPM actual_____

3. Evaporator

☐ Calibrated thermometers and pressure gauges installed in/out of evaporator on machine side of any valve or elbow.

☐ If evaporator pump controlled by unit control panel, is field wiring correct and complete?

☐ Evaporator pump(s) run, system and strainers properly cleaned and/or flushed.

☐ Evaporator water strainer in close proximity to entering connection of evaporator.

☐ Provisions installed to properly maintain water treatment additives.

☐ Initial water treatment added to system.

☐ Flow or differential pressure switch installed and wired in series with auxiliary of pump motor starter. Operation of circuit verified.

☐ Evaporator water flow balanced. Ft H20 PD design_____ Ft H20 actual_____

GPM design_____ GPM actual_____

4. Electrical and Controls

a. Motor starter panel

- ☐ All terminals tightened.
- ☐ Wiring free from abrasion, kinks, and sharp corners.
- ☐ Contactors and relays have freedom of movement.
- ☐ All contacts are free of corrosion or dirt. Panel is free of dust, debris etc.
- ☐ Check the correctness of the power connections from the starter to the motor.
- ☐ Check the wiring to the starter for size, voltage, and correct phase rotation (A-L1, B-L2, C-L3).
- ☐ Check for equal phase representation in each power wiring conduit.

b. Control panel

- ☐ All terminals tightened.
- ☐ Wires free from abrasion, kinks, sharp corners.
- ☐ Low voltage wires are isolated from high voltage wires.
- ☐ Panel is free of debris, dust, etc.
- ☐ Check the setting of the oil pressure regulating valve
    1. Adjust the oil pressure regulating valve to maintain proper oil pressure as described in the unit Operation And Maintenance Manual.
- ☐ Check vane operator and vanes.
    1. Vane movement is smooth to open/close.

B. Preparation for Start-up

1. Electrical

☐ Power up the motor starter. Check for control voltage at control panel terminals

☐ Check current to the oil sump heater. _____ amperes

☐ As the oil heats up, finish any operations not yet completed in preparation for starting the unit.

C. Chiller Start-up

1. Make all preliminary checks.

☐ Oil temp, oil level, chilled water flow, chilled water load available (cooling units on) etc.

2. Start the unit.

☐ If the phase rotation of the electrical power has not been positivly confirmed, the actual rotation of the motor must be checked. Observe the rotation of the motor shaft through the sight glass on the end of the motor at the moment of start-up. Rotation must be CLOCKWISE. If the phase sequence is incorrect, then L1 and L3 power leads to the starter must be reversed.

☐ As the unit starts and runs, observe closely all operating conditions.

☐ Readjust the oil pressure regulator to.the proper setting.

☐ After the unit has the system down to design leaving chilled water temp and is under control, and the purge is no longer relieving non-condensables, begin taking the startup test log. Log operating data on the conversion log sheet.

☐ When the logging is complete, shut the chiller down. Allow the unit to sit idle for 5-10 minutes. Attach a piece of clear plastic hose between the 1/2 inch valve at the bottom of the evaporator and the 1/4 inch valve near the top of the evaporator. Open the valves and record or mark permanently the refrigerant level in the hose. At a later time, the refrigerant charge can be easily checked and verified.

☐ Restart the chiller and carefully observe the starting and loading sequence.

3. Instructions to the Chiller Operator.

☐ Instructions for starting, operating, and shutting down.

☐ Instructions for logging the unit.

☐ Instructions for periodic maintenance.

D. After 2 weeks of operation.

1. Recheck bolt torques.
2. Take a refrigerant and oil sample and have it analyzed.

Piping Modifications - PCV

Required piping modifications when replacing a Louis Allis RCS frame motor or an old style General Electric motor with a Louis Allis RPS, RVS or a new style General Electric frame motor on Model PCV CenTraVacs®.

Discussion

The original Louis Allis RCS and General Electric motors had liquid refrigerant cooled stators. They also used refrigerant vapor from the economizer to cool the rotor and motor end windings. The Louis Allis RCS motors were replaced with the newer style RPS motors. The RPS style motors have stator shrouds. There is a refrigerant feed tube in the motor that directs a small amount of liquid from the end shroud onto the compressor end of the rotor for cooling the rotor.

The RPS style motors were replaced with RVS style Louis Allis motors. The RVS motors have a liquid jacket surrounding the stator with a slot in the center of the stator from which liquid refrigerant flows directly into the rotor cavity. The motor end windings are cooled by liquid splashed off the rotor ends directly onto the windings.

The RPS, RVS and new style General Electric motors all require drain lines to remove excess refrigerant which collects in the motor end bells.

The original General Electric motors have a cooling system identical to the Louis Allis RCS motors. The General Electric motors were later redesigned to have a cooling system similar to the RVS motor where liquid is fed to the rotor through a stator slot.

Piping Modification Procedure

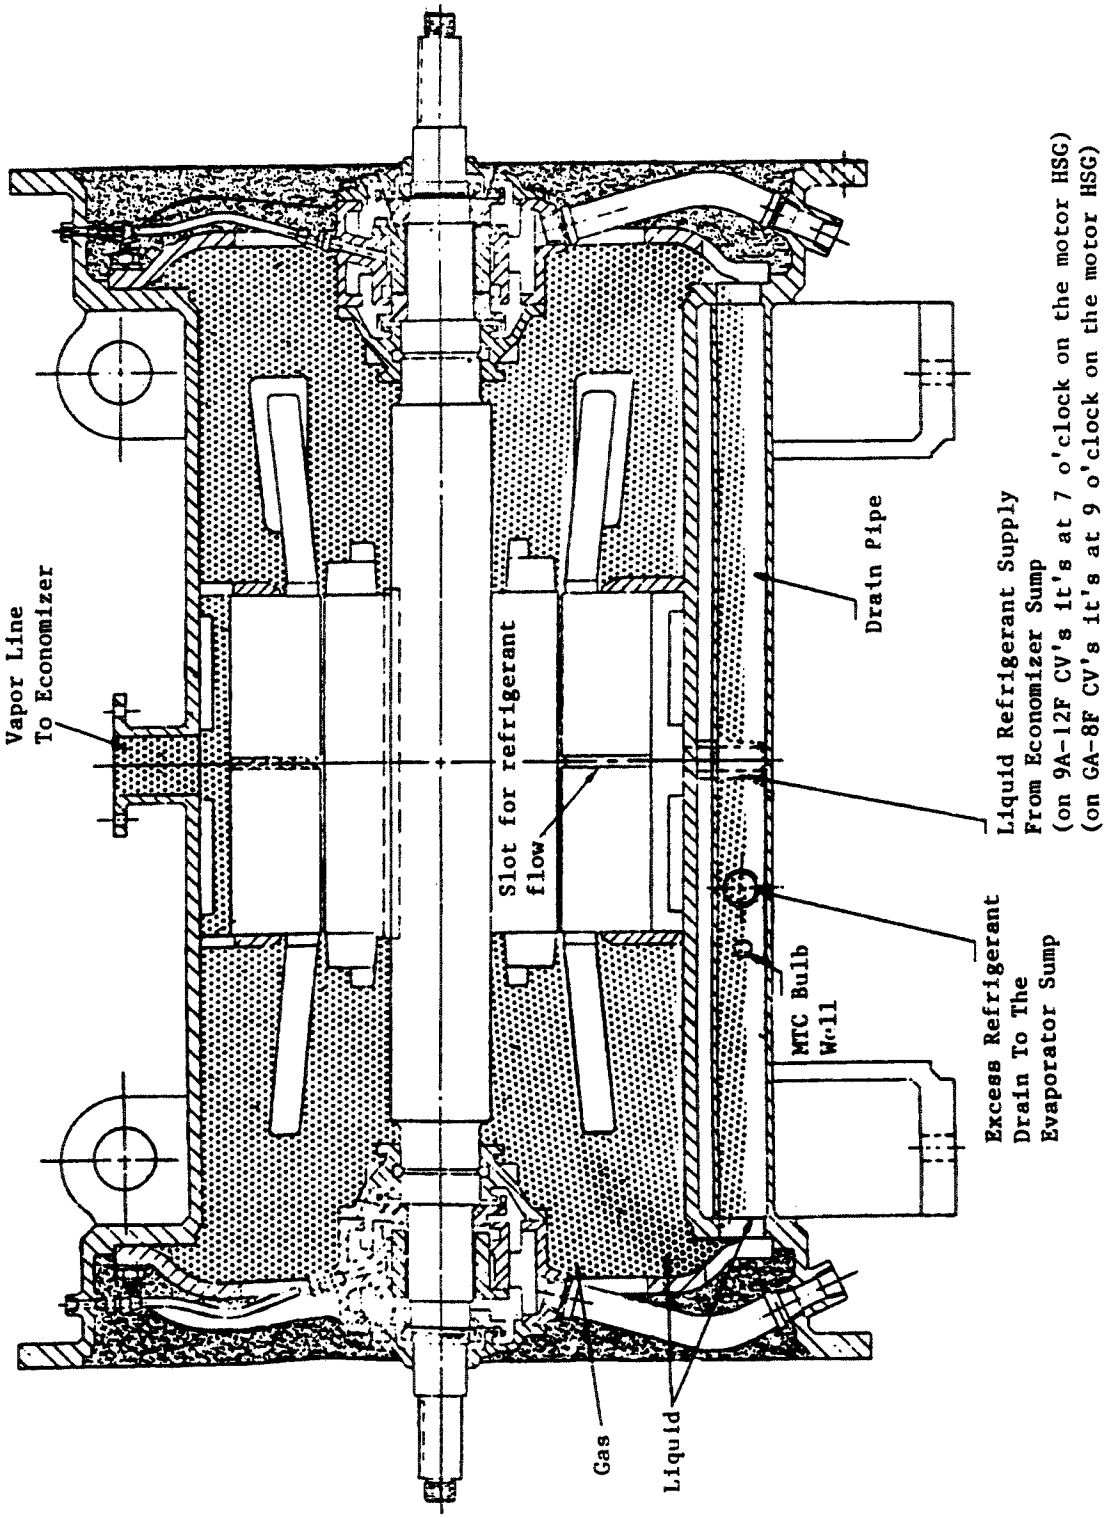
The piping conversion package will include a drawing which shows proper piping procedures.

1. Cut a 1-3/16" diameter hole in the evaporator shell (terminal end). When cutting the hole through the evaporator shell, protect the eliminators from damage. Weld a pipe nipple to the shell.
2. Cut a 7/8" diameter hole in the evaporator shell near the bearing drain line (compressor end). Protect the eliminators from damage.
3. Install the new motor in the unit.
4. Assemble the terminal end refrigerant drain line. Be sure the pipe to flare adapter assembly at the evaporator contains an orifice.
5. Assemble the compressor end refrigerant drains line. Be sure the pipe to sweat adapter contains an orifice and screen assembly.
6. The PCV-2C - 2F RPS motors do not have an outer oil slinger on the compressor end, which the RCS motors have. The restricted end bearing is on the terminal end of RPS motors. A special spacer is provided in the kit.

Appendix B
Piping Modifications - CV

Required piping modifications when replacing a Louis Allis RCC frame motor with a Louis Allis RVX style motor on Model CV CenTraVacs®.

Figure 4 is a cross-section of the RVX motor showing the liquid and gas flow.



The RVX motor is cooled by liquid and gaseous refrigerant. The liquid refrigerant enters the motor housing from the side and flows into a chamber surrounding the stator. This liquid level is 4" to 7" above the center line of the motor. The liquid refrigerant that flashes off is vented from the top of the housing to the economizer. Some of the liquid refrigerant flows from the chamber through a slot in the stator into the windings and rotor area cooling this area. The excess liquid and gaseous refrigerant is drained from the bottom of the motor housing. The liquid indicator in the drain line should have a bubbling action in it, indicating proper refrigerant cooling. The motor temperature control (MTC) bulb well is in a new location as shown in Figure 4. The old MTC capillary tube is not long enough to reach the new bulb well location. A new MTC CNT0322 should be ordered when this occurs.

Because of the redesigned RVX motor cooling piping, there have been questions on how to fabricate the piping for the RVX motor. Figures 5-9 show the various piping arrangements of the redesigned RVX motor cooling piping.The piping components can be bought locally.

Note: A cleanable strainer is to be installed in the liquid supply line on all the CV sizes. Be sure the direction of flow is checked before you install the strainer.

Appendix C
Refrigerant Filter Screen Installation

All field motor replacements with new style Louis Allis RVS or RPS built motors must have a screen installed on the compressor end orifice.

Should it become necessary to field fabricate a strainer screen, use the following procedure:

The special strainer screen must be made from a piece of #12 wire mesh (0.025" wire) which is 3" by 1.1813". The screen must be installed in the orifice fitting on the compressor end of the motor and soft- soldered in place. See Figure 10. A 3/8" diameter tubing cap should then be soldered on top of the tube assembly with soft solder. After soldering, the orifice must be checked to see that it is not plugged with solder. When reassembling the unit, the fitting with the strainer must be installed on the compressor end. A strainer is not required for the terminal end of the motor.

The tube assembly can also be ordered from Trane. See Table 3 for proper parts identification.

Appendix D
Ejector System Installation

The ejector system can be used to reclaim oil from the evaporator refrigerant circuit on a periodic or permanent basis.

Figure 11 illustrates an oil ejector system installed on a PCV/CVHA style unit. Prior to installation, the following items should be taken into serious consideration:

- The ejector must be installed slightly above the highest possible refrigerant level in the evaporator in order to prevent refrigerant flowing directly into the oil tank when the unit is not operating.
- Since the ejector is most efficient when the unit condensing pressure is highest, it is possible to over dilute the oil sump with refrigerant during machine operation. Therefore, it is advisable to install a solenoid valve and a thermostat to control the amount of refrigerant flow. A normally closed solenoid valve should be installed in the hot gas line to the ejector, and wired in series with a temperature control. On a fall in oil tank temperature (below 120°F), the thermostat should open its contacts and deactivate the solenoid. The thermostat sensor would be installed in the oil sump. An oil tank temperature of a least 120° F must be maintained continuously. An excessive amount of refrigerant flow to the oil tank will cause excessive dilution of the oil and possible bearing damage due to marginal lubrication. A sight glass should be installed in the supply line to the oil tank to visually confirm the amount of refrigerant flow.

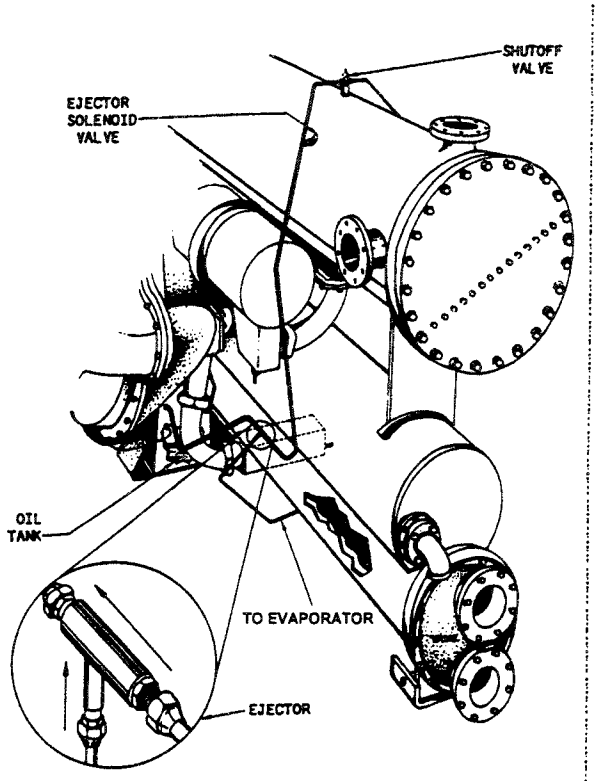
Note: There is no provision for a thermostat sensor in the oil sump. When installing a sensor well, be sure it is below the oil level in the sump. The back of the oil tank can be drilled and tapped to accept a well.

- Oil tank-venting on early Model PCV-2C through PCV-5F units using RCS style Louis Allis and General Electric motors, typically had an oil sump operating pressure which was well above evaporator pressure. The original vent line from the oil tank to the first stage evaporator suction area does not keep the oil sump pressure close enough to the evaporator pressure to allow the ejector to function properly. These units can be easily identified since they have a vent line which supplies rotor cooling gas from the economizer into the terminal housing end bell. See Figure 12.

  This problem can be eliminated by installing an additional vent line from the back of the oil tank to the evaporator. The back of the oil tank can be drilled and tapped to accommodate the added vent line. This vent line is in addition to the original vent and should be of the same size (5/8" OD copper). Refer to Figure 12 for a schematic of a RCS style motor lubrication system. All other style centrifugal chillers should not require additional modifications to their original vent piping.

Appendix D
Ejector System Installation

Figure 11 - Typical Oil Recovery System



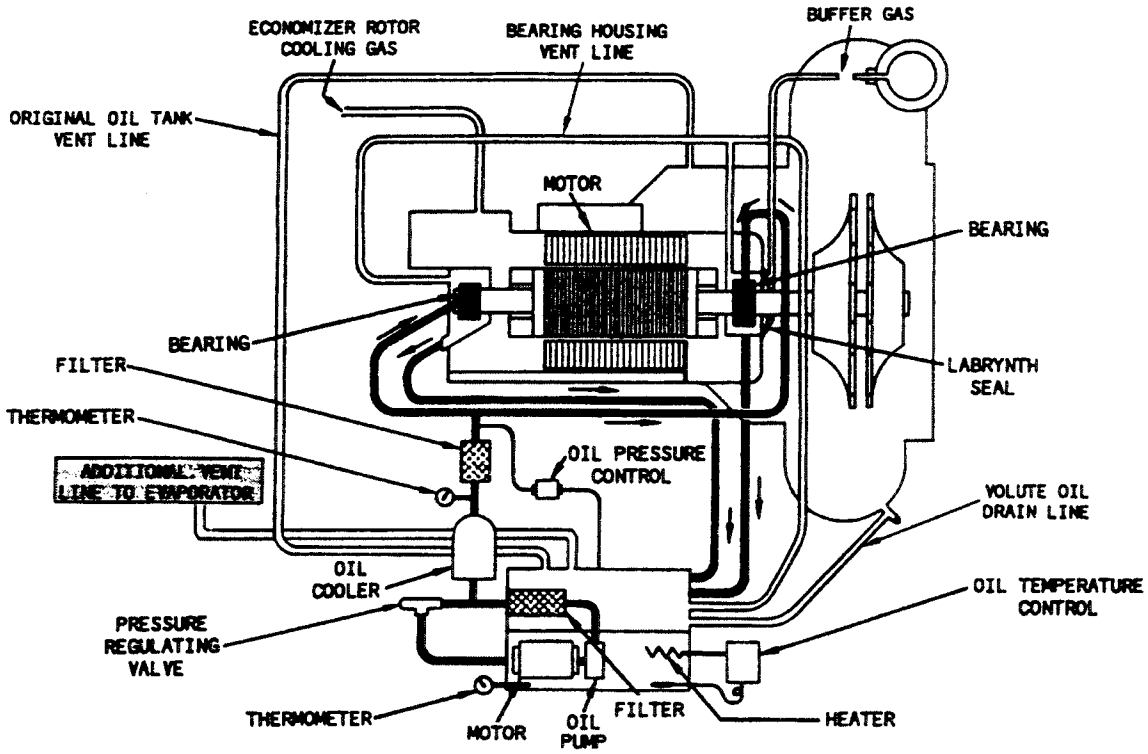


Figure 12 - Schematic of Lubrication System (RCS Style Motors)

Appendix D
Ejector System Installation

Install the ejector using the following piping guidelines to insure proper operation:

1. The line feeding the ejector with hot gas from the condenser should be 3/8" OD copper. This line should be located near the top of the condenser bundle to prevent condensed liquid from entering the line during unit operation. A tee can be installed between the condenser purge connection and the solenoid valve for this purpose. However, it is recommended that a separate connection be added to the condenser.
2. The suction line from the evaporator should be taken from an area near the top of the refrigerant level, preferably near the compressor suction connection. In most cases, a tee can be used to connect the line to the extra bulb well connection originally supplied on the evaporator. The suction line to the ejector should be 1/4" OD copper with an in-line shutoff valve to regulate flow through the ejector.
3. The ejector supply line to the oil tank should be 1/2" OD copper. This line should be brought into the oil tank above the oil level. A hole can be tapped into the face or back of the oil tank for this purpose. The line into the oil tank should be pointed in the proper direction to prevent the oil and refrigerant mixture being sprayed into the oil tank from being pulled into the line which vents the oil tank to the evaporator. This line should be as short as possible to minimize pressure drop. A sight glass should be installed in this line.

Parts Ordering Information

Table 4 lists the parts required for adding an oil ejector system. All other required materials should be purchased locally.

Table 4 - Oil Ejector System Parts

Thermostat Well	WEL0014
Thermostat	SWT0380

Appendix E
Oil Filter Modification

To minimize oil loss and refrigerant vapor release it is recommended that the oil filter system be modified to utilize a screw-on filter in the horizontal position. In addition to the horizontal oil filter, a refrigeration valve is installed on the top of the assembly. This refrigeration valve will be used for oil sampling.

Refer to Figures 13 and 14 for illustration of the following parts:

- A. (1) 3/8 inch ball valve, Apollo number 70-802-3/8 or VAL 4260
- B. (1) 1/2 inch 3 way valve, Apollo number 70-903-1/2 or VAL 4261
- C. (1) 3/8 inch NPT refrigeration angle valve or VAL 0031
- D. (1) Tee
- E. Modified oil filter top assembly

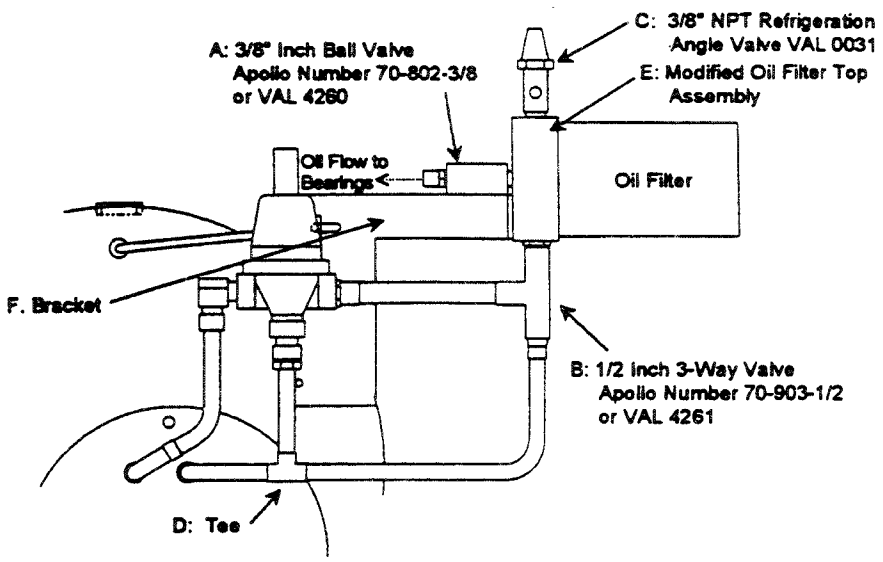
The existing oil filter top assembly can be field modified, refer to Figure 14 or order new oil filter top (COV 2131).

- F. Oil Filter Bracket (BRK 1804)

Note: If valves with handles are used, remove handles to prevent tampering after installation is complete.

Appendix E
Oil Filter Modification

Figure 13 - Recommended Modifications



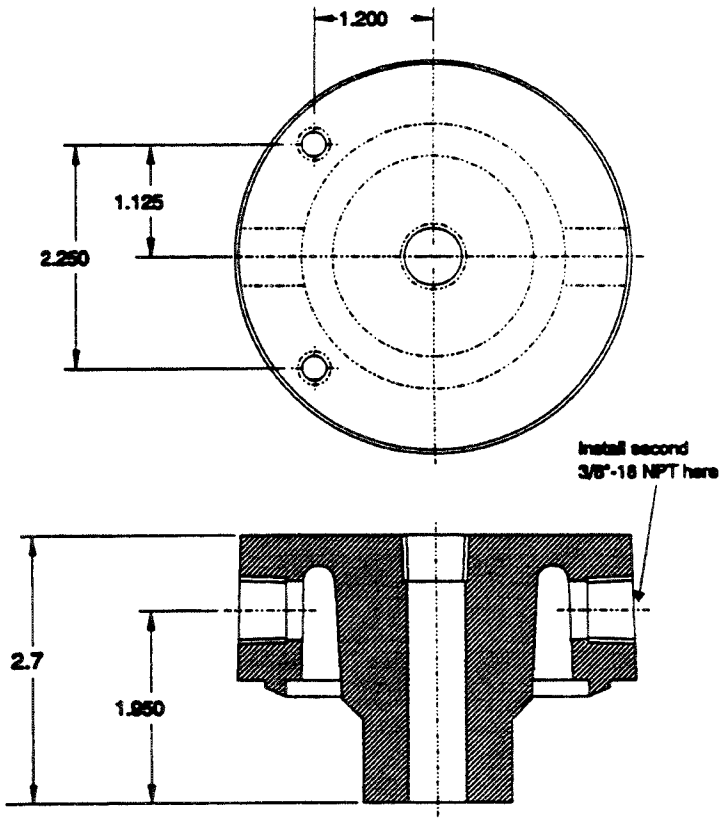


Figure 14 - Oil Filter Top Assembly Modification

Appendix E
Oil Filter Modification

Oil Sampling Technique With Modification:

To ensure an accurate and useful oil analysis, follow these guidelines.

It is strongly recommended that only approved sample bottles be used for oil analysis. The oil sample bottle used must be clean, dry, and free of any contamination.

A minimum of 4 fluid ounces of oil is required for analysis.

Make sure the centrifugal unit has been operating for 30 minutes or more. This will ensure the oil is well circulated.

With centrifugal unit operating, collect oil circulated to the bearing through the lubrication system. The recommended sample location is the 3/8" refrigeration angle valve (Valve C) on the oil filter top assembly. See Figure 13.

Do not collect oil samples from the charging valve on the oil tank.

Send oil samples in for analysis as soon as possible. Do not store oil samples; since moisture may infiltrate the sample container and distort analysis results.

Oil Filter Change With Modification:

These instructions are for changing a screw-on type oil filter in the horizontal configuration. Other filter arrangements will require different methods for change out. Whatever method is used, it is very important to minimize the loss of oil and the release of refrigerant vapor.

1. Turn compressor and oil pump motor off .
2. Turn three-way valve handle (Valve B) to a 45 degree position from the normal operating position.

Note: During normal operation the handle of 3-Way valve should be in the horizontal position, or in a position to allow oil flow from the oil regulator into the oil filter.

3. Close 3/8" ball valve (Valve A).

Note: With the three-way valve handle set to a 45 degree position and the 3/8" ball valve closed, the oil filter will drain into the sump. Allow the oil filter to drain for a minimum of 30 minutes.

4. Open the 3/8" refrigeration angle valve (Valve C). Quickly rotate the three-way valve handle (Valve B) to a 90 degree position from the normal operating position. This isolates the oil filter and diverts oil flow from the oil regulator back to the oil sump.
5. Close 3/8" refrigeration angle valve (Valve C).
6. Remove and replace oil filter.

Note: Dispose of used oil filter per applicable federal, state and local regulations.

7. Open 3/8" ball valve (Valve A) and return three-way valve handle (Valve B) to 0 degrees (handle in the horizontal position or in a position to allow oil flow from oil regulator into oil filter).
8. Restart centrifugal unit.

Appendix F
Oil Flow Measurement

Table 5 lists the minimum and maximum oil flow limits for Louis Allis motors. The procedure for measuring oil flow through compressor motor bearings is as follows:

1. Drain the oil sump and refill with new compressor oil. The only oil recommended for use in all Trane CenTraVac® chillers (excluding models CVHC and LOCV) is Trane OIL0022. The flow rates shown in Table 5 are for new compressor oil. Dilution of the compressor oil with refrigerant can significantly lower the viscosity of the oil which could affect flow readings.
2. Energize the crankcase heater and bring the oil to 135° F.
3. Energize the unit and operate the motor in the proper rotation.
4. Set the oil pressure regulator to maintain proper oil pressure.
5. Collect an oil sample from each motor bearing for a one minute period and compare the amount to Table 5.

⚠ Caution:
Do not run a motor without cooling for more than five minutes or damage to the motor will result.

Once the motor has been operated, it should not be re-started for 24 hours.

Table 5 - Oil Flow Limits for Louis Allis motors

Type and Frame	Min. Flow	Max. Flow
LCF & LCC All Frame	.5 pints/min.	2 pints/min.
RCS 1500 - 1700 - 1900 Term. End.	.6 pints/min.	1.8 pints/min.

RVS-RPS 1300 Comp. (Bk.)	.6 pints/min.	1.8 pints/min.
RVS-RPS 1500 & 1700 Term. (Frt.)	.6 pints/min.	1.8 pints/min.
RVS-RPS 1500 & 1700 Comp. (Bk.)	1.5 pints/min.	3.5 pints/min.
RVX All Frames	1.5 pints/min.	3.5 pints/min.
DRV Term. (Thrust)	.5 gallons/min.	.8 gallons/min.
DRV Drive (Compressor)	1.3 gallons/min.	1.7 gallons/min.

Appendix G
Loctite Gasket Eliminator 515

Loctite Gasket Eliminator 515 is a relatively fluid substance that will not harden in the presence of air. It will set up to form an effective seal between the O-ring and the casting surface in the absence of air after the casting has been properly torqued. Loctite should not be applied to any O-ring mating surfaces where excessive amounts of it can seep out and fill a groove, making removal of additional components difficult. An example of this is the suction elbow to suction cover O-ring on CVHE units. The Loctite will flow when the mating surfaces are tightened and fill the groove between the inlet vanes and the suction housing. When the sealant is allowed to set in the groove, removal of the inlet vane housing becomes difficult.

When using Loctite on O-rings. a 1/8-inch diameter bead should be placed in the bottom of the O-ring groove around the entire circumference. Place the O-ring into the groove and gently press it into the sealant. Apply a 1/8-inch bead of sealant to the outer portion of the O-ring where it will fit up against the mating casting surface. The lubricant/sealant will help keep the O-ring in place during assembly of the mating casting.

In any application using Loctite 515 as a sealant, back-off holes should be present for future disassembly. If back-off holes are not present use the following procedure to tap the casings. The procedure is for CVHE units, but can be modified for all other units.

Note: Model CVHE CenTraVacs® built prior to November 1983 do not have jack bolt holes. Some of these chillers were assembled with Loctite and will need jack bolt holes. Casings should not be forced apart without the use of jack bolt holes. Uneven force could cause the casings to crack.

1. Remove three of the 5/8-11 bolts that hold the casings together (120 degrees apart). The bolt clearance hole openings are 3/4-inch diameter.
2. Refer to Table 6 and select the proper tap for the 3/4-inch bolt hole opening. For this example, use a 7/8-9 tap.

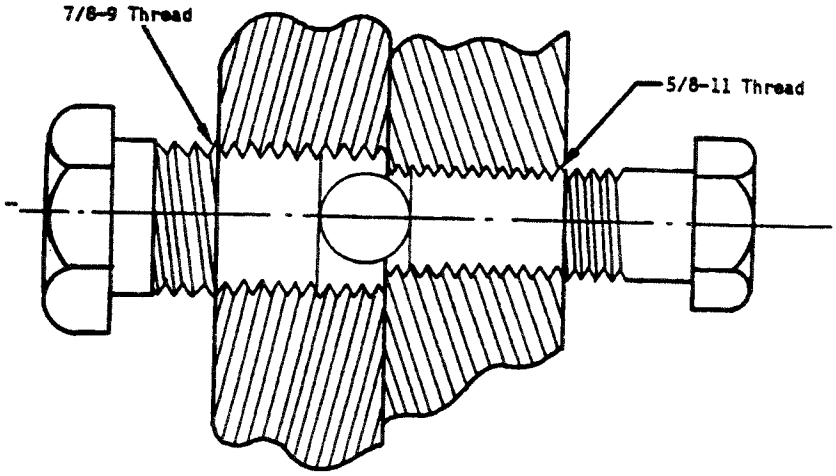
Table 6 - Tap Sizes

Bolt Hole Opening	Size	Threads per inch
5/16	3/8	16
27/64	1/2	13
17/32	5/8	11
3/4	7/8	9

Appendix G
Loctite Gasket Eliminator 515

3. Tap the hole with a 7/8-9 tapered tap, which will allow several threads to be started easily. The remaining tapping should be done by using a 7/8-9 bottoming tap. This will allow the maximum number of threads to be formed without damaging the 5/8-11 threads in the adjoining piece.

Note: When tapping, a cutting oil should be used to minimize the possibility of tap breakage or thread damage.



4. To separate the casings, insert the 5/8-11 bolt as shown in Figure 15. Insert a 1/2-inch steel ball and the 7/8-9 bolt. By removing the remaining 5/8-11 bolts and inserting the rigging and guide pins as necessary, the 5/8-11 bolts can be tightened until they exert force on the steel ball and the 7/8-9 bolts. This force, when uniform at all three points, will separate the casings.

5. With proper rigging, the casing can be removed safely.

When Loctite 515 has been used, field clean-up of the casings can be difficult. Loctite offers a gasket removing compound called "CHISEL", which is available in aerosol cans. When using the "CHISEL" manufacturer's safety recommendations should be followed completely.

The use of Loctite 515 on flat gaskets is not recommended.

Figure 15 - Bolt Connection Modified for Back Off Hole

Appendix H
Trim Balancing CVHE

Whenever vibration analysis on a CVHE indicates an excessive amount of vibration, the compressor's entire rotating assembly must be balanced. Trim balancing a unit in the field requires a substantial investment in expensive vibration analysis equipment. The portable vibration analyzers typically used for fan balancing are usually unsuitable for balancing a CVHE compressor; they are not designed to provide the shaft orbit measurements that are critical for proper compressor balancing.

Trane service personnel use a Bentley Nevada Model DVF2 or equivalent (plus supporting equipment) to trim balance CVHEs since it provides the sensitivity and features necessary for proper trim balancing. To trim balance the compressor, phase angle and the orbit of the compressor rotor shaft are tracked by non contact "proximity" probes during initial and trial weight runs. (Because the probes must monitor a smooth surface, the standard shaft nut is replaced with a special trim balance nut.) Data recorded during these runs is then fed into a single-plane balance program that determines the amount of weight required at specific locations to balance the assembly.

Appendix I
CVHE Oil Sump Vent Line Piping Modifications

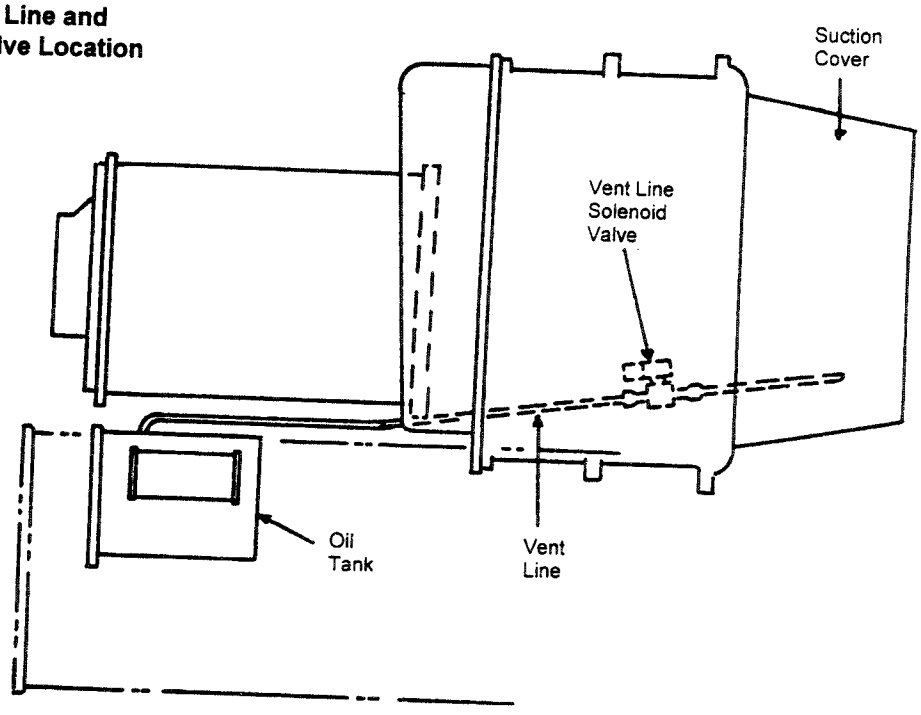
Increase the vent line (Figure 16) size to 1-1/8" if required. The vent line size is 7/8" on units manufactured prior to October 1990. Cut off the 7/8" line as close as possible to the oil tank and use a 1-1/8" x7/8" reducing coupling. At the suction cover, cut the line and remove the screw-in fitting. Replace it with a 90-degree elbow (Mueller No. W2164) or straight adaptor (Mueller No. W1 164), whichever is appropriate for the job. Both are 1-1/8" solder vs. 3/4" NPT. The bent tube in the old suction cover fitting is not required.

Next, install a new ALCO vent-line solenoid valve (Trane Part No. VAL3217) at the location shown in Figure 16.

Finally, install a second eductor (Trane Part No. TEE0077) on the 1/4" valve on the evaporator. Tee a 3/8" line from the condenser supply to the eductor, 1/4" line to the evaporator and 3/8" line to the oil tank.

Parts Information

The parts listed below are required to complete the piping modifications.



Obtain the parts listed below locally:

- 1-1/8 Copper Tubing (field supplied)
- (1) 90-Degree Elbow (Mueller No. W2164)
- (1) Straight Adaptor (Mueller No. W1164).

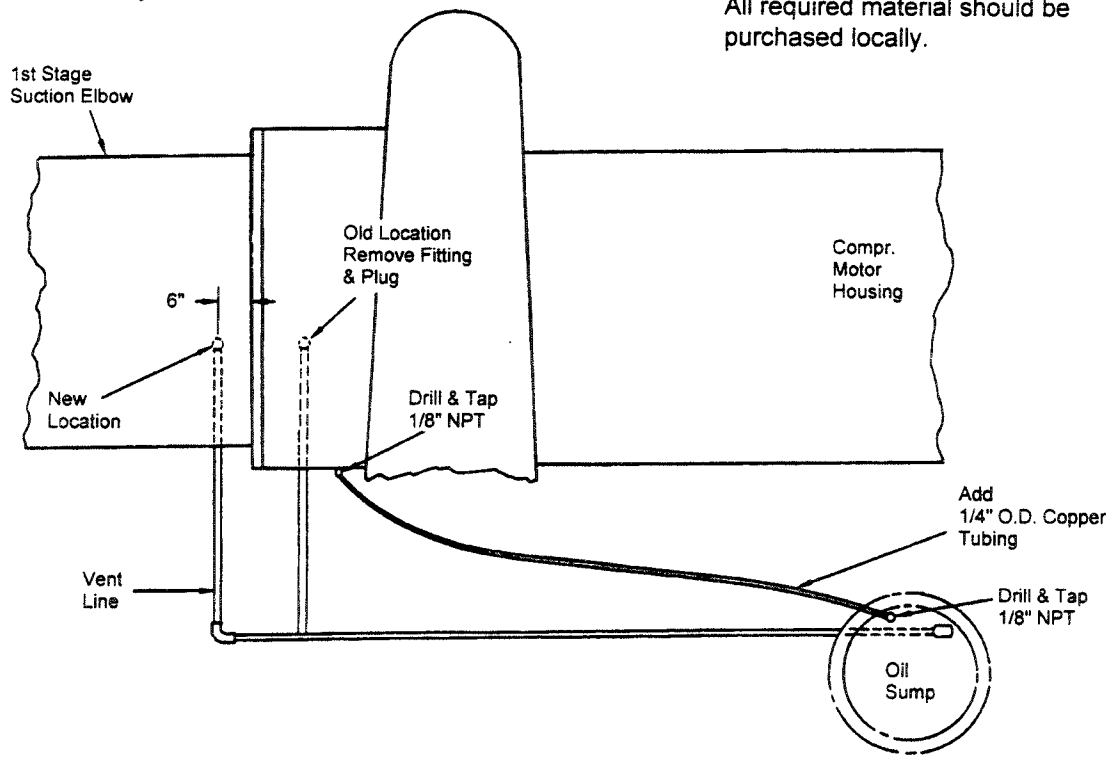
Trane parts:

- VAL3217 - ALCO Vent-Line Solenoid Valve
- TEE0077 - Oil Eductor

Figure 16 - CVHE Vent Line and Vent-Line Solenoid Valve Location

Appendix J
CV, CVHB Oil Sump Vent Line Piping Modifications

The oil sump vent line should be moved to the evaporator side of the compressor first stage inlet vanes. In other words, the vent is to be connected at the suction elbow. The new location of the oil sump vent line will retard the speed of oil sump pressure reduction, since it will be at the same pressure as the evaporator.



This will effectively stop oil pressure loss and oil migration. In the event that some oil is carried from the sump, return of this oil to the sump is assured by the addition of a 1/4" O.D. drain line between the bottom of the first stage suction cover throat and the oil sump. This line will drain any accumulated oil back to the oil sump during the compressor shutdown period. Figure 17 is a schematic representation of the system and the modifications to be made.

Procedure:

1. Weld a 1/2" pipe coupling to the inner heel of the suction elbow, approximately mid-point elevation wise.
2. After welding, pressure test the welding work by applying nitrogen pressure to the coupling through an appropriate fitting.
3. After pressure testing, drill a 3/8" hole thru the elbow skin.
4. Move the vent line from the suction cover to the new location and plug the original opening.
5. Drill and tap a 1/8" NPT hole at the very bottom of the suction cover and at a high point of the oil sump backface.
6. Install a 1/8" NPT to 1/4" flare adapter at these points.
7. Connect a 1/4" O.D. copper line with appropriate fittings between these points.

All required material should be purchased locally.

Figure 17 - Oil Sump Vent Line

Appendix K
Refrigerant Charges

Points to consider when determining the charge level of a CenTraVac® unit:

1. The refrigerant charge for a standard (non-heat recovery or free-cooling) machine is always based on evaporator size.
2. A typical heat recovery CenTraVac with a split bundle condenser uses 50 pounds more refrigerant than a standard evaporator/condenser version of the same machine.
3. CVHA and CVHB machines with auxiliary heating condensers use a standard evaporator charge.
4. CVHE CenTraVacs with auxiliary condensers use 50 pounds additional refrigerant.
5. Early model machines have a number and/or letter combination that identifies the compressor, evaporator and condenser, in that order.
6. Standard combinations of CVHA and CVHB compressors, evaporators and condensers are listed in the tables of this bulletin.
7. The evaporator size of "pre-PDS" CenTraVacs are identified in the unit model number. Refer to appropriate table in this appendix.

Exception: PCV and CV-style machines that shipped after November 1, 1971, require a smaller refrigerant charge. Changes were made in the evaporator design that are not reflected in the machine model number. Refer to the original start-up record to determine optimum refrigerant charge.

8. When certain machines are converted to motors that have a liquid refrigerant-cooled rotor, the refrigerant charge must be increased.
9. As of January 1, 1990, for CVHE units and May 14, 1991, for CVHB units, the evaporator shell size (CVSZ) and evaporator tube bundle sizes (EVBS) are identified in the Product Description Block of the unit nameplate. Unit refrigerant charge information is also included on the unit nameplate.

The following tables list HCFC-123 refrigerant charge recommendations for typical chillers, including current production models. Variations are also listed where applicable.

CenTraVac
OIL/REFRIGERANT PUMP

Design Benefits

- Cool compressor motor under all head conditions. Permit chiller operation at low head.
- Improve chiller KW/ton efficiency by 1%.
- Eliminate motor terminal sweating and need for terminal box heater option.
- Reduce oil foaming during startup that causes oil loss, marginal bearing lubrication and nuisance shutdowns.
- Eliminate the unreliable vent line solenoid valve.
- Simplify and reduce the cost of the oil cooler.
- Reduce the complexity copper piping.

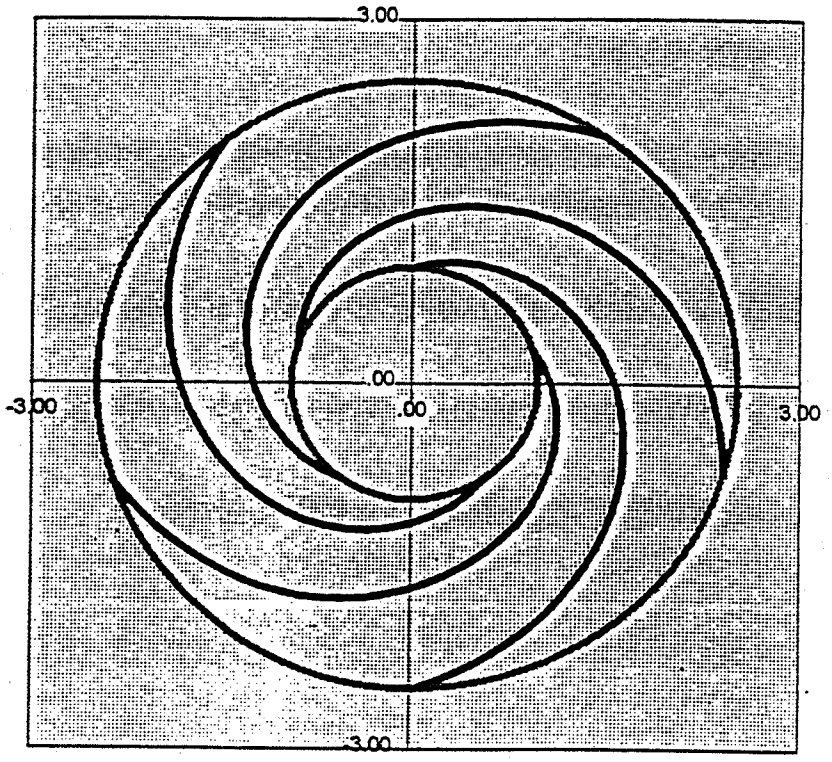
Parts Information

CHM00172 - Chemical, corrosion inhibitor, quart container, may be ordered through Trane Parts Center per the Pride System.

Production Changes

No production changes required per this bulletin.

Units Affected



CVHE, CVHF and CDHF units that are in service which have AFDB, AFDC and AFDD drives installed.

Literature Order Number	AFDB-SVB02A-EN
File Number	SV-RF-CTV-AFDB-SVB02A-EN-0701
Supersedes	New
Stocking Location	Inland

Since The Trane Company has a policy of continuous product and product data improvement, it reserves the right to change design and specifications without notice. Only qualified technicians should perform the installation and servicing of equipment referred to in this publication.

CenTraVac
OIL/REFRIGERANT PUMP

Oil Tank Assembly

Refer to oil tank cross section view enclosed. This design consists of an oil pump and a refrigerant pump; each mounted on the outboard ends of a common motor shaft.

The oil pump is an internal/external gear type pump, referred to as a Gerotor. The internal pumping element is mounted directly on the motor shaft by a key. The external element rotates in the housing that also supports the rear motor bearing. The pump has inlet and outlet ports that are cast into the port plate housing. The inlet opening draws oil from the bottom of the sump and the outlet opening is piped to the inside of the tank cover. The 3 GPM pump delivers 2 GPM to the bearings.

The refrigerant pump is a centrifugal type having an impeller and volute. This pump type was chosen since it can have low inlet losses in order to pump a saturated fluid without cavitating. The pump also has no contacting moving parts, which assures reliability while running in liquid refrigerant. A key drives the impeller similar to the oil pump. A small diameter shaft seal separates impeller refrigerant from oil in the tank. The pump adds about 12 psi or 20 ft above the condenser pressure.

The motor is similar to the motor currently used in today's oil tank, except it has a longer stack length to provide ¾ hp for both pumps. The motor stator is mounted in a steel shell and the rotor is supplied with the finished shaft. The motor assembly is mounted to the oil tank cover using (6) long capscrews that are outside of the stator shell.

The rotor is supported by two size 6204 ball bearings, which is one the most common, low cost bearings in production.

Power to run the motor is brought through the tank cover through a bolted and gasketed Fusite connector.

The tank heater, temperature measuring probe, oil filter block, oil reclaim dirt filter are current production parts.

Tank Installation on CenTraVac Chillers

For reference, a schematic is enclosed showing the oil tank location on today's production chiller. This location between the compressor motor and the evaporator results in many mounting variations depending on the selection of evaporator, compressor, and motor frame.

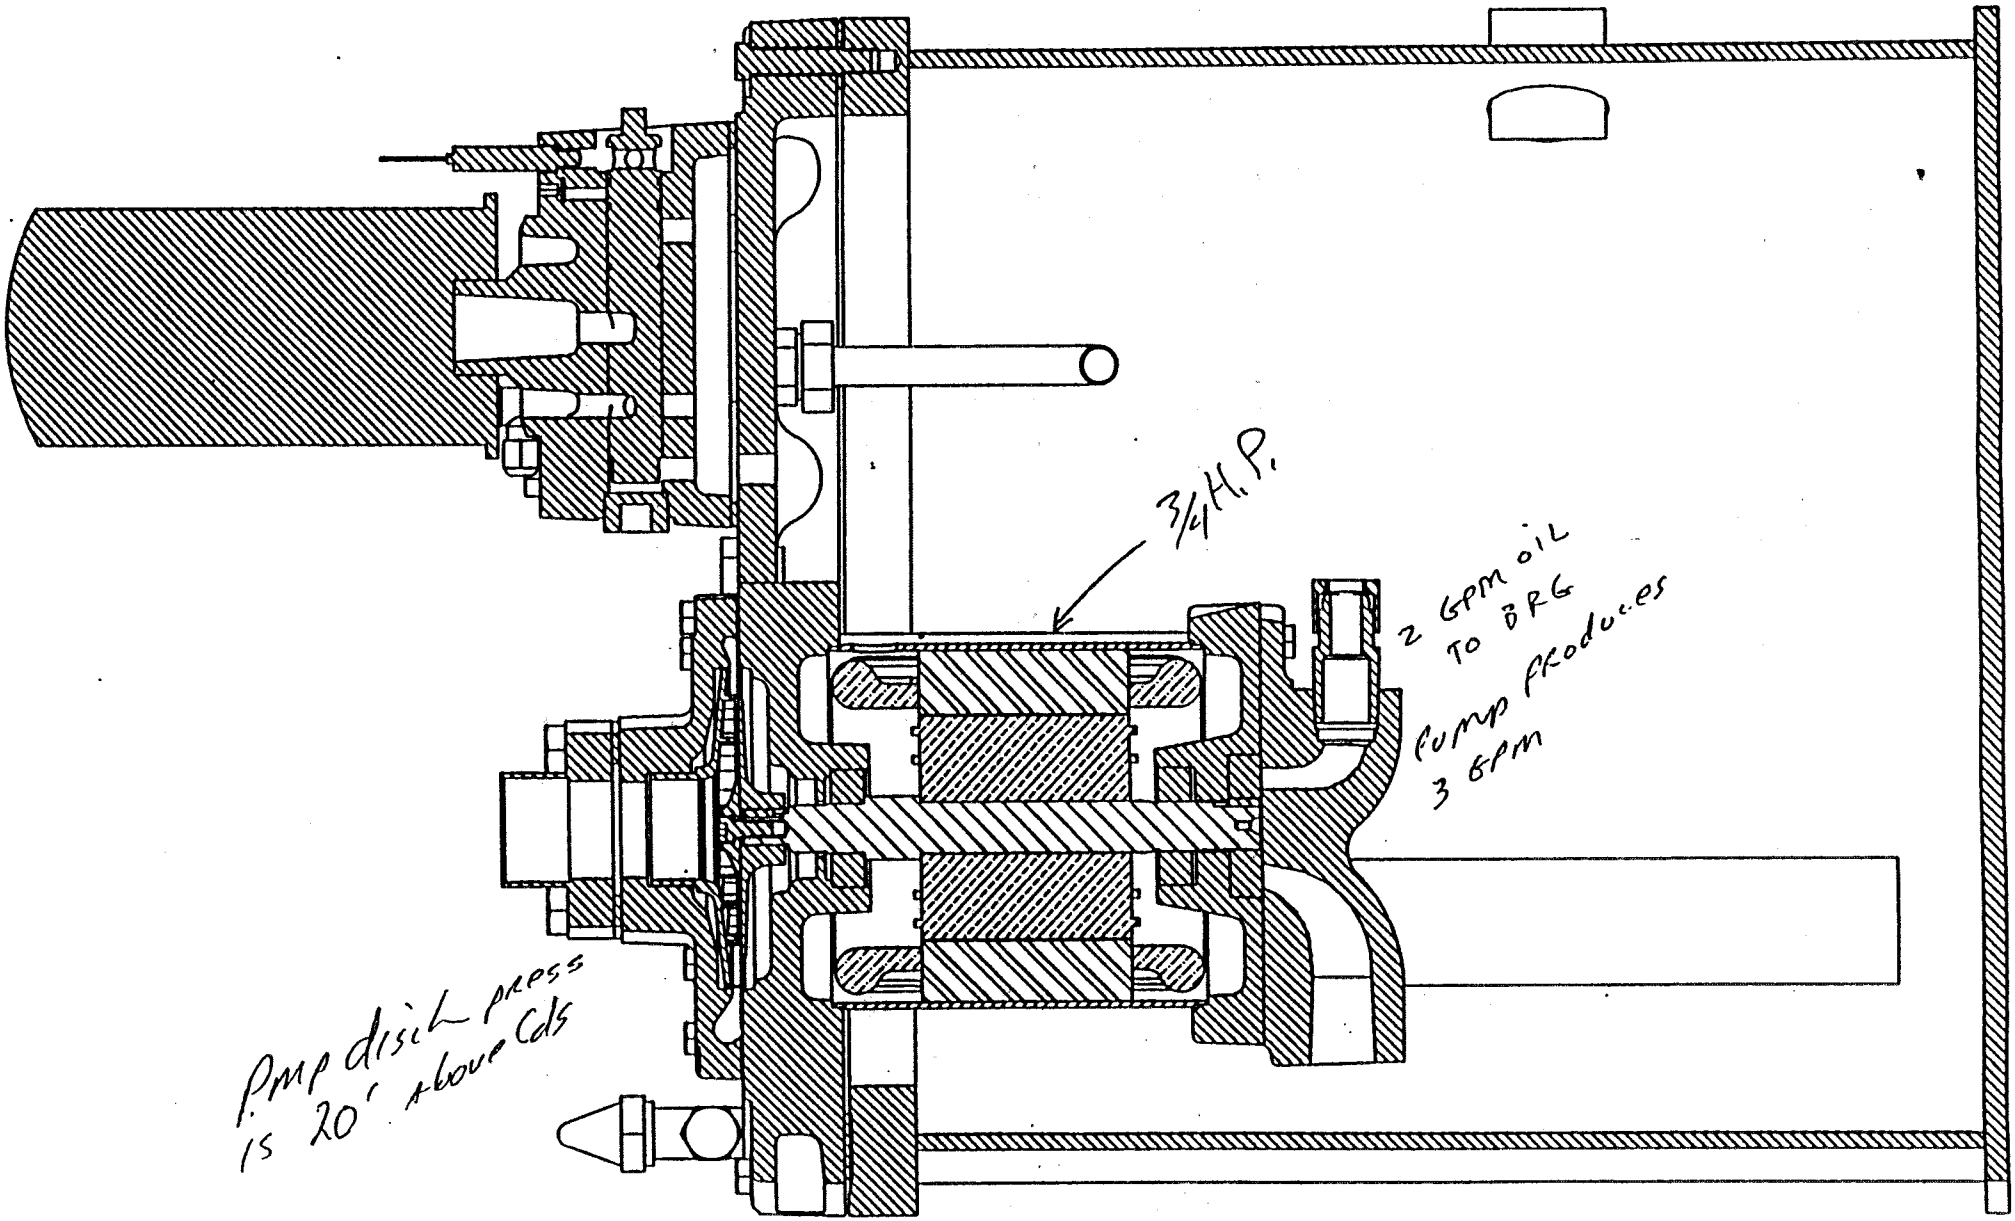
The refrigerant pump must be located low on the chiller. Liquid refrigerant in either the evaporator or condenser is in a saturated state. If the pump inlet is located above or too close to the liquid level, refrigerant will flash as the pump tries to pull the liquid into the pump inlet. If the refrigerant flashes, the pump will not develop pressure or flow.

The condenser was chosen as the liquid source for the pump for the following reasons:

- The liquid level is higher that in the evaporator.
- Higher pressure saturated liquids are easier to pump.
- Condenser liquid offers cycle improvement benefits.

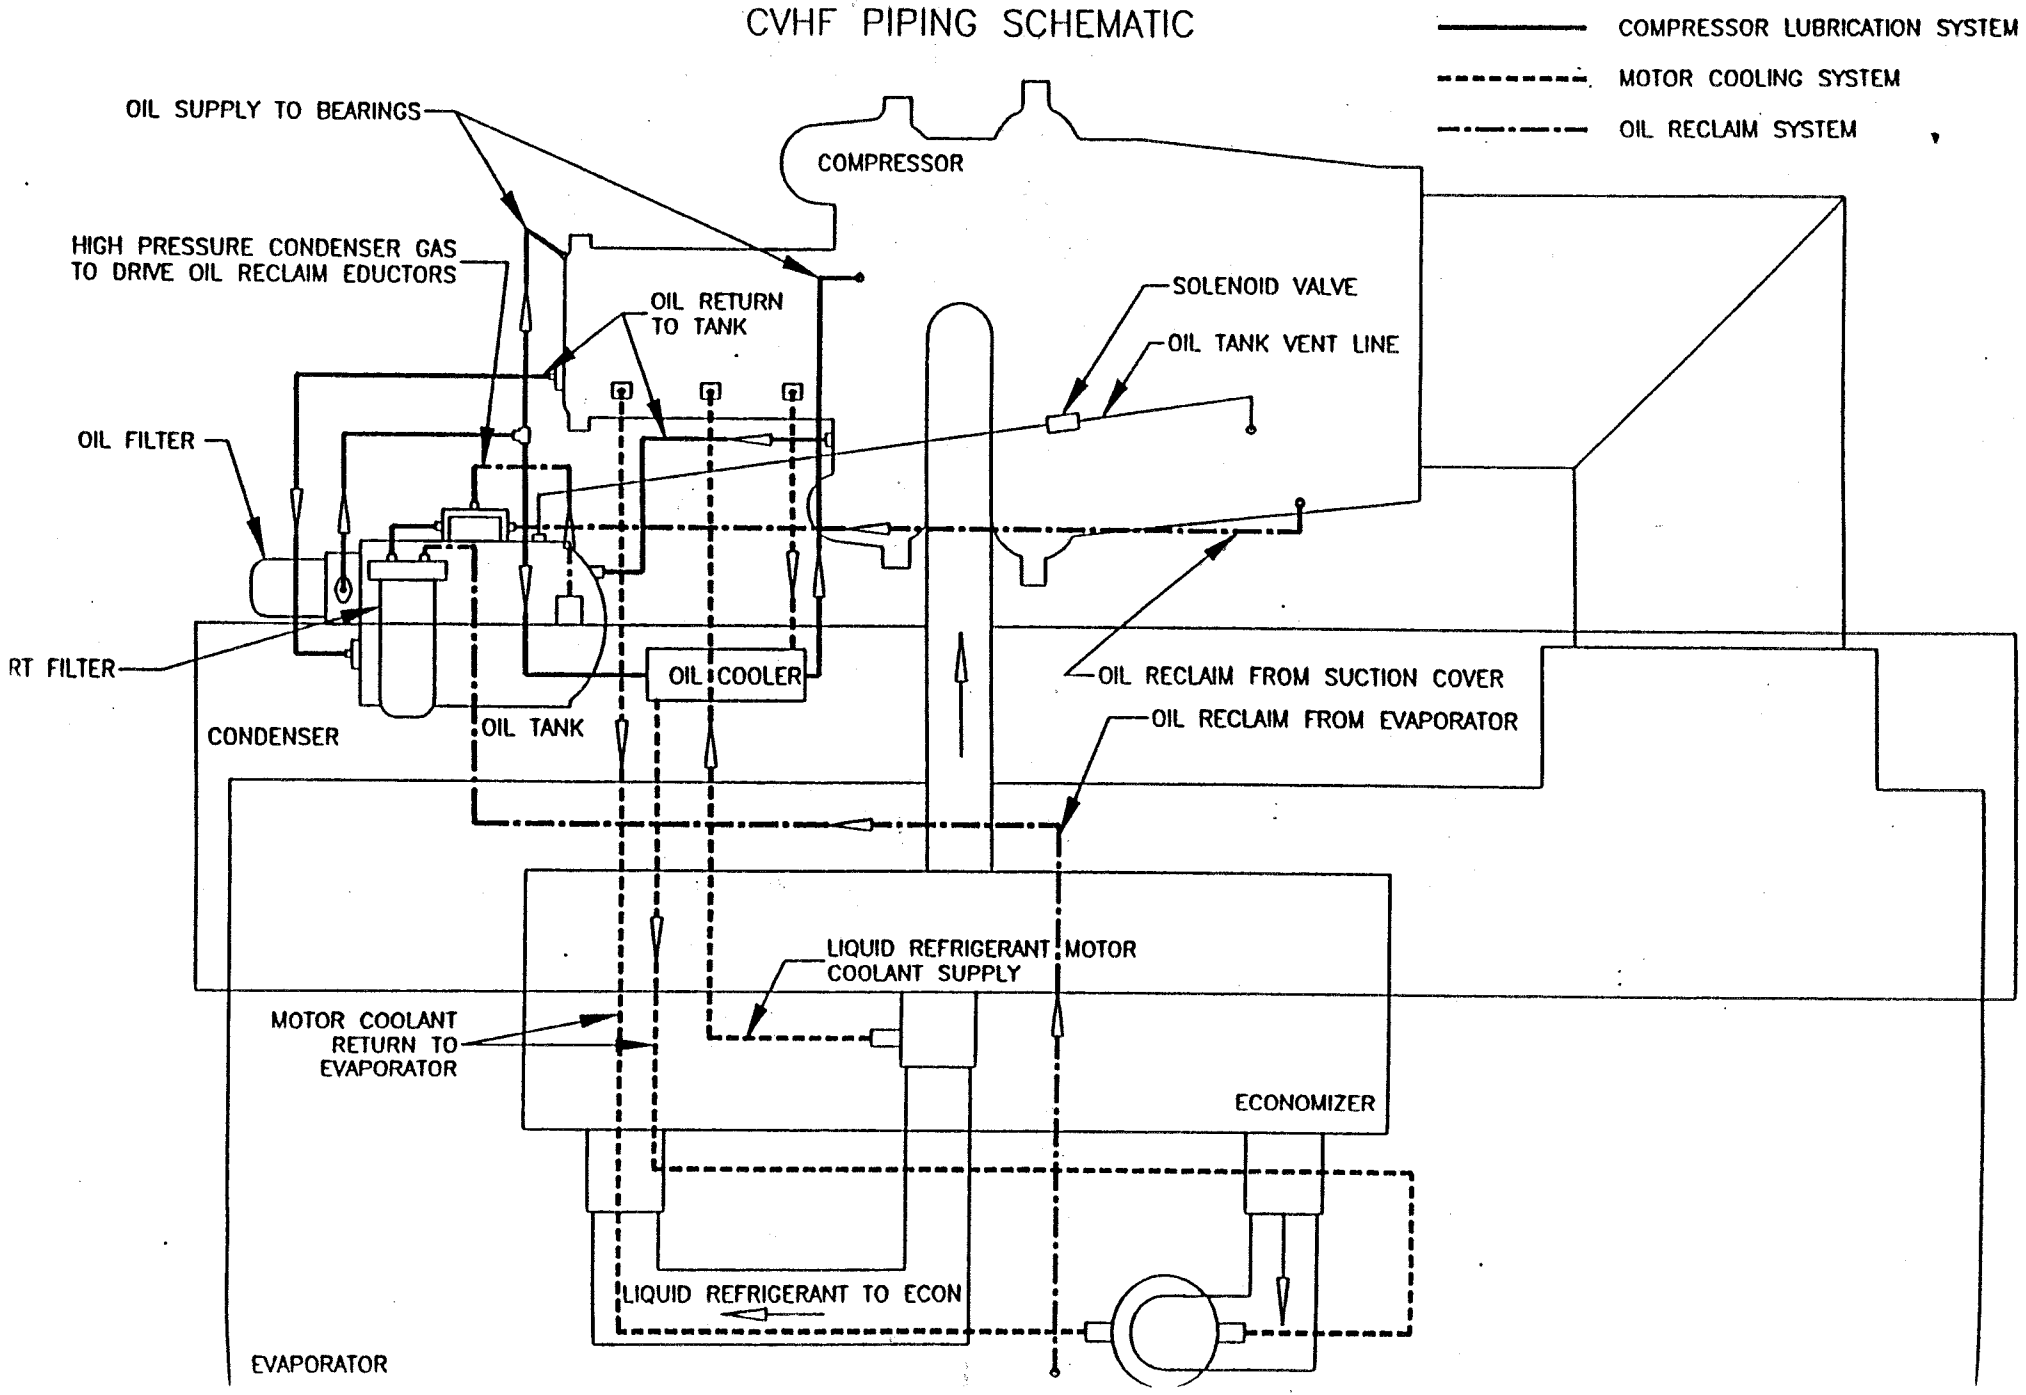
The tank assembly is mounted off the leg of the condenser on the left side of the chiller as viewed from the back, motor end. This location requires less copper pipe and fittings compared to the right side location. There is also less interference with free cooling and other chiller options.

System Piping



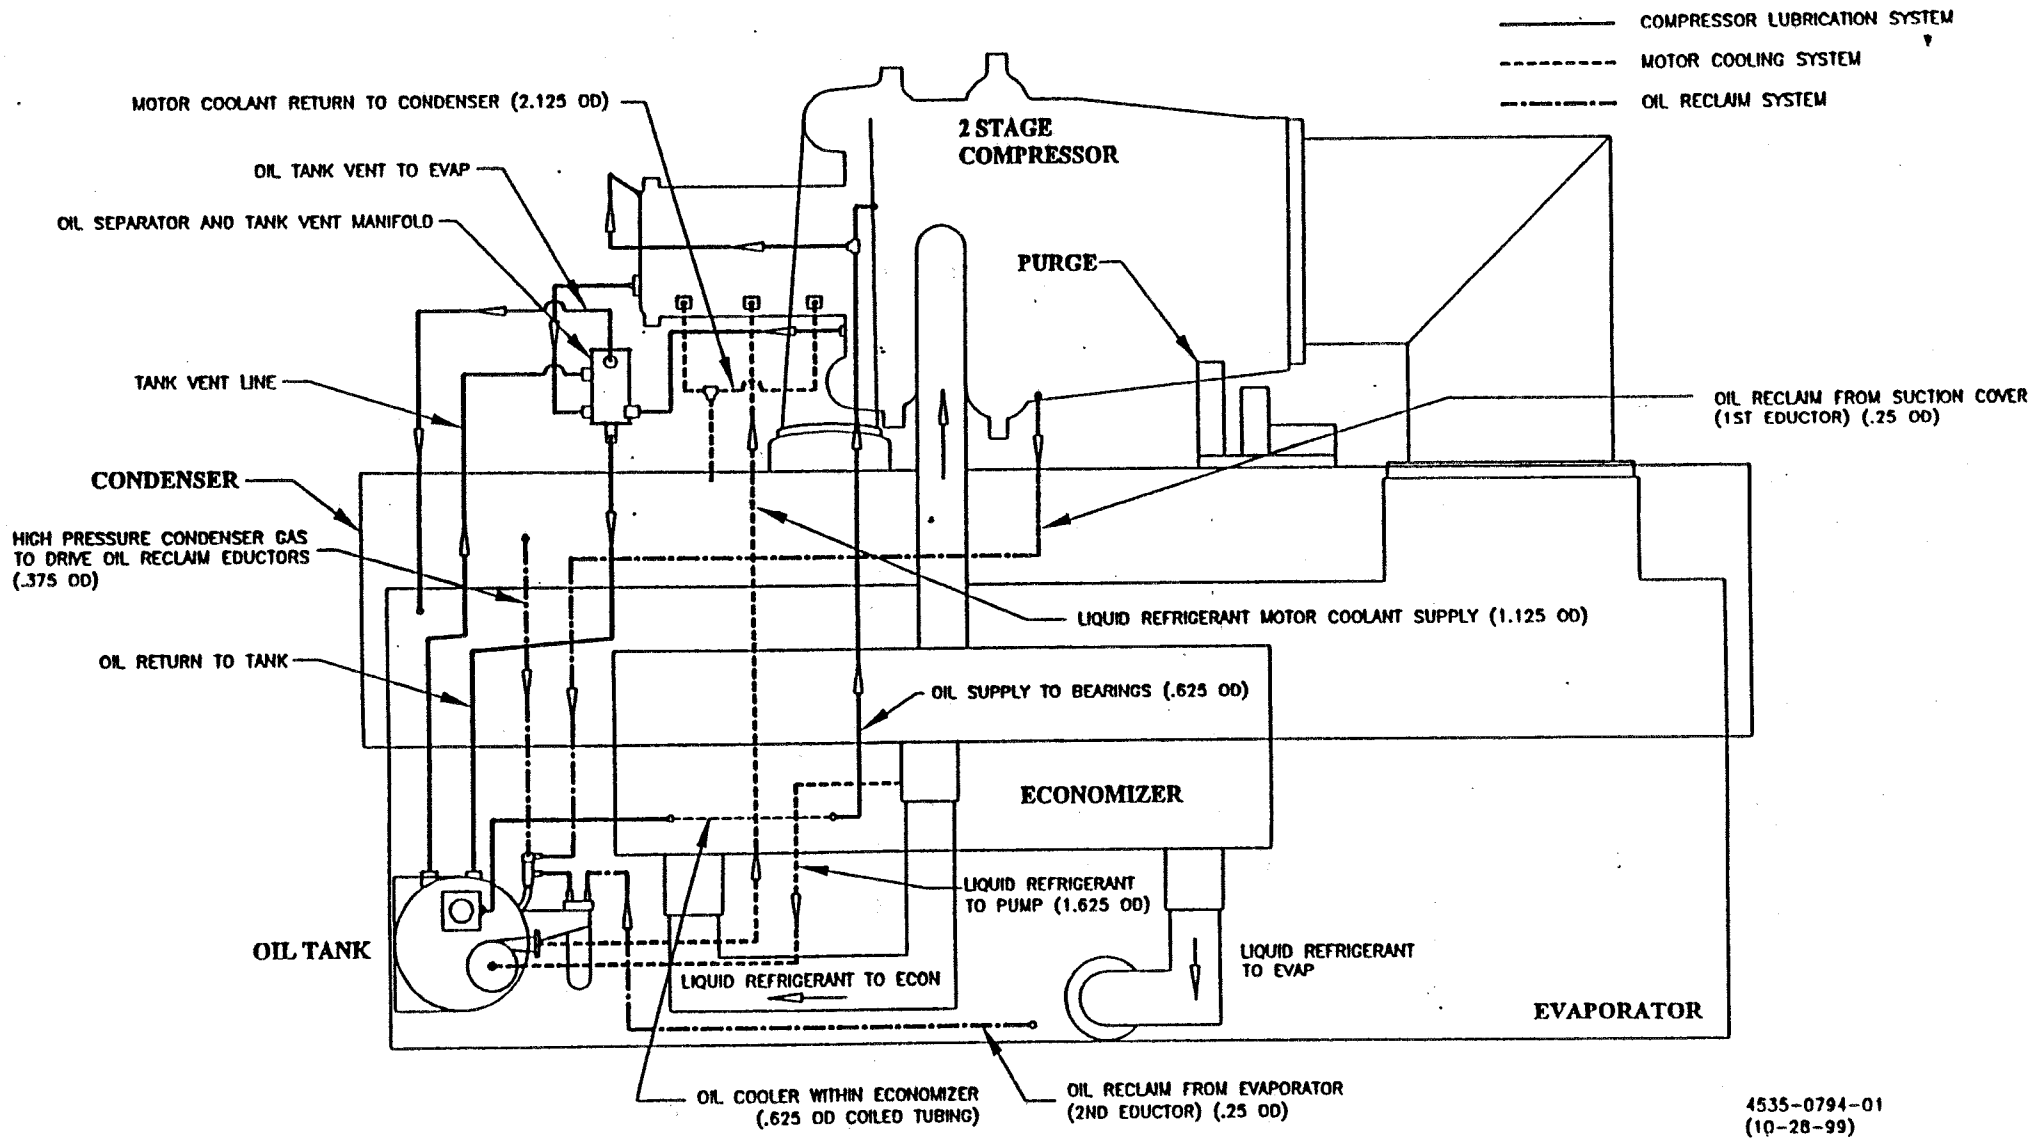
The refrigerant pump inlet is connected to the well at the bottom of the condenser. The connection is on the side where a weir assures a preferential supply of liquid to cool the motor. Refrigerant is delivered to the motor through the same connection as used in production with no modifications to the motor. Motor drain lines are routed to the condenser versus the evaporator in today's CVHF with the following advantages:

- The motor barrel is at condenser temperature eliminating sweating of motor terminals at high humidity conditions.
- Chiller efficiency improves since the heat of the motor is rejected to the condenser (cooling tower) rather than the evaporator.
- Refrigerant pump operation is not affected by operating conditions since the source and delivery point pressures are the same.



Oil routing is through the oil pressure regulator and oil filter currently used in production. After the oil filter, oil is routed through a cooler located in the economizer. The cooler consists of a one-piece wound coil. This cooler eliminates today's separate pressure vessel and external mounting/piping. Oil flow to both bearings is cooled and oil supply connections to the compressor and motor are unchanged.

Oil return lines from both bearings also transport refrigerant gas that leaks through the labyrinth seals adjacent to the bearing cavities, see enclosed compressor section view. Since the motor barrel is at condenser pressure, the volume of gas flow is greater than today's system where the motor barrel pressure is slightly above evaporator pressure in the CVHF. Oil return lines are routed into a manifold under the motor. Gas flow exits the top of the manifold and is vented to the evaporator. The tank is vented to the evaporator rather than the suction cover as in today's system. This provides for slower tank pressure reduction during chiller start that makes oil foaming less violent to better control oil loss. The vent line solenoid used today is therefore not required. Oil exits the bottom of the manifold and returns to the tank. Separation of the seal leakage gas in the manifold keeps this gas out of the tank, reducing loss of oil from the tank during chiller startup.



Three-stage, CVHE/G, chillers have a few modifications to ensure proper operation. An orifice is added to the manifold vent line. This increases the oil tank pressure, approx. 2-3 psi at full load, above the evaporator to reduce startup oil foaming and loss. The oil cooler is moved to the lower pressure side of the economizer to adequately cool the oil.

TRADITIONAL METHOD OF MOTOR COOLING VS. THE REFRIGERANT PUMP

Traditional Method of Motor Cooling

1. Used the natural ΔP (condenser refrigerant pressure – evaporator refrigerant pressure CVHF or low side economizer refrigerant pressure CVHE) to drive the refrigerant through the motor.
2. The liquid refrigerant in the motor flows through a small orifice to the lower refrigerant pressure (as a liquid/gas refrigerant mixture). This liquid/gas refrigerant mixture flows through the motor slots to cool the motor internals.
3. Occasionally, there are special provisions required to prevent moisture condensation on the motor terminal studs.
4. Thermal insulation of the outside of the motor is required to prevent sweating.
5. The minimum ΔP (condenser refrigerant pressure – evaporator refrigerant pressure) is defined by CTV-EB-84.

With The Refrigerant Pump

Better efficiency

1. The refrigerant pump sends condenser liquid refrigerant to the motor. [This improves the cycle efficiency 1 – 1-1/2%].

More Effective Motor Cooling

2. The liquid refrigerant flows through the motor slots to cool the motor internals. [It is more effective to circulate liquid refrigerant (rather than a liquid/gas mixture) through the motor slots.]

No Motor Terminal Sweating

3. No special provisions are required to prevent moisture condensate on the motor terminal studs.
   [The motor terminal studs are at the condensing refrigerant temperature or slightly higher.]

Thermal Insulation of Motor Not Required

4. Thermal insulation of the outside of the motor is not required. [The motor housing is at the condensing refrigerant temperature or slightly higher.]

ΔP (Condenser P_{ref} – Evaporator P_{ref}) is reduced.

5. The minimum ΔP (condenser refrigerant pressure – evaporator refrigerant pressure) is 3 PSID at all loads.

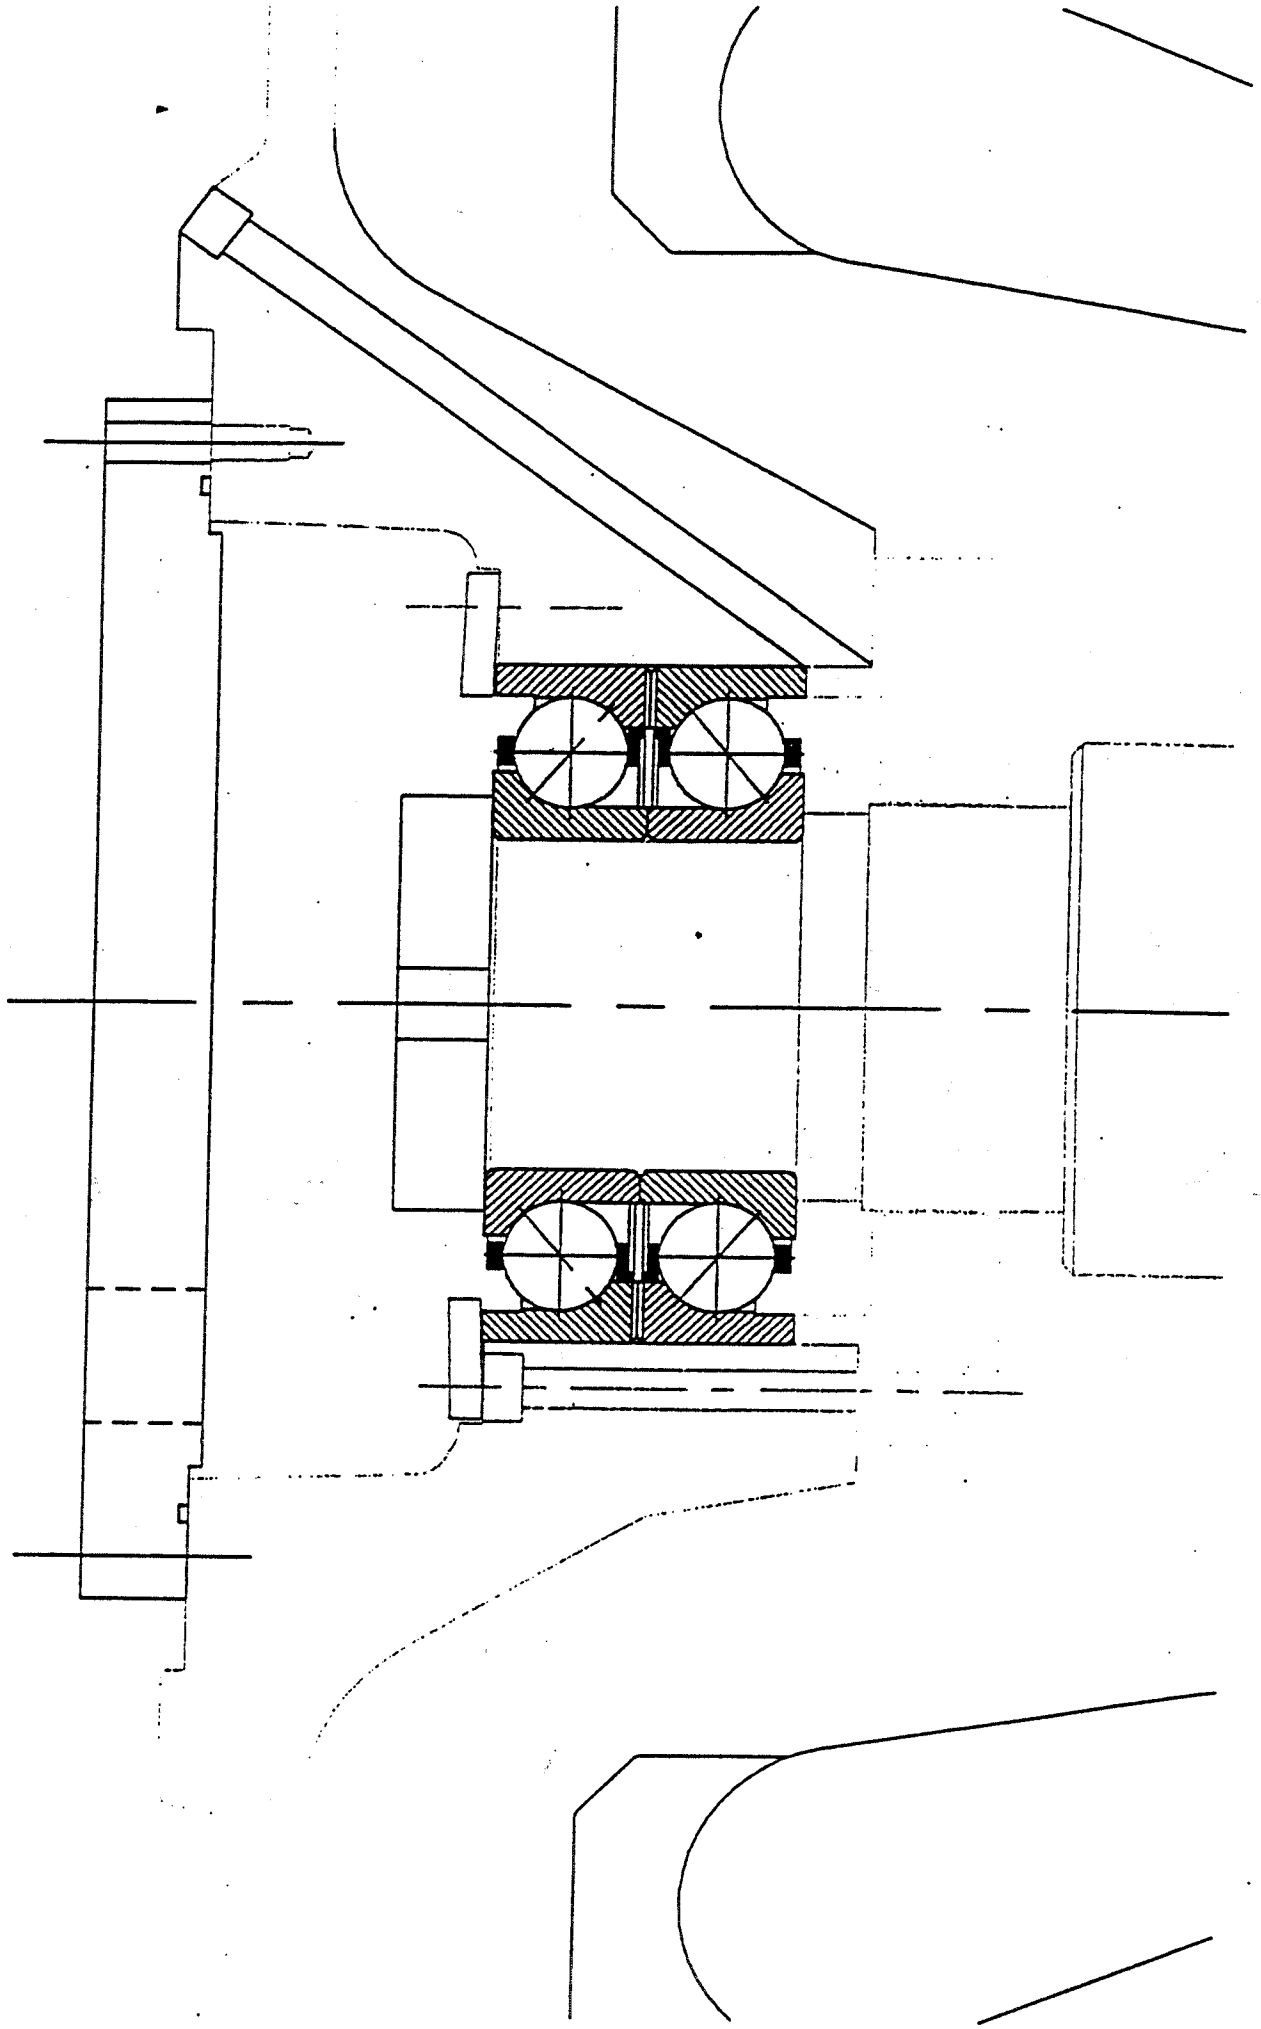
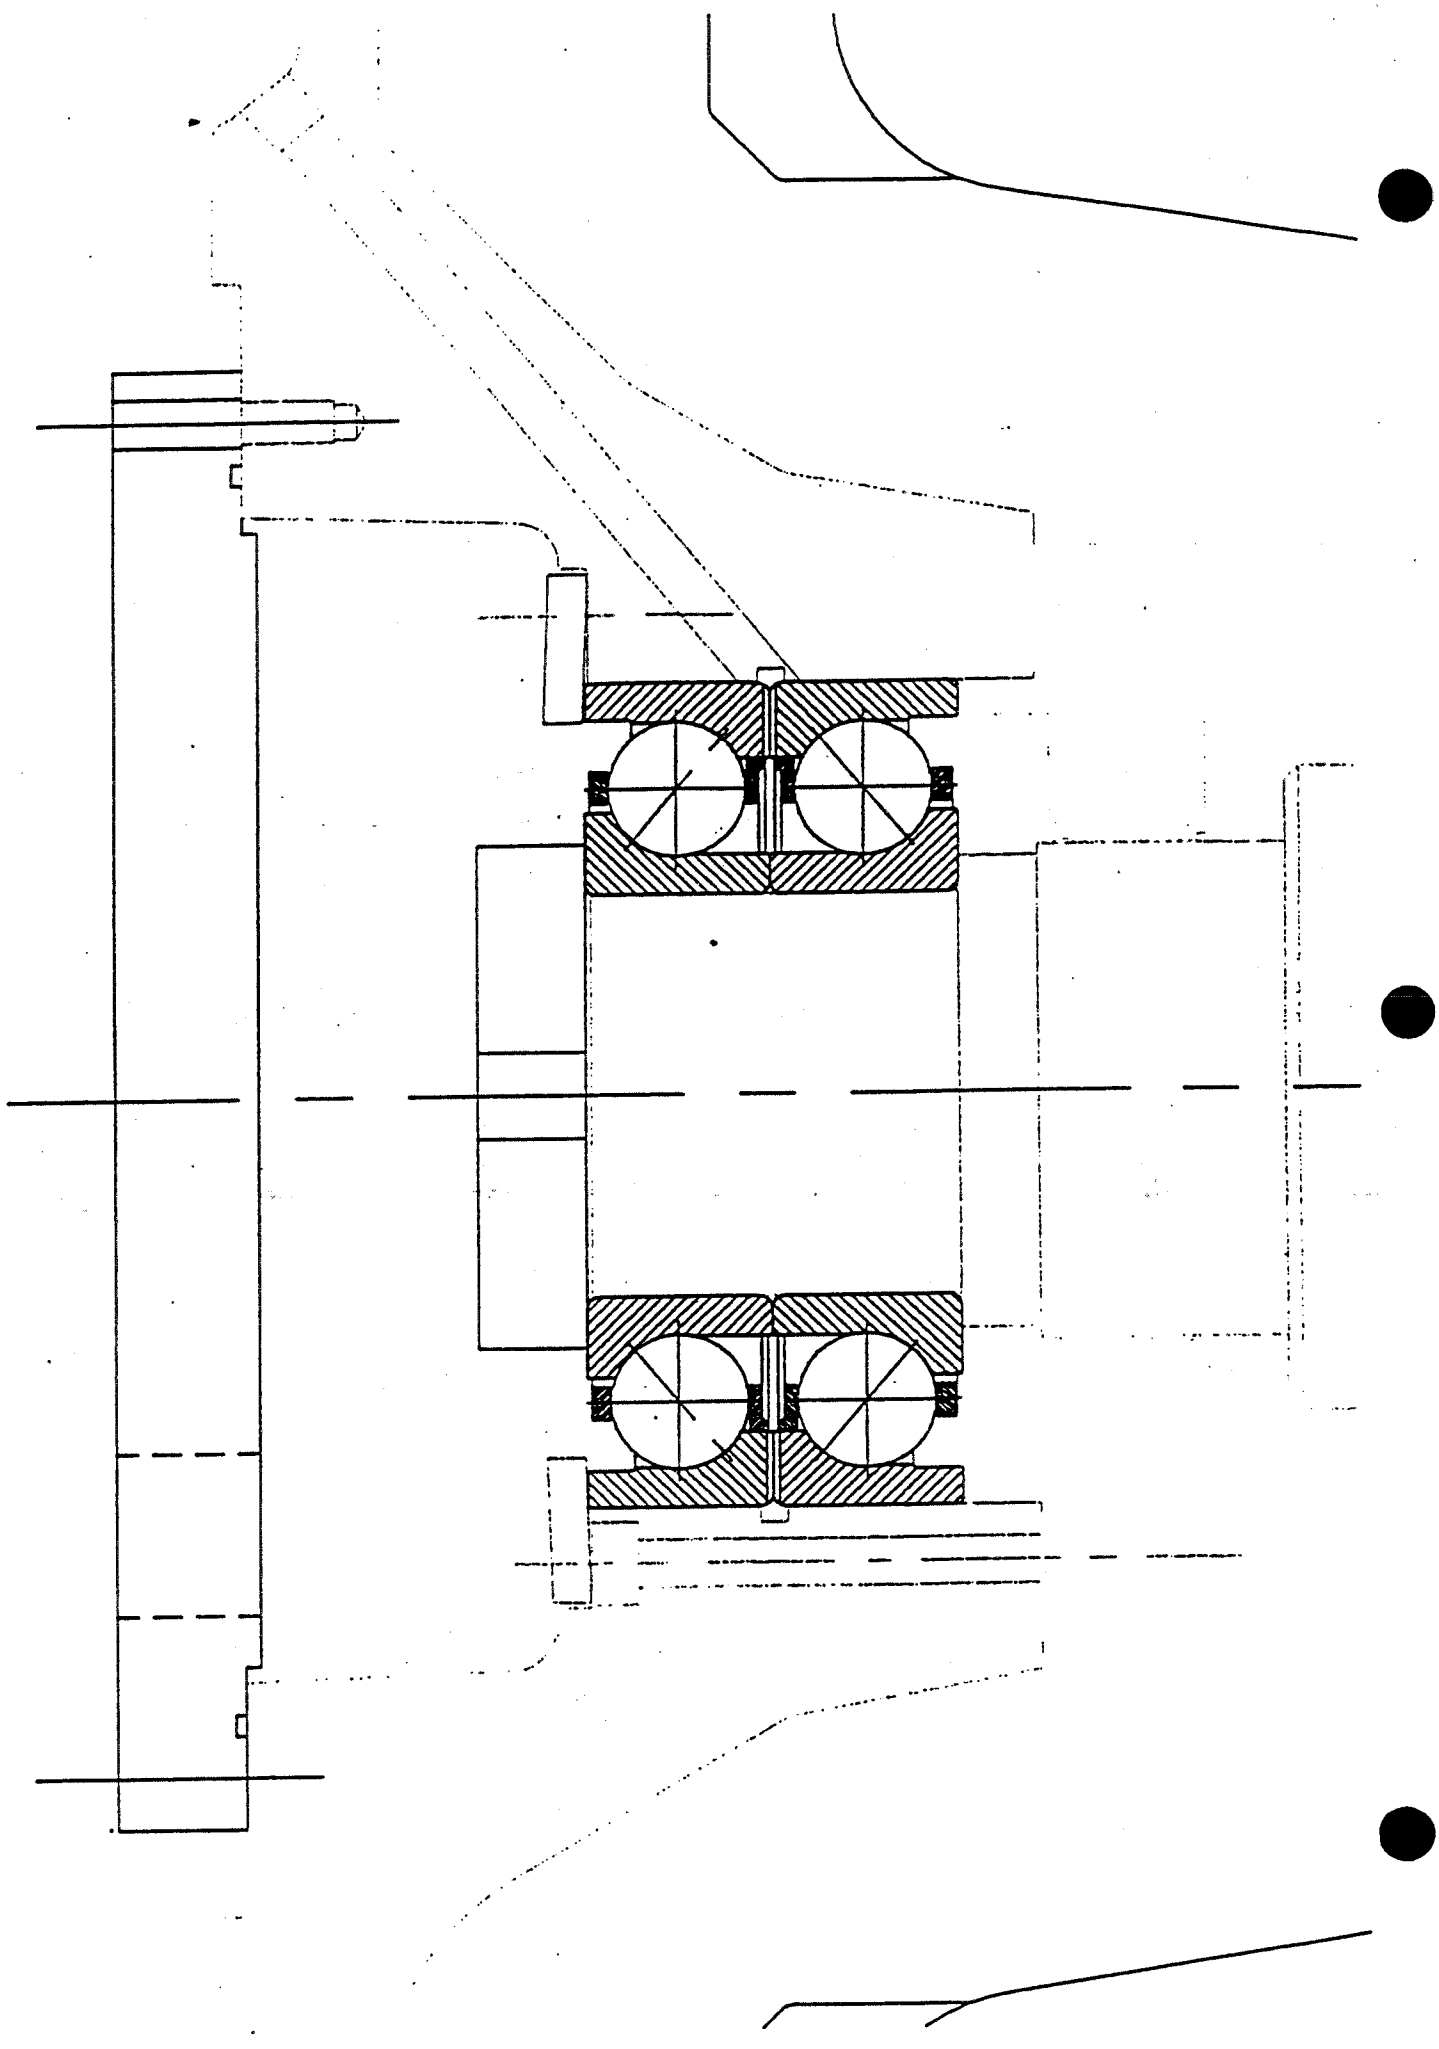
Oil Feed

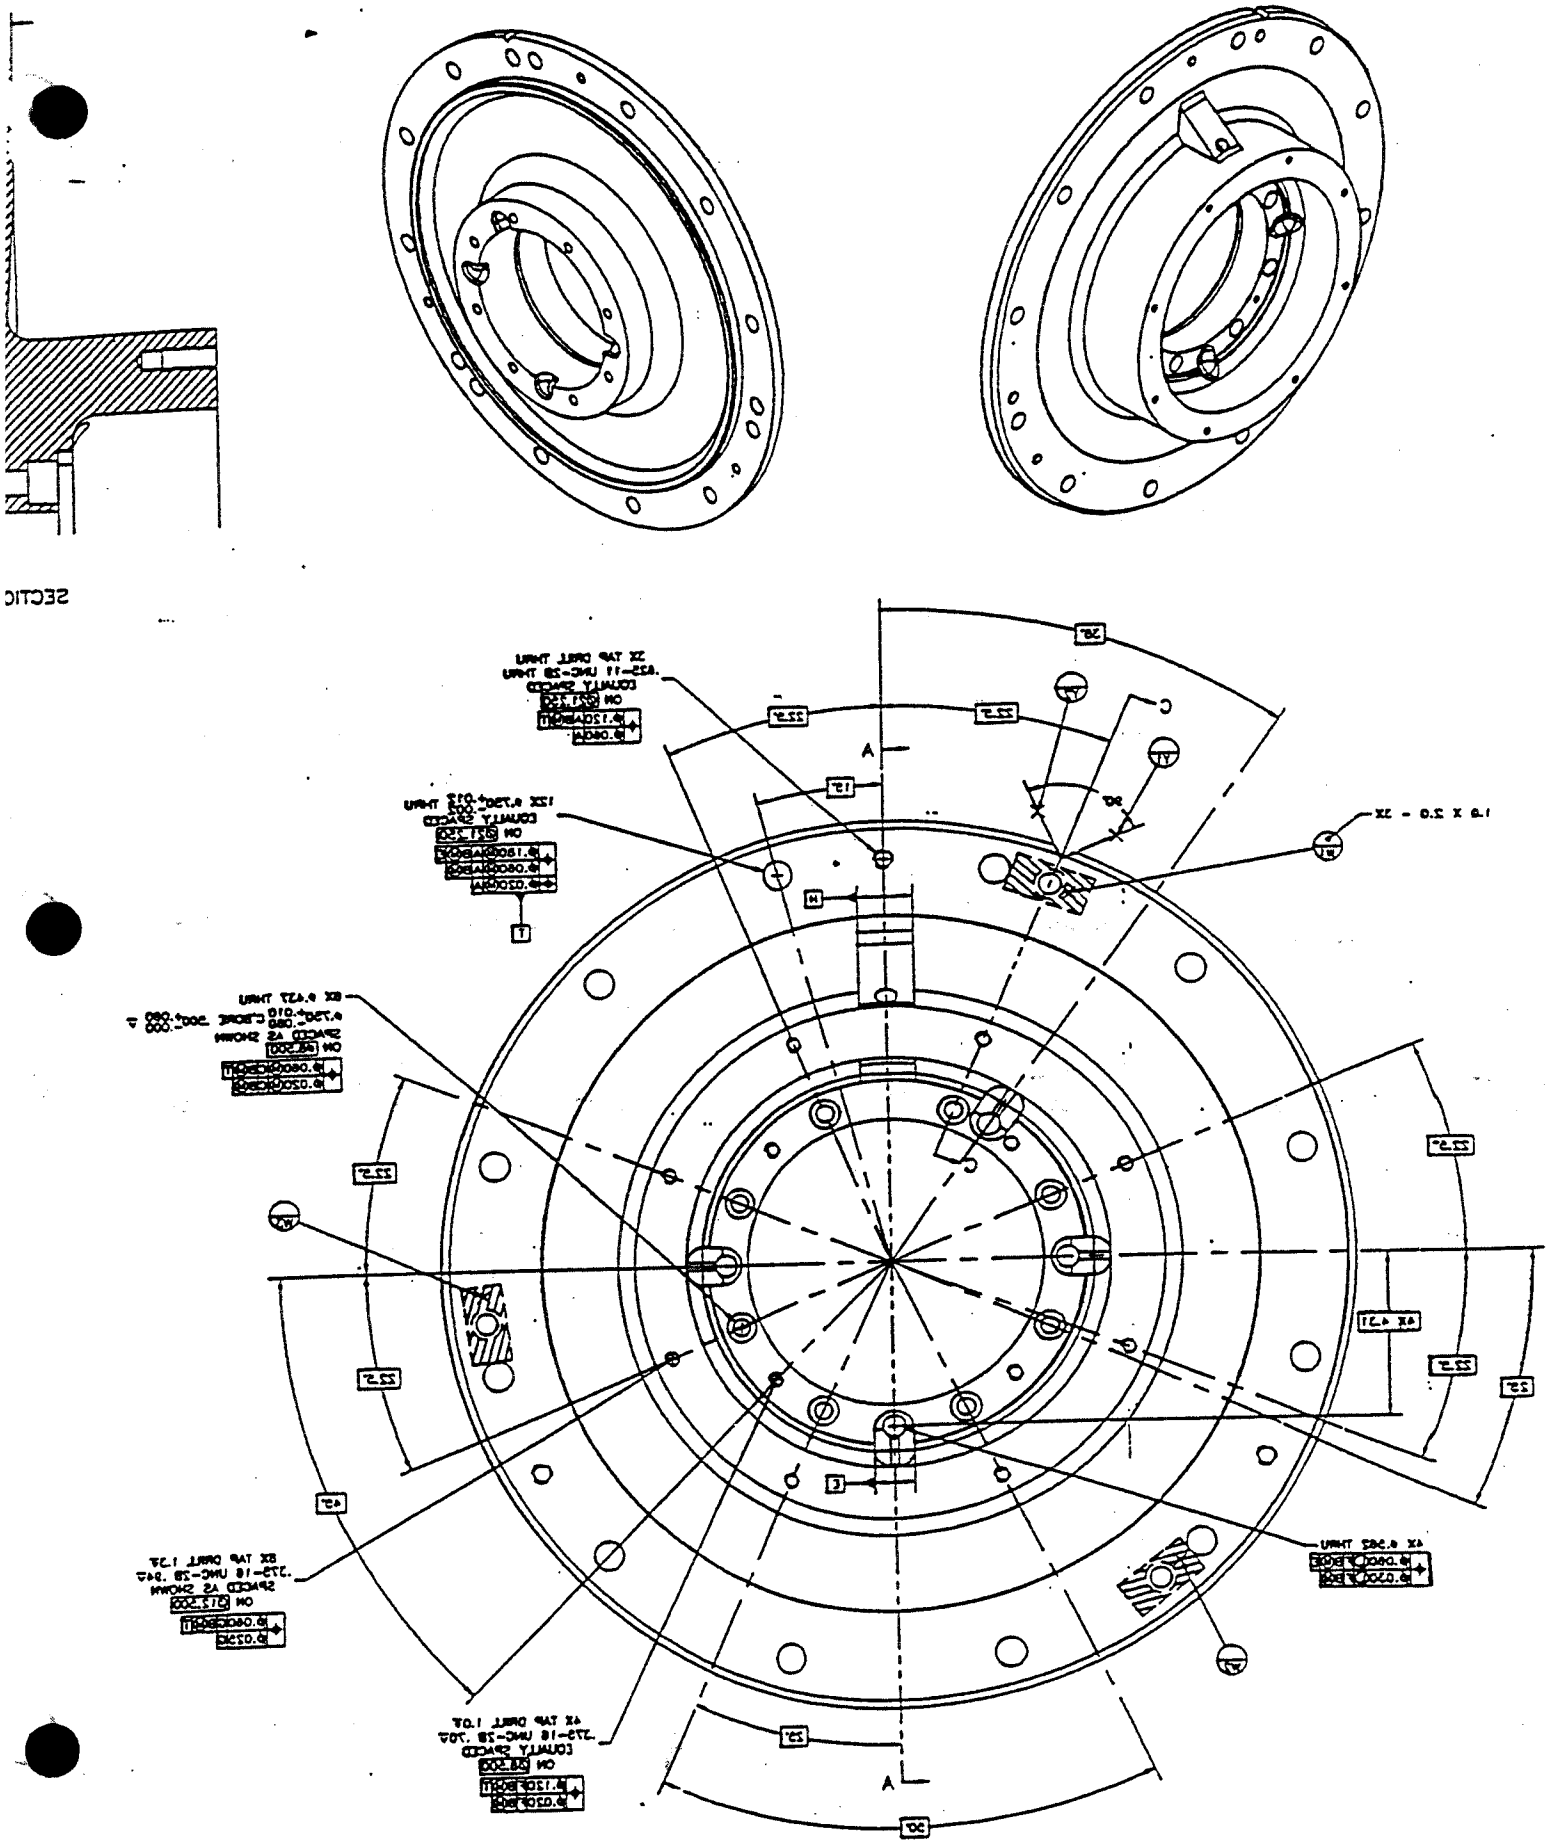
Thrust Bearing



10/25/1999

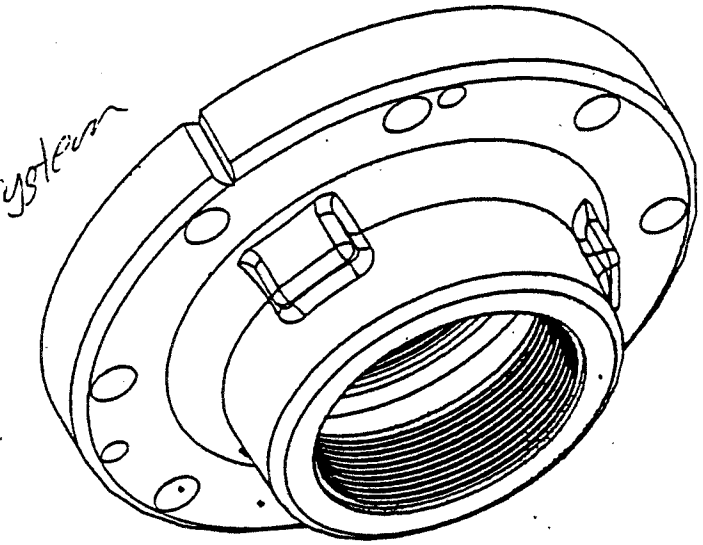


CenTraVac Thrust Bearings
History



- 1982
  Bearing clearance I.D.: +.0004 to -.0005 (transition fit)
  Bearing 0609 and 0610

- 1995 (January)
  Bearing clearance I.D. -.0002 to -.0011 (press fit onto a K4 shaft)
  Bearing 0609 and 0610 press onto a K4 shaft with hydraulic nut.
  To get the same equivalent bearing load on a non-K4 shaft
  Use Brg 0913 and 914.



- 1999 (new center feed thrust bearing: Brg 1209 & 1210)
  Bearing clearance -.0002 to -.0011 press fit with the hydraulic nut.
  Bearing 1209 & 1210 have to be used with the K4 shaft only. They can not be used with Non-K4 shafts (reason: non-K4 have a smaller shaft OD) . So the bearings are backward compatible with K4 shafts only.

Service Alert

AFDB

Subject: AFDB VARIABLE FREQUENCY DRIVE - COOLANT SYSTEM INHIBITOR

ORDER No: AFDB-SVA001-EN DATE: March 27, 2001

Introduction:

This service alert recommends procedures and materials to be used when servicing the cooling loop of water-cooled AFDB drives installed on Trane CVHE/F and CDHF chillers.

Discussion:

The approved inhibitor for use in all Trane AFDB 350, 450, 600, 750, and 1000 Hp water-cooled drives is now Trane CHM00172.

The inhibitor is supplied pre-diluted in quart plastic bottles and will be further diluted when mixed with the distilled water of the primary cooling loop. When charging an empty system on a factory installed drive it is recommended that 1-quart (32 oz.) of CHM00172 be installed in the primary cooling loop, regardless of the size of the drive. If pre-mixing distilled water and the inhibitor, or if charging fluid to a field mounted drive with an unknown total fluid capacity, CHM00172 may be mixed at a ratio of approximately 12 oz. per gallon of clean distilled water.

It is recommended that the inhibitor and distilled water of the primary loop be replaced on an annual basis. Inhibitor should always be installed along with a new charge of clean distilled water. Do not simply add inhibitor to an existing or dirty charge of water.

Remaining stocks of inhibitor CHM00159 may be used in 350, 450, and 600 Hp drives only. Do NOT use CHM00159 in the 750 and 1000 Hp drives. This is necessary because of the different materials in the 750 and 1000 Hp drive heat exchanger.

© 20001American Standard Inc. All rights reserved.

Primary Loop Fluid Amounts
The maximum total fluid capacity of the primary cooling loop of the factory installed 750/1000 Hp drive is 3 gallons, the 350/450/600 Hp factory installed drives will require up to 2.5 gallons. Use only clean distilled water and the proper inhibitor as the fluid in the primary cooling loop.

Drain/Fill Procedures

To drain the primary loop it is necessary to attach a hose to the drain valve found on the bottom of the drive. This is the lowest point of the system. Place the opposite end of the hose in an appropriate container and open the drain valve. Loosen the fill plug and bleed port cap that are on the top of the primary loop expansion tank. Allow several minutes for the loop to drain.

To fill an empty primary system you should first ensure that the drain valve on the drive is fully closed. Remove the plug from the water fill connection and the cap from the bleed connection that are on top of the primary loop expansion tank. Add the correct charge of inhibitor to the expansion tank. After the inhibitor is installed add distilled water to the expansion tank until a correct fluid level is observed in the expansion tank sight glass. Start and operate the primary loop cooling pump for a minimum of 2 minutes to evenly mix and distribute the inhibitor and distilled water through the drive. Recheck the fluid level in the expansion tank sight glass during pump operation and immediately add more distilled water if the sight glass indicates a low level.

If a chiller and it's drive is inactive for an extended period of time it is recommended that the drive-cooling pump be started at least once a week and allowed to run for one or two minutes. This will help maintain an even distribution of inhibitor in the system.

It is recommended that the primary loop be completely drained of its fluid if it is not possible to run the drive-cooling pump occasionally during extended storage. Place a tag on the drive that indicates the drive will require service before it can be placed back into operation.

Parts Information:

CHM00172 - Chemical, corrosion inhibitor, quart container

Date of Expiration:

This service alert expires June 30, 2001.

Service Alert

AFDB

Subject: 1000 Hp AFDB Drives - PRESSURE LIMIT

ORDER No: AFDB-SVA002-EN DATE: March 27, 2001

Introduction:

This service alert states the requirement to limit the water pressure applied to the primary cooling circuits of 1000 Hp AFDB (Rockwell Liqui-Flow) AC Drives.

Disussion:

The 750 and 1000 Hp AFDB AC drives use a sealed primary cooling loop design that has a lower maximum allowable water pressure than the smaller size drives. The maximum allowable water pressure within the primary cooling loop of the 750 and 1000 Hp drive is 50 psig.

Application of more than 50 psi to the primary cooling loop of the 750 or 1000 Hp drive can result in a failure of the drive's internal heat exchanger sealant, resulting in leakage of the cooling medium into the starter enclosure.

Only the 750 and 1000 Hp drives, factory mounted or field installed, are affected. The smaller Liqui-Flow drives (350 Hp, 450 Hp, and 600 Hp) have a 150 psi limit and are not affected by the 50 psi limit..

Action:

When testing or back-flushing the primary loop of a 750 or 1000 Hp AFDB drive, do NOT exceed 50 psi of applied water pressure. Install a gage at the water inlet point and monitor the applied water pressure closely. Throttle or regulate the water flow to maintain an inlet pressure of 50 psi or less. Use an in-line water pressure regulator if available. When flushing the drive do NOT restrict or block the free flow of water out from the drive.

© 20001American Standard Inc. All rights reserved.

Be aware that municipal water pressures in many locations can be 90 psi or even higher, if such pressure is applied directly to a 750 or 1000 Hp AFDB drive internal damage can result. Proper care must be taken.

Expiration Date:

This service alert is discontinued June 30, 2001.

General Service Bulletin

AFDB Primary Coolant Loop Service and Maintenance

CVHE, CVHF and CDHF

Order No: AFDB-SVB02A-EN November 12, 2001

Introduction

This service bulletin defines the required procedures and materials to be used when servicing the primary cooling loop of water-cooled AFDB drives installed on Trane CVHE, CVHF and CDHF chillers. This bulletin can also be applied to retrofit AFDC and the CH530 AFDD drives installed on other chillers.

Inhibitor

The approved inhibitor for use in all Trane AFDB 350, 450, 600, 750, and 1000 Hp water-cooled drives is Trane CHM00172. The inhibitor is supplied pre-diluted in quart plastic bottles and will be further diluted when mixed with the distilled water of the primary cooling loop. When charging an empty system on a factory installed drive it is recommended that 1-quart (32 oz.) of CHM00172 be installed in the primary cooling loop, regardless of the size of the drive.

If pre-mixing distilled water and the inhibitor to use as make-up for lost fluid, or if charging fluid to a field mounted drive with an unknown total fluid capacity, CHM00172 may be pre-mixed at a ratio of approximately 12 oz. of CHM00172 per each gallon of clean distilled water. Inhibitor should always be installed along with clean distilled water. Do not simply add inhibitor to an existing or dirty charge of water. Do not add distilled water to a drive unless you have pre-mixed it with the proper inhibitor as described above.

© 2001 American Standard Inc. All rights reserved.

Primary Loop Fluid Amounts

The maximum total fluid capacity of the primary cooling loop of the factory installed 750 and 1000 Hp drive is approximately 3 gallons, the 350, 450 and 600 Hp factory installed drives will require up to 2.5 gallons. Use only **clean distilled water** and the proper inhibitor as the fluid in the primary cooling loop.

Flushing and Cleaning

The use of the proper solution and maintenance intervals will help ensure that the primary cooling loop never needs extensive cleaning or flushing. Back-flushing or flushing the drive heat sink and primary cooling loop is not allowed. If excessive pressure is applied to the drive heat sink it may fail and allow leakage of the cooling medium into the drive enclosure.

CAUTION

Primary Cooling Loop Overpressurization!

The maximum allowable pressure in the primary cooling loop must not exceed 50 psig. Use of pressures above 50 psig may cause structural damage to equipment.

Do not exceed 50 psi of applied water pressure to the 750 or 1000 Hp drive heat exchanger or drive damage may occur. Be observant for the following warning label:

CAUTION

MAXIMUM ALLOWABLE PRESSURE IS 50 PSIG

DO NOT EXCEED MAXIMUM ALLOWABLE PRESSURE

Use of pressure greater than 50 psig may cause structural damage to equipment

X39001794010A

Drain and Fill Procedures

To drain the primary loop it is necessary to attach a hose to the drain valve found on the bottom of the drive. This is the lowest point of the system. Place the opposite end of the hose in an appropriate container or open floor drain and open the drain valve. Ensure that the fill plug and bleed port cap located on top of the primary loop expansion tank are both open. Allow several minutes for the loop to drain freely. **Do not** use compressed air or other pressure sources to force coolant from the drive. To fill an empty primary system you should first ensure that the drain valve on the drive is fully closed. On the top of the primary loop expansion tank remove the plug from the fill connection and ensure the cap on the bleed connection is removed. Add the correct charge of inhibitor to the expansion tank through the fill port. After the inhibitor is installed, add **distilled water** to the expansion tank until a correct fluid level is observed in the expansion tank sight glass. Use a funnel and simple gravity to add the solution components to the expansion tank. **Do not** use a hose with a pump or with city water pressure to add water to the drive as the high pressures that may result can damage the drive. Start and operate the primary loop cooling pump for a minimum of 2 minutes to evenly mix and distribute the inhibitor and distilled water through the drive. Recheck the fluid level in the expansion tank sight glass during pump operation and immediately add more distilled water if the sight glass indicates a low level. **Do not** over fill the expansion tank; insure that there is a minimum of 4-inches (101.1mm) air gap at the top of the tank at all times.

After filling and starting the system, the vent cap or bleed valve on the top of the expansion tank should be left open slightly, so that the expansion tank is exposed to atmospheric pressure. Do not open the cap or bleed valve fully or pre-mature inhibitor depletion due to the excessive contamination with oxygen may occur.

Maintenance Intervals

Once a week the AFD coolant system primary loop should be visually inspected for leakage and for proper solution levels in the expansion tank sight glass. It is recommended, after 12 months, that the primary cooling loop of the AFD drive be drained and refilled with new inhibitor and distilled water.

Storage

If a chiller and its drive is inactive for an extended period of time it is recommended that the drive-cooling pump be started at least once a week and allowed to run for one or two minutes. This will help maintain an even distribution of inhibitor in the system. It is recommended that the primary loop be completely drained of its fluid if it is not possible to run the drive-cooling pump occasionally during extended storage. Place a tag on the drive that indicates the drive will require service before it can be placed back into operation. Drives that will be exposed to freezing temperatures during storage may have a temporary solution of 100% propylene glycol installed to prevent freeze damage. The solution should be installed and the circulating pump should run for several minutes to evenly distribute the solution. At the earliest opportunity and before operation of the drive is allowed the glycol solution must be removed and replaced with the proper inhibitor solution.

SUBJECT: CVHE/CVHB OIL HEATER ELECTRICAL CONNECTIONS

INTRODUCTION:

This service bulletin identifies corretive action to improve the electrical connections used on Model CVHE and CVHB oil tank heaters.

DISCUSSION:

The wire terminal connection between the oil heater element and the connecting wire must have sufficient surface area contact to dissipate heat. If the terminal is undersized or not making proper contact, it can overheat and burn off the wire.

The wiring to the terminal connector can also cause a similar overheating situation if some of the insulation is crimped between the wire and the connector.

The present replacement terminal connectors have more surface contact area which should reduce the potential for overheating and failure of the connector.

CORRECTIVE ACTION:

When it is necessary to replace an electrical connection terminal on CVHE or CVHB oil tank heaters, use the following procedure:

1. Strip off enough insulation from the wire to allow for the wire to be doubled over in the terminal with a 1/16" gap of bare wire between the insulation and the terminal.
2. Use the correct terminal and crimp it in the proper position.

PARTS ORDERING INFORMATION:

The replacement electrical connection terminal for CVHE/CVHB oil heaters is Trane part number TER-807. Order to ship from Location 31.

SUBJECT: MODEL CVHE CENTRAVACS - COMPRESSOR DOWELING

INTRODUCTION:

This service bulletin describes the procedure for doweling a CVHE compressor/motor assembly prior to lifting it from the shells. Doweling is factory installed on a special order basis. If factory doweling is not provided, do not separate the compressor/motor assembly from the shells until locating dowels have been installed.

DISCUSSION:

The compressor/motor assembly can be removed from the shells in cases where installation access is limited. Misalignment of the compressor castings can occur when a compresssor assembly without doweling is moved.

The alignment of the compressor/motor assembly is determined by the position of the discharge volute. A shift in volute position at either the discharge flange or the compressor foot can change the suction elbow to compressor alignment. When the suction elbow is tightened to final torques, the compressor/motor assembly can shift from its original position. The resulting interference between seals and rotating components can adversely affect machine performance. The third stage volute must be doweled at the discharge flange and at the compressor foot.

Dowel pins are also required between the casings since it is possible for the casings to shift position relative to each other. The compressor assembly procedure calls for the seal clearances to be set after the casings are in place, which means that a shift in position can take up the seal clearances and cause interference.

If the compressor is disassembled for repair or component replacement, doweling is not required because the seals can be set as the compressor is reassembled.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet

Dowel pins are recommended at the following locations when the unit is disassembled in the field.

1. Compressor foot
2. Compressor discharge to condenser flange (2 places)
3. Motor to compressor volute
4. Compressor volute to casing
5. Casing to casing
6. Suction cover to casing

Figure 1
Discharge Flange
Doweling

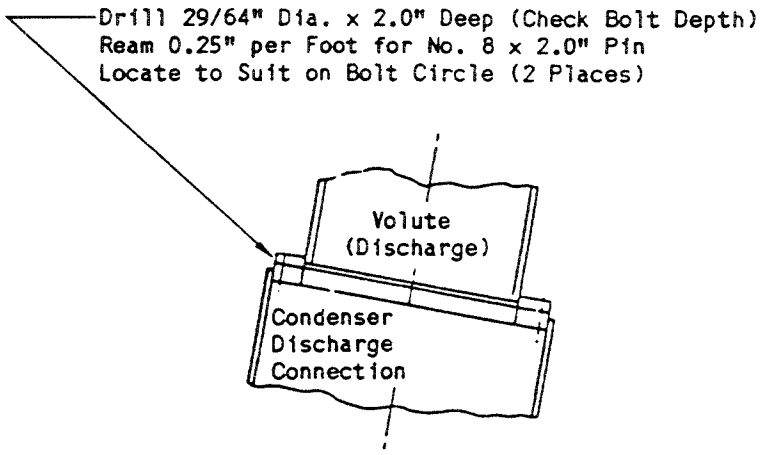

Figure 2
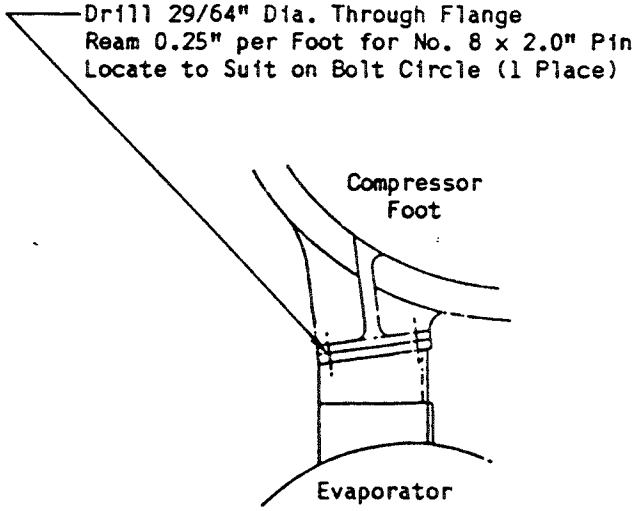
Compressor Foot
Doweling



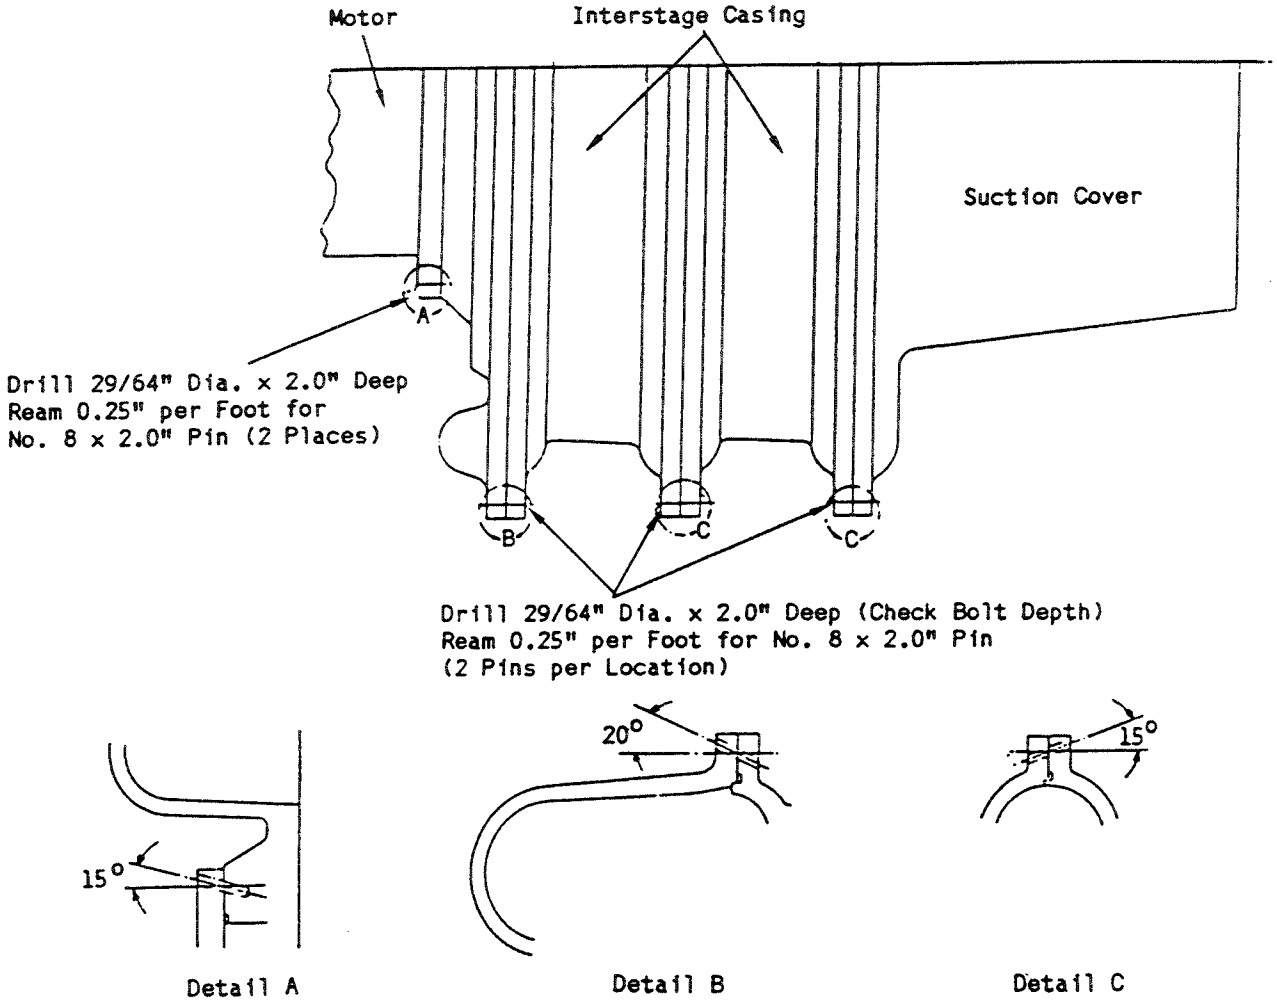


Figure 3
Compressor Doweling

Note: Two Dowel Pins Required for each
Flange Joint - 90 Apart.

PROCEDURE:

The following procedure can be used to dowel the units prior to disassembly.

The following tools will be required:

- Drill bit for 7/16" or 29/64" diameter.
- Tapered reamer for 0.25" per foot (or No. 8 dowel).
- No. 8 dowel pins.
- Various hand tools.

1. Dowel the condenser discharge flange at two locations and the compressor foot at one point. The drilled holes into the discharge flange of the condenser should be no deeper than the existing bolt holes. Deeper holes

will penetrate the flange and cause refrigerant leakage. The same size dowel pins can be used in all locations.

2. Use the 29/64" drill bit and tapered reamer at the locations indicated in Figures 1 and 3. The pilot area of the reamer must be removed to ream those holes that are blind. Be sure the holes do not penetrate the flange.

3. Install all dowel pins except those on the third stage discharge flange, and the compressor foot connection to the evaporator.

4. Refer to Table 1 for the number of dowels required and the appropriate depth of the holes. To determine the depth of the dowel hole at the motor flange to discharge volute, remove a bolt and measure the hole depth. The holes should be drilled straight whenever possible. However, they can be angled when necessary up to the maximum shown in Figure 3.

The compressor/motor assembly can now be removed. Refer to Installation manual CVHE-IN-3 for details.

SUBJECT: CVHE COMPRESSOR TO CONDENSER O-RING REPLACEMENT

INTRODUCTION:

This service bulletin describes a method to replace the compressor to condenser discharge o-ring on Model CVHE CenTraVacs. This procedure recommends rigging and movement of the compressor/motor assembly as a single unit.

DISCUSSION:

When rigging heavy components, such as the compressor/motor assembly, it is important to use the proper lifting locations to insure adequate safety. The safety chain and rigging members should have a sufficient safety factor to support the weight of the entire compressor/motor assembly. The compressor/motor assembly weights are given in Table 1.

Table 1
Compressor/Motor
Assembly Weights

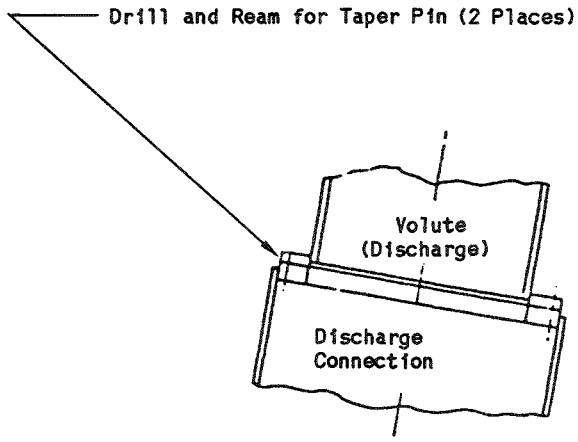
Unit Size	Compressor/Motor Weight (lbs.)
013-020	5,665
022-032	6,880
035-050	7,175
055-080	9,175
089-125	11,125

Before the compressor/motor assembly is lifted from the shells, the third stage casing must be doweled to insure proper alignment of the suction elbow during reassembly. Doweling between individual casing components is not necessary if

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

the connecting bolts have been checked for proper torque. Doweling is necessary when the assembly will be removed and transported. Refer to service bulletin CVHE-SB-10 for compressor doweling.

Move the compressor/motor assembly just enough to clean the flange surfaces and replace the compressor discharge to condenser and compressor to suction elbow o-rings.



O-RING REPLACEMENT PROCEDURE:

Use the following procedure to replace the compressor discharge to condenser and compressor to suction elbow o-rings.

1. Remove the refrigerant from the unit by pressurizing it with dry nitrogen to 2 or 3 psig. After all the liquid refrigerant has been removed, connect a vacuum pump to the unit to create a partial vacuum (25 to 26") to remove the remaining refrigerant. Once the partial vacuum is achieved, bring the unit to atmospheric pressure (0 psig) using dry nitrogen.

2. The condenser discharge flange should be doweled in two places and the compressor foot in one place before separating the assembly from the shells. See Figures 1 and 2 for the preferred doweling locations. Refer to service bulletin CVHE-SB-10 for doweling details.

Figure 1
Discharge Flange
Doweling Detail

3. Rigging of the compressor/motor assembly is important due to the weight involved. On larger units where the compressor foot is not a level pad, the compressor/motor assembly will have a tendency to rotate toward the motor terminal side. The recommended method for picking up the entire compressor/motor assembly involves the use of a portable gantry as shown in Figure 3. One of the A-frames is used to support the motor end of the assembly, while the other is used to support the first stage compressor suction housing. Attach a safety chain to the motor at the terminal casing to prevent rotation of the entire assembly.

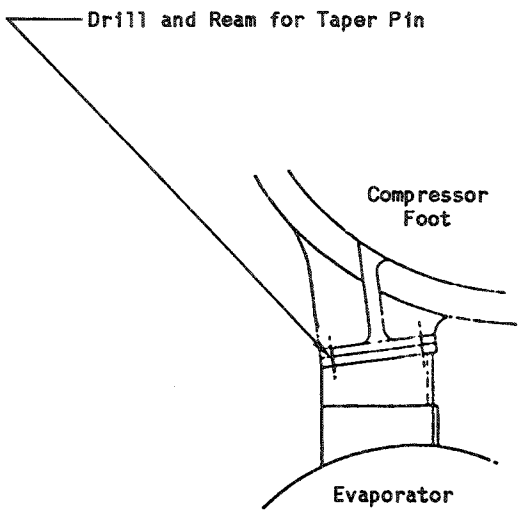
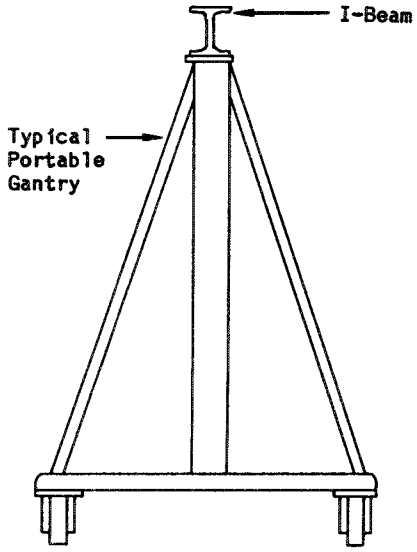
Figure 2
Compressor Foot
Doweling Detail





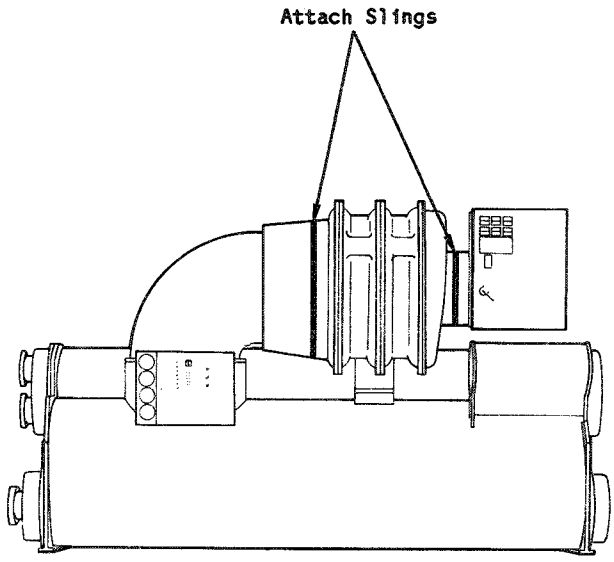


Figure 3
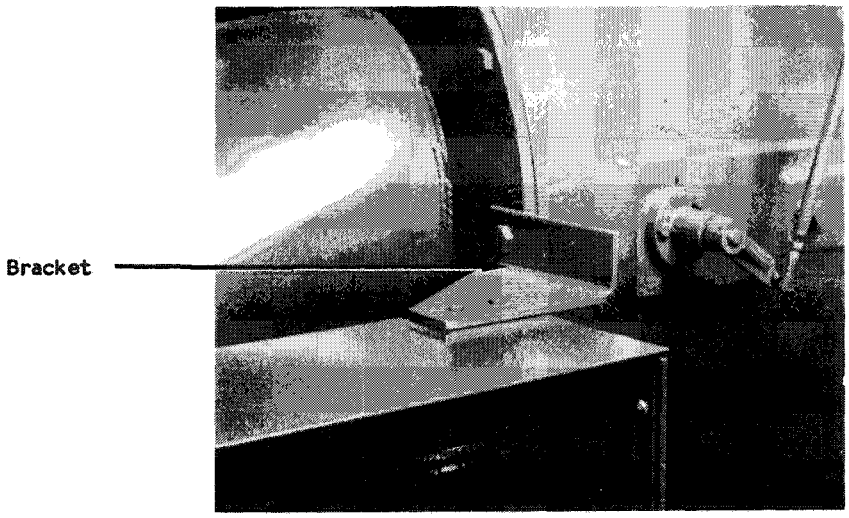
Recommended Compressor/
Motor Assembly Lifting
Equipment

Set up the rigging and attach it to the compressor/motor assembly to the point where it will just begin supporting the weight of the assembly. Before lifting the assembly from the shells, complete the following steps. Cover all openings immediately to prevent the entrance of debris and contamination to the internal side of the motor and chiller.

a. Disassemble the suction elbow to suction cover connection.

1. Disconnect and remove the control panel support bracket. See Figure 4.

2. Remove the bolts on the suction cover to suction elbow connection. The suction elbow will be left attached to the evaporator through all remaining steps.



b. Remove the economizer vent lines to the compressor.

1. Loosen the bolts on the condenser liquid line flange which is located at the bottom of the condenser. See Figure 4. Do not remove the bolts at this time.

2. Loosen the bolts on the evaporator liquid line flange which is near the bottom of the evaporator. See Figure 5. Do not remove the bolts at this time.

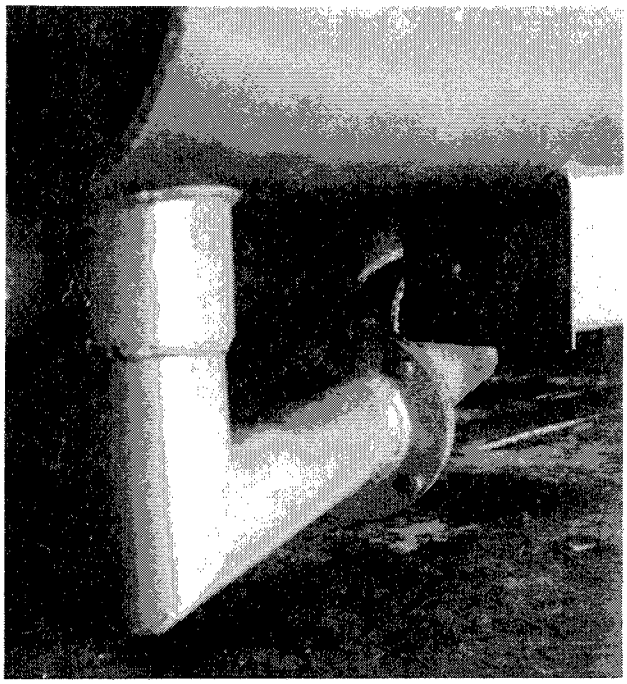
3. Place a floor jack under the economizer sump as shown in Figure 6 to support the weight of the economizer. The economizer should be supported by wrapping a sling or chain, supported by an overhead lift or A-frame, around it. Both support methods require a lifting capacity of 3,000 pounds.

Figure 4
Control Panel
Support Bracket

4. Loosen the economizer vent pipe bolts which hold the vent pipe flanges to the compressor interstage castings. Do not remove the bolts.

5. Remove the bolts from the condenser and evaporator liquid lines. Adjust the floor jack or overhead lift, as necessary, to support the weight of the economizer.

Figure 5
Condenser Liquid
Line Flange



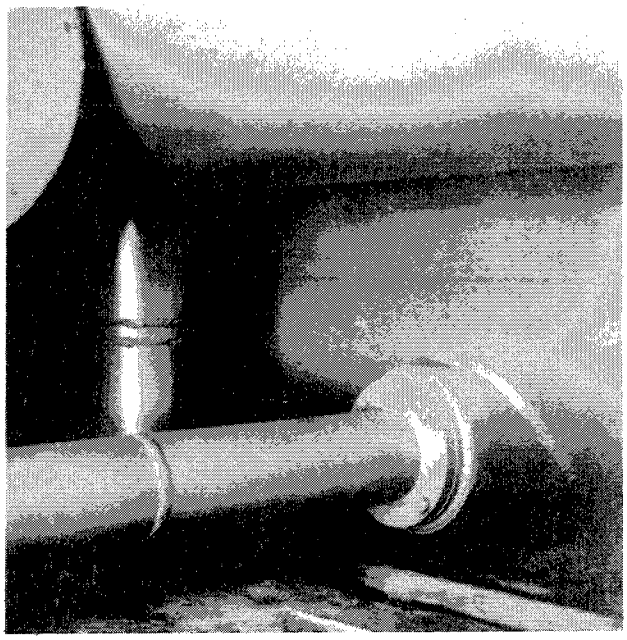


Figure 6
Evaporator Liquid
Line Flange

6. Carefully remove the economizer vent pipe flange bolts and loosen the economizer. When the bolts are free, back the economizer away from the chiller. See Figure 7. If a floor jack is being used, the economizer will tend to rotate off the jack towards the compressor. Be prepared to offset this rotation.

c. The remaining connections are motor cooling lines, oil supply lines and drain lines. See Figure 8. Many of these are flare or flange connections that can be removed. On those lines that must be cut, remove any paint to minimize internal chiller contamination.

1. Cut the 7/8" vent line between the oil sump and the suction cover. Sand off all paint where the cut will be made. Make the cut in a straight section of pipe with a pipe cutter. Refer to Figures 9 and 10.

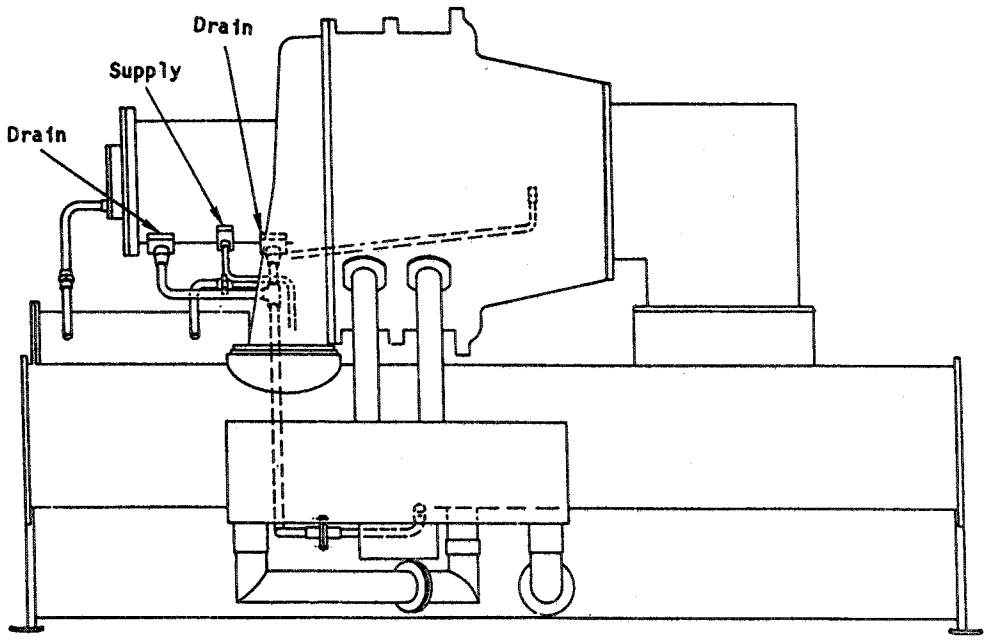
2. Disconnect the oil supply and return lines at the thrust end of the motor. See Figures 11 and 12.

3. Disconnect the refrigerant supply and drain lines from the motor by unbolting the flanges from the motor. See Figures 13 and 14.

Figure 7
Removing the
Economizer

d. Various electrical connections must be disconnected to facilitate movement of the compressor/motor assembly.

Note: Some models have enough slack in the conduit harness to allow movement of the compressor/motor assembly without removal of all of the connecting wiring.



1. If the unit has a factory mounted motor starter, remove it from the motor terminal casting. Remove and mark all motor power leads and interconnecting wiring of the factory mounted starter. If a remote starter is used, mark and disconnect the motor power leads and remove the conduit box.

2. Mark and remove the motor winding temperature sensor leads.

3. Mark and disconnect all power leads to the inlet vane actuator motor. Remove the conduit assembly from the actuator motor.

4. With the appropriate electrical and piping connections removed, the compressor can be lifted away from the unit. Remove the connecting bolts at the compressor foot and discharge flange. As an added precaution, install guide rods before removing the bolts to prevent the compressor/motor assembly from rolling towards the motor terminal side of the unit. The compressor should be raised approximately 10 inches to facilitate the o-ring changeout. Place wood blocks between the flanges to prevent shifting of components. Remove the old o-ring and clean the mating surfaces. Check the o-ring groove and mating surfaces for knicks and burrs which could deform the o-ring.

Figure 8
Motor Cooling
Supply and
Drain Lines

5. Place a bead of Loctite 515 into the o-ring groove, install the o-ring and apply a bead of Loctite 515 on top of it. This will make up for any minor imperfections in the castings.

   The suction elbow connection at the suction cover should also have a new o-ring installed. This o-ring should be held in place with vaseline. Do not use Loctite at this connection because it may flow into the gap between the inlet vane housing and the suction cover which could make further removal of the inlet vane housing very difficult. Once both o-rings are in place, move the compressor toward the suction elbow and lower it into position.

6. Install the discharge flange and compressor foot bolts. Snug them down to prevent the compressor from shifting. Install the dowel pins to locate the compressor/motor assembly. After the dowel pins are installed, tighten the discharge flange and compressor foot bolts to their torque of 150 ft. lbs. Tighten the suction elbow using Figure 15 for the tightening sequence. Connect the economizer and make all piping and electrical connections using new gaskets and o-rings. Any brazing should take place while nitrogen is bled through the line to minimize oxidation. All copper to copper joints must be brazed according to A.W.S. B-CUP-3 (SIL-Phos). After all of the connections are made, pressurize and leak test the unit. After leak testing, evacuate the unit to 2.5 millimeters and recharge it.

Literature Changes:

Modified "Parts Ordering Information".

SUBJECT: CVHE/CVHB MOTOR OVERLOAD MODULE PROTECTION

INTRODUCTION:

This service bulletin discusses the addition of a surge suppressor across the power supply of CVHE and CVHB solid state motor overload modules. The addition of the suppressor is recommended to provide protection from high voltage spikes which can lead to module failures.

DISCUSSION:

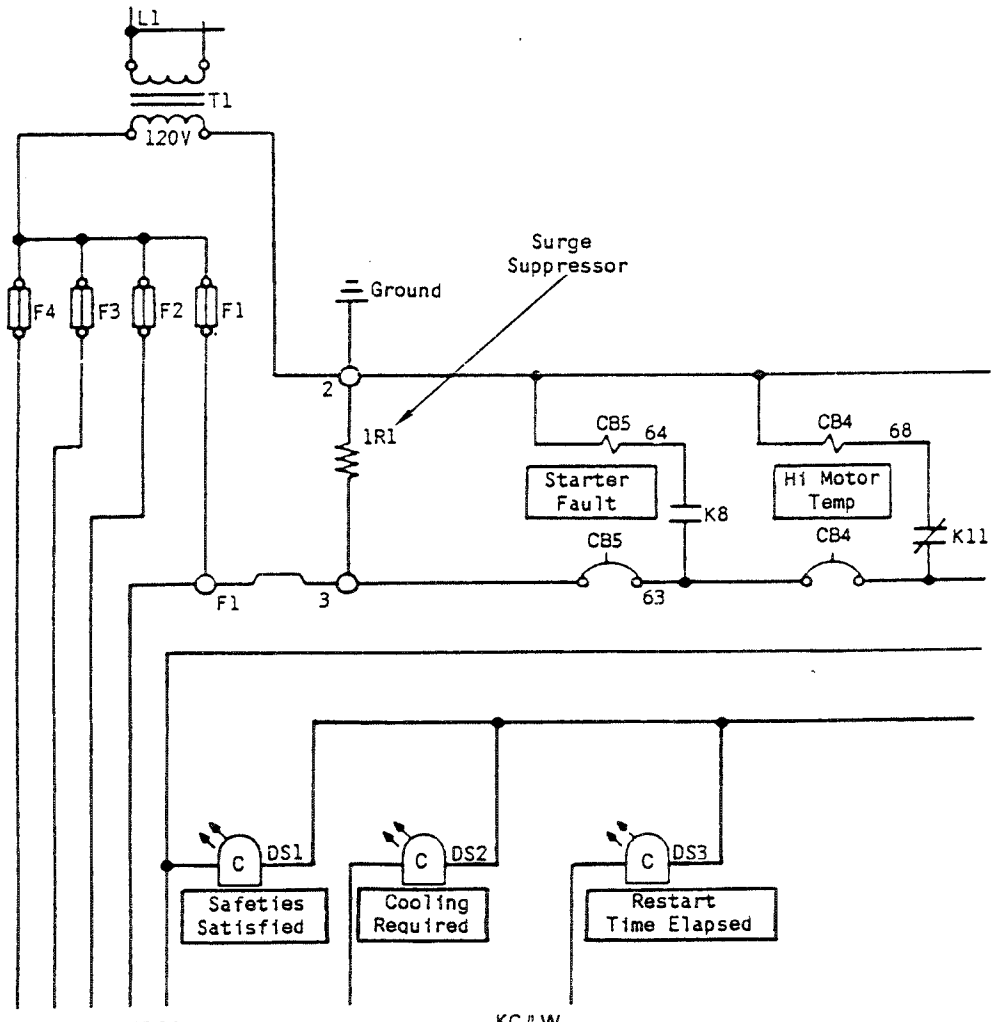
A number of Cutler-Hammer overload modules (Trane part number RLY-765) that have been returned as failed, appear to have been exposed to a high voltage condition. This high voltage could have been caused by inadvertent application of 110 volts through the low voltage side of the module or through transient line voltage spikes which can enter the module through its power supply. The module can be protected from these voltage spikes by the addition of a surge suppression device that connects to the module power supply. These devices are generally referred to as MOV's (metal oxide varistors).

CORRECTIVE ACTION:

Surge suppressors should be installed on all CVHE and CVHB units with solid state overload modules at unit start-up. Units which are being retrofitted to add the new solid state motor protection module should also have the suppressor added. Units that are already started should have the surge suppressor added on an opportunity basis such as a service call or annual maintenance.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Install a surge suppressor in the unit control panel across terminals 2 and 3 as shown in Figure 1. The suppressor (MOV) should have the following values:



- Maximum RMS volts -150
- Maximum energy rating - 80 joules
- Average power dissipation - 1 watt
- Peak pulse amps - 6,500

A surge suppressor can only protect against high voltage surges that do not exceed its design rating. Voltage surges in excess of this rating will cause the suppressor to fail. A failed surge suppressor is evident due to its almost total physical destruction. Failure of the suppressor will not interfere with the operation of the unit control system. Periodic inspection of the suppressor should be included with other normal maintenance procedures.

PARTS ORDERING INFORMATION:

The part number for the surge suppressor is SPS-11.

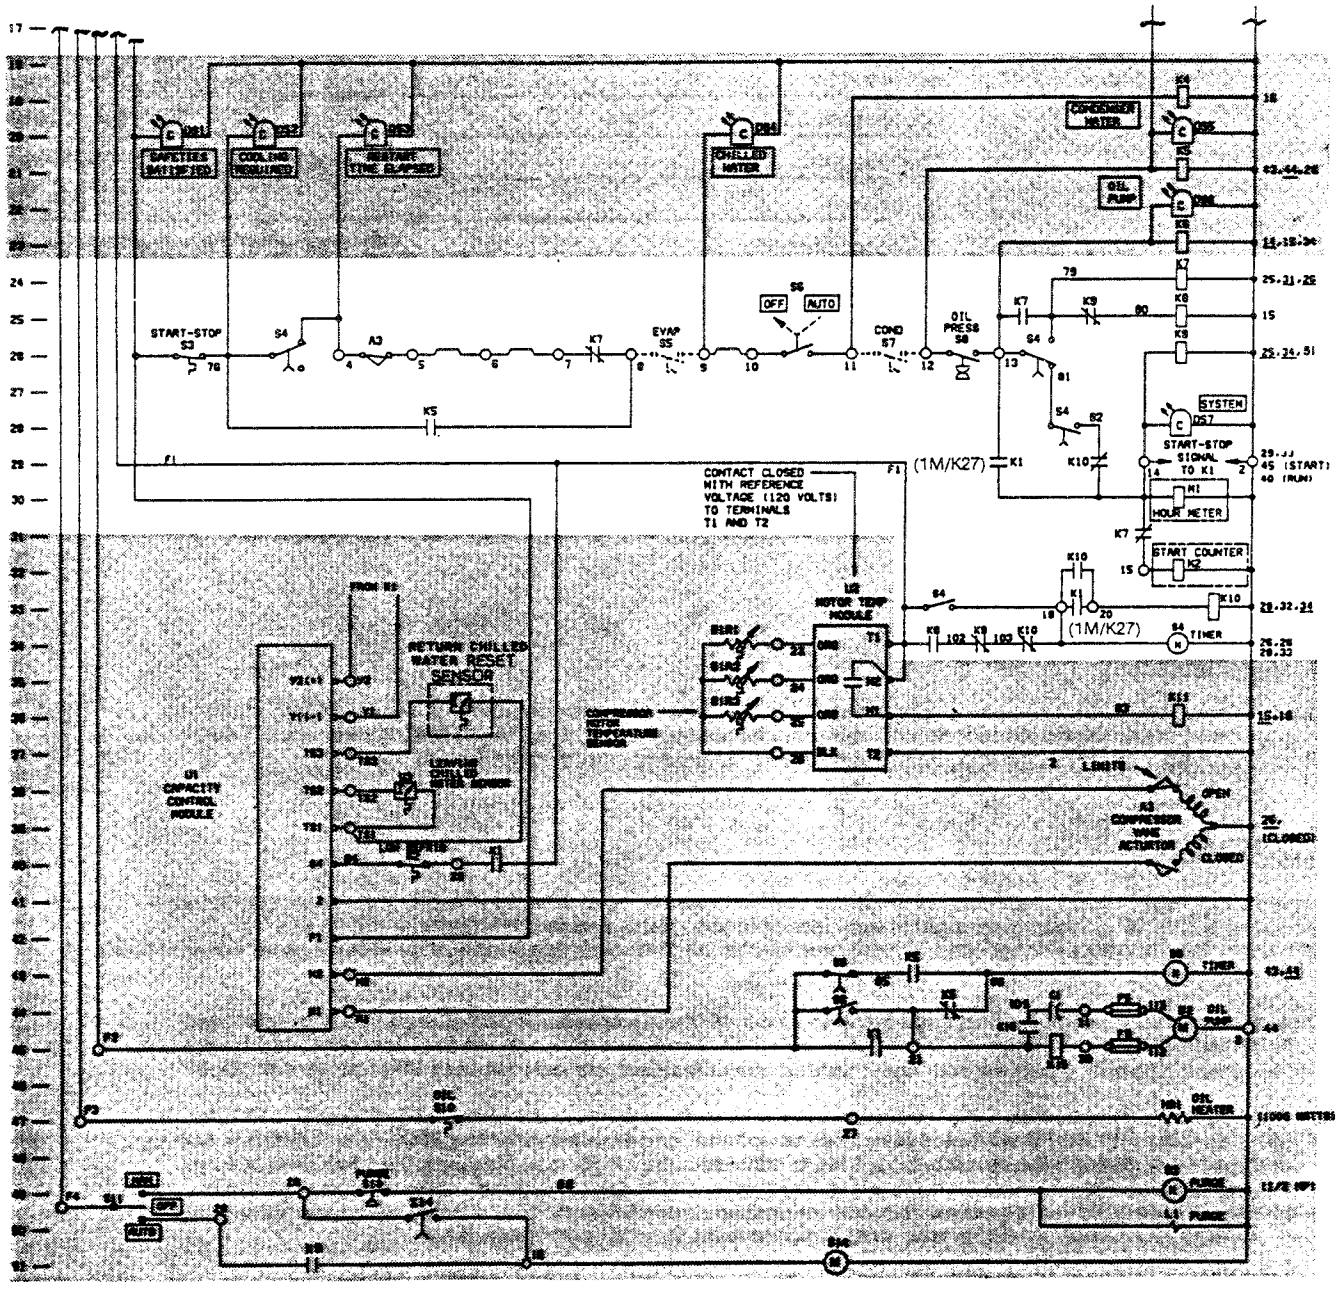
SUBJECT: "STARTER-FAULT" BREAKER/K10 RELAY RACE (CVHEs OF "A" THRU "J" DESIGNS)

INTRODUCTION:

Nuisance tripping of the unit control panel's "starter-fault" circuit breaker may occur in CVHEs of "A" through "J" design as a result of a "relay race" between the K10 relay and the auxiliary contacts on the 1M (K27) contactor. This service bulletin discusses why these nuisance trips occur, as well as what can be done to prevent them.

DISCUSSION:



Ordinarily, a normal "start" signal from Terminal 14 of the unit control panel energizes the 1M (K27) contactor which, in turn, closes 2 sets of normally-open auxiliary contacts. (Refer to the typical electrical schematic in Figure 1.) The auxiliary contacts located between Wires 13 and 14 (Lines 26 and 29) close first, followed by those located between Wires 19 and 20 (Line 33).

Notice that closure of the auxiliary contacts between Wires 13 and 14 establishes a "holding" circuit for the "start" signal before the contacts between Wires 19 and 20 can close. This sequence of events assures that the "start" signal is not interrupted when the K10 relay energizes and opens its normally-closed contacts between Wires 82 and 14 (Line 29).

Let's look at what would happen if the contact closure sequence were reversed. Once the inhibit circuit (Line 26) is satisfied (i.e., evaporator and condenser water flows are proven, and oil pressure is established), a "start" signal is sent to the starter panel through the normally-closed set of K10 contacts. If the K10 relay energizes (via closure of the auxiliary contacts between Wires 19 and 20) before the "holding" circuit is established, the starter energizes--but only momentarily. As soon as the normally-closed K10 contacts between Wires 82 and 14 open, the starter panel drops out of the circuit, and the unit control panel's "starter fault" circuit breaker trips 15 to 20 seconds later.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

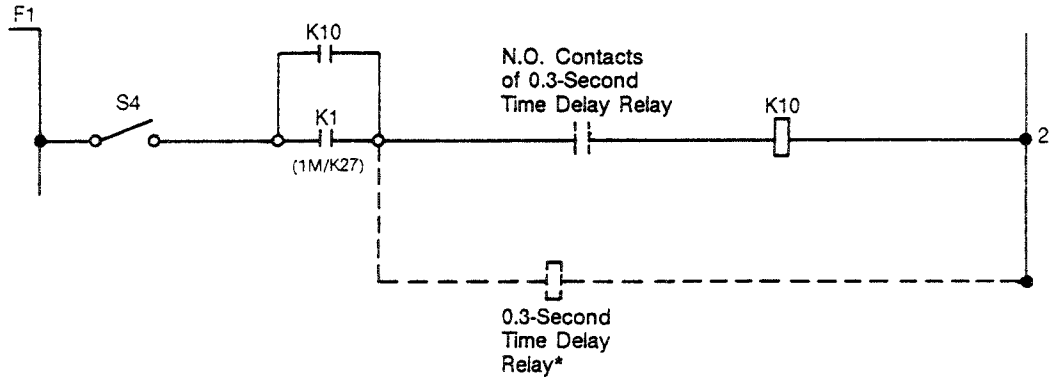
CORRECTIVE ACTION:

Following are 2 solutions designed to eliminate nuisance "starter fault" circuit breaker trips caused by a "relay race" between the K10 relay and the 1M (K27) contactor:

1. Establish the correct wiring sequence for Wires 13 and 14, and Wires 19 and 20.

Ensure that Wires 13 and 14 are connected to a set of normally-open, auxiliary contacts on the 1M (K27) contactor; contacts selected for this purpose should be located as close to the auxiliary-contact actuator as possible (i.e., the auxiliary switch located nearest the starter back panel). Then, connect Wires 19 and 20 to a set of normally-open auxiliary contacts located farther out on the auxiliary contact stack.

This wiring arrangement encourages establishment of the "holding" circuit before the normally-closed contacts of the K10 relay can open.



Note: The corrective action recommended above will successfully eliminate nuisance "starter fault" circuit breaker trips in most instances. However, if adjustments to the wiring sequence of Wires 13-14 and Wires 19-20 do not prevent this type of nuisance trip from recurring, it may be necessary to install a time delay relay. See Item 2 below for instructions.

2. Add a 0.3-second time delay relay to the K10 relay circuit.

Connect the normally-open contacts of 0.3-second time delay relay in series with the K10 relay; make sure that the contacts of the time delay relay are installed upstream of the K10 relay coil. Figure 2 illustrates this wiring arrangement.

The addition of this relay postpones the energizing of the K10 relay by 0.3 seconds, thereby assuring that the start signal "holding" circuit is established before the normally-closed K10 contacts open.

Figure 2
Addition of a 0.3-Second Time Delay Relay to the K10 Relay Circuit

*The 0.3-second time delay relay typically used for this purpose is RLY-872.

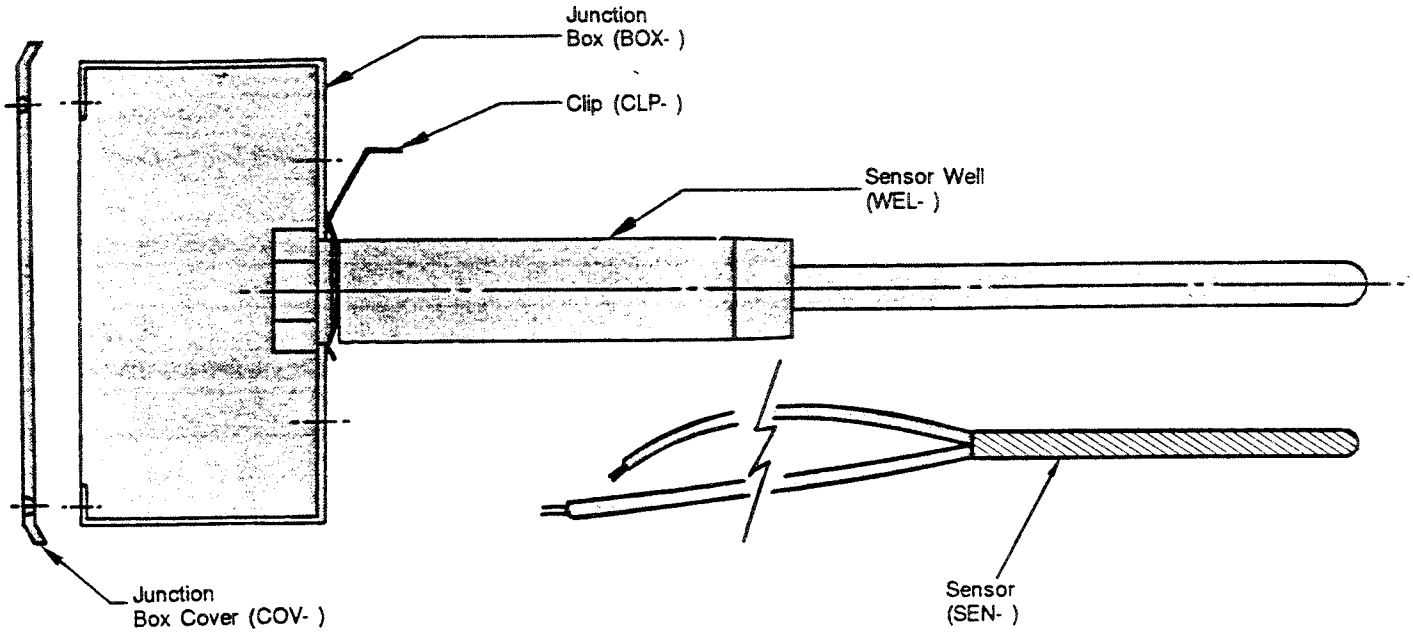
Subject: UCP695/SCP699 Sensor Identification and Locations

Introduction:

This service bulletin clarifies the proper identification of sensors used with CenTraVac UCP695 and SCP699 control panels.

Discussion:



Based on the number of similar questions regularly received from the field, it is apparent that there is some confusion about the sensors used with both UCP695 chiller control panels and SCP699 system control panels. Most of these questions pertain either to sensor identification or sensor location in the chiller system.

Tables 1 and 2—along with Figures 1 and 2—specifically identify each sensor in the UCP/SCP control system by the characteristics listed below. The relative location of each UCP695 and SCP699 temperature sensor is illustrated in Figures 3 and 4, respectively.

a. sensor description (e.g., "leaving evaporator water temperature sensor")
b. Trane mnemonic part number (e.g., "SEN-132")
c. vendor code number (e.g., "X13790038-01")
d. electrical designation (e.g., "4RT1")
e. installed location (e.g., "connecting 'water-out' piping from evaporator")
f. control panel terminal connections

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Notes:

1. Trane's mnemonic part number appears on the outside of the box containing the sensor(s); the vendor code number is stamped on the sensors
2. Do not order this sensor to replace one of a matched sensor pair (e.g., entering and leaving water temperature sensors for the evaporator or condenser).
3. Ordering SEN-118 yields a matched pair of sensors. Sensors used as a matched pair must be replaced as a pair; do not replace an individual sensor from a pair!
4. Other components required to install each sensor are listed below (and identified in Figure 1):
   a. For SEN-113 and SEN-118 used for water temperature applications (4RT1 thru 4RT4):
      BOX-802, CLP-158, COV-91, RSN-2 and WEL-46.
   b. For SEN-114 used for oil sump temperature applications (4RT7):
      BOX-802, CLP-158, COV-91, RSN-2 and WEL-46.
   c. For SEN-114 used for bearing temperature applications (4RT8, 4RT9), unless epoxied to oil return lines:
      BOX-802, COV-91, NUT-20, RNG-178, RSN-2 and WEL-30.
   d. For SEN- 96 used for evaporator refrigerant temperature applications (4RT5):
      BOX-802, CLP-158, COV-91, RSN-2 and WEL-46.

Drwg. X39470473

Figure 4
SCP Sensor Locations (Typical 3-Chiller, Parallel-Piped, Decoupled System Shown)

Notes:
1. See Table 2 for additional sensor information.
2. For sensor installation instructions, refer to the installation manual that shipped with the SCP.

Note: Sensor installation instructions are provided in the current editions of CVHE-IN-4, CVHB-IN-5, CVRA-IN-1 (UCP695 retrofit kit), and CVMA-IN-1 (SCP). However, there are a couple of important points to remember:

1. Evaporator Water Temperature Sensors. All CVHEs with UCP695 panels ship with the standard leaving evaporator water temperature sensor (SEN-113 or SEN-132), regardless of what other control options are ordered. Therefore, if either the chilled water reset (CWR) or matched-pair evaporator sensors are specified, the unit will ship with an extra evaporator water sensor.

If the chiller was ordered with the CWR option, install the extra sensor (i.e., the standard leaving evaporator sensor; SEN-113 or -132) in the outside air and wire it to the micro module's ambient temperature input. See Tables 1 and 2.

If the chiller was ordered with the matched-pair evaporator sensors but does not include CWR, discard the extra sensor (i.e., the standard evaporator sensor).

2. Extending Sensor Leads. The leads on current temperature sensors may not reach all the way back to the UCP or SCP. If this is true of your installation, route the sensor leads to a junction box mounted in a convenient location. Splice the sensor leads inside the junction box; then route the added length of wire back to the control panel in conduit. (Remember that jacketed cable can be cut to length.)

Note: To extend the leads of "new"- and "old"-style sensors, use 14-18 AWG, 600V wire. The wire added between the junction box and the control panel must be either shielded or run in conduit. If shielded cable is used, be sure to tape off the shield wire at the junction box and ground it at the control panel. If the wires added to extend the sensor leads will be run in conduit, do not run them in the same conduit with other circuits carrying 30 or more volts.

Caution: To prevent possible sensor malfunction due to electrical noise, never route low-voltage sensor leads with other conductors carrying 30 or more volts!

3. Matched-Pair Evaporator or Condenser Water Temperature Sensors. All of the water temperature sensors used in the UCP and SCP control systems are accurate to within ± 1.0 F, and are typically offered as "matched" pairs.

The term "matched sensor pair" indicates that both sensors in a given pair have the same accuracy. For example, a sensor that registers a temperature that is 0.5 F higher than the "actual" value is paired with another sensor that also registers 0.5 F high. If entering and leaving water temperature sensors are not replaced with another matched pair of sensors, the accuracy of the temperature readings displayed on the face of the control panel is reduced. (That is, if one sensor in a matched pair "reads" 1.0 F high and the other sensor "reads" 1.0 F low, the inaccuracy of the front panel display is 2.0 F.)

For further information on this product or other Trane products, refer to the "Trane Service Literature Catalog", ordering number IDX-IOM-1. This catalog contains listings and prices for all service literature sold by Trane. The catalog may be ordered by sending a $20.00 check to: The Trane Company, Service Literature Sales, 3600 Pammel Creek Road, La Crosse, WI 54601.

Subject: CVHE Vibration Analysis and Trim Balance Procedures

Introduction:

This service bulletin outlines the proper method for checking vibration levels on Model CVHE CenTraVacs, and also describes the appropriate corrective action to take if vibration levels are excessive.

Discussion:

The information presented in this bulletin is divided into 3 sections; a brief summary of the topics covered in each of these sections is provided below:

Section 1: Routine Vibration Analysis

This section describes 2 types of vibration analysis that can be performed routinely to evaluate (1) thrust bearing condition, and (2) rotational imbalance. It also outlines the procedures and types of equipment to use when conducting these vibration checks.

Section 2: Checking Vibration After Unit Disassembly or Compressor Rework

Outlined here are procedures for checking vibration levels following: (1) suction elbow removal; (2) removal of the entire compressor/motor assembly; and, (3) disassembly of any portion of the compressor's rotating assembly.

Section 3: Trim Balancing

Included in this section is a brief summary of how the trim balancing process is used to reduce excessive compressor vibration.

While excessive vibration levels can be caused by worn bearings—or when components in the compressor's rotating assembly are out of alignment, it most often results if the additive imbalance of the individual, prebalanced components exceeds the allowable imbalance for the entire rotating assembly. This is evidenced by the fact that approximately 10% of all CVHE compressors built today require trim balancing before leaving the factory. (All CVHE compressors are factory-analyzed for vibration.)

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Section 1:

Routine Vibration Analysis

Though not required for proper, routine unit maintenance, 2 types of vibration analysis can be performed on CVHE-style compressors; one type of analysis is used to ascertain the condition of the thrust (outboard) bearing, while the other checks for rotational imbalance. Both types of vibration analysis (described below) can be incorporated into the chiller's periodic maintenance program or "service contract" terms.

Analyzing Thrust Bearing Condition

The thrust (or "outboard") bearing used in CVHE compressors is an antifriction-type, "duplex" ball bearing. As a result, the classic oil analysis program—successfully used to evaluate the condition of the babbitted inboard bearing—does not indicate the condition of the thrust bearing.

"Audio" Check. The simplest, least expensive method of checking for thrust bearing failure is to listen to the bearing during operation and coastdown. A failed bearing will "howl" while the unit is running and "click" during coastdown. While the howling noise is readily apparent, the best way to listen for "clicking" during coastdown is to place a stethoscope against the thrust bearing inspection cover; the "clicking" sound will be most noticeable just before the rotor stops turning.

Note: Stethoscopes for listening to machine noise are commonly available from automotive supply stores. If necessary, a screwdriver can be used in lieu of a stethoscope: simply place the tip of the screwdriver against the inspection cover; then press your ear lightly against the handle.

If the "audio" method of bearing evaluation indicates that a thrust bearing is bad, the bearing will usually continue to be operable for several months before failing.

* * * * *

"Mechanical" Check. An alternative method for determining thrust bearing quality is to monitor bearing condition with a "bearing-gear" analyzer. We tested several popular makes of this type of vibration analyzer on good bearings as well as on bearings with "manufactured" defects. Though none of the analyzer makes tested provided an obvious signal of a failed bearing in all cases, the "SWAN-1 Bearing/Gear Analyzer" yielded the best results and is considered acceptable for use as a routine diagnostic tool.

Important! While vibration analyzer readings indicating high vibration levels (i.e., over 40,000 SWE on a SWAN analyzer) may be symptomatic of a potential bearing problem, do not change out the thrust bearing unless the audible symptoms described above are also present!

SWAN-1 Bearing/Gear Analyzer

During our evaluation of the SWAN analyzer, we obtained vibration readings from a variety of locations on the motor. Based on this experience, the optimum location for monitoring thrust bearing condition is on the outboard bearing inspection cover in the radial direction. See Figure 1. (Though this location yields the best results with the SWAN analyzer, be sure to follow the instructions provided by the manufacturer for the bearing-gear analyzer you are using.)

It is difficult to specifically define "good" and "bad" readings for bearing/gear analyzers like the SWAN; bearings of identical quality in similar units may well show different levels of "stress wave" output. Most commonly, this type of analyzer is used to monitor the change in a bearing's quality over its entire life.

To correctly monitor a thrust bearing, it is important to record a vibration reading while the bearing is fairly new; this establishes a "base line" vibration level that can be used for comparison with future vibration level checks. Note that it is important for the unit to be operating at similar conditions each time bearing condition is checked; for this reason, it is advisable to record vibration level readings at various operating load points.

Once the "base line" is established, use a bearing/gear analyzer to periodically check bearing deterioration.

Note: While there are undoubtedly other types of vibration analyzers that can be used to indicate thrust bearing degradation, the SWAN analyzer yielded the best results in our laboratory tests. For more information about the "SWAN-1 Bearing/Gear Analyzer", phone or write to this address:

Figure 1
Checking Thrust Bearing Quality
with a SWAN-1 Bearing/Gear Analyzer

Instructions:

1. Drill a 13/32"-diameter clearance hole in the sensor mount (i.e., to accommodate the 3/8" bolt on the thrust bearing inspection cover).

2. Clean the following to ensure that they are free of dust, paint and metal chips:
(a) the sensor base and the threads of its 10-32 mounting screw; and,
(b) the sensor mount's surface and its 10-32 tapped hole.

3. With the brass washer in place, screw the sensor onto the sensor mount and hand-tighten.

4. Tighten the sensor to 30-35 inch-pounds (1.8-2.0 nm) using a torque wrench and a 5/8"-deep well socket.

5. Loosen the bolt at the 2 o'clock position on the thrust bearing inspection cover; then slide the sensor mount into place. Make sure that the sensor is positioned perpendicular to the center line of the shaft (see inset). Retighten the bolt to its normal torque.

6. Plug the end of the sensor cable into the input jack on the SWAN-1 analyzer.

7. Ensure that the "Test Interval" toggle switch is set at "15 Sec", and that the "Sensitivity" dial is set at "D".

8. Flip the "Power" toggle switch to "On"; then press the "Push to Read" button to activate the digital display. Note that the numbers appearing on the display will stop changing after 15 seconds; this is the cumulative "Stress Wave Energy" (SWE) value. The analyzer will continue to update the SWE value at 15-second intervals.

9. Record at least 10 consecutive SWE readings. If the recorded values consistently increase or decrease, continue to log SWE readings until the trend reverses or disappears.

10. To arrive at a final SWE value, compute the average of all the recorded readings; then round off the result to 2 significant figures. Compare the final SWE value against the general guidelines below; keep in mind that the ranges indicated are necessarily broad because of the variance between base line SWE values from one chiller to the next.

0 to 20,000 SWE ("D" sensitivity):	Typical at Initial Start-Up
20,000 to 40,000 SWE ("D" sensitivity):	"Normal" Thrust Bearing Wear
Over 40,000 SWE ("D" sensitivity):	Thrust Bearing Replacement May Be Indicated

Analyzing Rotational Imbalance

Measurements associated with this check not only verify that alignment of the compressor's rotating assembly did not shift during shipment and installation, but also establish "base line" readings that can be used for comparison with future rotational imbalance measurements. The best time to begin vibration analysis for trend logging purposes is at initial start-up.

Normally, rotational imbalance does not change once the unit is in operation; however, compressor rework can change the level of imbalance, just as worn motor bearings can sometimes magnify rotational imbalance.

Equipment Requirements. Our factory uses a "Scientific Atlanta Model 2521 Tracking Vibration Recorder" to analyze compressor rotation imbalance, though any one of a number of popular vibration analyzers can be used for this purpose. Just make sure that the analyzer you elect to use includes these features:

a. Battery-Powered Operation. Battery-powered meter operation is convenient for those job sites where building power is inaccessible. More importantly, though, this feature eliminates the erroneous vibration measurements that can be produced if an electrical ground loop exists.

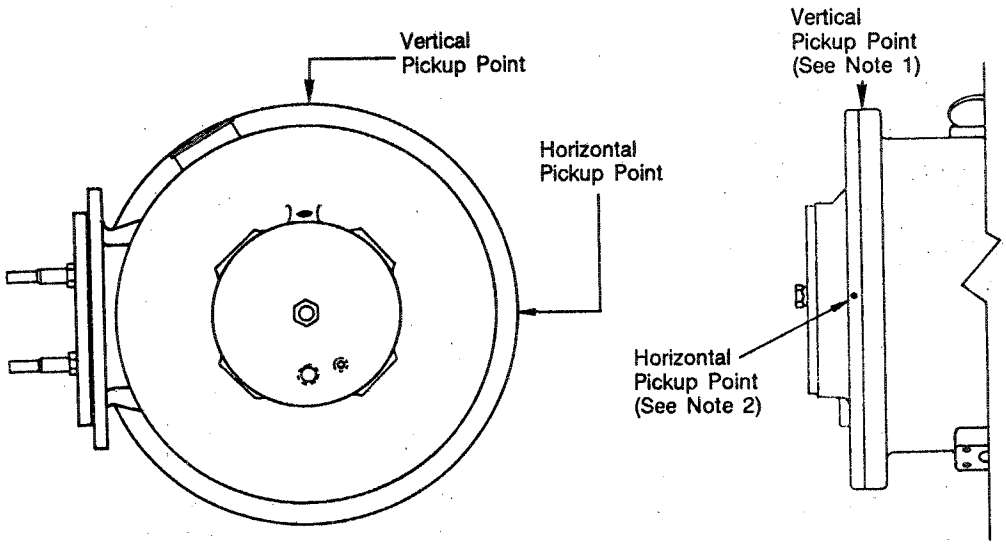
An "electrical ground loop" is an undesirable current flow that results when the ground potentials of 2 circuits differ. For example, an electrical ground loop may occur if the ground potential of a vibration analyzer plugged into a 115 VAC power supply differs from that of the chiller.

b. Analyzer Pickup Probe. To obtain consistent vibration readings in velocity ("in/sec peak") at high frequencies (over 1000 Hz), the meter must include an accelerometer with a magnetized base.

c. Scale. Make sure that the analyzer selected has a full-scale deflection sensitivity of 0.0 to 0.2 in/sec peak, minimum. To eliminate over-range plots and allow the user to monitor 2 frequency ranges (0-150 Hz and 0-1500 Hz), the meter scale and frequency ranges must be field-selectable, too.

Note: If an analyzer with the features described in "C" is not available, use an instrument that measures displacement (mils) and includes a tuneable filter (allowing the operator to adjust the meter to a specific frequency).

d. Output. To simplify measurement recording and analysis, the vibration meter used should produce a hard-copy, X-Y plot of velocity (in/sec) versus frequency (Hz).



* * * * *

Vibration Pickup Points. Rotational imbalance is indicated by the degree of horizontal and vertical vibration, and is always measured at the outboard end of the motor. Specific locations or "pickup points" for accelerometer placement are illustrated in Figure 2.

Before placing the accelerometer on the motor, remove all insulation, glue and excess paint from the surface of the bearing bracket at each "pickup point". To assure accelerometer stability and reading accuracy: (1) make sure that the surfaces of the vibration "pickup points" are smooth and clean; and, (2) position the accelerometer so that its magnetized legs are parallel to the rotor shaft.

When measuring horizontal and vertical vibration, tune the analyzer to the vibration peak at running speed (60 Hz) and at twice running speed (120 Hz). If the vibration analyzer generates a hard-copy report, use the low frequency scale (or the scale that covers the 0-150 Hz range) for these readings.

Figure 2
Measuring Vertical and Horizontal Vibration
(Scientific Atlanta Model 2521 Tracking Vibration Recorder)

Notes:
1. Vertical Vibration Measurement. Place the vibration analyzer pickup probe on the vertical axis of the outboard bearing bracket. Be sure to position the magnetized legs of the probe parallel to the rotor shaft to prevent rocking during vibration measurement.
2. Horizontal Vibration Measurement. Place the vibration analyzer pickup probe on the horizontal axis of the outboard bearing bracket. Be sure to position the magnetized legs of the probe parallel to the rotor shaft to prevent rocking during vibration measurement.

To determine whether or not compressor rotational imbalance falls within acceptable limits, compare the actual horizontal and vertical measurements obtained with the values shown in Table 1. Notice that this table indicates the maximum allowable horizontal/vertical vibration levels for 3 different unit configurations: (1) an air-run compressor (without the elbow); (2) an air-run unit (complete chiller without refrigerant); and, (3) a Freon-run unit (complete chiller with refrigerant). While the same pickup points are used for each of these variations, notice that the allowable vibration limits change from one configuration to the next.

Table 1
Maximum Allowable Horizontal and Vertical Vibration Levels at 60 Hz

Unit "Configuration"	Horizontal or Vertical Velocity at 60 Hz (Filtered)
Air-Run Compressor (w/o Suction Elbow)	0.10 in/sec peak
Air-Run Chiller (complete unit w/o refrigerant)	0.15 in/sec peak
Freon-Run Chiller (complete unit w/refrigerant)	0.25 in/sec peak

Section 2:
Checking Vibration After Unit Disassembly or Compressor Rework

Check the vibration level of the chiller when it is restarted following:

a. suction elbow removal;
b. removal of the entire motor/compressor assembly; or,
c. disassembly of any portion of the compressor's rotating assembly.

In all cases (where it is easy to do so), check the unit's vibration level before teardown. This provides a "base line" measurement that can be compared to the vibration level recorded after rework is completed.

Suction Elbow Removal

For those teardowns that require removal of the suction elbow---but the compressor is neither removed nor rebuilt, use the procedure outlined below to reinstall the elbow.

1. Set the elbow on the evaporator flange; then align it with the suction cover without using guide pins.

2. Insert 2 bolts through the suction cover flange at the 3 o'clock and 9 o'clock positions. Tighten both bolts enough to draw the elbow flush with the suction cover.

3. Install the evaporator flange bolts. Do not use pry bars or guide pins to align the bolt holes!

4. Using the appropriate bolt-tightening sequence, tighten the evaporator flange bolts to the specified torque.

5. Loosen the 2 bolts installed in the suction cover in Step 2, and watch for compressor-to-suction-elbow movement. Normally, the compressor will lift slightly when these bolts are loosened.

Inspect the gap between the suction elbow and suction cover. The width of this gap should be the same around the entire circumference of the joint. If the gap is uneven, note where the widest and narrowest widths are located.

Note: If the vibration levels recorded when the assembled unit is air-run exceed the maximum levels allowable (Table 1), it may be necessary to equalize this gap by realigning the elbow (where possible).

6. Install the bolts in the suction cover flange and tighten them to the specified torque; be sure to follow the appropriate bolt-tightening sequence.

7. Air-run the assembled unit; to do this, complete Steps 7a through 7f.

Caution: To prevent possible equipment damage when the compressor is air-run (with or without the suction elbow), exercise these precautions:
[ ] Lock the inlet guide vanes in the closed position.
[ ] Disable the transition circuit so that the starter cannot transition.
[ ] Isolate the water flows through the chiller to prevent condensate from forming on the tubes.
[ ] Do not start the compressor motor more than 5 times (3 times for across-the-line starters) without refrigerant cooling. After the 5th start (3rd start for across-the-line starters), allow the motor to cool down for at least 24 hours.

a. Lock the inlet guide vanes in the closed position.

b. Isolate the chilled water and condenser water flows so that condensation does not form on the tubes. (To enable the unit to run, the "proof-of-flow" circuits must be jumpered.)

c. Units w/Reduced-Voltage Starters Only. Disable the transition circuit to prevent the unit from running in the delta formation. The steps required to do this on "A"- through "J"-design CVHEs with classic control panels are shown in Figure 3; for "K"- and later-design CVHEs with UCP695 control panels, see Figure 4.

d. Start the chiller and run it for 10 minutes before recording any vibration readings. During this "warm-up" period, monitor the unit's vibration level with a vibration analyzer set up for running speed (i.e., 60 Hz or 3600 rpm).

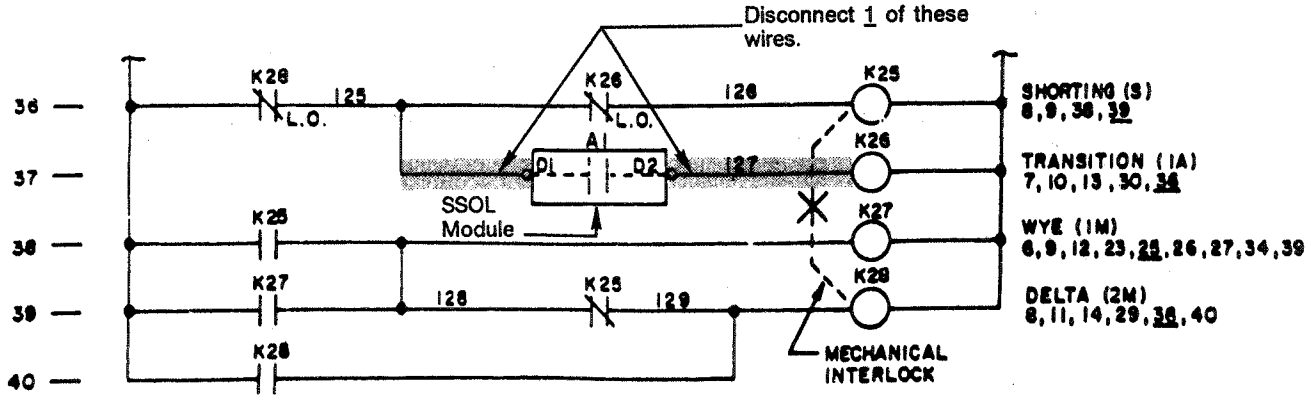
If the vibration level is excessive (i.e., exceeds 0.25 in/sec peak), shut down the compressor and prepare it for trim balancing.

e. Once the 10-minute "warm-up" period expires, take a complete set of vibration readings.

Note: If the vertical vibration is high---but all other readings are acceptable, loosen the motor support bracket (Figure 5) and retake both the vertical and horizontal vibration measurements. If the new vibration levels registered are higher than before, retighten the motor support bracket bolts; if the new measurements are lower, discard these bolts.

f. Shut down the compressor; then compare the horizontal and vertical vibration readings obtained with the allowable vibration levels shown in Table 1 for an air-run chiller.

If the actual vibration levels recorded are acceptable, evacuate the unit and charge it with refrigerant. However, if unit vibration exceeds the values shown in Table 1, realign the suction elbow.



Removal of the Entire Motor/Compressor Assembly

Occasionally, limited access at a job site makes it necessary to remove the entire motor/compressor assembly from the chiller before the unit can be installed. In this situation, it is important to dowel the motor/compressor assembly before it is removed from the shells to prevent the compressor components from shifting during the rigging process.

Normally, the "compressor removal for unit installation" requirement is known before the unit is ordered, making it possible to specify optional factory-dowelling. However, if field-dowelling is necessary, be sure to review the compressor dowelling instructions described in Trane General Service Bulletin CVHE-SB-10.

When the chiller is reassembled (i.e., the motor/compressor assembly is set on the shells), careful alignment of the discharge flange and compressor foot is of critical importance since it determines suction elbow alignment, as well. (Follow the elbow alignment procedure described under "Suction Elbow Removal" in Section 2 of this bulletin.)

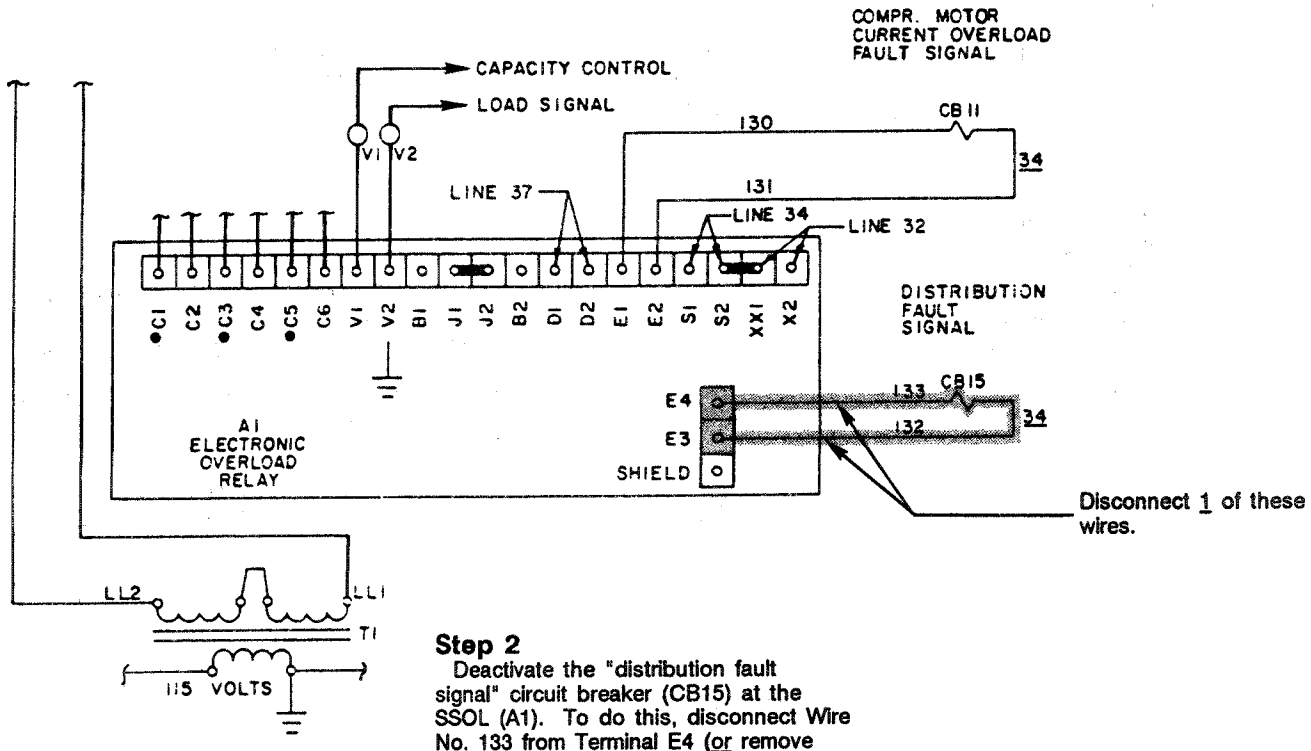


Figure 3
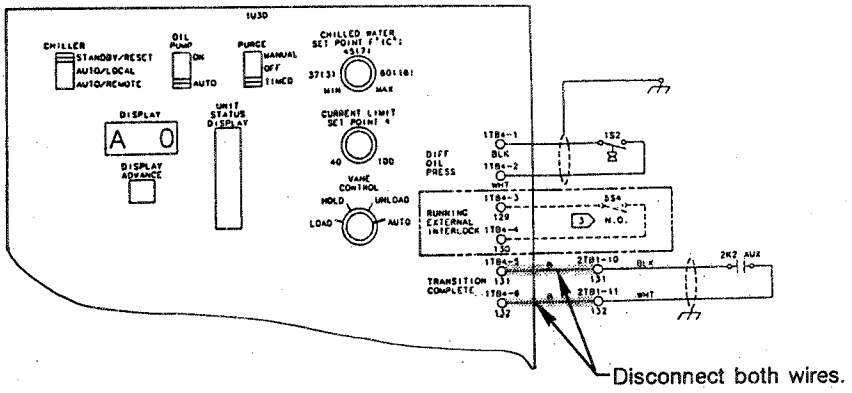
Air-Running a CVHE w/"Classic" Control Panel in the "Wye" Configuration

WARNING!
Disconnect electrical power supply to prevent injury or death due to electrical shock.

Step 1
Deactivate the starter panel's "transition" circuit. To do this, locate SSOL module A1 in the starter panel and remove Wire No. 125 from Terminal D1 (or remove Wire No.127 from Terminal D2).

Insulate the end of the disconnected wire with black electrician's tape.

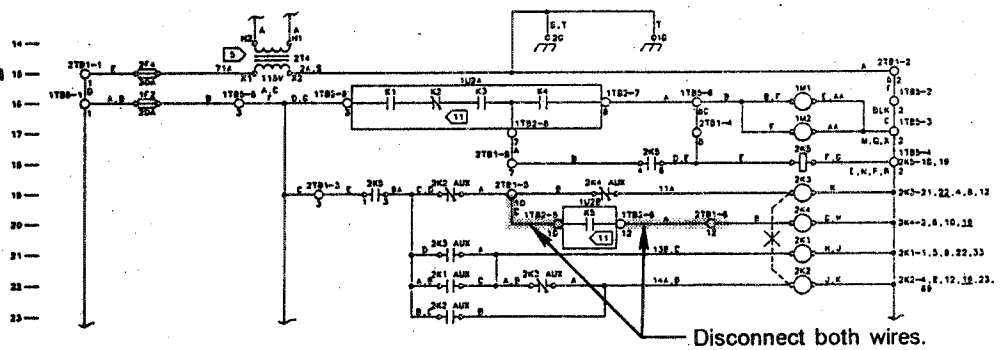
Step 2
Deactivate the "distribution fault signal" circuit breaker (CB15) at the SSOL (A1). To do this, disconnect Wire No. 133 from Terminal E4 (or remove Wire No. 132 from Terminal E3).



Insulate the end of the disconnected wire with black electrician's tape.

Figure 4
Air-Running a CVHE w/UCP695 Control Panel in the "Wye" Configuration

Step 1



Disconnect Wires 131B and 132B from micro module Terminals 1TB4-5 and -6, respectively. Wrap the exposed end of each lead with electrician's tape

WARNING!
Disconnect electrical power supply to prevent injury or death due to electrical shock.

Step 2

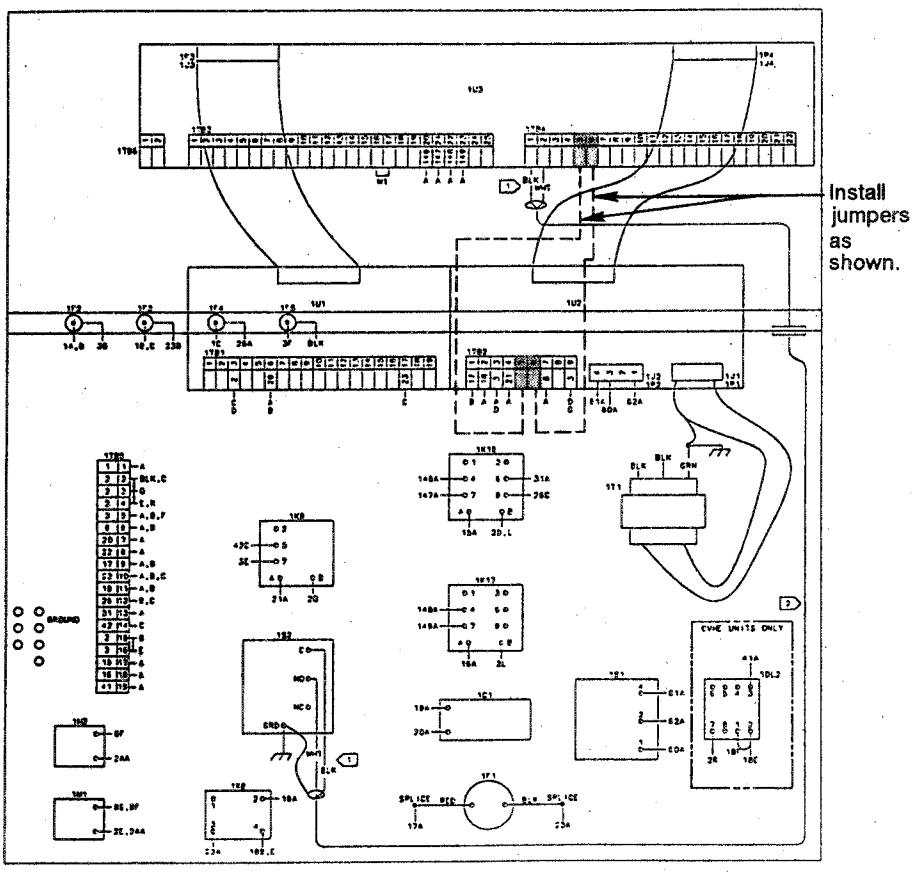
Disconnect Wires 10C and 12A from Terminals 1TB2-5 and -6 in the UCP. Insulate the free end of each wire with electrician's tape.

Step 3

Connect Terminals 1TB4-5 to 1TB2-5, and 1TB4-6 to 1TB2-6. Use #14 AWG, 600V copper wire.

Note: These connections prevent the starter from "transitioning" the compressor motor into the "delta" configuration.

Caution!
Exercise extreme care when connecting the 1TB4 terminals in the low-voltage (<30V) section of the UCP to the 1TB2 terminals in the 115V section. Improper connections in these temporary circuits can result in fatal damage to micro module 1U3.



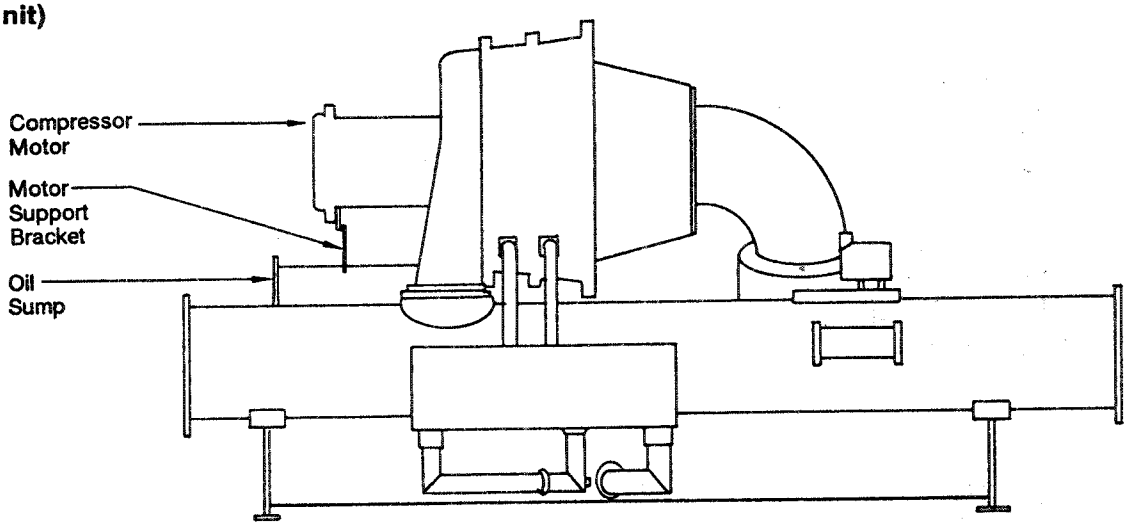


Figure 5
Motor Support Bracket Location
(Back View of Unit)

Compressor Disassembly

Whenever the compressor must be disassembled for any reason, be sure to comply with the recommendations outlined below.

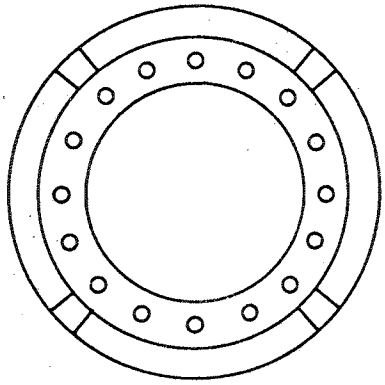
1. After removing the suction elbow and inlet guide vanes, examine the nut on the end of the compressor shaft. If the nut is a "trim balance" nut (see Figure 6), record the locations of the balance weights with respect to the keyway before removing the nut.

2. Complete the compressor teardown. During the teardown process, be sure to mark each component to indicate its relative position on the shaft.

3. Reassemble the compressor; follow the standard procedures described in the CVHE service guide (CTV-SG-2).

Important! As you install each impeller on the shaft, make sure that the keyway is facing up; this is especially important when the first-stage impeller is installed. The keyway must face up when the shaft nut is tightened.

Note: If the shaft nut is actually a "trim balance" nut, a couple of additional steps must be performed as the compressor is reassembled:



a. If none of the rotating assembly components were replaced, reinstall the trim balance nut so that the balancing weights are in their original positions (before the nut was removed) with respect to the keyway.

b. If any of the rotating assembly components were replaced, record the locations of the balancing weights in the nut; also, label each weight so that it can be replaced if necessary. Then, remove the balancing weights from the trim balance nut before reinstalling it on the shaft. (Imbalance problems are likely to occur if weights are added to the trim balance nut at this time.) Note that a standard, nonbalancing nut can be substituted for the trim balance nut in this situation.

4. Continue the standard rebuild procedure, including reinstallation of the inlet guide vanes. After the vanes are installed, air-run the compressor and monitor its vibration levels before reinstalling the suction elbow. (To air-run the compressor, see Step 7 of "Suction Elbow Removal" in Section 2 of this bulletin.)

Caution: To prevent possible equipment damage when the compressor is air-run (with or without the suction elbow), exercise these precautions:
[ ] Lock the inlet guide vanes in the closed position.
[ ] Disable the transition circuit so that the starter cannot transition.
[ ] Isolate the water flows through the chiller to prevent condensate from forming on the tubes.
[ ] Do not start the compressor motor more than 5 times (3 times for across-the-line starters) without refrigerant cooling. After the 5th start (3rd start for across-the-line starters), allow the motor to cool down for at least 24 hours.

Figure 6
Typical Trim Balance Nut
(Face of Nut Shown)

Note: The holes around the face of the trim balance nut are threaded. Several balance weights (i.e., bolts and washers) are installed in each trim balance nut, as shipped.

5. Compare the horizontal and vertical vibration measurements obtained in Step 4 with the allowable vibration levels listed in Table 1 for an air-run compressor.

If the levels of vibration are acceptable, reinstall the suction elbow on the unit. (Follow the instructions provided under "Suction Elbow Removal" in Section 2 of this bulletin.)

If unit vibration is not acceptable—and the compressor does not have a trim balance nut, the unit must be trim balanced. (See "Section 3: Trim Balancing" in this bulletin.)

If the compressor vibration measurements observed in Step 4 are unacceptable—but the unit does include a trim balance nut, reinstall the balance weights (removed in Step 3) at their original positions in the trim nut. Air-run the compressor again and check the vibration levels. If vibration still exceeds the maximum levels allowable, the compressor must be trim balanced. (See "Section 3: Trim Balancing".)

Note: If the horizontal and vertical vibration levels recorded following thrust bearing replacement are excessive, do not schedule the unit for trim balancing without first redoing the bearing installation and checking the amount of vibration that results.

Section 3:
Trim Balancing

Whenever any of the recommended vibration analyses described in this bulletin indicate an excessive amount of vibration, the compressor's entire rotating assembly must be balanced. Trim balancing a unit in the field requires a substantial investment in expensive vibration analysis equipment. The portable vibration analyzers typically used for fan balancing are usually unsuitable for balancing a CVHE compressor; they are not designed to provide the shaft orbit measurements that are critical for proper compressor balancing.

La Crosse service personnel use a Bentley Nevada Model DVF2 (plus supporting equipment) to trim balance CVHEs since it provides the sensitivity and features necessary for proper trim balancing. To trim balance the compressor, phase angle and the orbit of the compressor rotor shaft are tracked by noncontact "proximity" probes during initial and trial weight runs. (Because the probes must monitor a smooth surface, the standard shaft nut is replaced with a special trim balance nut.) Data recorded during these runs is then fed into a single-plane balance program that determines the amount of weight required at specific locations to balance the assembly.

* * * * *

Note: Occasionally, high compressor vibration levels can be reduced without trim balancing. If the rotational vibration analysis indicates a high level of vertical vibration, locate the shipping support bracket (Figure 5) mounted between the end of the motor and the oil sump; then loosen the 2 bolts that secure this bracket to the motor. If the vibration level improves, discard the 2 bolts.

A worn thrust bearing can also be responsible for excessive vibration. If no rework has been done on the unit to date and it goes out of balance after operating normally, try replacing the thrust bearing before scheduling the unit for trim balancing.

For further information on this product or other Trane products, refer to the "Trane Service Literature Catalog", ordering number IDX-IOM-1. This catalog contains listings and prices for all service literature sold by Trane. The catalog may be ordered by sending a $20.00 check to: The Trane Company, Service Literature Sales, 3600 Pammel Creek Road, La Crosse, WI 54601.

Subject: CVHE Oil Pressure Loss during Start-Up

Introduction:

Under certain conditions, a CVHE unit will trip on "low oil pressure" during the chiller's start sequence. This can be a nuisance for the owner/operator since a manual reset is required to resume operation. This bulletin describes the condition that prompts a nuisance "low oil pressure" trip during start-up, and recommends corrective action that will prevent this type of trip from recurring.

Discussion:

During each chiller "off" cycle, refrigerant migrates into the oil sump until an oil-refrigerant equilibrium is established at sump temperature and unit pressure. When the unit cycles on again, oil pump operation is initiated as the chiller progresses through its start sequence. With the oil pump running, oil pressure gradually increases to the "cut-in" value (15 psig) of the oil pressure differential switch. (Remember that this control "monitors" the difference between the refrigerant pressures in the oil sump and at the oil pump discharge.) Closure of this switch indicates that sufficient oil pressure exists; the unit control panel then issues a "start" signal to the starter panel to initiate compressor operation.

Because the oil sump is vented to the cavity between the first-stage inlet vanes and the first-stage impeller (i.e., lowest pressure in the unit), sump pressure drops dramatically as soon as compressor rotation begins. This pressure drop creates a new equilibrium point for the oil-refrigerant mixture in the oil sump. At the new equilibrium, the oil is unable to absorb as much refrigerant; this induces the excess refrigerant to vaporize, which—in turn—causes the oil to foam.

The oil pump continues to pump the now foaming oil. However, since the oil is discharged from the pump at a pressure higher than that existing in the sump, the refrigerant vapor trapped in the oil liquefies. When this change of state occurs, the volume of the oil-refrigerant mixture decreases significantly, and the pressure drop that accompanies this phenomenon can be severe enough to trip the unit's low oil pressure safety.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Units Affected:

All CVHE units of "A" through "L" designs are vulnerable to this nuisance "low oil pressure" condition during start-up. CVHE's of "M" and subsequent designs include a time delay relay and solenoid valve that temporarily reduces the amount of oil sump venting during the chiller start sequence. This prevents the loss of oil pressure that can occur during start-up by isolating the oil sump from the low-pressure cavity at the opposite end of the sump vent line.

Note: To determine the design sequence of a particular unit, check the 10th digit of the model number stamped on the chiller nameplate.

Corrective Action:

Add a solenoid vent-line valve and time delay relay to any "A"- through "L"-design CVHE application that is troubled by nuisance tripping of the low oil pressure control. Figure 1 indicates the installation location for the solenoid valve; notice that the direction of flow is from the oil tank to the suction cover. Figures 2 and 3 show the necessary wiring connections for "old"-style and UCP695 control panels.

Once installed and properly wired, the time delay relay will energize whenever the unit control panel issues a "start" signal to the starter panel. Once this time delay relay energizes, it will close the normally-open, solenoid vent-line valve for a period of approximately 2 minutes. After the 2-minute timing period expires, the solenoid valve will open completely, allowing full flow through the sump vent line during normal machine operation.

Note: The solenoid vent-line valve assembly includes a manual lift-stem accessory that must be field-adjusted to allow some venting of the oil tank to occur during the 2-minute time delay period. Use the following procedure to properly adjust the valve's manual lift-stem:

1. Turn the manual lift-stem screw (on the bottom of the valve assembly) counterclockwise as far as possible.

2. Electrically energize the solenoid valve to close it; then apply a small amount of air pressure (i.e., approximately 2-3 psig) to the inlet side of the solenoid valve.

3. Turn the adjusting stem clockwise until the valve just begins to allow air to bleed through it. At this point, mark the stem position in relationship to the valve body.

4. Once the "bleed-through" point described in Step 3 is established and marked, turn the adjusting stem an additional 1/4-turn clockwise. This final adjustment will unseat the valve far enough to allow some venting to occur during the initial 2-minute timing period.

Once the solenoid vent-line valve is properly set up, no further field adjustment is necessary.

Parts Ordering Information:

One solenoid vent-line valve, 1 time delay relay and 1 relay base are required for each affected CVHE unit; see Figure 4. Order these parts from La Crosse, "Ship from 31", and specify the part numbers identified below:

RLY-1102 = Time Delay Relay (1 required)
PLU-0172 = Plug-in Base for Relay (1 required)
VAL-2690 = Solenoid Valve (1 required)

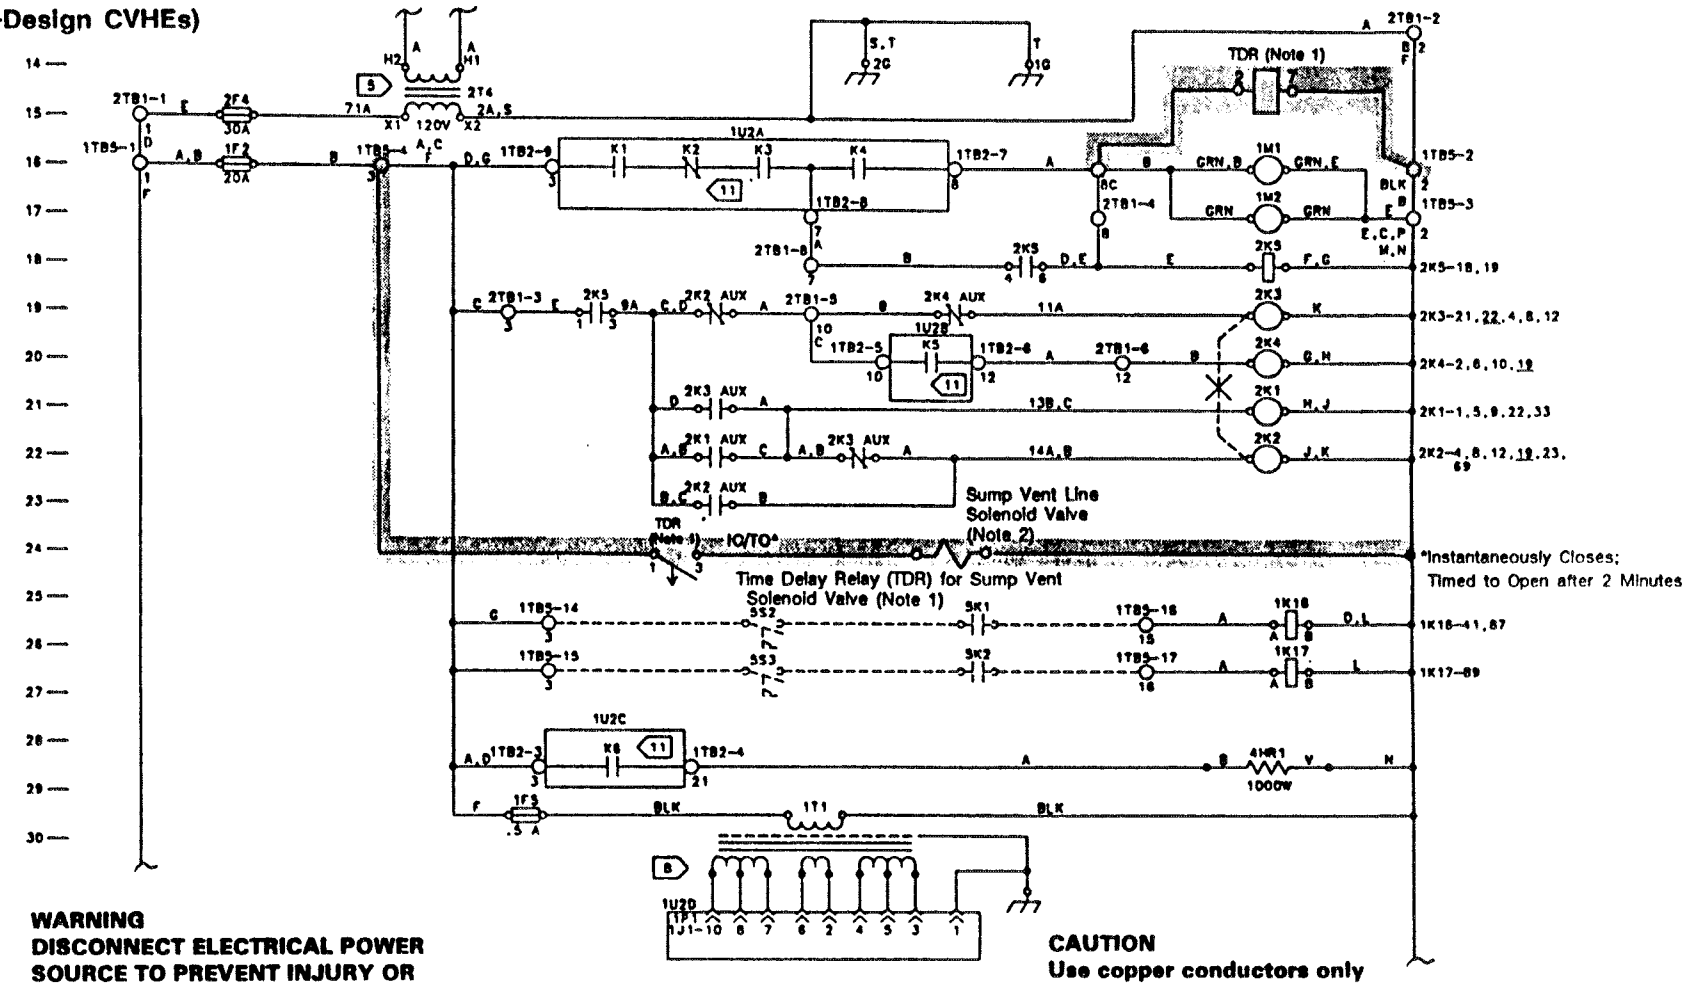
Wiring Connections Required
for "Old"-Style CVHE Control Panels
("A"- thru "J"-Design CVHEs)

WARNING
DISCONNECT ELECTRICAL POWER SOURCE TO PREVENT INJURY OR DEATH FROM ELECTRICAL SHOCK

CAUTION
Use copper conductors only to prevent equipment damage

Notes:



1. Wire the coil of the sump vent line time delay relay (TDR) into the "start-stop signal" circuit of the unit control panel, as shown above; then wire a set of normally-open TDR contacts in series with solenoid valve installed in the oil sump vent line. This electrical configuration assures that the solenoid valve closes the sump vent line as soon as the unit control panel issues a "start" signal to the starter panel.

Be sure to use TDR Terminals 2 and 7 to wire the coil, and TDR Terminals 1 and 3 to wire the normally-open TDR contacts upstream of the solenoid valve.

2. The solenoid valve field-installed in the oil sump vent line is normally open. When the TDR energizes, its normally-open contacts close for approximately 2 minutes; during this period, the solenoid valve in the oil sump vent line is closed.

Sequence	21A
Date	6/7/89
File No.	SV-RF-CTV-CVHE-SB-21A-689
Supersedes	CVHE-SB-21 5/88

Literature Changes:
CVHE-SB-21 (5/88) – Original issue of bulletin
CVHE-SB-21A (6/89) – Bulletin revised, to include additional purge maintenance and checkout procedures.

Subject: CVHE/CVHB Oilless (ITT) Purge Compressor Rebuild Kit/Maintenance Checks

Introduction:

Effective approximately May 15, 1988, the ITT oilless purge compressor rebuild kit was upgraded to include additional parts. At that time, KIT-1043 became obsolete and was replaced by KIT-1346.

This bulletin does not authorize replacement material and is intended for informational purposes only.

Discussion:

ITT oilless purge compressors rebuilt with Trane KIT-1043 were not always successful for 2 reasons: First, replacement of the compressor cylinder liner was sometimes necessary due to corrosion; and, second, the piston ring was difficult to install without detailed instructions.

To improve the likelihood of a successful purge compressor rebuild, a cylinder liner and compressor rebuild instruction sheet are being added to the purge compressor rebuild kit. With these additions, the new ITT oilless purge compressor kit, KIT-1346, will include the items listed below.

KIT-1346 Contents
(1) piston ring U-cup
(1) piston skirt
(1) 10-32 x 3/8" piston-head screw
(1) cylinder head gasket
(1) cylinder liner gasket
(2) reed valves
(1) cylinder liner
(1) "compressor rebuild" instruction sheet

Note that the piston and valve plate are not included in the standard oilless purge compressor rebuild kit (KIT-1346). Inspect the piston and valve plate periodically, and replace them only when necessary.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Purge Unit Maintenance

The ITT oilless purge compressor has a useful service life of 700 to 800 hours of operation, depending on the environment to which it is exposed. This performance level has been obtained through the use of rings specifically designed for this application.

As a part of the routine maintenance program for the purge unit, rebuild the purge compressor after every 700 hours of operation—or sooner, if the compressor fails the "leak-back" check outlined below. Shop rebuild as opposed to field rebuild is recommended to obtain reliable performance. A one-hour "run-in" period after rebuild is needed to seat the compressor ring before the compressor-ring-leak-back check test is performed.

Compressor Ring "Leak-Back" Check

1. Turn off the purge compressor.

2. Remove the suction and discharge lines from the purge compressor. Be sure to plug the lines to the condenser and purge drum to prevent air from entering the unit.

3. Install a pressure gauge on the purge compressor's discharge port; then run the compressor. With the discharge blocked and air entering the suction, it should be possible to develop a minimum pressure of 50 psig.

If you are unable to obtain a gauge reading of at least 50 psig, a problem exists with the valves or piston rings.

4. Turn off the compressor.

5. Plug the purge compressor discharge port.

6. Attach a pressure gauge and shutoff valve to the suction side of the purge compressor. Make sure that the shutoff valve is upstream of the pressure gauge.

7. Open the shutoff valve, and pump compressed air into the purge compressor until the pressure gauge registers 35 psig; then close the shutoff valve.

Start a stop watch when gauge pressure drops to 30 psig and time for 10 seconds. If, after 10 seconds, the head pressure falls below 20 psig, piston ring replacement is indicated.

Note: Replacement of the compressor rings with standard parts will result in a refrigerant-loss rate that is approximately 8 times greater than the leakage rate associated with Trane parts.

Important: Some leakage around the head gasket—and from the cylinder liner—is normal. If this leakage is excessive, a new cylinder head may be required to achieve a satisfactory leak rate. Do not use excessive torque when installing suction and discharge adaptors since this may distort the head. After installing a new piston ring, be sure to operate the purge compressor for 1 hour to "run-in" the new ring; then perform another "leak-back" check.

Other Maintenance Checks

Compressor Suction Solenoid

The suction solenoid is used to isolate the condenser when the purge is off. The solenoid is installed with the directional arrow pointing toward the purge compressor suction. This position provides a positive seal to keep freon from leaving the machine and air from entering, down to a minimum vacuum of 14-inches mercury. The solenoid must be checked periodically to insure proper operation. The solenoid can be tested whenever the compressor-ring leak-back check is performed. Remove the condenser connection and perform items 6 and 7 of the compressor-ring leak-back check. Apply 30 psig to the solenoid to determine if the solenoid leaks, then energize the solenoid coil and complete the compressor-ring checkout.

Discharge Check Valve

The compressor discharge check valve can get dirty which will keep it from seating or cause the compressor to operate at a higher discharge pressure, increasing piston seal leakage.

To test the check-valve, open the discharge line at the compressor and with pressure in the purge condenser sump, leak check the open end of the check-valve. The check-valve should also be removed and inspected for obstructions.

Compressor Vibration

Current-production machines have a pig-tail in the compressor discharge line to minimize the transmission of compressor vibration. Although not mandatory, it is advisable to change the compressor discharge line-size to 1/4-inch and add a pig-tail whenever practical.

Purge Operation

The primary function of the ITT purge is to remove non-condensables from the machine when it is operating. A machine with a normal leak-rate will require no more than 1/2-hour of purging per week to maintain efficient operation. If the purge is turned on with the machine as a method to maintain chiller performance or for other reasons, excessive amounts of freon will be lost. Since the optimum freon charge is important to efficient chiller operation, excessive purging can significantly affect CVHE performance during a typical cooling season.

Due to the non-hermetic design of the ITT compressor, recommended purge run-time should not exceed ten minutes per every 2 hours of unit operation. In many cases, this is much more than needed to maintain efficient machine performance. In those cases where the owner demands simultaneous purge and machine operation, freon moisture filtration should be recommended as an alternative to continuous purge operation.

Units Affected:

The updated ITT purge compressor rebuild kit, KIT-1346, is usable for the oilless purge compressors factory-installed on CVHE and CVHB CenTraVacs shipped in late May 1984 and thereafter. It can also be used to rebuild the purge compressors included as an option with the UCP695 (micro panel) retrofit kit.

Recommended Action:

Whenever an ITT oilless purge compressor must be rebuilt, use existing KIT-1043 plus cylinder liner LNR-0062 until local stock is depleted. New rebuild kits—KIT-1346—are now available from La Crosse stock.

General Service Bulletin

CVHE-SB-22A

Library	Service Literature
Product Section	Refrigeration
Product	Centrifugal Liquid Chillers
Model	CVHB, CVHE CVHF
Literature Type	General Service Bulletin
Sequence	22A
Date	March 23, 1993
File No.	SV-RF-CTV-CVHE-SB-22A-393
Supersedes	CVHE-SB-22 Dated 9/7/88

Literature Changes:
CVHE-SB-22 (9/88) - Original Service Bulletin.
CVHE-SB-22A (3/93) - Bulletin revised to update electrical schematics, cover UCP revisions and Purifier Purge implementation.

Subject: Control Operation, Setup and Troubleshooting for CVHB, CVHE and CVHF Centrifugal Chillers with UCP-695 Control Panels

Introduction:

The purpose of this service bulletin is to provide control operation and general troubleshooting information for Trane CenTraVac Model CVHB, CVHE and CVHF units that are equipped with Trane UPC-695 unit-mounted microprocessor control panel.

Discussion:

The following control information is only applicable to CVHE units that are "K" design sequence and later; CVHB units that are "V" design sequence and later, and to all CVHF units w/UCP695.

Although this information applies generally to all design sequences indicated above, the wiring diagrams that appear in this service bulletin apply to specific design sequences only. Check the 10th digit of the unit model number (stamped on the chiller nameplate) to determine its design sequence.

Caution: Be sure to refer to wiring diagrams that apply specifically to the design sequence of the unit being serviced.

Micro Module 1U3 Overview

The micro module (1U3) information presented in this section is subdivided into 4 categories:

[ ] **Operator Interface**, which provides information on control setpoints and display data that is typically accessed on a daily basis;

[ ] **Service Interface**, which contains information on control setpoints that are normally only adjusted at initial chiller start-up; and,

[ ] **Factory DIP Switch Settings**, which includes information about unit configuration. Control settings described in this subsection are provided for information only, and are normally performed in the factory so no field adjustments are normally required.

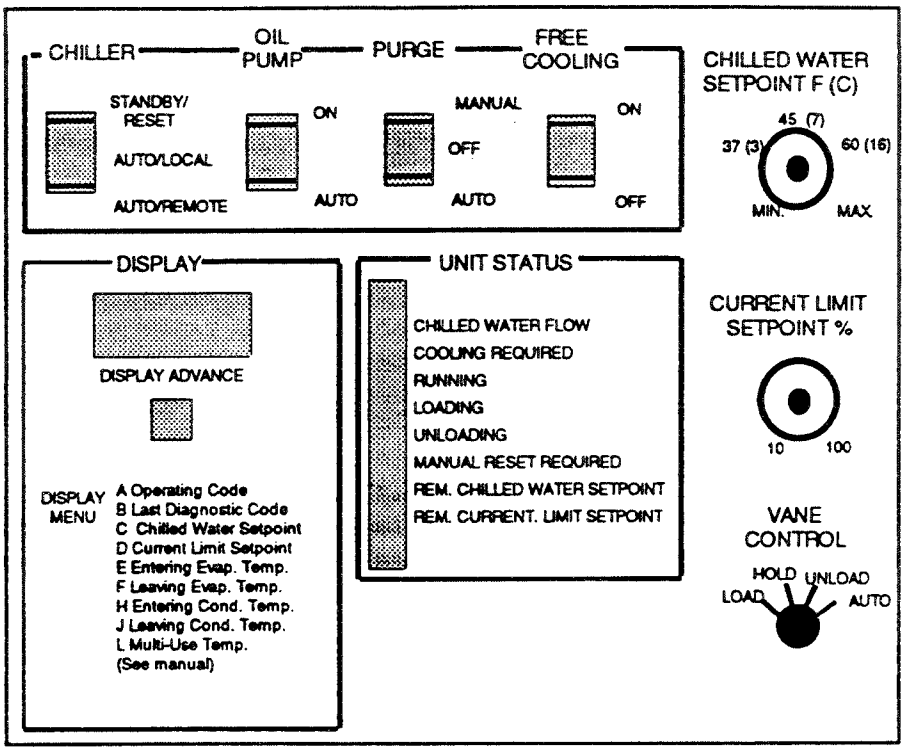
[ ] **Input Connections**, a description of the three micro module terminal strips (i.e., 1TB6, 1TB3 and 1TB4)--and the devices connected to them--comprises the remainder of this section.

Operator Interface

Monitoring devices and all chiller control components requiring adjustment for normal chiller operation are accessible without opening the unit control panel door. These components, which are a part of micro module 1U3, are illustrated in Figure 1 and discussed in the following paragraphs.

Chiller Switch

Located above the display window on the micro module, this 3-position switch enables the owner/operator to define chiller control mode:



[ ] **Standby/Reset.** When power is applied to the unit with the chiller switch set at STANDBY/RESET, the UCP is activated but unit operation is prohibited; operating code **A O** appears on the display. This switch position can be used by the operator or service technician to clear a latching diagnostic (i.e., fault that requires manual reset), or to shut down the unit.

[ ] **Auto/Local.** This switch position allows the chiller to run automatically, using the operational setpoints set at the unit.

[ ] **Auto/Remote.** With the chiller switch in this position, the unit runs automatically using the setpoints established at a remote device and communicated to the chiller with the optional serial communication interface (SCI). (If no setpoints are sent by the remote controller, the UCP uses the operational setpoints set at the unit control panel.)

Note: When the unit is equipped with the SCI option, a SCP699 or Trane BAS can place the unit in the STANDBY/RESET mode even though the chiller switch is positioned at AUTO/REMOTE. However, a latching diagnostic condition at the unit cannot be cleared from a remote device.

Figure 1
Operator Control Panel

Notes:

1. Control panel shown applies to :
   CVHE = Des. Seq. 1C & later;
   CVHB = Des. Seq. 1D & later;
   CVHF = All Units.w/UCP695.
2. Item "L" on Display Menu available on above design sequences only.
3. Purge switch positions are MANUAL/OFF/TIMED for units of earlier design sequences.
4. All controls shown accessible without opening UCP door.
5. Free Cooling switch is optional.

Oil Pump Switch

A 2-position oil pump switch is located to the right of the chiller switch, above the display window. Switch position functions are described below:

[ ] On. This switch position provides continuous operation of the oil pump, even when the chiller switch is positioned at STANDBY/RESET.

Note: The ON switch position is designed for use by service personnel only; do not leave it in this position! The compressor will not start if the oil pump switch is in the ON position. Latching diagnostic code **b E8** will flash alternately with operating code **A 72** on the UCP's display.

[ ] Auto. Oil pump operation is controlled by the UCP, ensuring oil flow when the compressor is running. This is the normal switch operating position.

Purge Switch

Located next to the oil pump switch (Figure 1), the purge switch enables the owner/operator to select 1 of 3 purge operational modes.

[ ] Manual. This switch position provides continuous operation of the purge compressor, regardless of centrifugal compressor operation, or the position of the chiller switch.

[ ] Off. Purge operation will not occur when the purge switch is set at this position for CVHE units of design sequence "1C" and later, CVHB units, design sequence "1D" and and later, and all CVHF units (equipped with UCP695 and a Purifier Purge). For all units with design sequences earlier than this, purge operation will not occur when the switch is set in the OFF position, unless the purge compressor is already operating due to

closure of the purge run delay timer (3DL1) contacts. Refer to the chiller operation and maintenance literature for a further explanation of purge unit operation.

WARNING!: To prevent injury or death due to electrical shock, open unit disconnect switch before servicing to ensure purge unit is de-energized.

[ ] Timed. CVHE Units = Design Sequence "1B" and earlier only.
CVHB Units = Design Sequence "1C" and earlier only.

This is the normal switch operating position. When switch is in TIMED position, the purge compressor will operate for 5 minutes out of every 2-hour interval. Purge time is automatically extended whenever sufficient noncondensibles remain in the unit since the 4-minute purge timer (3DL1) is reset every time the purge pressure switch trips. (This is true even if the purge switch is readjusted to the OFF position.)

It is important to note that if the chiller is shut down when the purge switch is set at TIMED, the purge will continue to operate for 5 minutes out of every 2-hour period only if the chiller switch is set at either AUTO/LOCAL or AUTO/REMOTE and there is chilled water flow.

If the chiller switch is set at STANDBY/RESET and the purge switch is set at TIMED, the purge unit is also shut down (i.e., provided that 4-minute purge run delay timer 3DL1 has timed out). However, if the chiller switch is set at STANDBY/RESET and the purge switch is set at MANUAL, the purge compressor will run continuously!

[ ] Auto. CVHE Units = Design Sequence "1C" and later only.
CVHB Units = Design Sequence "1D" and later only.
CVHF Units = All units with UCP695.

These units are equipped with the air-cooled Purifier Purge. AUTO is the normal switch operating position. (There is no TIMED switch position.) With this switch set at AUTO, the purge will run continuously when the CenTraVac is in powered cooling operation.

If the chiller switch is set at STANDBY/RESET and the purge switch is set at AUTO, the purge unit is also shut down. However, if the chiller switch is set at STANDBY/RESET and the purge switch is set at MANUAL, the purge compressor will run continuously! On those units equipped with more than one condenser, purge only from the active condenser. Use the manual valves provided to isolate the inactive condenser.

Note: The UCP must be properly configured for the type of purge system provided on the chiller at Dip Switch # 1 on switch block S9 of the UCP. This applies to CVHE units of design sequence "1C" and later, CVHB units, design sequence "1D" and and later, and all CVHF units with UCP695. Refer to "Factory Dip Switch Settings" in this bulletin.

Free Cooling Switch (Optional)

Free cooling enables the chiller to function as a simple heat exchanger, using refrigerant as the working fluid; however, it does not provide control of the leaving chilled water temperature. When condenser water is available at temperatures lower than the desired chilled water temperature, the free cooling option provides "average selection" chiller capacity without operating the compressor.

When the free cooling option is ordered, this two-position switch, located next to the purge switch, allows the operator to select 1 of 2 switch operating positions:

[ ] On. Placing the free cooling switch in this position forces the chiller to enter the free cooling mode (**A 9**); the compressor shuts down if the unit is operating in the powered cooling mode.

Note: Operating code **A 9** appears on the display once the free cooling valves are open; the unit cannot return to the powered cooling mode until these valves are closed. Remember, too, that when the unit is equipped with the SCI option, a remote device can "turn off" free cooling operation while the free cooling switch is set at ON.

[ ] **Off.** This setting enables normal chiller operation within the parameters established for the powered cooling mode. There is a 2-minute delay of the load pulse after start-up.

Note: When the unit is equipped with the SCI option, a remote device can "turn on" the free cooling function while the free cooling switch is positioned at OFF (i.e., provided that the chiller switch is set at AUTO/REMOTE).

Chilled Water Setpoint Potentiometer

Used to set the leaving chilled water temperature, this manually adjustable potentiometer is located at the right-hand side of the window in the control panel door (Figure 1). Available dial settings range from MIN to MAX, with intermediate temperatures indicated in degrees F as well as degrees C. Control deadband is ± 1 F.

To view the front panel chilled water setpoint, adjust the vane control switch to HOLD and press the display advance pushbutton until the "⊢ " code prefix appears on the display. The integer value (i.e., in increments of 1 F or 1 C) immediately to the right of "⊢ " is the UCP's chilled water setpoint. Standard operating range is 37 to 60 F (3 to 16 C), while the temperature range for extended operation is 20 to 70 F (- 6 to 22 C).

Note: To view the active chilled water setpoint, check the entry for code prefix **"C"** of the operator's menu. When the chiller is set at AUTO/REMOTE, and the "Remote Chilled Water Setpoint" status light is lit, the **"C"** value displayed was entered at a remote system control panel (SCP).

Current Limit Setpoint Potentiometer

Located directly below the chilled water setpoint control, this manually adjustable potentiometer is used to register the desired current limit setpoint. Dial settings range from 40% to 100% of the compressor rated-load-amps (RLA) value.

To view the front panel current limit setpoint, turn the vane control switch to HOLD and press the display advance pushbutton until the " ⎯ " code prefix appears on the display; the integer value (i.e., indicated in increments of 1%) at the right of " ⎯ " is the UCP's current limit setpoint.

Note: To check the active current limit setpoint, locate the entry for code prefix **"d"** in the operator's menu. Whenever the chiller switch is set at AUTO/REMOTE and the "Remote Current Limit Setpoint" status light is lit, the **"d"** value displayed was set at the a remote system control panel (SCP).

Vane Control Switch

The four-position, compressor inlet guide vane control switch is located beneath the current limit setpoint control. Each switch position is described below:

[ ] **Load.** As long as the vane control switch remains in this position, the "vanes open" (1U1Q7) relay is continuously energized and automatic vane control is suspended during the "Normal Run" mode (**A 74**). Manual loading does not take precedence over the current limit (**A 75**), condenser limit (**A 76**), or evaporator limit (**A 77**) modes of operation.

[ ] **Hold.** With the vane control switch set at HOLD, both the "vanes open" (1U1Q7) and "vanes close" (1U1Q8) relays are de-energized, so the inlet guide vanes remain at their current position. Automatic vane control is suspended when the unit is in the "Normal Run" mode (**A 74**). However, a current limit (**A 75**), condenser limit (**A 76**), or evaporator limit (**A 77**) mode will override the manual "hold" setting.

Note: Positioning the vane control switch at HOLD redefines the menu of codes appearing on the UCP's display. See " Operator's Display".

[ ] **Unload.** As long as the vane control switch remains in this position, the "vanes close" relay (1U1Q8) is continuously energized and automatic vane control is suspended regardless of the chiller's operating mode.

[ ] **Auto.** Inlet guide vane position is automatically controlled by the UCP when the vane control switch is in AUTO position.

Unit Status Lights

A series of eight status indicator lights are located directly below the purge switch. These blue lights, along with the operating and diagnostic information found on the display, allow the operator to monitor unit operation. The purpose of each status indicator light is described below.

[ ] **Chilled Water Flow.** Illumination of this light indicates that the chilled water flow switch 5S2 is closed.

[ ] **Cooling Required.** This light only illuminates when the UCP proves chilled water flow and detects a cooling requirement (i.e., leaving chilled water temperature exceeds the chilled water setpoint by a value greater than the differential-to-start criteria).

[ ] **Running.** Illumination of this status light indicates that:

- the unit is running (or is in one of the "run" modes);
- the chiller switch is set at AUTO/LOCAL or AUTO/REMOTE, and;
- the start sequence (or transition) is complete. It also remains lit through the chiller's post-lube cycle after the compressor shuts down.

[ ] **Loading.** When this light pulses (on and off), the UCP is loading the chiller (i.e., the vane actuator is driving the vanes open). There is a two-minute delay between unit start-up and load pulse initiation.

[ ] **Unloading.** When this light is on, the UCP is unloading the chiller (i.e., the vane actuator is driving the vanes closed).

Note: It is normal for the "Loading" and "Unloading" status lights to flash on and off in short pulses.

[ ] **Manual Reset Required.** Illumination of this light indicates that the UCP detected a "latching" diagnostic condition and shut down the chiller. Operation cannot resume until the UCP is manually reset (i.e., chiller switch is turned to STANDBY/RESET, then back to AUTO/LOCAL or AUTO/REMOTE).

[ ] **Remote Chilled Water Setpoint.** When this light is on, the UCP is ignoring its front panel chilled water setpoint, and is using the remote chilled water setpoint:

- determined by the optional chilled water reset module, or;
- entered at a remote source (i.e., an SCP699 system control panel or a Trane BAS).

It also illuminates if the chilled water reset function is active. If remote communications are severed, the UCP "defaults" to the control value of its chilled water setpoint potentiometer.

[ ] Remote Current Limit Setpoint. Illumination of this light indicates that the UCP is using a current limit setpoint communicated from a remote source (e.g., SCP or Trane BAS), and is ignoring its front panel current limit setpoint. Again, if remote communications are severed, the UCP "defaults" to the control value set with the current limit setpoint potentiometer.

Operator's Display

The UCP operator's display consists of a blue, four-digit vacuum fluorescent display and a display advance pushbutton. Both are located to the left of the unit status indicator lights. See Figure 1. The first letter of the four-character display identifies the type of data shown in the display window. A list of these indicator codes, along with their meanings, is provided in Table 1. An abbreviated version of this list is also provided on the face of the UCP, directly below the display advance pushbutton.

Table 1
UCP Display Menus

Operator's Menu		Serviceman's Menu (1, 2)	
Code Prefix	Parameter Description	Code Prefix	Parameter Description (and Display Range)
A	Operating Mode (see Table 2)	A	Operating Mode (see Table 2)
b	Last Diagnostic (see Table 3)	b	Last Diagnostic (see Table 3)
C	Active Chilled Water Setpoint: Std. Range = 37-60 F (3-16 C) Extd. Range = 20-70 F (-6-22 C)	c	Panel Chilled Water Setpoint (---, 20-70 F, ---)(---, -6-22 C, ---)
d	Active Current Limit Setpoint (40% thru 100% RLA)	-	Panel Current Limit Setpoint (---, 40% thru 100% RLA, ---)
E	Entering Evap. Water Temp. (Opt.) (---, 12-91 F, ---)(---, -11-33 C, ---)	_	Evaporator Refrigerant Temp. (3) (b Ad, -4-42 F, ---)(b Ad, -20-6 C, ---)

H	Entering Cond. Water Temp. (Opt.) (---, 28-142 F, ---)(---, -2-62 C, ---)	O	Start Differential Setpoint (2-10 F) ((-17 thru -12 C)
J	Leaving Cond. Water Temp. (Opt.) (---, 28-142 F, ---)(---, -2-62 C, ---)	P	Condenser Limit Setpoint (80-120% HPC)
L	Multi-Use Temperature (4) (---, -5-135 F, ---)	U	Evap. Refg. Trip Setpoint (b A3) Std. Range = 29-34 F (-1 thru 1 C) Extd. Range = 0-34 F (-18 thru 1 C)

Notes:
1. To redefine the "operator's menu" to the "serviceman's menu" turn vane control switch to HOLD.
2. For additional information on any item listed in the "serviceman's menu", contact a qualified service organization.
3. Actual measured evaporator refrigerant temperature.
4. "Multi-Use Temp." applications are: Cond. Lvg. Refg. Temp.; CWR Ambient Temp.; CWR Temp. from Analog Input. (This feature applies to CVHE units "1C" design sequence and later, CVHB units "1D" design sequence and later, and to all CVHF w/UCP695.)

The three remaining alphanumeric characters of the display indicate unit operating mode, diagnostic condition, setpoints or actual temperatures as defined by the code prefix. Refer to Tables 1, 2 and 3. A code prefix of **"A"** or **"b"** is followed by a space and a two-digit operating code (Table 2) or diagnostic code (Table 3), respectively.

Note: If the UCP detects a diagnostic condition, it alternately flashes the appropriate diagnostic code and the unit operating mode (at the time of shutdown) on the display. Latching diagnostic conditions can only be cleared manually at the unit, and not from a higher level device (i.e., SCP699 or Trane BAS). In the case of multiple diagnostic condition, only the last diagnostic is displayed.

Table 2
Codes for Unit Operating Modes

4-Character Code	Operating Mode Description
Blank	Power Off
A 0	Standby/Reset
A 1	Auto (Local or Remote)
A 9	Free Cooling
A 70	Restart Inhibit
A 71	Establish Cond. Water Flow
A 72	Start
A 74	Run: Normal
A 75	Run: Current Limit (1)
A 76	Run: Condenser Limit (2)
A 77	Run: Evaporator Limit (3)
A 78	Run: Surge Condition (4)
A 79	Post-Lube
A 88	Reset
A100 (5)	External Inhibit (Remote Start/Stop)

Notes:
1. As current limit setpoint is approached, 1U3 restricts further opening of the inlet guide vanes.
2. As condenser limit setpoint is reached, 1U3 restricts additional compressor loading to avoid shutdown on high condenser pressure (b F5) and initiates "head relief request" (i.e., optional relay).
3. 1U3 restricts further opening of the inlet guide vanes to avoid unit shutdown on low evaporator refrigerant temperature (b Fb).
4. 1U3 limits compressor loading and initiates "head relief request" (i.e., optional relay) when unit enters a surge condition. An automatic unit shutdown occurs if unit remains in surge for 15 minutes (b dA).
5. This feature provided on CVHE units, design sequences "1C" and later, CVHB units, design sequences "1D" and later and all CVHF units w/UCP695.

Table 3
Unit-Level Diagnostic Codes

Diag. Code	Diagnostic Explanation	Reset Type(1,2)	Diag. Code	Diagnostic Explanation	Reset Type(1,2)
b A3	Evaporator Refrig. Temp. Range	Manual	b E8	Differential Oil Pressure Switch	Manual
b A4	Motor Temperature Sensor # 1	Manual	b E9	Stop Relay	Manual
b A5	Max. Acceleration Time Range	Manual	b EA	High Inboard Brg. Temp. (Sen. # 1)	Manual
b A7	Motor Temperature Sensor # 2	Manual	b Eb	High Outbrd. Brg. Temp. (Sen. # 2)	Manual
b A8	Motor Temperature Sensor # 3	Manual	b EC	Running Overload	Manual
b A9	Oil Temperature Sensor	Manual	b Ed	Chilled Water Flow	Auto
b Ab	Leaving Water Temp. Sensor	Manual	b EE	Max. Acceleration Time Exceeded	Manual
b AC	Cond. Refrig. Pressure Sensor (3)	Manual	b F0	Transition	Manual
b Ad	Evap. Refrig. Temperature Sensor	Manual	b F1	Running External Interlock (3)	Manual
b AE	Ambient Temperature Sensor (3)	Manual	b F2	Low Oil Pressure	Manual
b AF	Bearing Sensor # 1 (Inboard) (3)	Manual	b F3	Low Oil Temperature	Auto
b b0	Bearing Sensor # 2 (Outboard) (3)	Manual	b F4	High Oil Temperature (4)	Manual
b d9	Extended Power Loss	Auto	b F5	High Condenser Refrig. Pressure	Manual
b dA	Surge	Manual	b F7	Condenser Water Flow	Auto
b dC	Condenser Water Flow Overdue	Manual	b F8	Improper Unit Identification	Manual
b E2	Momentary Power Loss	Auto	b F9	Free-Cooling Valves	Manual
b E3	Phase Imbalance	Manual	b FA	Actuator	Manual
b E4	Phase Loss	Manual	b Fb	Low Evaporator Refrig. Temp.	Manual
b E5	Phase Reversal	Manual	b Fd	External Interlock (5)	Manual
b E7	High Motor Temperature	Manual	b FF	Unit Control Module	Manual

Notes:
1. Check the "Manual Reset Required" status indicator light to determine if manual reset is necessary.
2. It is not possible to clear a latching diagnostic condition (i.e., one requiring manual system reset) at the unit from a higher-level device (e.g., an SCP699 or Trane BAS).
3. Optional feature.
4. Feature provided for CVHE units design sequence "1C" and later, CVHB units design sequence "1D" and later, and all CVHF units w/UCP695.
5. Feature provided for CVHE units before design sequence "1C"; CVHB units before design sequence "1D". Replaced by operating code A 100, "External Inhibit" (remote start/stop) at that time.

Codes prefixed by a "C" or "d" are followed by the corresponding setpoint value (i.e., chilled water or current limit, respectively) presently used to control the chiller. If the chiller switch is set at AUTO/LOCAL, setpoint values displayed are those set manually at the chiller's UCP. However, when the chiller switch is set at AUTO/REMOTE, and the proper status indicator lights are on, the setpoint values displayed were established at remote device (e.g., SCP699 or Trane BAS).

"E", "F", "H", "J" and "L" code prefixes are followed by an actual measurement of a system parameter (e.g., entering evaporator water temperature). (Code prefixes "E", "H" and "J" and "L" represent sensor options; if these sensors are not installed, a bar [—] appears on the display.)

Use the display advance pushbutton to scroll from one menu entry to the next. A blank display marks the end of the "operator's menu" for CVHE units of design sequence "1B" and earlier and CVHB units, design sequence "1C" and earlier. When the multi-use temperature sensor (4RT6) is ordered, the end of the operator's menu is indicated by the "L" operating code prefix for these units:

— CVHE Units = Design Sequence "1C" and later;
— CVHB Units = Design Sequence "1D" and later;
— CVHF Units = All units with UCP695.

If the multi-use temperature sensor option is not used, a bar [—] appears in the last position on the display.

To return to the top of the menu, press the pushbutton once.

Turning the vane control switch to the HOLD position redefines the display code prefixes to indicate the "local" (or front panel) chilled water and current limit setpoints, actual evaporator refrigerant temperature, and settings for control response, start differential, condenser limit and evaporator refrigerant "trip" point. See Table 1. Code prefixes "A" and "b" remain unchanged when the operating menu is redefined.

Important! Do not leave the vane control switch in HOLD. In this position, control of leaving chilled water is suspended. Only the "safety" features are functional!

Note: While in the serviceman's menu, the integer values displayed for the panel chilled water, condenser limit, and evaporator refrigerant trip setpoints represent the entire adjustment for these potentiometers. Unless the unit is specifically designed for "extended range" operation, the UCP will adhere to the parameters established for "standard range" chillers.

Important! Advancing past the "Last Diagnostic Code" entry in the menu automatically clears the code registered there from memory!

Service Interface

The following components can only be accessed by opening the control panel door. Each of these devices (Figure 2) is set at initial unit start-up by a qualified service technician.

Figure 2
UCP Service Interface and DIP Switch Locations
(Accessible Only With UCP Door Open)

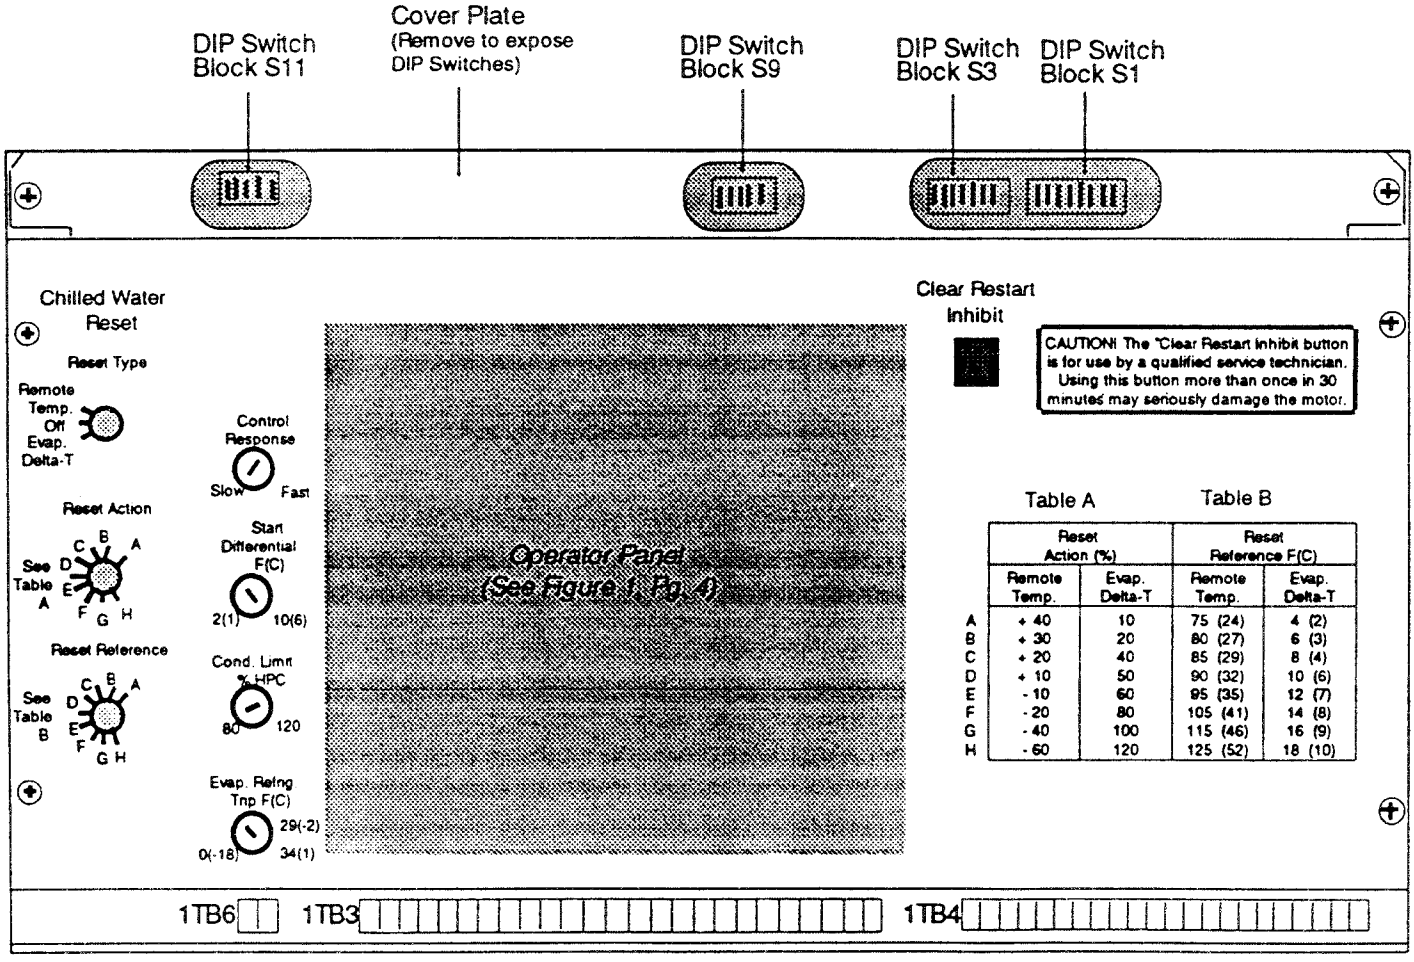

Table A / Table B

	Reset Action (%)		Reset Reference F(C)	
	Remote Temp.	Evap. Delta-T	Remote Temp.	Evap. Delta-T
A	+ 40	10	75 (24)	4 (2)
B	+ 30	20	80 (27)	6 (3)
C	+ 20	40	85 (29)	8 (4)
D	+ 10	50	90 (32)	10 (6)
E	- 10	60	95 (35)	12 (7)
F	- 20	80	105 (41)	14 (8)
G	- 40	100	115 (46)	16 (9)
H	- 60	120	125 (52)	18 (10)

WARNING! To prevent injury or death due to electrical shock, exercise extreme care whenever working with energized electrical components.

Caution: To ensure proper chiller operation, never tamper with any UCP-695 controls located behind panel door without first consulting a qualified service technician.

Clear Restart-Inhibit PushButton

By pressing this pushbutton, located to the right of the chilled water setpoint potentiometer, the service technician can clear the restart inhibit timer.

Caution: The clear restart inhibit pushbutton is for use only by a qualified service technician. Using this button more than once in 30 minutes may seriously damage the compressor motor.

Note: When the clear restart inhibit (CRI) button is pressed while the chiller switch is in the STANDBY/RESET position, only the remaining portion of the 30-minute anti recycle timer is cleared. Toggling the chiller switch to one of the AUTO positions results in the activation of either a 4- or 15-minute run-inhibit timer. If the CRI pushbutton is pressed while the chiller switch is in one of the AUTO positions, all restart-inhibit timers are cleared and the UCP will initiate a start sequence if cooling is required.

Control Response Setpoint Potentiometer

(To be set/calibrated by a qualified Trane service technician only.)
Located to the left of the display window, this manually adjustable potentiometer can be set at any position between 1 and 237. The units used to delimit these settings are arbitrary.)

The control response setting directly affects the vane controller's speed of response to changes in cooling requirements; the lower the control response setting, the slower the response time of the vane controller. To view the actual control response setting, position the vane control switch at HOLD and press the display advance pushbutton until code prefix "L " appears.

Use the following equation to determine the recommended control response setting for a particular unit application:

$$\text{Recommended Control Response Setpoint} = \frac{250}{\text{Design Delta-T}} \times \frac{\text{Actual Flow Rate}}{\text{Design Flow Rate}},$$

where "design delta-T" is the design temperature drop in the evaporator. For example, if a unit is designed for a 55 F entering evaporator temperature and a 45 F leaving evaporator temperature, its "design delta-T" is 10 F.

Start Differential Setpoint Potentiometer

With an adjustment range of 2 F to 10 F (1 C to 6 C), this manually adjustable potentiometer is used to establish the number of degrees that the chilled water temperature must rise above the setpoint before the unit will start. (It also determines the actual compressor "stop" point; see Table 4.)

To display the actual start differential in the display window, position the vane control switch at HOLD and press the display advance pushbutton until code prefix "O" appears.

Recommended differential to start setpoints, along with the corresponding compressor stop differential setpoints, are indicated in Table 4.

Table 4
Compressor "Start/Stop" Points

Chiller Delta-T F (C)	Recommended Differential to Start F (C)	Corresponding Differential to Stop F (C)
4 or less (2.2 or less)	2 (1)	2.0 (1.1)
5 or 6 (2.8 or 3.3)	3 (2)	2.0 (1.1)
7 or 8 (3.9 or 4.4)	4 (2)	2.0 (1.1)
9 or 10 (5.0 or 5.5)	5 (3)	2.0 (1.1)
11 or 12 (6.1 or 6.7)	6 (3)	2.0 (1.1)
13 or 14 (7.2 or 7.8)	7 (4)	2.0 (1.1)
15 or 16 (8.3 or 8.9)	8 (4)	2.4 (1.3)
17 or 18 (9.4 or 10.0)	9 (5)	3.2 (1.7)
19 or more (10.6 or more)	10 (6)	4.0 (2.2)

Condenser Limit Setpoint Potentiometer (% HPC; Optional)

The control range of this optional, adjustable potentiometer is 80% to 120% of the rated high pressure control setpoint. For standard units (i.e., with an HPC setting of 15 psig), then, the condenser limit setting range is 12 to 18 psig. The range for ASME units--with a 25 psig HPC setting--is 20 to 30 psig.

To display the actual condenser limit setpoint in the display window, turn the vane control knob to HOLD and press the display advance pushbutton until "P" appears on the display. The integer value immediately to the right of "P" is the condenser limit setpoint.

Note: The condenser high pressure cutout switch (1S1) remains active and will shut down unit operation on latching diagnostic **b F5** (i.e., high condenser refrigerant pressure) if its "trip" point is exceeded.

Recommended Condenser Limit Setpoint

The recommended condenser limit setpoint is 93% of the condenser high pressure cutout switch (1S1) setting.

Condenser Limit Operation (A 76)

Optional condenser limit control provides a means for maintaining chiller operation while high head pressure conditions exist. The control scheme used is outlined below, and an example follows:

1. Micro module 1U3 continually monitors condenser refrigerant pressure via condenser pressure transducer 1R1.

2. When condenser pressure rises to within 90% to 96% of the condenser limit setpoint, 1U3 slows the opening of the inlet vanes and allows for normal vane closure.

3. When condenser pressure rises to within 96% to 100% of the condenser limit setpoint, 1U3 prohibits further vane opening but allows vane closure.

4. If head pressure reaches the condenser limit setpoint, 1U3 initiates a **regulated vane closure** that continues until the condenser pressure is under control. (Notice that the micro module does not issue a "hard close" signal to the vane actuator--shutting the vanes to their minimum open position--at this time.)

5. If the controlled vane closure begun in Step 4 does not bring condenser pressure under control, the unit shuts down on latching diagnostic **b F5** when the high pressure switch (1S1) setpoint is exceeded.

[ ] **Example.** To better understand the condenser limit control scheme just described in Steps 1 through 5, calculate the condenser limit setpoint in psig--along with the "control points"--for a unit with these characteristics:

[ ] Standard Unit
[ ] Condenser Rating = 15 psig
[ ] HPC Switch (1S1) Setpoint = 15 psig
[ ] Condenser Limit Setpoint = 93% of HPC setpoint

a. Calculate the psig value of the condenser limit setpoint.

Condenser Limit Setpoint = Condenser Rating x % HPC
= 15 psig x 93%
= 14 psig (approximately)

b. Using the condenser limit setpoint just calculated, determine the condenser limit "control points".

90% x 14 psig = 12.6 psig
96% x 14 psig = 13.4 psig
100% x 14 psig = 14.0 psig

In this example, then:

a. The UCP will limit vane opening when condenser head pressure is between 12.6 and 13.4 psig.

b. The UCP will not allow the vanes to open further when condenser head pressure is between 13.4 and 14 psig, though vane closure is allowed.

c. When condenser head pressure reaches 14 psig, the UCP will initiate a controlled vane closure signal until the condenser pressure drops.

d. If condenser head pressure exceeds 15 psig, the unit is shut down on latching diagnostic **b F5**.

Evaporator Refrigerant Limit Potentiometer

With a standard adjustment range of 29 F to 34 F (-2 C to 1 C), this manually adjustable potentiometer is used to establish the chiller's low refrigerant temperature "trip" point. An optional "extended range" is also available which provides an adjustment range of 0 F to 34 F (-18 C to 1 C). To view the actual control setting, adjust the vane control knob to "HOLD" and press the display advance pushbutton until "U" appears on the display.

Note: Attempting to adjust the evaporator refrigerant "limit" point below the minimum range value will result in a latching diagnostic (i.e., requiring manual reset). Diagnostic code **b A3** will flash alternately on the display with the current operating code at the time the minimum range value was violated.

Caution: To assure proper chiller operation, adjustment of this control must always be performed by a qualified service technician.

Recommended Evaporator Refrigerant Limit Setting

Set the evaporator refrigerant "trip" point at 32 F unless a lower setpoint is required (i.e., because the design refrigerant temperature is less than 34 F).

Evaporator Refrigerant Limit Specifications

Adjustment Range:

29 F to 34 F for standard-range operation; and,
0 F to 34 F for extended-range operation.

Adjustment Resolution:

1.0 F or 1.0 C

Setpoint Out of Range:

Too Low = Diagnostic **b A3** occurs.
Too High = No diagnostic; UCP uses end-of-range value (i.e., 34 F).

Evaporator Refrigerant "Limit" Operation (A 77)

Freeze protection is provided by a multistep control algorithm built into the micro module. As the control point is approached, 1U3 sequentially initiates the following actions:

1. At 5-6 F above trip setting, limits the amount of vane opening, but allows vane closure;

2. At approximately 2 F above trip setting, prohibits additional vane opening, but allows vane closure;

3. At approximately 1 F above trip setting, initiates a regulated vane closure until evaporator refrigerant temperature is above the control point;

4. At trip setting, fully closes the inlet vanes; and,

5. Shuts down chiller operation while the vanes are fully closed if the setpoint violation persists.

Note: Chiller shutdown is not instantaneous; the micro module integrates to 30 F-seconds when the setpoint violation occurs.

This control scheme is designed to maintain chiller operation at the maximum capacity allowable without excessive vane modulation. Each of the five stages described above is further modified by the rate at which the refrigerant temperature is changing.

Note: The "control point" mentioned in Step 3 is 2 F above the evaporator refrigerant "trip" setpoint. However, if the evaporator refrigerant "trip" point is 29 F, then the "control point" is 1.5 F, relative, for standard-range units.

Evaporator Refrigerant Temperature Sensor Checkout
It is good practice to check the evaporator refrigerant temperature thermistor (4RT5) whenever setting up or adjusting the evaporator refrigerant "trip" setpoint. To check thermistor integrity:

1. Adjust the chiller switch to the STANDBY/RESET position.

2. Remove thermistor 4RT5 from its bulbwell but do not disconnect the thermistor leads from the micro module.

3. Place the thermistor in an ice bath along with an accurate thermometer. Use the thermometer to verify that the ice water is at 32 F.

4. View the refrigerant temperature display at the control panel. To do this, set the vane control switch at HOLD and press the display advance push button until "—" appears on the display.

Agitate the sensor in the ice bath for several minutes to allow the sensor temperature to stabilize; then check the display window. The evaporator refrigerant temperature displayed should be 32 ± 2 F.

Notes:
a. Evaporator refrigerant temperature "sensing system" accuracy is specified for ± 0.8 F accuracy at 29 F, although the accuracy of ± = 1.0 F at 30 F and ± 2.0 F at 32 F are acceptable.

b. If the sensor registers + 2.0 F (on the control panel display) at a 32 F temperature, and a control point above 32 F is desired--it may be necessary to compensate for the discrepancy by resetting the "trip" point upward.

5. Remove the 4RT5 thermistor sensor leads from terminals 1TB3-12 and 1TB3-13 on micro module 1U3; then check the resistance of sensor 4RT5.

Refer to the 4RT5 resistance table in the "Troubleshooting with Diagnostics" section of this bulletin, and find the measured resistance reading. The corresponding temperature in this table should match the actual temperature measured in Step 3 (i.e., within the accuracy criteria defined at the bottom of the 4RT5 resistance table).

Chilled Water Reset (CWR)

Chilled water reset is designed for those applications where the design chilled water temperature is not required when the chiller system is operating at part load. In these cases, the leaving chilled water temperature setpoint can be reset upward using the chilled water reset option.

Note: To enable CWR, the chiller switch must be set at AUTO/REMOTE. The remote chilled water setpoint status light will energize. CWR is active as long as the chiller switch is in AUTO/REMOTE even when the chiller is not operating.

The chilled water reset option consists of a factory-installed module in the unit control panel and a field-installed sensor. Sensor location is dependent on whether "load" or "ambient" chilled water setpoint reset is desired:

[ ] If "load" CWR is selected, the CWR sensor is field-installed in the return chilled water piping and connected to terminals 1TB3-3 and 1TB3-4 on micro module 1U3.

[ ] With the selection of "ambient" CWR, the sensor leads are connected to terminals 1TB3-14 and 1TB3-15 on micro module 1U3, and the sensor itself is typically field-installed just inside the building's fresh air intake duct, or on the north exterior wall of the building. In either case, shelter the sensor from direct sunlight and the elements.

Operator selection of the type of chilled water reset desired for a given application is accomplished at the unit control panel. See Figure 2, page 12; the conversion tables needed to determine the CWR control settings (i.e., Tables A and B) are provided on the face of the micro module, at the immediate right of the current limit setpoint potentiometer.

WARNING! To prevent injury or death due to electrical shock, use care when measurements, adjustments, or other service-related operations are performed with power on.

Load-Based CWR
When load-based chilled water reset is desired, the CWR controls must be adjusted as described below:

1. Reset Type Knob: Set at "Evap. Delta-T".

2. Reset Reference Knob: Set at the design delta-T (DDT) for the unit. Use the "Evaporator Delta-T" column of Table B (Figure 2, page 12) to convert the unit DDT value to a letter code (i.e., A through H).

Note: In those instances where the DDT value falls between the values listed, always use the next lower value.
Example: Chiller A is designed to operate with an entering chilled water temperature of 56 F, and a leaving chilled water temperature of 44 F.

a. Determine Chiller A's design delta-T.
   DDT = Design Ent. Chilled Water Temp. - Design Lvg. Chilled Water Temp.
   DDT = 56 F - 44 F
   DDT = 12 F
b. Convert Chiller A's DDT to a letter code. Locate 12 F DDT in Table B under "Evap. Delta-T"; 12 F DDT = "E".
c. Turn the reset reference knob to control setting "E".

3. Reset Action Knob: Set at the amount of reset desired. Use the following equation and the "Evaporator Delta-T" column of Table A (Figure 2, page 12) to determine the amount of reset desired; then convert this amount to a letter code (i.e., A through H).

RCWS = PCWS + RAS [DDT - (ENT - LVG)] where:
   RCWS = Reset Chilled Water Setpoint
   PCWS = Front Panel Chilled Water Setpoint
   RAS = Reset Action Setpoint
   DDT = Design Delta-T
   ENT = Entering Chilled Water Temperature
   LVG = Leaving Chilled Water Temperature

Notes about this equation:

a. To convert the reset action values in Table A from percentages to decimal values, divide by 100. Decimal values must be used for the RAS variable in the equation.

b. System control will not allow chilled water reset downward even though it is possible in this equation.

c. Increasing the reset action setpoint (RAS) to a larger number results in more reset.

d. If you know how many degrees of chilled water reset are desired (i.e., RCWS), as well as the DDT, ENT and LVG, the equation can be rearranged to solve for the reset action setpoint (RAS):

$$RAS = \frac{RCWS - PCWS}{[DDT - (ENT - LVG)]}$$

Review Examples 1 and 2 below to ensure that it is understood both how to calculate a load-based reset chilled water setpoint, and how this reset value changes with the selected reset reference and reset action control settings.

Example #1:

DDT = 10.0 F
PCWS = 45.0 F
RAS = 0.5 (i.e., "50" in Table A)

When the unit is operating at full load, ENT is 55 F and LVG is 45 F, so:

RCWS = 45.0 F + 0.5 F [10.0 F - (55 F - 45 F)]
RCWS = 45.0 F + 0 F
RCWS = 45.0 F

Since LVG and RCWS are equal (i.e., both are 45 F), there is no reset at this full load condition.

If this same unit is only half loaded (i.e., ENT - LVG = 5.0 F), then:

RCWS = 45.0 F + 0.5 [10.0 F - 5.0 F]
RCWS = 45.0 F + 2.5 F
RCWS = 47.5 F

In this situation, the chilled water setpoint will be reset 2.5 F upward, and the chiller will operate with an entering chilled water temperature of 52.5 F and a leaving chilled water temperature of 47.5 F.

Example #2:

DDT = 10.0 F
PCWS = 45.0 F
RAS = 1.0 (i.e., "100" in Table A)

Chiller B is operating at full load, and the delta-T across the evaporator (ENT - LVG) is 10 F, so:

RCWS = 45.0 F + 1.0 [10.0 F - 10 F]
RCWS = 45.0 F + 0 F
RCWS = 45.0 F

Under this full load condition, LVG and RCWS are again equal (i.e., both are 45.0 F), so there is no reset.

If this same unit is only half loaded (i.e., ENT - LVG = 5.0 F), then:

RCWS = 45.0 F + 1.0 [10.0 F - 5.0 F]
RCWS = 45.0 F + 5.0 F
RCWS = 50.0 F

In this situation, the chilled water setpoint will be reset 5.0 F upward, and the chiller will operate with an entering chilled water temperature of 55.0 F and a leaving chilled water temperature of 50.0 F. Notice that an RAS of 1.0 yields a constant return temperature; as unit load varies, the leaving chilled water setpoint is reset so that the entering chilled water temperature is always 55 F.

Ambient-Based CWR

When ambient-based chilled water reset is desired, the CWR controls must be adjusted as described below:

1. Reset Type Knob: Set at "Remote Temp."

2. Reset Reference Knob: This knob is used to set the temperature below or above which reset begins (i.e., design ambient). Use the "Remote Temperature" column of Table B (Figure 2, page 12) to convert the desired design ambient temperature to a letter code (i.e., A through H).

Example: Chiller A's design ambient temperature is 90 F (i.e., chilled water reset is desired if the ambient temperature falls below 90 F).

a. Convert Chiller A's design ambient to a letter code. Locate 90 F in Table B under "Remote Temp."; 90 F = "D".
b. Adjust the reset reference knob to control setting "D".

3. Reset Action Knob: Set at the amount of reset desired. Use the following equation and the "Remote Temperature" column of Table A (Figure 2, page 12) to determine the amount of reset desired and then convert this amount to a letter code (i.e., A through H).

RCWS = PCWS + RAS (RRS - AMB) where:

RCWS = Reset Chilled Water Setpoint
PCWS = Front Panel Chilled Water Setpoint
RAS = Reset Action Setpoint
RRS = Reset Reference Setpoint
AMB = Outdoor Ambient Temperature

Notes about this equation:

a. To convert the reset action values in Table A from percentages to decimal values, divide by 100. Decimal values must be used for the RAS variable in the equation.
b. Increasing the RAS to a larger number results in more reset.
c. Using a negative RAS causes the chilled water setpoint to be reset upward whenever the ambient temperature exceeds the design ambient. System control will not allow the chilled water setpoint to be reset downward even though it is possible in this equation.

Review Example 3 below to ensure that the correlation between the reset action setting and the reset chilled water setpoint in ambient-based chilled water reset is understood.

Example #3:

PCWS = 45.0 F
RAS = 0.2 (i.e., "20" in Table A)
RRS = 90.0 F

When the outdoor air temperature is 80 F, then:

RCWS = 45.0 F + 0.2 (90.0 F - 80 F)
RCWS = 45.0 F + 2.0 F
RCWS = 47.0 F

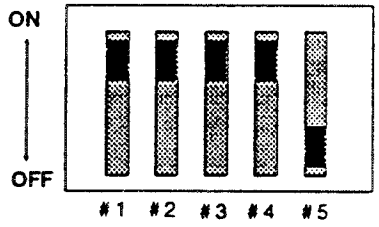
If the outdoor air temperature drops to 70 F, then:

RCWS = 45.0 F + 0.2 (90.0 F - 70 F)
RCWS = 45.0 F + 4.0 F
RCWS = 49.0 F

Thus, a RAS of 0.2 (i.e., +20%) provides 2 F of reset for every 10 F drop in outdoor air temperature below the design ambient.

Factory DIP Switch Settings

Controls discussed in this section are factory-set, and do not normally require adjustment at initial start-up or during operation of the unit. Use the information provided here only to check the switch settings at initial start-up, or when a new micro module (1U3) is installed. To access the UCP control components described below, open the unit control panel door and remove the access cover strip located at the top of the micro module. All of the necessary factory inputs are set at four DIP switch blocks. See Figure 2 on page 12.



WARNING!: To prevent injury or death due to electrical shock, always open unit disconnect switch before opening control panel door.

Caution: To ensure proper chiller operation, never tamper with any UCP695 controls located behind panel door without first consulting a qualified service technician.

Switch Block S11: Unit Address

This DIP switch block Shown below in Figure 3, must be set when the unit is used with an SCP699 system control panel. The switches are set to "tag" the chiller with a binary address of either "1", "2" or "3" as indicated in Table 5 below:

Figure 3
Unit Address DIP Switch Block (S11)

Note: See Figure 2, Page 12 for DIP Switch Locations.

Table 5 - Settings for DIP Switch Block S11

Switch Block S11 DIP Switches					Corresponding Binary Unit Address
1	2	3	4	5	
NA	NA	NA	ON	OFF	1
NA	NA	NA	OFF	ON	2
NA	NA	NA	OFF	OFF	3

Note: All units communicating with an SCP must have separate, unique addresses. If 2 or more units connected to an SCP have identical addresses, SCP-UCP communications are automatically terminated.

Switch Block S9: Purge/Unit Identification; Temperature Range; Unit-of-Measure

Unit Identification For:

— CVHE Units = Design Sequence "1B" or earlier, only, and;
— CVHB Units = Design Sequence "1C" or earlier only.

For these units, DIP Switch Nos. 1, 2 and 3 on this block (S9) tell the micro module (1U3) what type of unit it is controlling. See Figure 4. Unit identification is established using various combinations of "On" and "Off" DIP switches. Unit type should match the corresponding code, as indicated in Table 6 below:

Figure 4
Unit Identification/Temperature Range/Unit-of-Measure DIP Switch Block (S9)

Note: See Figure 2, Page 12 for DIP Switch Locations.

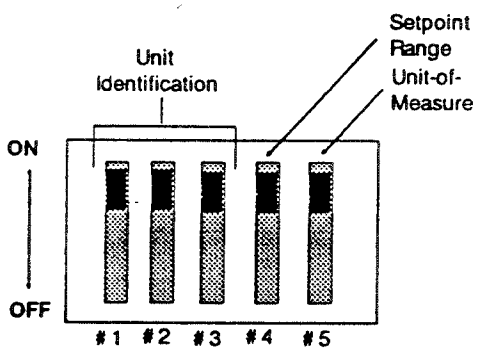


Table 6 - Settings for DIP Switches 1, 2, 3 On Switch Block S9

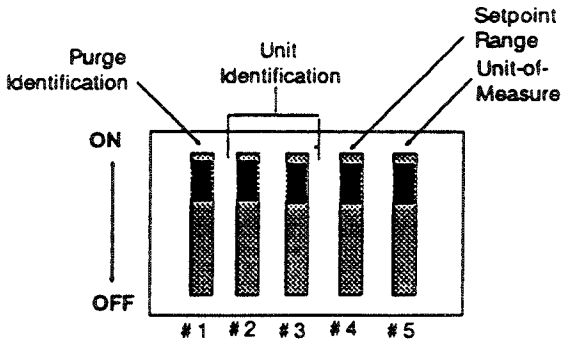
Switch Block S9 DIP Switches					Corresponding Unit Identification
1	2	3	4	5	
ON	ON	OFF	n/a	n/a	CVHE or CVHB (STD)
ON	OFF	OFF	n/a	n/a	CVHE or CVHB (ASME)



CVHE Units = Design Sequence "1B" or earlier, only, and;
CVHB Units = Design Sequence "1C" or earlier only.

Unit Identification For:

— CVHE Units = Design Sequence "1C" and later;
— CVHB Units = Design Sequence "1D" and later;
— CVHF Units = All units w/UCP695.

For these units, DIP Switch No. 1 on this block (S9) is used to identify (for the micro) the type of purge unit provided on the chiller (Table 7). DIP Switch Nos. 2 and 3 tell the micro module (1U3) what type of unit it is controlling. See Figure 5. Unit identification is established using various combinations of "On" and "Off" DIP switches. Unit type should match the corresponding code, as indicated in Table 7:

Figure 5a
Purge/Unit Identification/Temperature Range/
Unit-of-Measure DIP Switch Block (S9)

Note: See Figure 2, Page 12 for DIP Switch Locations.

Table 7 - Settings for DIP Switch 1 On Switch Block S9

Switch Block S9 DIP Switches					Corresponding Unit Identification
1	2	3	4	5	
ON	n/a	n/a	n/a	n/a	Oilless/Hermetic Purge
OFF	n/a	n/a	n/a	n/a	Purifier Purge

Table 8 - Settings for DIP Switches 2 and 3 Switch Block S9

Switch Block S9 DIP Switches					Corresponding Unit Identification
1	2	3	4	5	
n/a	ON	OFF	n/a	n/a	CVHE or CVHB (CFC- 11/ HCFC-123)
n/a	OFF	OFF	n/a	n/a	CVHE or CVHB (ASME CFC-11/HCFC-123)

CVHE Units = Design Sequence "1C" or later, and;
CVHB Units = Design Sequence "1D" or later, and;
CVHF Units = All units w/UCP695

The position of DIP Switch No. 4 on switch block S9 (Figures 4 and 5a) determines the range of adjustability for the chilled water and evaporator refrigerant "trip" point potentiometers as shown in Table 9:

Table 9 - Settings for DIP Switch 4 On Switch Block S9

Switch Block S9 DIP Switches					Corresponding Temperature Range
1	2	3	4	5	
n/a	n/a	n/a	ON	n/a	Standard
n/a	n/a	n/a	OFF	n/a	Extended

The standard temperature range for the chilled water setpoint is 37 F to 60 F, and that of the evaporator refrigerant "trip" point is 29 F to 34 F. When the extended temperature range function is enabled, however, these control ranges are expanded to include 20 F to 70 F for the chilled water setpoint, and 0 F to 34 F for the evaporator refrigerant "trip" point.

Caution: DIP Switch No. 4 should be ON unless the unit is designed to operate beyond the standard temperature range. Improper chiller operation at "extended temperature range" conditions may result in catastrophic equipment failure!

English or SI Unit-of-Measure

DIP Switch No. 5 of switch block S9 (Figure 4 and 5a) determines whether the temperatures shown on the micro module's display are indicated in degrees F or degrees C. See Table 10 below:

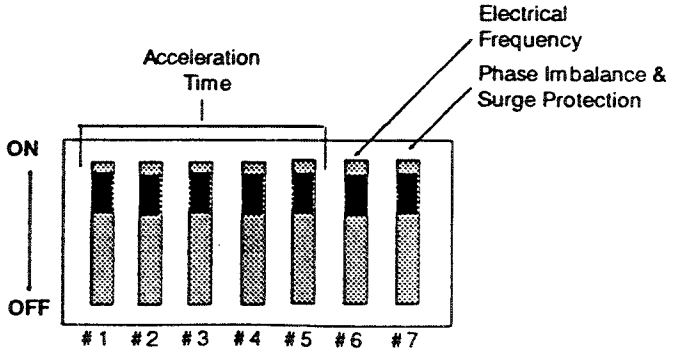
Table 10 - Settings for DIP Switch 5 On Switch Block S9

Switch Block S9 DIP Switches					Corresponding Units-of-Measure
1	2	3	4	5	
n/a	n/a	n/a	n/a	ON	English (Degrees F)
n/a	n/a	n/a	n/a	OFF	SI (Degrees C)

Note: DIP Switch No. 5 should remain in the "ON" position for all domestic chiller applications.

Switch Block S3: Acceleration Time; Frequency; Phase Imbalance/Surge Protection

Maximum Acceleration Time



The positions of DIP Switch Nos. 1 through 5 on switch block S3 (Figure 5b) determine the maximum length of time which will be allowed for transition to occur. (Acceleration time is measured from compressor motor start to transition — that is, the point at which inrush current is reduced to 85% of RLA.) Following are "trip" setpoint specifications for the maximum acceleration time function:

[ ] Adjustment Range:
6 seconds minimum to 65 seconds maximum

[ ] Adjustment Resolution:
3 seconds minimum

[ ] Timing Accuracy:
2.5 Seconds

Figure 5b - Acceleration Time/Electrical Frequency/ Surge Protection DIP Switch Block (S3)

Note: See Figure 2, Page 12 for DIP Switch Locations.

Note: Though this setpoint is factory-adjusted (i.e., based on starter type and available starting torque), it may be necessary to modify this setting in the field. Acceleration times and DIP switch settings are given in Table 11. Recommended maximum acceleration times for various starter types are as follows:

27 seconds for "star-delta" starters;
16 seconds for "auto-transformer" starters;
11 seconds for "primary reactor" starters
6 seconds for "across-the-line" starters.

Table 11
Available Max. Acceleration Time Settings for Switches 1- 5 On Switch Block S3 *(Note 1)*

Switch Block S3 DIP Switches					Corresponding Maximum Acceleration Time
1	2	3	4	5

OFF	OFF	OFF	OFF	ON	64 Seconds
OFF	OFF	OFF	OFF	OFF	65 Seconds

Notes:
1. Switches 6 & 7 on S3 not shown in this table.
2. CT network accuracy is approx. ± 5 percent. Some adjustment may be needed.

Frequency Adjustment (50/60 Hz)

DIP Switch No. 6 on switch block S3 allows the UCM to accept either 50- or 60-hertz supply power, depending on its position See Table 12 below. This DIP switch must be configured to match incoming power.

Table 12 - Settings for DIP Switch 6 On Switch Block S3

Switch Block S3 DIP Switches							Corresponding Frequency
1	2	3	4	5	6	7	
n/a	n/a	n/a	n/a	n/a	ON	n/a	50 Hertz
n/a	n/a	n/a	n/a	n/a	OFF	n/a	60 Hertz

Note: DIP Switch No. 6 should remain in the "Off" position for all domestic chiller applications.

Phase Imbalance and Surge Protection

DIP Switch No. 7 of switch block S3 determines whether or not this motor protection function is operational. Refer to Table 13.

Table 13 - Settings for DIP Switch 7 On Switch Block S3

Switch Block S3 DIP Switches							Motor Protection Function Status
1	2	3	4	5	6	7	
n/a	n/a	n/a	n/a	n/a	n/a	ON	Overriden
n/a	n/a	n/a	n/a	n/a	n/a	OFF	Operational

Note: DIP Switch No. 7 should remain in the "Off" position. However, if job site conditions cause nuisance "trips", this protection may be overridden temporarily until the problem is diagnosed and corrected.

Switch Block S1: Rated-Load-Amps (RLA) Setpoint

The RLA setpoint is factory-set using DIP Switch Nos. 1 through 8 of switch block S1 (Figure 3, page 12), and is based on nameplate RLA, current transformer ratio selection, and other design constants. Since all eight switches on switch block S1 are used, it is not illustrated here. Though the RLA setpoint is both accessible and resettable, field adjustment is discouraged. RLA "trip" point is based on current transformer (CT) selection. Adjustment resolution is 1% of RLA minimum. To determine the appropriate DIP switch setting combination, review the data provided in Tables 14 and 15. Use Steps 1 through 5 that follow — along with Table 14 — to determine the appropriate RLA "factor" for your unit; then locate that "factor" in Table 15 to verify that the factory-set S1 DIP switch arrangement is correct.

1. Check the unit nameplate (or design specifications) to establish the chiller's RLA.

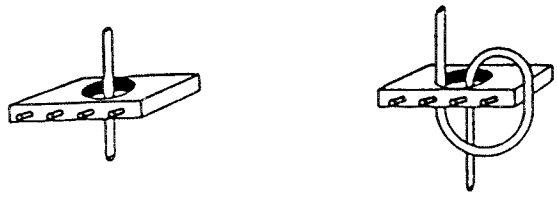
2. Determine the appropriate "meter scale" value from Table 14. To do this, compare the unit RLA with the RLA range values in Table 14; select the appropriate RLA range and read across the table to find the corresponding meter scale value.

3. Use the following equation to determine the "RLA factor":

$$\text{RLA Factor} = \frac{\text{RLA} \times 1.4}{\text{Meter Scale}}$$

4. Use Table 15 to find the S1 DIP switch settings that correspond to the RLA factor determined in Step 3.

Note: Select the RLA factor in Table 15 that is closest to the RLA factor calculated in Step 3.



5. Compare the DIP switch settings identified in Table 15 (See "Step 4") with the factory-set S1 DIP switch setting combination.

Table 14
Unit RLA Meter Scale Conversion

RLA Range	CT Ratio (1)	Primary Turns (2)	Meter Scale (3)
28.6 to 35.7	150 : 5	3	50
35.8 to 42.8	180 : 5	3	60
42.9 to 53.5	150 : 5	2	75
53.6 to 64.2	180 : 5	2	90
64.3 to 71.4	200 : 5	2	100
71.5 to 89.2	250 : 5	2	125
89.3 to 107.1	150 : 5	1	150
107.2 to 128.5	180 : 5	1	180
128.6 to 142.8	200 : 5	1	200
142.9 to 178.5	250 : 5	1	250
178.6 to 214.2	300 : 5	1	300
214.3 to 250.0	350 : 5	1	350
250.1 to 285.7	400 : 5	1	400
285.8 to 357.1	500 : 5	1	500
357.2 to 428.5	600 : 5	1	600
428.6 to 500.0	700 : 5	1	700
500.1 to 571.4	800 : 5	1	800
571.5 to 714.2	1000 : 5	1	1000
714.3 to 857.1	1200 : 5	1	1200
857.2 to 1071.4	1500 : 5	1	1500
1071.5 to 1285.7	1800 : 5	1	1800
1285.8 to 1500.0	2100 : 5	1	2100
1500.1 to 1785.7	2500 : 5	1	2500

Notes:
1. The CT ratio represents the size of the current transformers used with the specified RLA range.
2. Each "primary turns" (PRI) value indicates the number of time that the main power line passes through its current transformer.

Examples: PRI = 1 PRI = 2

3. If ampmeters are used with the CTs, their full-scale deflection will equal the "meter scale" values in this table.

Note: Meter Scale = $\frac{\text{CT Ratio (1)}}{\text{Primary Turns}}$

Micro Module (1U3) Input Connections (and Terminal Designations)

All electrical connections made at micro module 1U3 are low voltage (i.e., 30 volts AC or less); never connect wires carrying more than 30 volts to terminal strips 1TB6, 1TB3 or 1TB4. Further, never route wiring carrying voltages exceeding 30 volts through the upper half of the unit control panel!

Caution: Connecting any device or wiring that carries more than 30 volts to 1TB6, 1TB3 or 1TB4 will destroy micro module 1U3.

Terminal strip connections for the micro module are illustrated in Figures 6 and 7 and described in the following paragraphs. Terminal strip 1TB3, -4, and, -6 locations are shown in these figures also.

Terminal Strip 1TB6

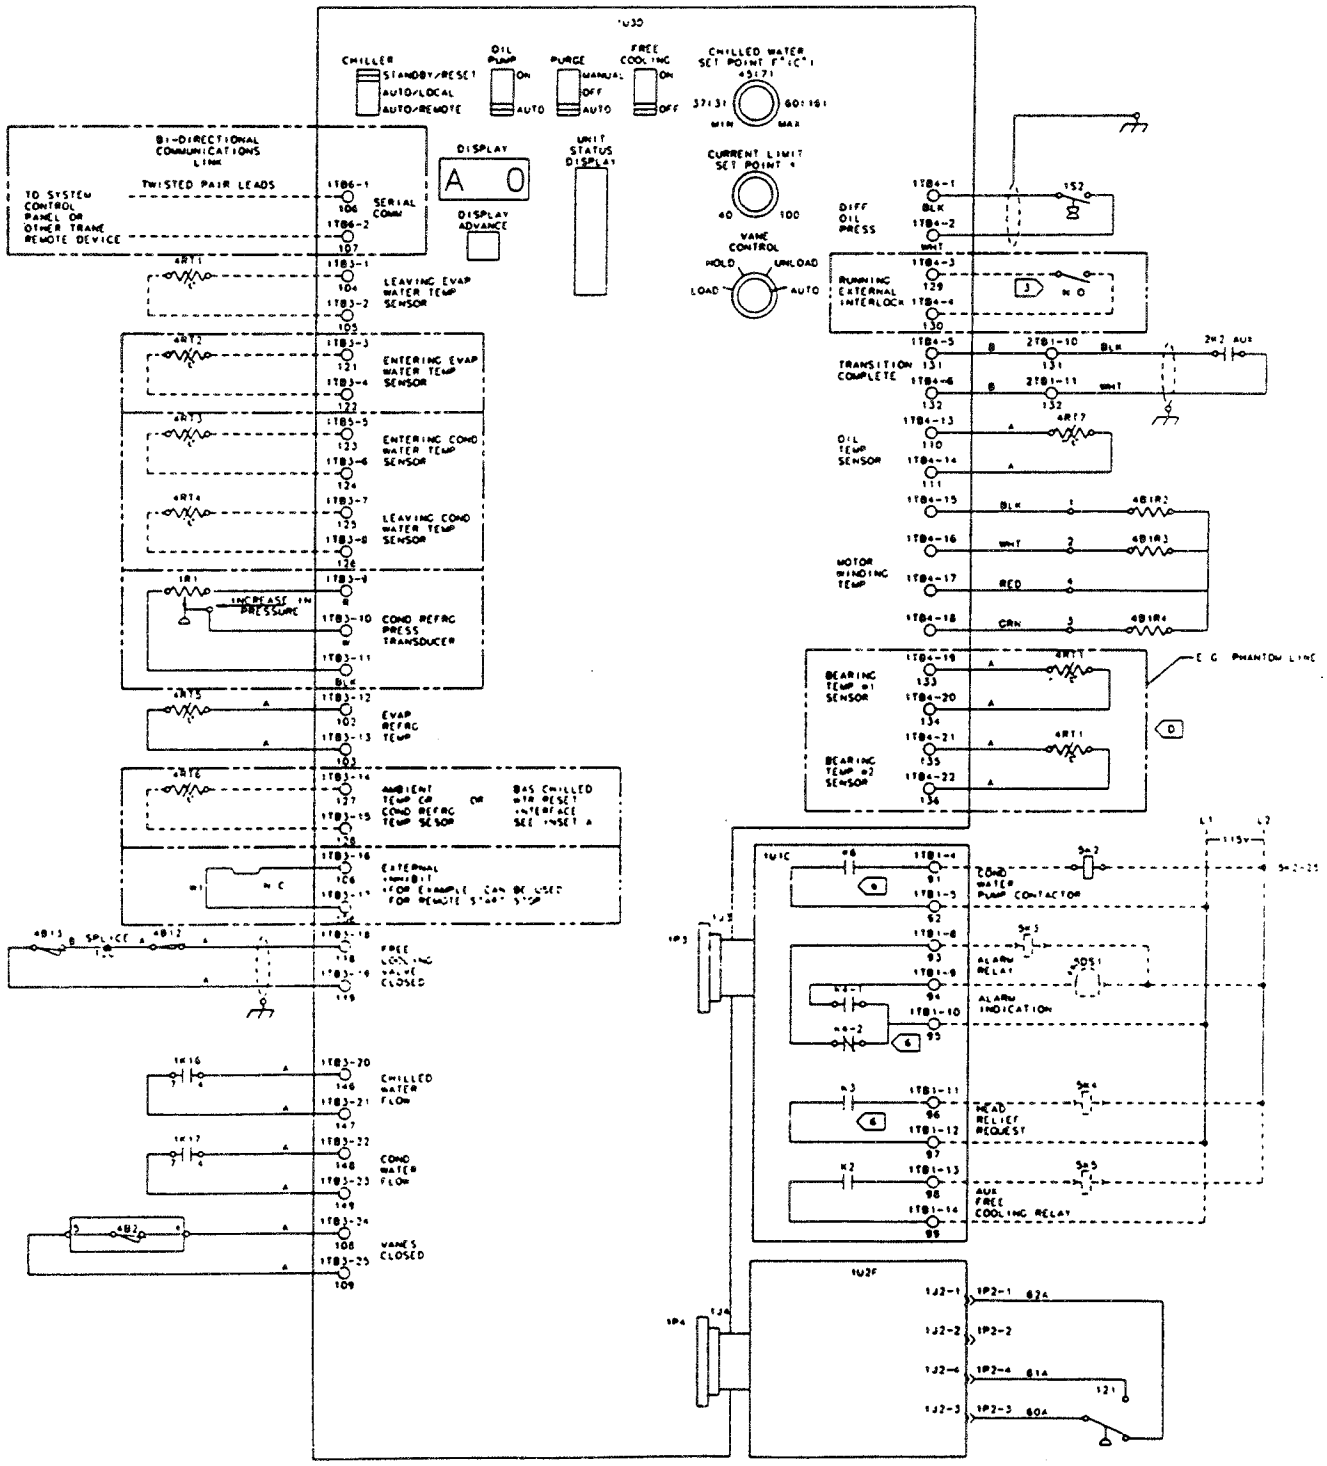
Bidirectional Communications Link (1TB6-1, -2)

This connection port is provided for a twisted-pair communications link; this link may be with another machine, or with a higher level control panel (e.g., an SCP699 system control panel).

Note: There are no polarity requirements when connecting communication wires.

Terminal Strip 1TB3

Note: See the individual sensor checkout procedures in "Troubleshooting With Diagnostics" for a breakdown of temperature and pressure input accuracies; only "displayed" accuracies are indicated below.



Leaving Evaporator Water Temperature Sensor (1TB3-1, -2)

Standard thermistor 4RT1, which monitors the temperature of the chilled water leaving the unit, is connected to these terminals.
Sensor and input specifications are as follows:

[ ] Operating Range:
    15 F to 90 F.
[ ] Displayed Accuracy:
    ± 1.5 F from 20 F thru 70 F;
    ± 2.5 F from 70 F thru 90 F; and,
    ± 2.5 F from 15 F thru 20 F.
[ ] Indication:
    At front panel display (i.e., Item **"F"** of operator's menu).
[ ] Shorted:
    No diagnostic; display reads "—".
[ ] Open:
    Diagnostic: **b Ab**.
[ ] Leaving Water Temperature Low Limit:
    35.3 F for standard-range units only.

Figure 6
Micro Module 1U3 Input Connections

This drawing is typical of:
CVHE units = Design Sequence "1C" and later;
CVHB units = Design Sequence "1D" and later;
CVHF units = All units with UCP695.

WARNING! Disconnect electrical power supply to prevent injury or death due to electrical shock.

Notes:
1. Terminals 1TB3-16, -17 must be jumpered if external interlock is not used.
2. 1TB3, 1TB4 and 1TB6 are located below the micro module faceplate (Figure 2, page 12).
3. Solid lines indicate Trane wiring: dashed lines (- - - -) represent field wiring; and, phantom lines(— - - —) enclose optional features.

Drg. X39470576D

Note: The UCP's "differential-to-stop" criteria are typically used to cycle off the chiller--not this "low limit" function! Notice, too, that the "Cooling Required" status indicator light goes out when a "low limit" occurs; no diagnostic is generated.

Entering Evaporator Water Temperature Sensor (1TB3-3, -4)

The optional thermistor (4RT2) connected to these terminals monitors the temperature of the chilled water entering the unit.
Sensor and input specifications are as follows:

[ ] Operating Range:
15 F to 90 F

[ ] Displayed Accuracy:
± 1.5 F from 20 F to 70 F;
± 2.5 F from 70 F to 90 F; and,
± 2.5 F from 15 F to 20 F.

[ ] Indication:
At front panel display (i.e., Item "E" of operator's menu).

[ ] Shorted:
No diagnostic; display reads "—".

[ ] Open:
No diagnostic; display reads "—".

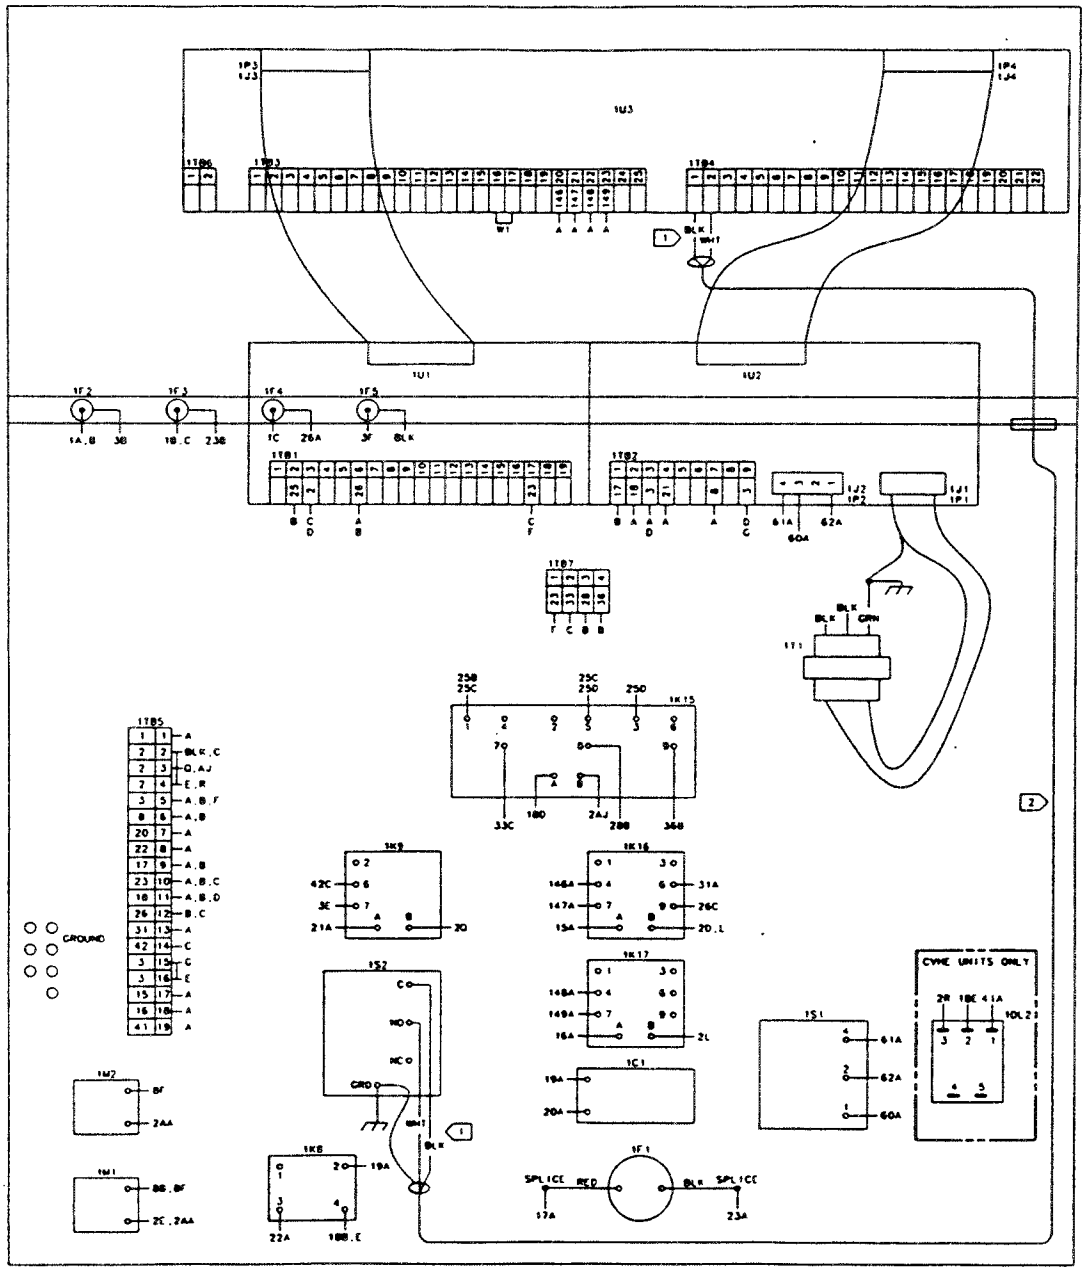
Spare Temperature Sensors (1TB3-5, -6; 1TB3-7, -8)

Thermistors (i.e., 4RT3 and 4RT4) connected to terminals 5 through 8 on 1TB3 are optional. These "spare temperature" inputs are expected to be used for monitoring entering (1TB3-5, 1TB3-6) and leaving (1TB3-7, 1TB3-8) condenser water temperatures. Actual sensor temperatures can then be viewed on the UCP display (i.e., menu item "H" for entering condenser water, and "J" for leaving condenser water).
Sensor and input specifications follow:

[ ] Operating Range:
30 F to 140 F

[ ] Displayed Accuracy:
± 1.8 F from 60 F to 110 F;
± 2.5 F from 30 F to 60 F; and,
± 2.5 F from 110 F to 140 F.

[ ] Indication:
At front panel display (i.e., Items "H" and "J" of operator's menu).



[ ] Shorted:
No diagnostic; display reads "—".

[ ] Open:
No diagnostic; display reads "—".

Condenser Refrigerant Pressure Transducer (1TB3-9, -10, -11)

This optional pressure transducer (1R1) is mounted inside the unit control panel (Figure 7), and is "T'd" into the condenser gauge line. Transducer output is of the 3-wire, variable resistance type. To assure proper operation, these 3 wires must be connected to terminals 9, 10 and 11 of 1TB3 in the order illustrated in Figure 6.
Pressure transducer and input specifications follow:

Figure 7
Typical UCP695 Panel Components (See 'Notes')

Notes:
1. Hot gas bypass unit shown.
2. This drawing typical of: CVHE - design sequence "1C" and later; CVHB - design sequence "1D" and later; CVHF - all designs w/UCP695. Refer to appropriate wiring manual for earlier designs.

[ ] Operating Range:
0 psig to 25 psig; see sensor checkout in "Troubleshooting With Diagnostics" for accuracies.
[ ] Indication:
None.
[ ] Shorted (1TB3-10 to -11):
Diagnostic **b AC**.
[ ] Open:
No diagnostic.

Evaporator Refrigerant Temperature Sensor (1TB3-12, -13)

This standard thermistor (4RT5) monitors evaporator refrigerant temperature. Following are sensor and input specifications:

[ ] Operating Range:
- 5 F to 150 F
[ ] Displayed Accuracy:
± 1.0 F at 29.0 F;
± 1.5 F at 30.0 F;
± 2.5 F from 0 F thru 28 F;
± 2.5 F from 31 F thru 34 F;
± 5.5 F from -5 F thru -1 F; and,
± 5.5 F from 35 F thru 40 F

As indicated by Table 1, page 8, the UCP displays evaporator refrigerant temperatures ranging from -4 F thru 42 F. See sensor checkout in "Troubleshooting With Diagnostics" for accuracies outside the display range.

[ ] Indication:
At front panel display (i.e., Item "__" of serviceman's menu).
[ ] Shorted:
Diagnostic **b Ad**; must not trip < 150 F.
[ ] Open:
Diagnostic **b Ad**; must not trip > -5 F.

Condenser Refrigerant Temperature Sensor; Ambient Temperature Sensor; Generic BAS Analog Input (1TB3-14, -15)

These three options are mutually exclusive of each other; that is, only one of these options can be functional at any given time. Actual sensor temperatures can be viewed on the UCP display as operator's menu item **"L"** on these units:

— CHVE Units = Design Sequence "1C" and later;
— CVHB Units = Design Sequence "1D" and later;
— CVHF Units = All units w/UCP695.

This display item is not available on earlier-design units.

CONDENSER REFRIGERANT TEMPERATURE SENSOR. This optional, field-installed thermistor (4RT6) must be used if the chiller is controlled by an SCP699 that is utilizing the SCP's "condenser limit" option. If this is done, these terminals cannot be used for an ambient sensor input or for a Generic BAS input. Refer to the SCP installation and operation literature.

AMBIENT TEMPERATURE SENSOR. This optional, field-installed thermistor (4RT6) is used with the optional, ambient-based, chilled water reset function.

GENERIC BAS ANALOG INPUT. This optional, interface device, designated the 1U4, is used to perform chilled water reset at the chiller level, based on a 0-10 VDC (or 4-20 mA) control signal issued by a generic BAS. This signal is translated into an "ambient temperature" input that the UCP uses to calculate a new chilled water setpoint. Sensor and input specifications follow:

[ ] Operating Range:
    -40 F to 150 F; see sensor checkout in "Troubleshooting With Diagnostics" for accuracies.
[ ] Indication:
    None
[ ] Shorted:
    Diagnostic **b AE**; must not trip < 150 F.
[ ] Open:
    No diagnostic.

External Interlock; External Inhibit (Remote On/Off Control) (1TB3-16, -17)

The external interlock input feature was provided on these units:

— CVHE Units = Design Sequence "1B" and earlier only, and;
— CVHB Units = Design Sequence "1C" and earlier only.

On later design units, the function of these terminals was changed to "External Inhibit". The external inhibit feature is provided on these chillers:

— CVHE Units = Design Sequence "1C" and later;
— CVHB Units = Design Sequence "1D" and later;
— CVHF Units = All units w/UCP695.

EXTERNAL INTERLOCK. Terminals 16 and 17 of 1TB3 accept a 2-position switch input used to indicate a system fault detected by a customer-supplied remote device . As long as the switch is closed (i.e., "shorted"), unit operation continues normally. However, if the micro module detects that this switch is open, it shuts down unit operation on latching diagnostic **b Fd**.

EXTERNAL INHIBIT. Terminals 16 and 17 of 1TB3 accept a 2-position switch input used to provide a chiller On/Off function from a customer-supplied remote controller and will allow an automatic chiller restart from the same controller. As long as these contacts remain closed, the chiller will run normally. If the contacts open, however, the chiller will go through its' shutdown cycle and remain off until the contacts reopen. When the chiller has shutdown on input at these terminals, the UCP will display operating code **A 100**, indicating that the external inhibit function is energized.

Note: Refer to Figure 7; notice that the unit ships from the factory with a jumper installed between the external interlock/external inhibit terminals. The unit will not operate unless Terminals 1TB3-16 and 1TB3-17 are shorted.. External interlock/external inhibit input specifications follow:

[ ] Circuit is monitored by a 12 VDC, 45 mA current.

[ ] Customer-supplied devices connected to these terminals must be compatible with current described above; gold-plated contacts are recommended to avoid oxidation resistance.

Note: Use an isolation relay to limit electrical noise interference, and to reduce the possibility of feeding voltage into micro module 1U3.

Free Cooling Valve Proof-of-Closure (1TB3-18, -19)

These terminals--used only on units equipped with the free cooling option--monitor the end switches on the free cooling valves to provide proof of valve closure. When this input is shorted, the free cooling valves are closed. If one or both of the free cooling valves are partially or fully open when the chiller is starting or running in the powered cooling mode, 1U3 responds to this open input by initiating latching diagnostic **b F9** to shut down unit operation. Specifications for the "free cooling valve closed" input are as follows:

[ ] The interlock circuit is monitored by a 12 VDC, 45 mA current.

Proof of Chilled Water Flow (1TB3-20, -21)

These terminals monitor the status of the chilled water pump relay (1K16) contacts.

If the contacts of 1K16 are closed (i.e., terminals 1TB3-20 and -21 are shorted), proof of closure is signalled by the illumination of the "chilled water flow" status indicator light. (These contacts must only close when there is actually chilled water flow--i.e., both chilled water flow switch 5S2 and auxiliary chilled water pump contactor 5K1 are closed.)

If 1K16's contacts are open, the input at terminals 1TB3-20 and -21 should also be open and the "chilled water flow" status indicator light off. Nonlatching diagnostic **b Ed** is generated if the chiller switch is set at one of the "Auto" positions and a start-up is attempted at this time. (The UCM will not generate a **b Ed** diagnostic if the chiller switch is set at STANDBY/RESET.)

Note: 1K16's contacts must open whenever the chilled water flow rate is either below the minimum acceptable level, or nonexistent (i.e., 5S2 or 5K1 are open).

Remember that the customer-supplied flow/pressure switch and pump interlock circuit must be connected to terminals 1TB5-14 and 1TB5-16 in the high-voltage section of the unit control panel; this circuit powers chilled water pump relay 1K16.

Caution: Do not connect the 120V flow switch interlock circuit to terminals 1TB3-20 and -21, or micro module 1U3 will be damaged.

Proof of Condenser Water Flow (1TB3-22, -23)

These terminals monitor the status of the condenser water pump relay (1K17) contacts.

If the contacts of 1K17 are closed (i.e., input terminals 1TB3-22 and -23 are shorted), proof of closure is signalled by advancement from operating code **A 71** (i.e., "establish condenser water flow") to **A 72** (i.e., "start").

Note: 1K17's contacts must only close when there is actually condenser water flow (i.e., proven by closure of both condenser water flow switch 5S3 and auxiliary condenser water pump contactor 5K2).

If 1K17's contacts are open, the input at terminals 1TB3-22 and -23 should also be open. In the event that condenser water flow is lost during chiller operation, the unit is shut down on nonlatching diagnostic **b F7** and a restart is attempted. Latching diagnostic **b dC** is generated if condenser water flow is not established within 3 minutes of initiation of operating mode **A 71**.

Note: 1K17's contacts must open whenever condenser water flow is either below the minimum acceptable rate, or nonexistent (i.e., both 5S3 and 5K2 are open).

Remember that the customer-supplied flow/pressure switch and pump interlock circuit must be connected to terminals 1TB5-15 and 1TB5-17 in the high-voltage section of the unit control panel; this circuit powers condenser water pump relay 1K17.

Caution: Do not connect the 120V flow switch interlock circuit to terminals 1TB3-22 and -23, or micro module 1U3 will be damaged beyond repair.

Proof of Inlet Vane Closure (1TB3-24, -25)

These terminals monitor the status of the "vanes closed" end switch on vane actuator motor 4B2. When the input at these terminals is shorted, the inlet vanes are fully closed; an open input indicates that the inlet vanes are either partially or fully open.

Micro module 1U3 checks the status of the inlet vanes during operating mode **A 71** (i.e., "establish condenser water flow"), and issues a "close" signal if they are open. Latching diagnostic **b FA** occurs if the vanes fail to close within 3 minutes.

Terminal Strip 1TB4

Differential Oil Pressure Switch 1S2 (1TB4-1, -2)

This terminal input (Figure 7, pg. 34) allows the micro module to monitor the status of the differential oil pressure switch (1S2) contacts. A shorted input at these terminals indicates that there is sufficient oil pressure available and 1S2's contacts are closed. If oil pressure is too low and 1S2's contacts are open, and the micro module detects an open input; chiller operation is shut down on latching diagnostic **b F2.**

Following is the specification for the differential oil pressure switch input to micro module 1U3:

[ ] The differential oil pressure switch circuit is monitored by a 12 VDC, 45 mA current.

Running External Interlock (1TB4-3, -4)

Terminals 3 and 4 of 1TB4 accept a switch input that indicates a system fault (i.e., detected by a customer-supplied remote device) requiring a unit shutdown. This function is only active when the unit is running and transition is complete.

Notice that as long as the micro finds an open input at Terminals 3 and 4, no fault is detected. If the input is shorted, however, a fault requiring unit shutdown occurred, and micro module 1U3 responds by initiating latching diagnostic condition **b F1**.

Specifications for the running external interlock input are as follows:

[ ] This fault circuit is monitored by a 12 VDC, 45 mA current.

[ ] Customer-supplied devices connected to these terminals must be compatible with the current described above; gold-plated contacts are recommended to avoid oxidation resistance.

Notes:
1. Use an isolation relay to limit noise interference, and to reduce the possibility of feeding voltage into micro module 1U3.
2. If the unit has hot gas bypass, discharge temperature switch 4S5 is connected to terminals 1TB4-3 and -4; this switch closes--yielding a "shorted" input-- if the discharge temperature exceeds 210 F.

"Transition Complete" Contacts (1TB4-5, -6)

This terminal input allows the micro module to monitor the main run starter contactor (2K2) to determine whether transition has occurred. A shorted input indicates that transition is complete, while an open input "tells" the micro that transition has not occurred.

Note: The shielded wire must be taped off at the 2K2 contacts and grounded to a ground lug provided in the starter panel (i.e., at the 2TB1 terminal strip end of these leads). These leads are not shielded between the starter panel and unit control panel.

Following is the specification for the "transition complete" input to micro module 1U3:

[ ] The "transition complete" circuit is monitored by a 12 VDC, 45 mA current.

3-Phase Current-Sensing Input (1TB4-7 thru -12)

These 6 terminals accept 3 AC signal inputs that are proportional to the compressor motor's AC current draw. Line current is stepped down by 2 sets of current transformers. Each set of current transformers contains 3 transformers; the first steps the line current down to a 0-5 amp signal, and the second further steps down the 0-5 amp signal to a milliamp (mA) signal.

Caution: Do not connect the 0-5 amp output signal of the primary transformer directly to micro module 1U3, or destruction of the module will result.

Following are specifications for the 3-phase current-sensing input:

[ ] Overall Accuracy:
15 to 140 ± 5% RLA

[ ] Open:
Diagnostic **b D9** (e.e., extended power loss),
Diagnostic **b E2** (i.e., momentary power loss), diagnostic **b E4** (i.e., phase loss), or diagnostic **b E5** (i.e., phase reversal).

Connections at terminals 7 through 12 are as follows:

[ ] Terminals 1TB4- 7 and - 8 are connected to secondary transformer 2T7 on L3.
[ ] Terminals 1TB4- 9 and -10 are connected to secondary transformer 2T6 on L2.
[ ] Terminals 1TB4-11 and -12 are connected to secondary transformer 2T5 on L1.

Note: It is essential that the correct polarity is maintained in all current transformer connections. Consult the appropriate starter wiring diagram to confirm that proper connection polarity is established.

Oil Temperature Sensor (1TB4-13, -14)

The temperature sensor that monitors oil sump temperature (i.e., thermistor 4RT7) is connected to these terminals.

Note: Remember that the oil temperature setting is not adjustable.

Specifications for the oil temperature sensor input are as follows:

[ ] Operating Range:
32 F to 180 F

[ ] Shorted:
Diagnostic **b A9**; must not trip < 180 F.

[ ] Open:
Diagnostic **b A9**; must not trip > 32 F.

[ ] Oil Heater Control:
140 F = "enable" point.
145 F = "off" point.
[ ] High Temperature Run Inhibit "Off" Point:
180 F; results in a latching diagnostic of **b F4**.

Motor Winding Temperature Sensors (1TB4-15 thru -18)

The leads of the 3 temperature sensors (4B1R2, 4B1R3, 4B1R4) imbedded in the compressor motor windings are connected to these input terminals. Check the unit wiring diagram to properly identify individual sensor wires.

Note: Notice that the "common" leg of each sensor is connected to Terminal 1TB4-17.
Specifications for the motor winding temperature sensor inputs are as follows:

[ ] Operating Range:
50 F to 310 F
[ ] Open:
Diagnostic **b A4**, **b A7** or **b A8**, as applicable.
[ ] Shorted:
No diagnostic.
[ ] Run Inhibit:
265 ± 15 F (i.e., UCP tolerance only); diagnostic **b E7**.
[ ] 15-Minute Start Delay:
> 165 ± 15 F (i.e., UCP tolerance only); operating code **A 70**.

Bearing Temperature Sensors (1TB4-19 thru -22)

The optional pair of sensors that monitor the temperature of the oil leaving the compressor motor bearings are connected to these terminals as described below:

a. Inboard sensor 4RT8 (i.e., sensor # 1) is connected to terminals 1TB4-19 and -20; and,
b. Outboard sensor 4RT9 (i.e., sensor # 2) is connected to terminals 1TB4-21 and -22.
Sensor and input specifications are as follows:

[ ] Range:
100 F to 180 F
[ ] Accuracy:
See sensor checkout in "Troubleshooting With Diagnostics" for MCSP temperature accuracies.
("MCSP" is the "motor/compressor start and protection" portion of micro module 1U3.)
[ ] Shorted:
Diagnostic **b AF** (4RT8) or **b b0** (4RT9); must not trip < 180 F.
[ ] Open:
No diagnostic.
[ ] Run Inhibit:
180 F; diagnostic **b EA** (4RT8) or **b Eb** (4RT9).

Tables 16 and 17 that follow, provide outpout voltage readings and contact status conditions for ribbon connectors 1P3 and 1P4 from the power supply output module (1U2) and relay output module 1U1.

Table 16
Ribbon Connector 1P4 Voltages (1) for Power Supply/Output Module 1U2

1P4 Terminal	VDC Signal Min.	VDC Signal Max.	Description of Status	1U2 Output Terminals

11	13.7	22.5	Common	----------

Notes:
1. The voltage values provided in this table apply only when ribbon connector 1P3 is connected to 1J3 of micro module 1U3.
2. This is a Triac output and cannot be checked in the same manner as a mechanical contact closure. Refer to "Vane Control Checkout Procedure" in this bulletin.
3. All voltages are to be measured with respect to 1P3-11.

Troubleshooting with UCP695 Control Panel Diagnostics

Note: This troubleshooting information is applicable only to those CVHB, CVHE, or CVHF units equipped with UCP695 control panels. These unit are:

— CVHE units; = "K" design sequence and later;
— CVHB units; = "V" design sequence and later;
— CVHF units; = All units.

UCP695 Overview

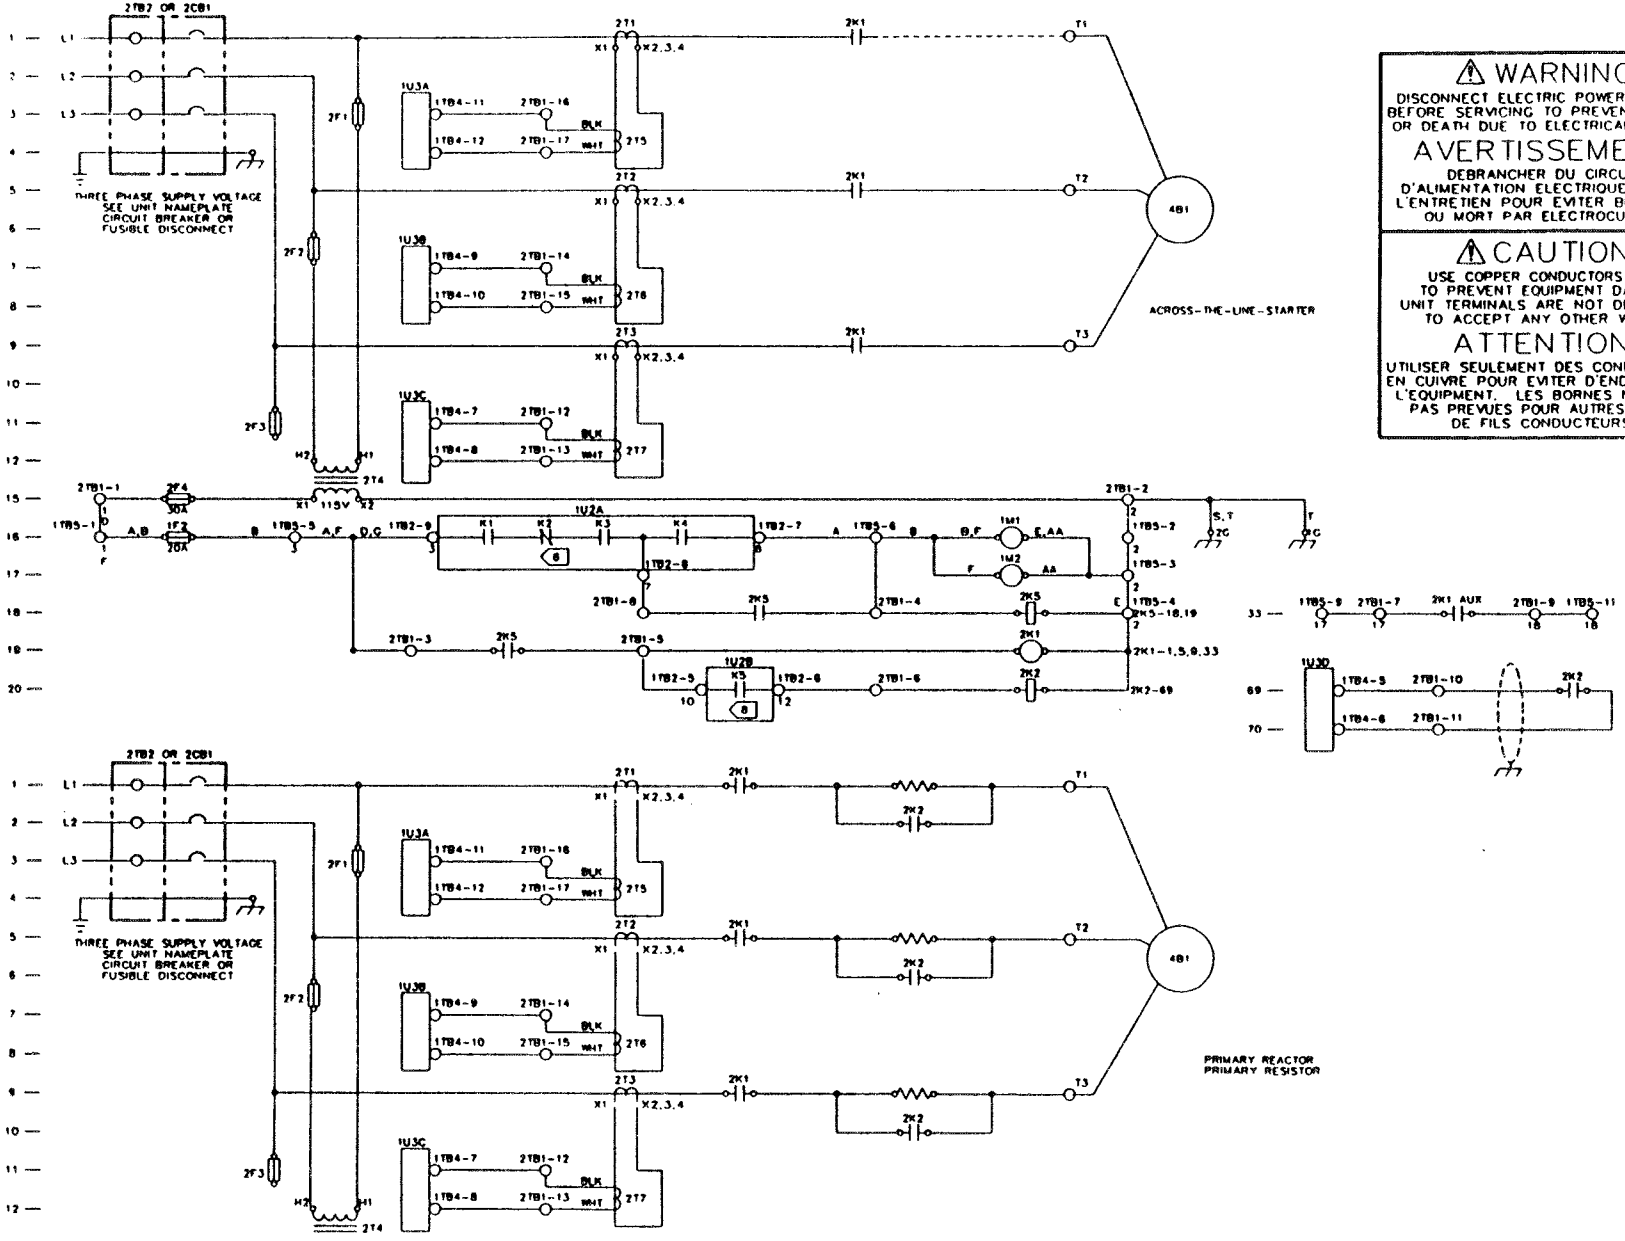
The microprocessor-based, UCP695 control panel visually indicates chiller operating and diagnostic codes on the operator display (refer to "Operator's Display" on page 8). If the UCP (i.e., unit control module) detects a diagnostic condition, it alternately flashes the 4-digit unit operating mode (i.e., code prefix **A**) that was in effect at the time the unit shutdown and the 4-digit diagnostic code (i.e., code prefix **b**) on the display. Use the information in the following section to identify and correct the cause of a unit shutdown.

Note: A latching diagnostic condition (i.e., one requiring manual reset) detected by the unit control panel cannot be cleared from a higher level device (i.e., an SCP, Tracer or generic BAS). The chiller must be manually reset at the UCP695 control panel.

Complete listings of the codes used to identify CVHE operating modes and diagnostic conditions--along with the display menus--are provided in Tables 1, 2 and 3 on pages 8, 9 and 10. For a more detailed explanation of UCP695 control panel features and functions, refer to the "System Control" portion of the CVHE operation and maintenance manual that shipped with the unit.

Troubleshooting

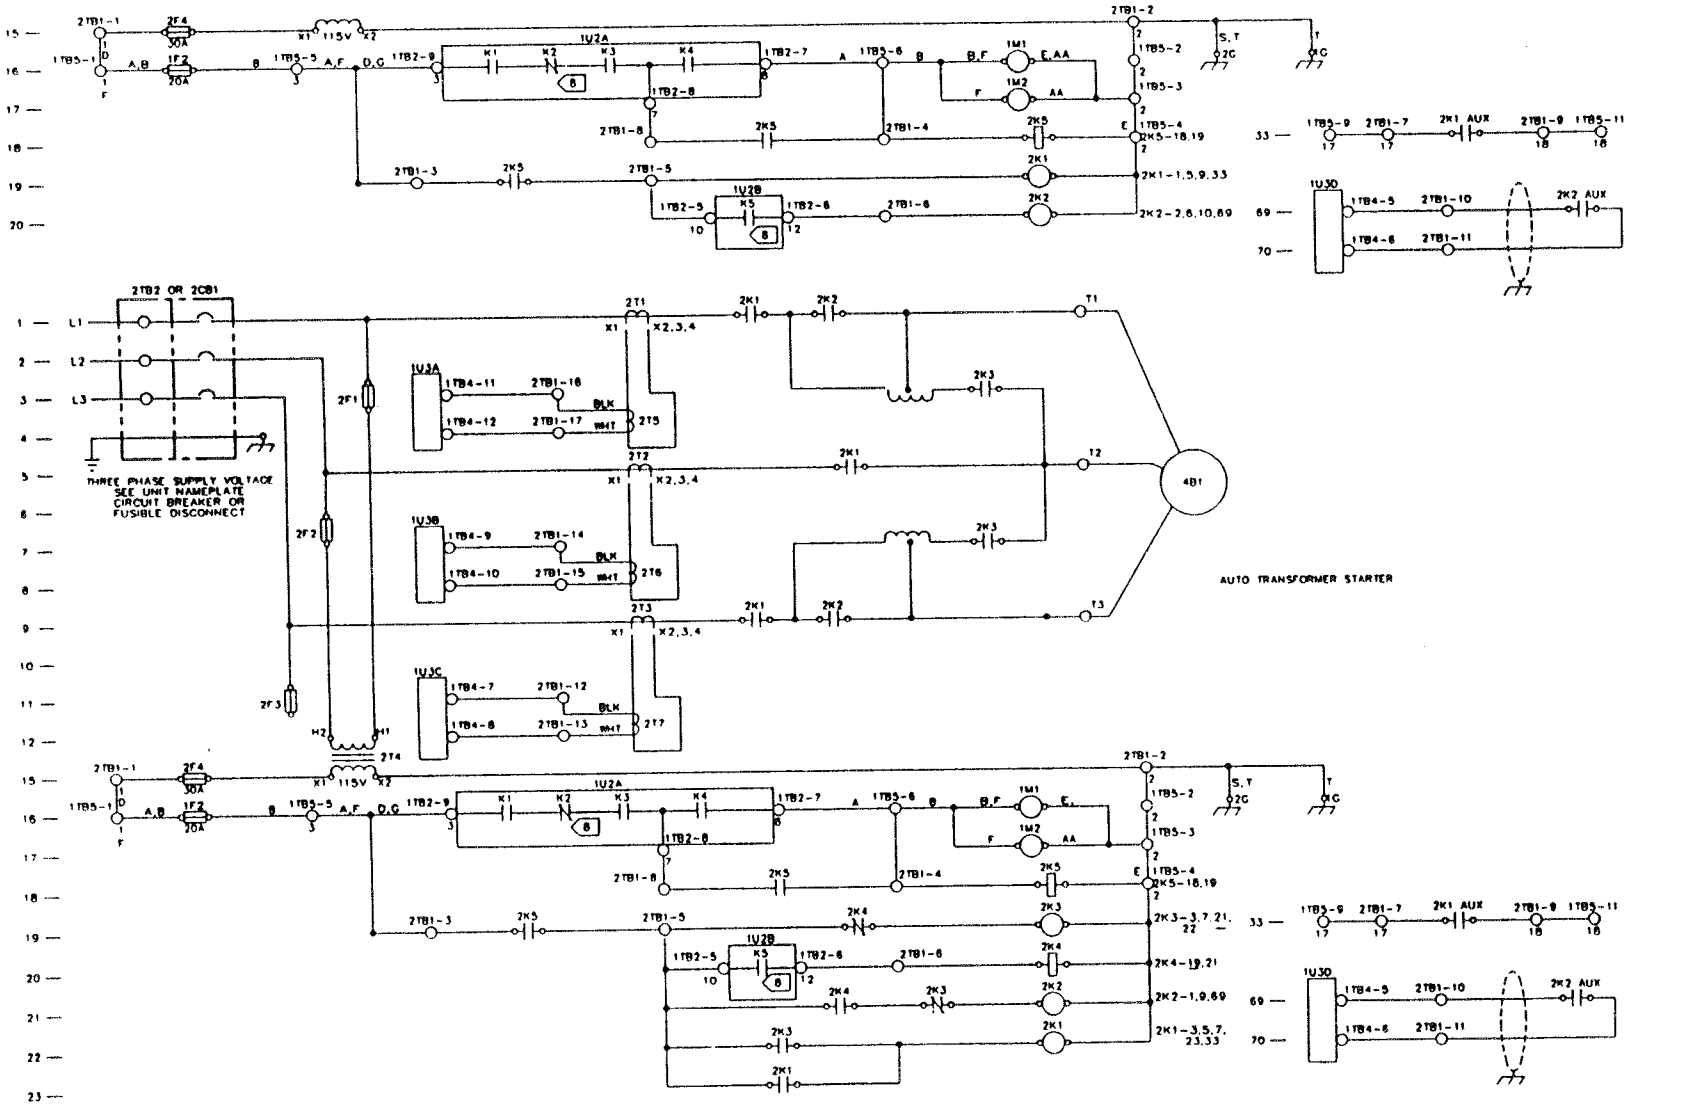
Note: Whenever checking any of the micro module's sensors, be sure to allow sufficient time for the sensor slew rate to "catch up" (i.e., 5 minutes maximum).



Unit troubleshooting information in this section is presented by diagnostic code, and follows the code sequence shown in Table 2 on page 9. Typical starter and chiller electrical schematics are provided in Figures 8 and 9 for reference. Terminal strip locations are shown in Figure 6 on page 34. Safety control cutout settings and operating time delay values are given in Table 18 on page 50.

WARNING: Failure to exercise caution when servicing unit may result in injury or death due to electrical shock.

Whenever micro module replacement is indicated by any of the following procedures, always check the power supply output module before replacing micro module 1U3 (See "Power Supply Checkout Procedure").



Note: When altering any of the micro module (1U3) settings, remember that none of the control setpoints can be changed if any of these diagnostic conditions exist: **b A3, b Ab, b AC, b Ad, b AE, b d9, b Ed, b F7, b F8, b F9, b FA, b Fb, b Fd** or **b FF**. In these instances, the condition that caused the diagnostic must be corrected first. For all other diagnostics, it is possible to change 1U3's control setpoints after manually resetting the chiller (i.e., adjust the chiller switch to STANDBY/RESET, then back to one of the AUTO positions).

NOTES

1. SOLID LINES INDICATE TRANE WIRING. DASHED LINES INDICATE FIELD WIRING. PHANTOM LINES INDICATE OPTIONAL FEATURES OR ALTERNATE CIRCUITRY.
2. UNLESS OTHERWISE NOTED, ALL SWITCHES ARE SHOWN AT 25°C (77°F), AT ATMOSPHERIC PRESSURE, AT 50% RELATIVE HUMIDITY, WITH ALL UTILITIES TURNED OFF AND AFTER A NORMAL SHUTDOWN HAS OCCURED.
3. NUMBERS ALONG THE RIGHT SIDE OF THE SCHEMATIC DESIGNATE THE LOCATION OF THE CONTACTS BY LINE NUMBER. AN UNDERLINED NUMBER INDICATES A NORMALLY CLOSED CONTACT. AN OPEN ARROWHEAD BELOW THE LINE NUMBER POINTING UPWARD INDICATES A TIMED CONTACT WHICH BEGINS TIMING WHEN ENERGIZED.

<4> SEE INSET D FOR TYPICAL INTERNAL WIRING OF ACTUATOR

Oilless Purge "Extend Run" Press. Switch — Closes / Opens	20 psig 25 psig	n/a	n/a

Notes:
1. See Tables 2 and 3 on pages 9 and 10 for complete code listing.
2. Since prelube timing can begin at any point during 33- second "oil pressure overdue" interval, actual elapsed time to "establish oil pressure" and "prelube" can be anywhere from 15 to 48 seconds.
3. The 165 F inhibit applies only when unit is first powered-up, or if chiller switch is turned from STANDBY/RESET to AUTO/ LOCAL or to AUTO/REMOTE. Otherwise, 30 minutes must elapse between compressor starts.
4. Operating code **A 9** will appear on operator display only when free cooling valve limit switches have opened.
5. See CVHB/E/F operation/maintenance manual for purge operation.
6. See "Electrical Sequence of Operation". Refer to Purifier Purge operation manual for details.
7. Reset at 3S6 or 6S6 on purge panel.
8. This timer closes sump vent line during prelube and during unit start sequence.
9. Fixed differential of 3-6 psid for switch closure on a rise in differential oil pressure.

Resetting Diagnostics

When instructed to RESET DIAGNOSTIC, turn chiller switch to STANDBY/RESET. (If the chiller switch is already at STANDBY/RESET, flip it to one of the AUTO positions--then back to STANDBY/RESET.) This should clear the diagnostic, and display operating code **A 0**.)

b A3
Evaporator Refrigerant Temperature Range

Diagnostic **b A3** is displayed if the selected evaporator refrigerant trip setpoint is below the minimum allowable setting. This setpoint is selected at the "Evap. Refrig. Trip" potentiometer on the UCP service interface (Figure 2, pg. 12). Minimum allowable setpoint is 29 F for standard range units; 0 F for extended range units. To reset the evaporator refrigerant temperature trip setpoint:

1. Turn evaporator refrigerant "trip" setpoint potentiometer fully clockwise.

2. Reset diagnostic.

3. Turn vane control switch to HOLD.

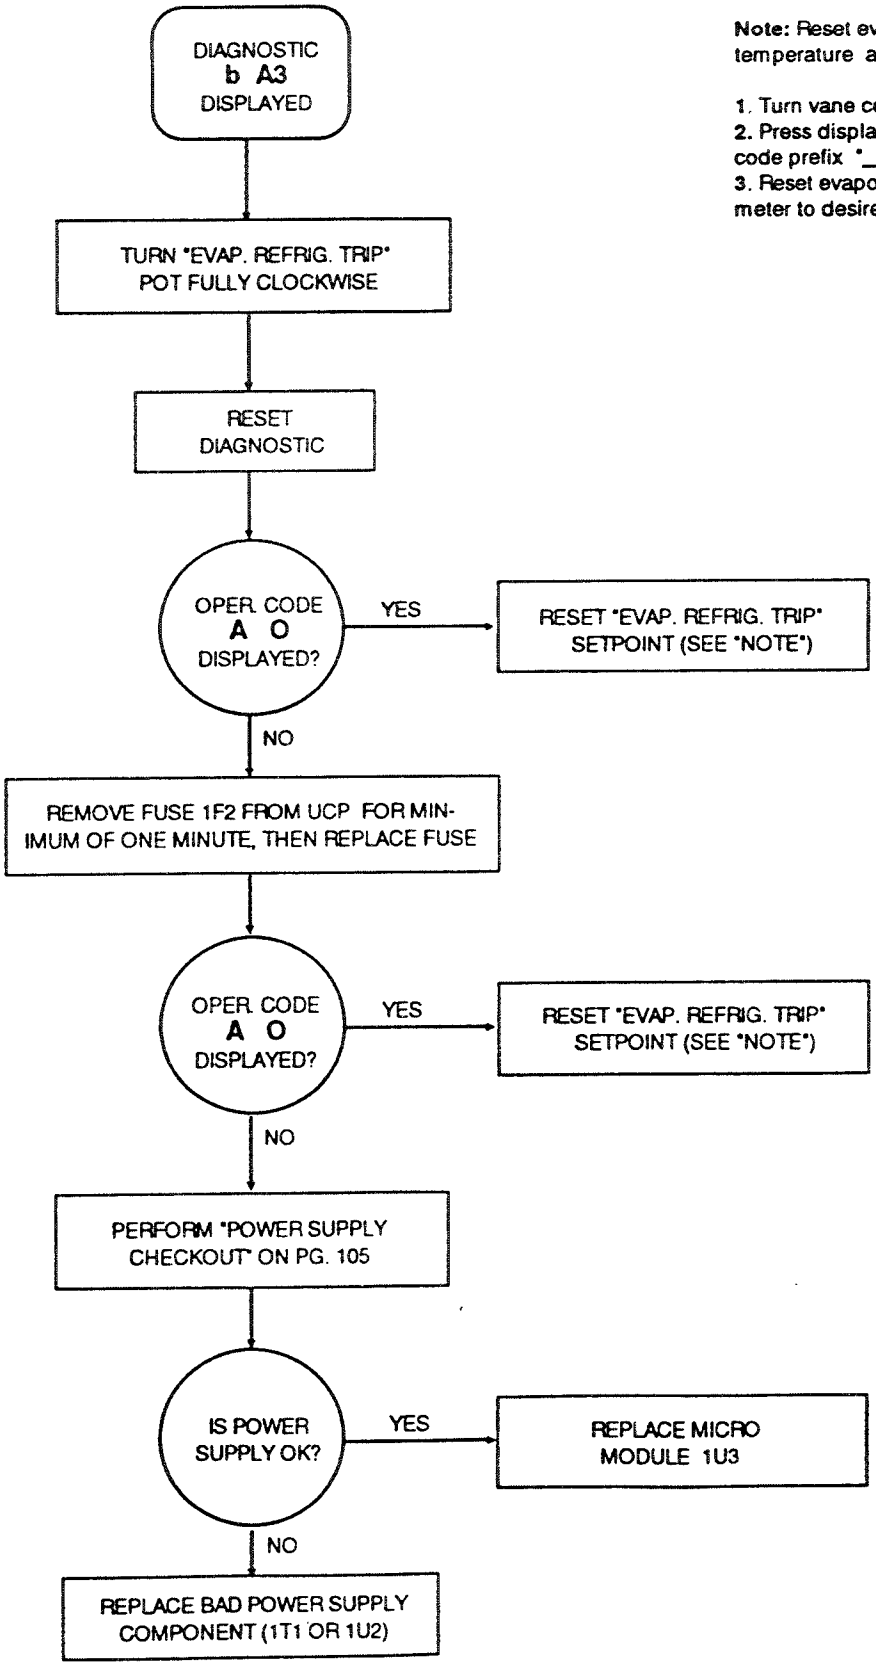
4. Press display advance pushbutton until evaporator trip setpoint code prefix **"U"** is displayed. Latching diagnostic **b A3** occurs if the setpoint is out-of-range low.

5. With the chiller switch still in STANDBY/RESET and the vane control switch at HOLD, reset the evaporator refrigerant trip setpoint by turning the potentiometer screw until the desired setpoint is reached.

If the display does not change when this adjustment is made, refer to the "b A3 Diagnostic Procedure" in Figure 10.

b A4, A7, A8
Motor Temperature Sensors

One of these diagnostics (i.e., **b A4, b A7 or b A8**) is displayed--and the unit shuts down--when the temperature measured at the corresponding sensor input (Figure 11) exceeds 310 F. To determine whether the sensor is open or malfunctioning, refer to the "b A4, b A7, b A8 Diagnostic Procedure" in Figure 11.



b A5
Maximum Acceleration Time Range

Latching diagnostic **b A5** is displayed if the acceleration time setpoint exceeds the maximum value allowable. The adjustment range for this setting--which is factory-set using DIP switch block S3-- is 6 to 65 seconds (± 2.5 seconds maximum). Refer to "Switch Block S3:.." on page 25.

Note: "Maximum acceleration time" is measured from compressor motor start to "transition" (i.e., when inrush current drops to 85% of compressor motor RLA). Starter type and available starting torque are used to determine this factory setpoint. Recommended maximum acceleration times for several starter types are:

27 seconds for "star-delta" starters;
16 seconds for "auto-transformer" starters;
11 seconds for "primary reactor" starters;
6 seconds for "across-the-line" starters.

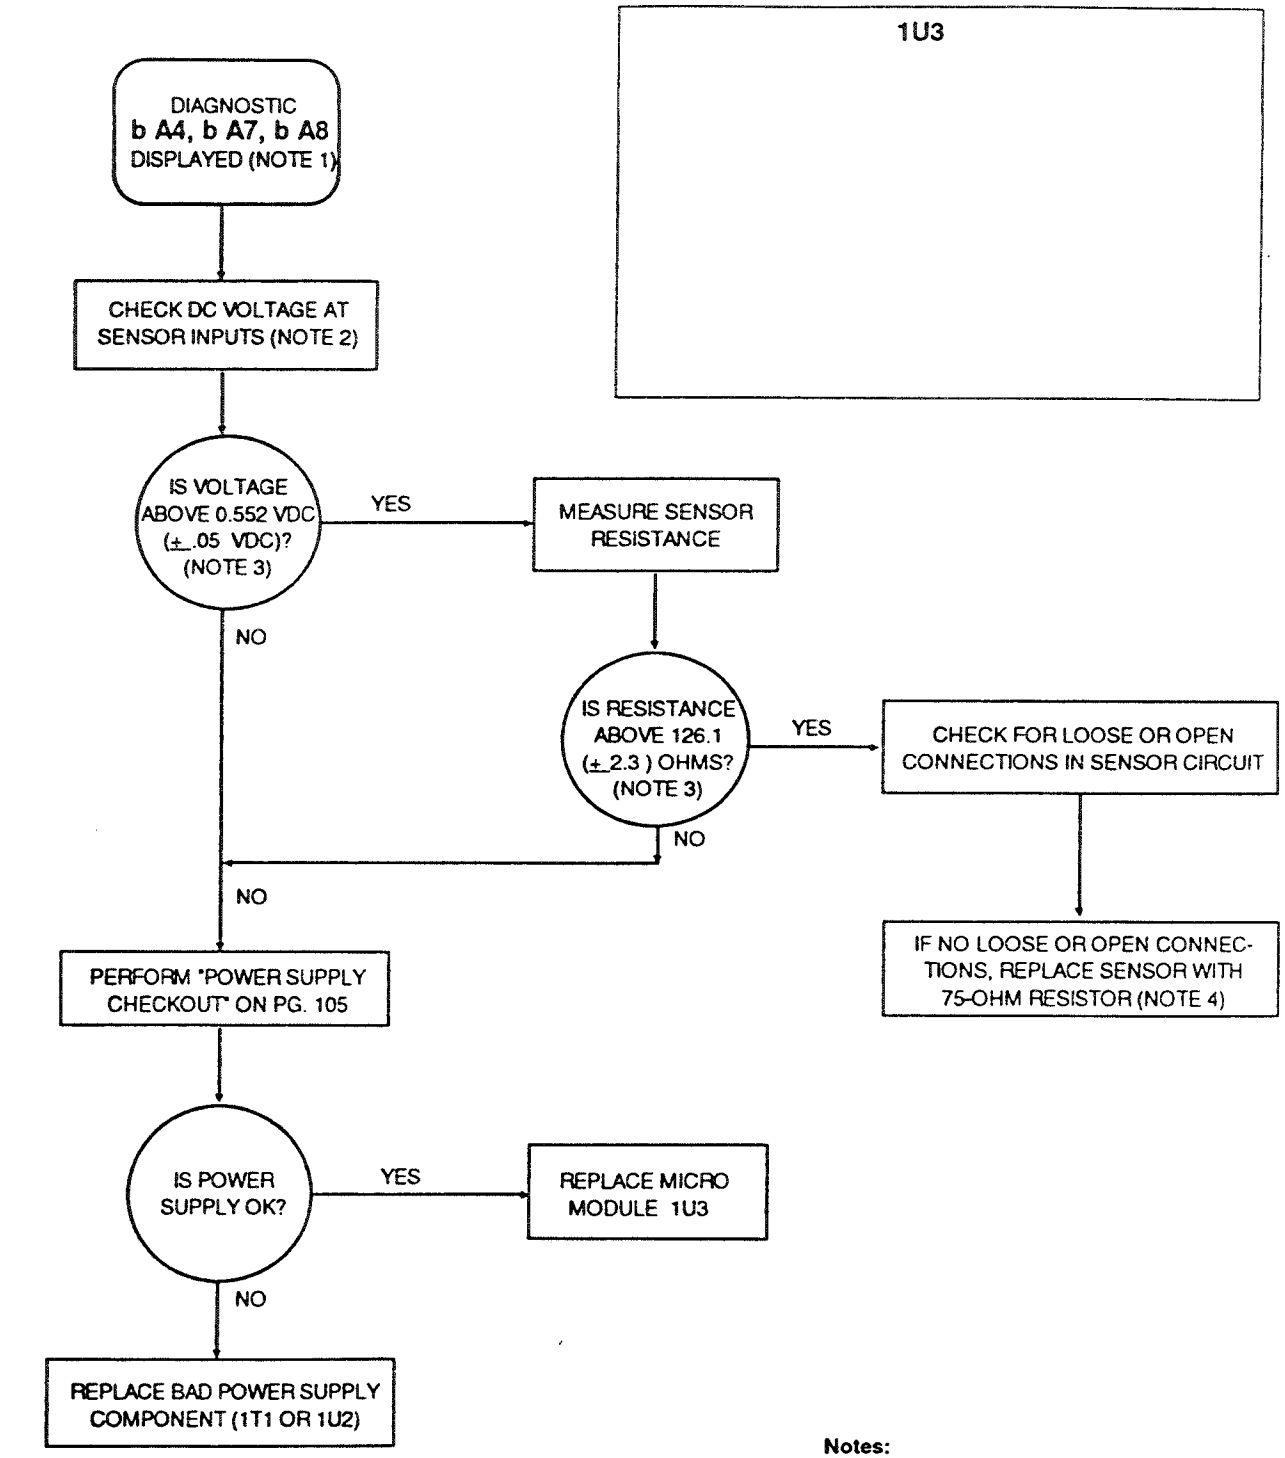


Figure 10 - Diagnostic "b A3" Evaporator Refrigerant Temperature Range

Note: Reset evaporator refrigerant trip temperature as follows:

1. Turn vane control switch to HOLD.
2. Press display advance pushbutton until code prefix "_" is displayed.
3. Reset evaporator refrigerant trip potentiometer to desired setpoint.

Figure 11- Diagnostic "b A4, b A7, b A8" Motor Temperature Sensor # 1, # 2 or # 3

Sensor Designation	Electrical Designation	Electrical Connections	Diagnostic Code
Sensor # 1	4B1R2	1TB4-15, -17	b A4
Sensor # 2	4B1R3	1TB4-16, -17	b A7
Sensor # 3	4B1R4	1TB4-18, -17	b A8

Notes:

1. These diagnostics can occur when the chiller is in any of the "start" or "run" modes.
2. Terminal 1TB4-17 is ground reference point.
3. Table 19 on the next page gives actual voltage and resistance for these rtd's over a wide range of temperatures.
4. Only two of the three motor temperature sensors can be replaced with resistors. After that, contact CenTraVac technical service department in La Crosse.

Table 19

270	0.514	116.4± 2.1	114.3	118.5
280	0.523	118.7± 2.2	116.5	120.9
290	0.532	121.1± 2.2	118.9	123.3
300	0.542	123.6± 2.3	121.3	125.9
310	0.552	126.1± 2.3	123.8	128.4

Note: To determine if thermistor is out of range, compare it's resistance (or voltage input) reading with "actual " temperature indicated by a thermometer, considering the thermometer's margin of error.

To check the maximum acceleration time setpoint:

1. Open the control panel door; then remove the narrow access strip immediately above the unit control module (Figure 2, page 12).

WARNING: Failure to exercise caution when servicing unit with power on may result in injury or death due to electrical shock.

2. With the DIP switch blocks exposed, check the maximum acceleration time setpoint established by the positions of Switches 1 through 5 on DIP switch block S3. Use Table 11 on page 26 to identify the proper switch positions for the recommended acceleration time settings.

Note: In the event that latching diagnostic **b A5** occurs, attempt to clear the diagnostic as described in the "b A5 Diagnostic Procedure" in Figure 12. If this diagnostic persists, micro module 1U3 is defective and must be replaced.

b A9
Oil Temperature Sensor

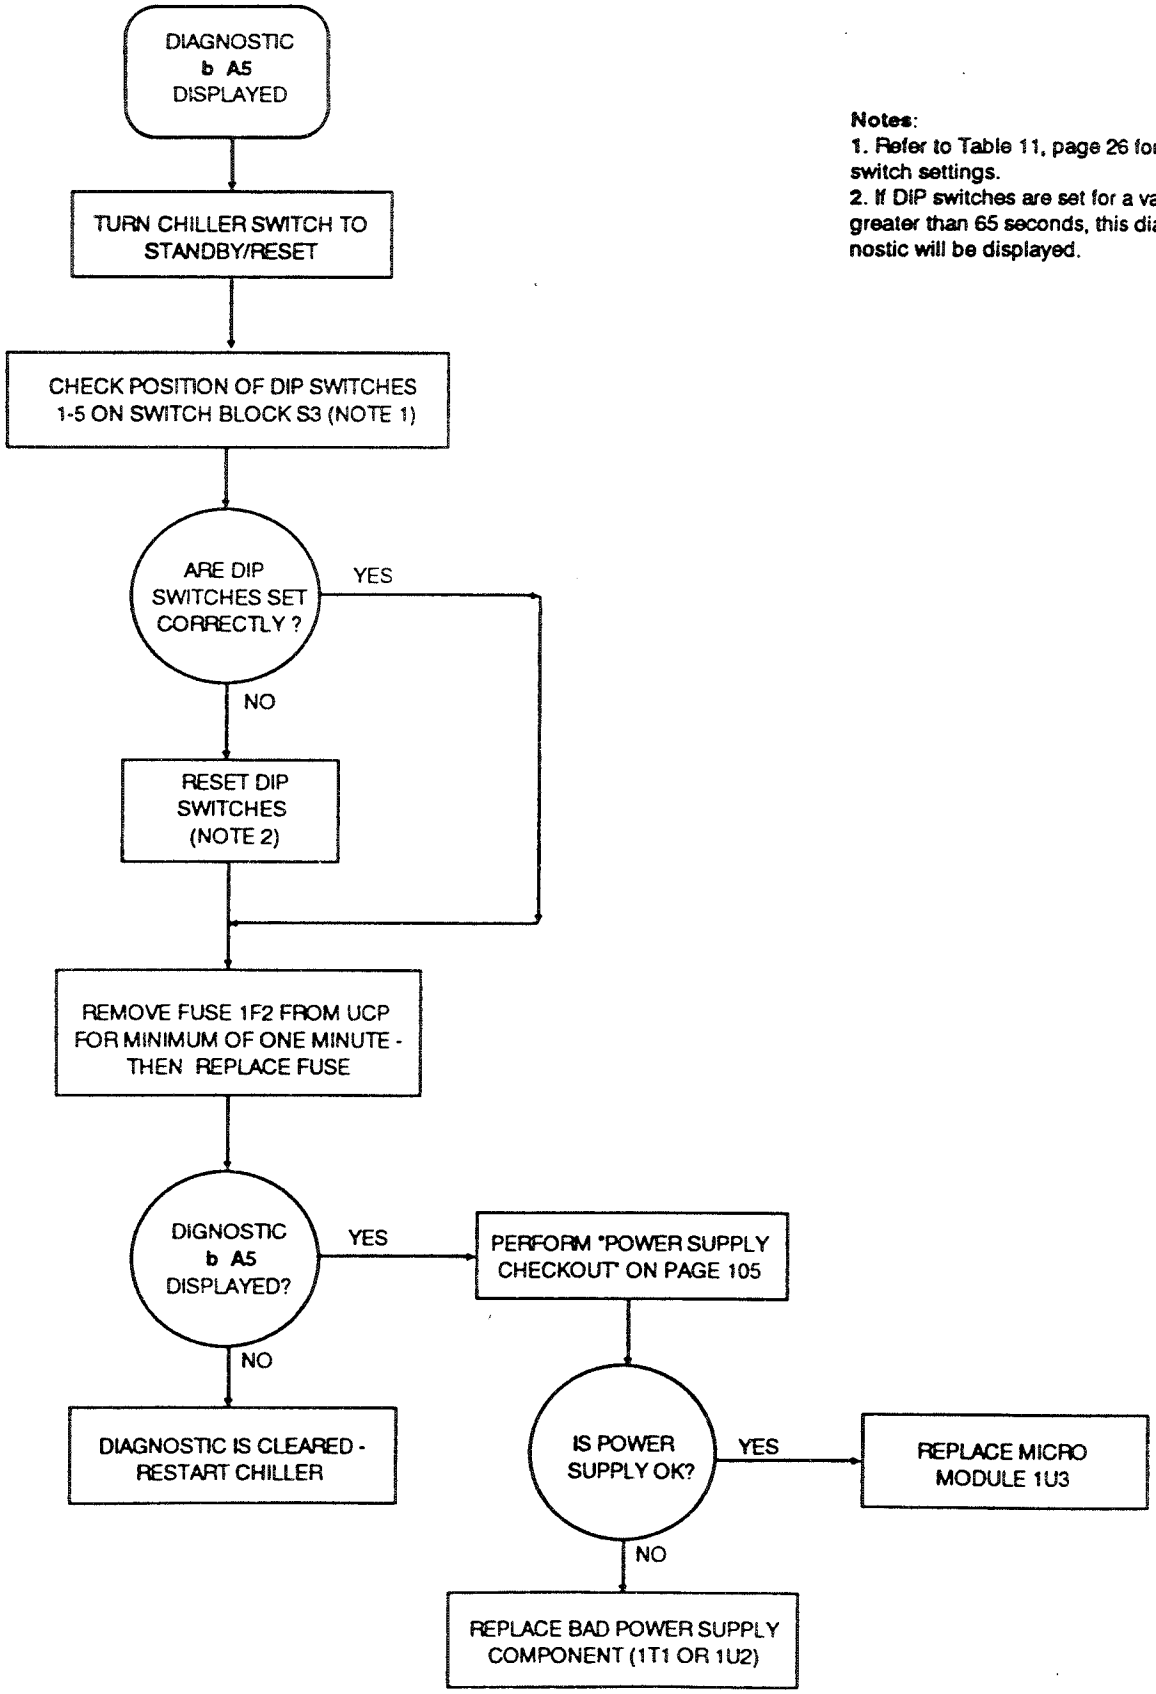
Diagnostic condition **b A9** occurs if the oil temperature sensor (4RT7) "reads" a temperature below 32 F or above 180 F. The oil temperature sensor is located in a bulbwell in the back of the oil sump, and its leads are connected to terminals 1TB4-13 and 1TB4-14 on micro module 1U3.

Use the instructions in the **"b A9** Diagnostic Procedure" in Figure 13 to determine whether 4RT7 is malfunctioning, shorted or open.

Note: It is unlikely that any machine's operating or nonoperating conditions would cause the oil temperature to fall below 32 F.

b Ab
Leaving (Evaporator) Water Temperature Sensor

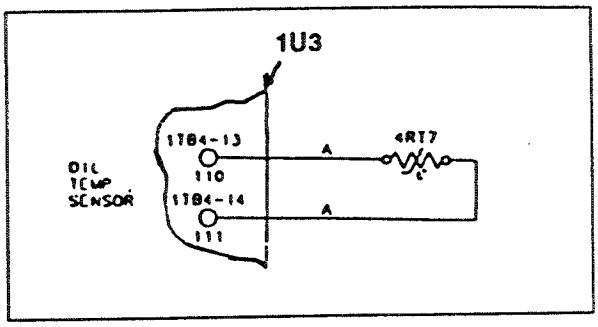
Latching diagnostic **b Ab** occurs whenever the temperature measured by the leaving evaporator water temperature sensor (4RT1) drops below 15 F. (A leaving water temperature "low limit" stops chiller operation at 35.3 F on standard range units only).



Use the instructions in the **"b Ab** Diagnostic Procedure" in Figure 14 to determine whether sensor 4RT1 is open or malfunctioning. (The sensor leads are connected to terminals 1TB3-1 and 1TB3-2 on micro module 1U3.)

If the results of the sensor checkout indicate that 4RT1 is functioning properly, determine why the leaving water temperature is so low; among the possible causes to consider are:

[ ] chilled water flow problems (e.g., plugged strainers or heat exchangers, bypassed water, pump malfunction, or erratic return water temperature).



[ ] control module or vane actuator malfunction (i.e., a loss of setpoint or actuator control can cause excessive loading).

Figure 12 - Diagnostic "b A5" Maximum Acceleration Time Range

Notes:
1. Refer to Table 11, page 26 for DIP switch settings.
2. If DIP switches are set for a value greater than 65 seconds, this diagnostic will be displayed.

Figure 13 - Diagnostic "b A9" Oil Temperature Sensor

DIAGNOSTIC b A9 DISPLAYED

CHECK DC VOLTAGE AT TERMINALS 1TB4-13, -14

IS VOLTAGE BETWEEN 2.1-5.21 VDC?

YES

NO

CHECK SENSOR RESISTANCE

DO VOLTAGE & RESISTANCE READINGS MATCH ? (NOTE 1)

YES

CHECK FOR LOOSE OR OPEN CONNECTIONS IN SENSOR CIRCUIT

ARE SENSOR CONNECTIONS OK?

YES

REPLACE SENSOR 4RT7 (NOTE 2)

CHECK SENSOR RESISTANCE

DO VOLTAGE & RESISTANCE READINGS MATCH ? (NOTE 1)

YES

RESET DIAGNOSTIC & RESTART CHILLER

NO

REPLACE MICRO MODULE 1U3

NO

REPAIR CONNECTION

NO

PERFORM POWER SUPPLY CHECKOUT ON PAGE 105

IS POWER SUPPLY OK?

YES

NO

REPLACE BAD POWER SUPPLY COMPONENT (1T1 OR 1U2)

Notes:
1. Compare voltage and resistance values given in Table 20 on next page.
2. Micro must be reset following 4RT7 replacement.

Notes:

1. Oil temperature sensor 4RT7 connected to 1U3 at 1TB4-13 and -14; overall accuracy is ±2 F at 100-180 F, ±5 F at 32-100 F.
2.. Bearing temperature sensors 4RT8 and 4RT9 connected to 1U3 at 1TB4-19, -20 and at 1TB4-21, -22; overall accuracy is + 2 F.
3. To determine if thermistor is out of range, compare resistance or voltage readings with "actual" temperature, considering the thermometer's margin of error.

52	18,916.69	3.027	90	7,330.53	1.791

Notes:
1. Sensor 4RT1 is connected between Terminals 1TB3-1 and -2 on micro 1U3; optional sensor 4RT2 is connected between Terminals 1TB3-3 and -4.
2. Overall accuracy for sensors 4TR1 and 4RT2 is ± 1 F from 20-70 F; ± 2 F from 70-90 F; and, ± 2 F from 15-20 F.
3. To determine if thermistor is out of range, compare resistance or voltage readings with "actual" temperature, considering the thermometer's margin of error.

b AC
Condenser Refrigerant Pressure Sensor (Optional)

The b AC diagnostic indicates that the micro module (1U3) has detected a problem with the optional pressure transducer (1R1). The diagnostic will be displayed if the transducer circuit between Terminals 1TB3-9 and 1TB3-10 — or between Terminals 1TB3-10 and 1TB3-11 — is shorted.

Troubleshooting A "b AC" Diagnostic

1. Remove the transducer wires connected to Terminals 1TB3-9, -10 and -11. Check the terminals for stray wires or other short circuits.

2. Reset (clear) the diagnostic at the control panel. If the diagnostic cannot be reset with the transducer disconnected, the micro module (1U3) is defective and must be replaced.

Note: Be sure to perform the power supply checkout procedure before replacing 1U3.

3. Check the wiring between the transducer and the terminal strip for any frayed or smashed areas that could cause a short. Repair same if found.

4. Measure the voltage between Terminals 1TB3-9 and 1TB3-11. This voltage should be 5.0 VDC or greater. If the voltage is less than 5.0 VDC, the micro module (1U3) is defective and must be replaced.

Note: Be sure to perform the power supply checkout procedure before replacing 1U3.

5. Reconnect the black wire to Terminal 1TB3-11 and the red wire to Terminal 1TB3-9. Measure the voltage between Terminals 1TB3-9 and -11. This voltage should be 5.0 VDC or greater. If it is not, the transducer is bad and must be replaced.

6. Connect the white wire to Terminal 1TB3-10. Measure the voltage at 1TB3-10 with respect to 1TB3-11. This voltage should be 2.5 VDC or greater. If it is less than 2.5 VDC, the transducer is bad; replace it. Check leads to ground for shorts in the transducer.

Table 22
Conversion Data for Condenser Pressure Transducer 1R1

Actual Pressure (PSIG)	Input Volts @ 1TB3-10,-11	Actual Pressure (PSIG)	Input Volts @ 1TB3-10,-11	Actual Pressure (PSIG)	Input Volts @ 1TB3-10,-11	Actual Pressure (PSIG)	Input Volts @ 1TB3-10,-11
0.0	4.759	8.0	4.036	16.0	3.313	24.0	2.590
1.0	4.669	9.0	3.946	17.0	3.223	25.0	2.500
2.0	4.579	10.0	3.855	18.0	3.132	26.0	2.409
3.0	4.488	11.0	3.765	19.0	3.042	27.0	2.319
4.0	4.398	12.0	3.675	20.0	2.951	28.0	2.228
5.0	4.307	13.0	3.584	21.0	2.861	29.0	2.138
6.0	4.217	14.0	3.494	22.0	2.771	30.0	2.048
7.0	4.127	15.0	3.403	23.0	2.680	----------	----------

Notes:
1. Optional transducer 1R1 is connected to Terminals 1TB3-9, -10 and -11 on micro module 1U3.
2. Overall accuracy of 1R1 is ± 1 psig from) psig to 25 psig.
3. To determine if the transducer is out of range, compare an input voltage reading withthe "actual" pressure reading indicated by the pressure gauge, considering the precision of the pressure gauge.
4. Due to the type of transducer used, the resistance generated cannot be read with a standard ohmmeter. However, the total resistance measured between the black and red wires should be approximately 10K.

b Ad
Evaporator Refrigerant Temperature Sensor

The evaporator refrigerant temperature sensor (4RT5) is factory-installed in a bulbwell located below the unit control panel, near the bottom of the evaporator shell. Latching diagnostic **b Ad** is initiated prior to start if 4RT5 senses an evaporator refrigerant temperature below -5 F or above 150 F.

Should this occur, use the sensor checkout procedure in Figure 15 to determine whether 4RT5 is open/shorted or malfunctioning. (4RT5 is connected to terminals 1TB3-12 and 1TB3-13 on micro module 1U3.)

Note: The **b Ad** sensor diagnostic normally occurs only during a nonoperating mode, since the evaporator trip setpoint is much higher than -5 F. No normal machine operating conditions will yield an evaporator refrigerant temperature lower than -5 F.

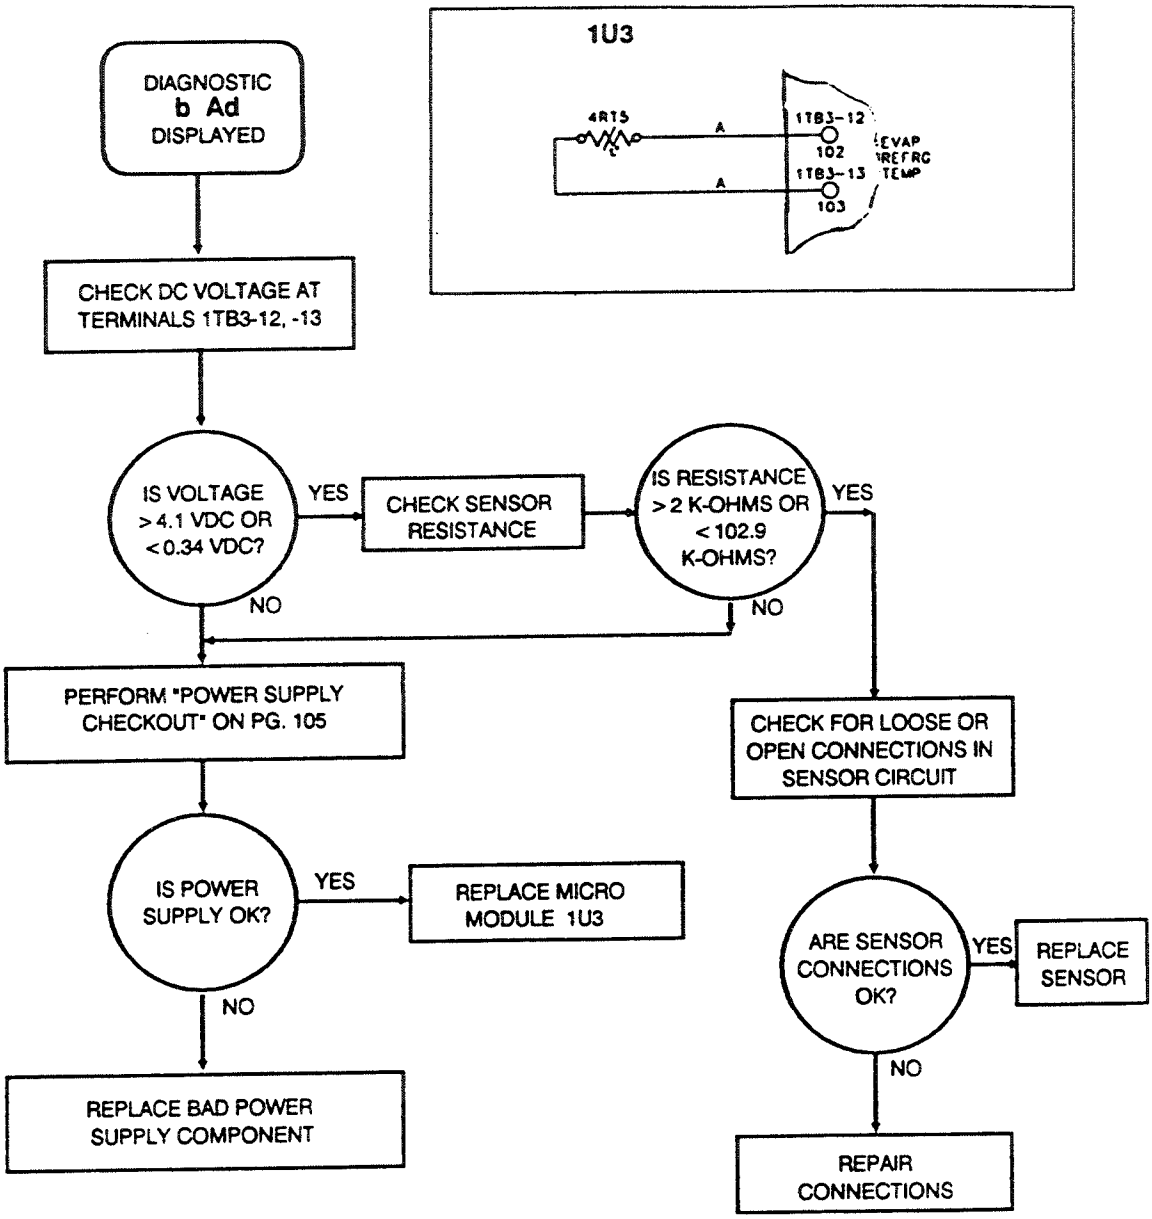
b AE
Ambient Temperature Sensor (Optional)

Latching diagnostic **b AE** occurs when the optional ambient temperature sensor (4RT6) registers an outdoor air temperature exceeding 150 F. If **b AE** appears on the display, determine whether or not 4RT6 is shorted or malfunctioning as described in Figure 16.

The optional ambient temperature sensor is connected between micro module (1U3) terminals 1TB3-14 and 1TB3-15.

b AF, b b0
Bearing Temperature Sensors (Optional)

Two optional sensors (4RT8 and 4RT9) are factory-installed in the oil drain lines of the compressor to monitor bearing temperature. Latching diagnostic **b AF** or **b b0** is displayed if the corresponding sensor (Figure 17, page 67) detects a temperature above the accepted range (i.e., 180 F).



The UCP (i.e., unit control module) checks these sensor inputs before start-up; a diagnostic is generated if either sensor registers a temperature exceeding 180 F. If a **b AF** or **b b0** diagnostic occurs, check the corresponding sensor for a malfunction or electrical short. See Figure 17, page 67 for sensor checkout instructions.

b d9
Extended Power Loss

Occurrence of this nonlatching, "power-up" diagnostic indicates that the UCP detected a power loss lasting 30 line-cycles or longer. All micro inputs are fixed so that memory is retained regardless of power outage duration. No action is required.

Once power is restored, the **b d9** diagnostic is retained in the "Last Diagnostic Code" register, and the UCP automatically initiates a "power-on" reset and the chiller will return to normal operation. Power losses lasting less than 30 line-cycles are considered "momentary". See "b E2: Momentary Power Loss" for further information.

Figure 15 - Diagnostic "b Ad"
Evaporator Refrigerant Temperature Sensor

Notes:
1. Sensor voltage and resistance values are given in Table 23 on next page.
2. Micro must be reset following 4RT5 replacement.

Notes:

1. Refrigerant temperature sensor 4RT5 is connected to 1U3 at 1TB4-12 and -13; overall accuracy is ± 0.80 F at 29 F, ± 1.0 F at 30.0 F, ± 2.0 from 0-26 F, and from 31-34 F, ± 5 F from -10 to -1 F and from 35-70 F.
2. To determine if thermistor is out of range, compare resistance or voltage readings with "actual" temperature, considering the thermometer's margin of error.

Figure 16 - Diagnostic "b AE" Ambient Temperature Sensor (Optional)

Notes:
1. Sensor voltage and resistance values are given in Table 24 on next page.
2. Micro must be reset following 4RT6 replacement.

Notes:

1. Optional ambient temperature sensor 4RT6 is connected to 1U3 at 1TB3-14 and -15; overall accuracy is ± 3 from 0-70 F, ± 5 F from -5 to 0 F, ± 8 F from 70-135 F .2. To determine if thermistor is out of range, compare resistance or voltage readings with "actual" temperature, considering the thermometer's margin of error. 3. As you compare a thermistor resistance (or input voltage) reading with the actual temperature indicated by the thermometer, be sure to consider the precision of the thermometer when you decide whether or not the thermistor is out of range.

Figure 17 - Diagnostics "b AF" and "b bO" Bearing Temperature Sensors (Optional)

Sensor Designation	Electrical Designation	Electrical Connections	Bearing Monitored	Diagnostic Code (3)
Sensor # 1	4RT8	1TB4-19, -20	Inboard	b AF (b EA)
Sensor # 2	4RT9	1TB4-21, -22	Outboard	b b0 (b Eb)

Notes:

1. Sensor voltage and resistance values are given in Table 20 on page 58.
2. Micro must be reset following 4RT8 or 4RT9 replacement.
3. Diagnostic codes **b AF** and **b bO** occur only during non-operating modes; diagnostics **b EA** and **b Eb** are "running" diagnostics that are generated whenever the UCP detects a high bearing temperature (i.e., > 180 F).

b dA
Surge

Occurrence of latching diagnostic **b dA** indicates that the UCP detected a surge condition during unit operation. Surge detection is based on current fluctuations in one of the three motor phases. To trigger the surge diagnostic, 5 fluctuations exceeding a special RMS-average current value and rate must occur within a 60-second time frame.

Initial detection of surge results in the energizing of an optional head relief request relay (i.e., K3 on relay output module 1U1). If the surge condition continues for 15 minutes, the UCP shuts down unit operation on latching diagnostic **b dA**.

"Surge" results from an unusually high pressure differential across the compressor. A partial list of chiller operating conditions that can produce surge is provided below:

[ ] high condenser water temperature
[ ] excessive air in the unit;
[ ] insufficient condenser water flow;
[ ] fouled condenser tubes; and,
[ ] a shortage of refrigerant.

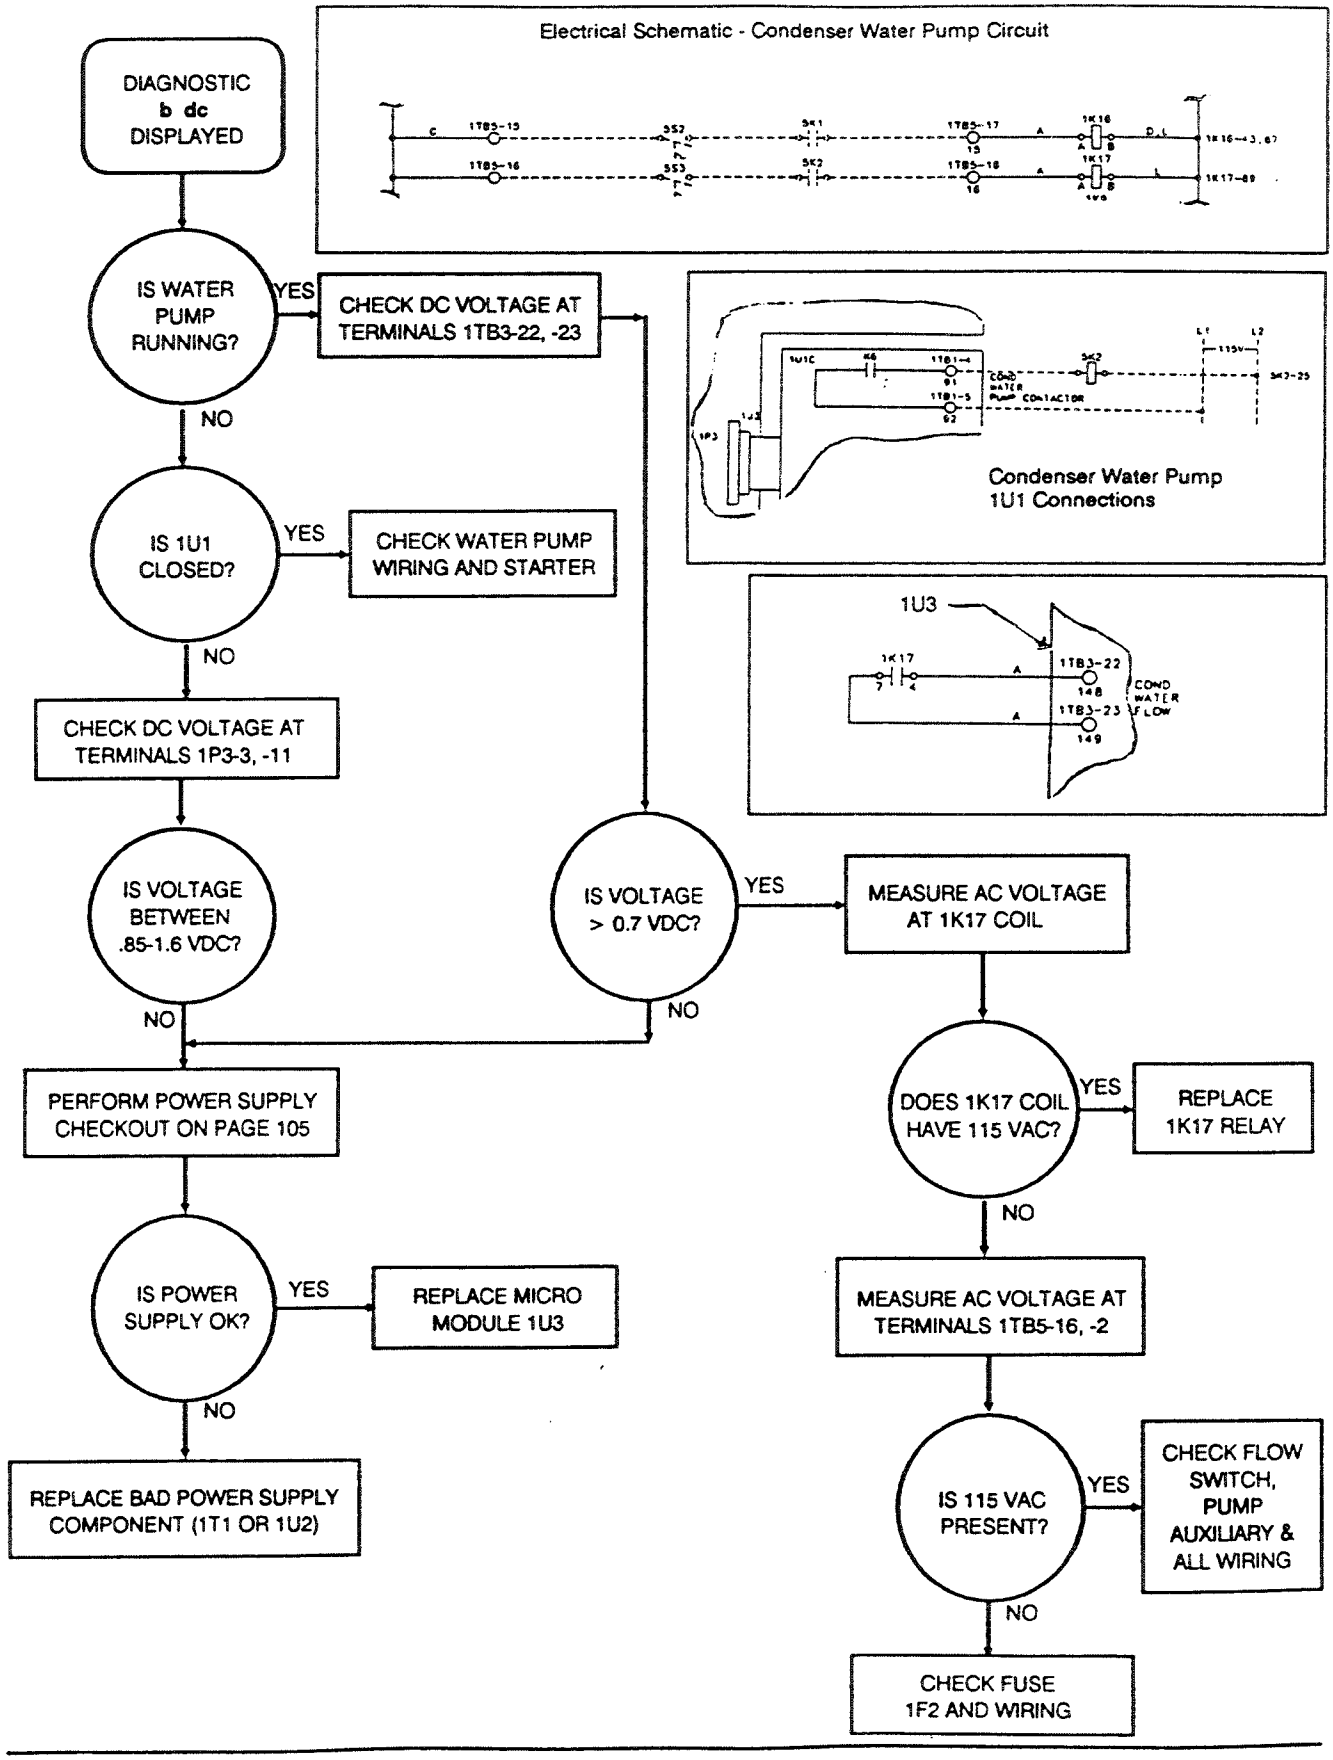
If the unit locks out on a surge diagnostic, check for--and correct--these problem conditions before restarting the chiller.

Note: To override the surge protection (and phase imbalance) feature, move DIP switch no. 7 on DIP switch block S3 to the ON position.

b dc
Condenser Water Flow Overdue

During the start sequence, the UCP closes condenser water pump relay K6 (i.e., located between terminals 1TB1-4 and 1TB1-5 on relay output module 1U1). Closure of the K6 contacts issues a signal to start the condenser water pump. As the UCP checks for condenser water flow, the operating code appearing on the display changes from **A 70** (restart inhibit) to **A 71** (establish condenser water flow).

If flow is not proven (i.e., condenser water flow switch 5S3 does not close) within 3 minutes of K6 contact closure, the unit will shut down on latching diagnostic **b dc**.



A number of component malfunctions and operating problems can result in a "condenser water flow overdue" diagnostic; below is a partial list:

1. faulty condenser water pump relay (K6);
2. faulty condenser water pump contactor (5K2);
3. faulty condenser water pump auxiliary contactor (5K2);
4. faulty condenser water flow switch (5S3);
5. faulty condenser water pump relay (1K17);
6. closed condenser water circuit valves;
7. condenser water circuit valves are open to too many machines; and,
8. plugged condenser water circuit strainers.

Before restarting the chiller, determine why condenser water flow was not established and correct the problem.

Note: To troubleshoot the condenser water pump electrical circuit, (i.e., Items 1 through 5 above), refer to Figure 18 on the next page.

Figure 18 - Diagnostic "b dc" Condenser Water Flow Overdue

b E2
Momentary Power Loss

Occurrence of this nonlatching diagnostic indicates that there was a brief loss of power. The CT input to the micro must drop below 23% of RLA for a period of at least 2 or 3 line-cycles in order for the micro module to detect it; 1U3 will then take the chiller off-line within 6 line-cycles (i.e., including detection time). Momentary power losses of this type are usually caused by an automatic switching gear in the main power lines.

A power loss lasting from 1 to 30 line-cycles results in a normal unit shutdown (i.e., the oil pump continues to run). The UCP undergoes a "power-on" reset and follows the normal start-up criteria. Diagnostic **b E2** is then stored in the "Last Diagnostic Code" entry of the display menu.

If the power interruption lasts more than 30 line-cycles, the UCP identifies this as an "extended power loss" and initiates a "power-on" reset after power is restored. The **b d9** diagnostic is retained in the "Last Diagnostic Code" register, and the unit follows the normal start-up criteria (e.g., restart inhibit, differential-to-start, etc.). (See "b d9: Extended Power Loss".) To troubleshoot an occurence of this diagnostic, refer to Figure 19 on the next page.

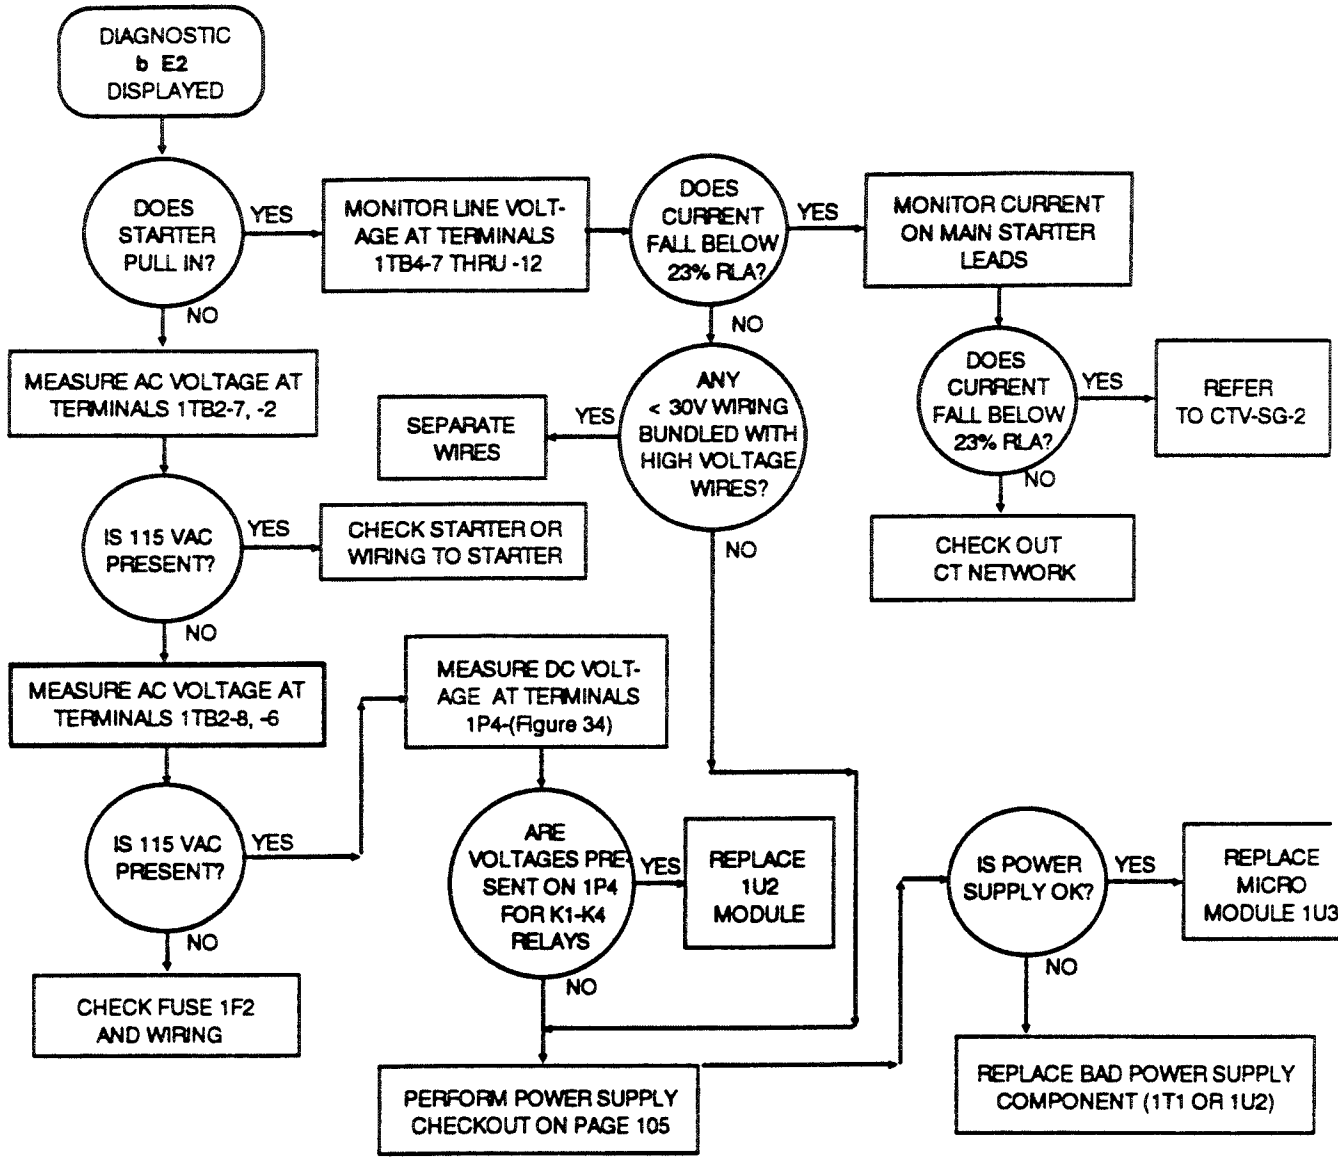
Note: The UCP identifies a "momentary power loss" condition when the incoming current is below 23% of the rated load amps (RLA).

b E3
Phase Imbalance (Optional)

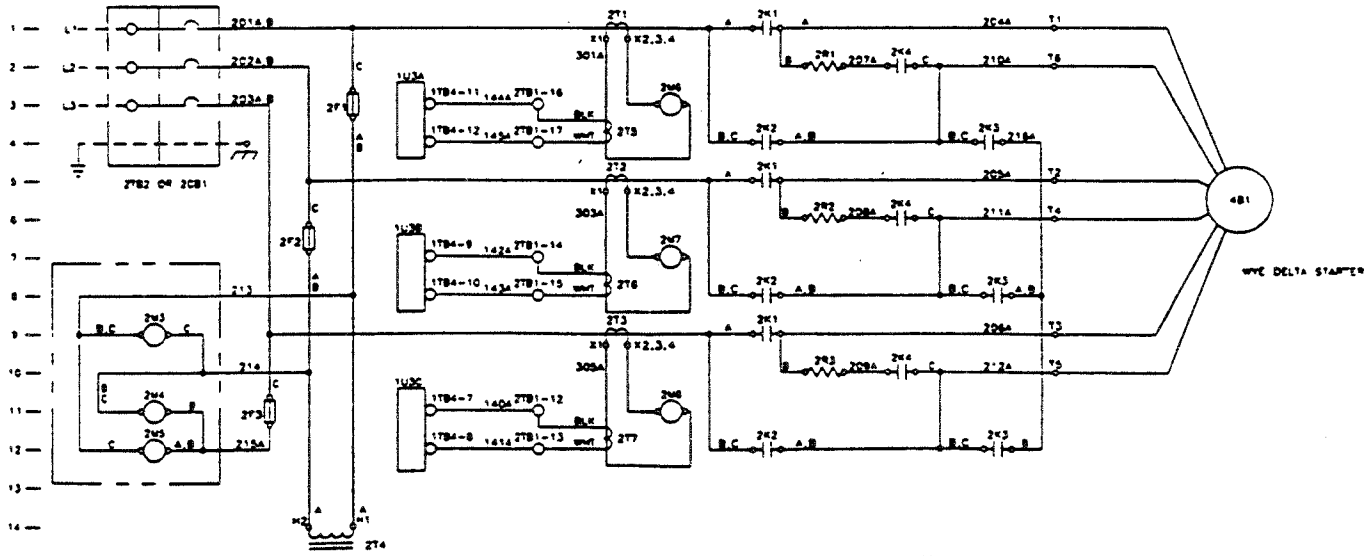
Latching diagnostic **b E3** occurs when a phase imbalance exceeding 15% occurs. The UCP recognizes that a phase imbalance condition exists when the following criteria are met:

[ ] the chiller is operating in one of the "run" modes (see Table 2, page 9);
[ ] the average 3-phase current is greater than 80% of the RLA;
[ ] the imbalance exists for longer than 1 second; and,
[ ] the percent of imbalance is greater than 15%.

Note: The percent of imbalance is calculated using this equation–



$$\frac{I_{Ph\#} - I_{Avg}}{I_{Avg}} \times 100$$



where $I_{Ph\#}$ is one of the 3 phases, and $I_{Avg} = \frac{IPh1 + IPh2 + IPh3}{3}$

Two possible (but not the only) causes of a phase imbalance are: (1) a voltage imbalance of the incoming power, and (2) a resistance imbalance of the compressor motor windings. (The latter is very rare because of the stringent specifications employed by the motor manufacturer during the winding and testing of new motors.)

If unit is equipped with an optional PFCC be sure to check for proper wire routing or refer to CVHE-IN-6 for additional information on PFCC.

Figure 19 - Diagnostic "b E2" Momentary Power Loss

To determine whether the fault lies with the line power or the motor, follow this procedure:

WARNING: To prevent injury or death due to electrical shock, use extreme care when working with energized electrical equipment.

Note: Amperage measured must be line current (not phase current), and should be measured at the line side of the starter (i.e., incoming power lines). Measure voltage at the motor terminals while the unit is operating; any voltage imbalance related to the starter or to wiring resistance will be included in the imbalance calculations.

1. Voltage imbalance can be caused by a voltage drop across any of the starter panel components:

a. Measure voltage across each of the starter components to the motor terminals on each phase while the unit is operating.

b. Use the low (i.e., 0 to 5 volts) scale of a volt-ohmmeter to read the voltage on either side of the same electrical phase on all contactors, fuses, circuit breakers, leads, etc. There should not be any appreciable voltage drop across any of these circuits.

If a measured voltage drop is observed across a lead or contactor, a poor connection or worn contact is indicated. Repair or replace as necessary.

c. If the results of Steps 1a and 1b indicate that the voltage imbalance is not caused by the starter or motor leads, contact the power company.

2. If there is a current imbalance with no measurable voltage imbalance, determine whether a motor or line problem exists. To do this, rotate the motor leads to verify whether the current imbalance stays with one particular motor winding, or follows one set of phase leads as the wires are rotated. Operate the motor just long enough to obtain current readings. (Since some motors have unidirectional bearings, rotate the motor leads twice to maintain proper motor rotation.)

If the current imbalance follows one set of phase leads, the incoming power is at fault and may be the result of unbalanced impedance or resistance somewhere in the power system.

Contact the power company for assistance.

If the current imbalance remains with a particular motor winding, contact the La Crosse Service Department with complete nameplate information.

Note: To override the phase imbalance (and surge) feature, move DIP switch no. 7 on DIP switch block S3 to the ON position.

b E4
Phase Loss

Occurrence of this latching diagnostic indicates that 1 leg of the 3-phase power supply has been lost. The phase loss "threshold" recognized by the UCP is any phase that drops below 23% of the RLA for more than 1 second.

A variety of causes can result in a phase loss condition; three of these include: (1) a blown fuse or breaker in one leg; (2) an incomplete or open line connector to one leg; and (3) a burned or open motor winding.

Be sure to determine and correct the fault condition that created the phase loss before restarting the unit.

b E5
Phase Reversal

Latching diagnostic **b E5** is generated by the UCP within 1 second of its detection of a counterclockwise phase rotation in the incoming power. (For proper machine operation, the incoming power must be phased for clockwise rotation.)

Possible reasons for a phase reversal condition include–but are not limited to–these:

1. incoming power is phased for counterclockwise rotation;

2. current transformer polarity (i.e., primary or secondary) is reversed;

3. a current transformer wiring error; and,

4. an electrical connection error between the current transformer and micro module 1U3.

If phase rotation is incorrect, the unit will shut down on the **b E5** diagnostic when a start-up is attempted. To reverse the rotation, change the phasing at the incoming power to the starter. Do not attempt to change rotation at the motor terminals!

WARNING: To prevent injury or death due to electrical shock, open chiller disconnect switch before reversing phasing.

If you determine that the incoming power is phased correctly, conduct a thorough checkout of the current transformer polarity and wiring. (Current transformer checkout is provided in the "Checkout Procedure for Compressor Transition Relay" section of this bulletin.)

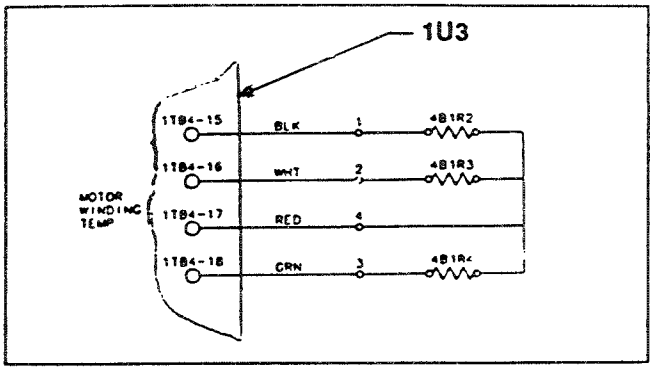
b E7
High Motor Temperature

Three RTD-type sensors embedded in the motor windings enable the UCP to monitor the temperature of the compressor motor. If the UCP detects a motor winding temperature exceeding 265 F (i.e., ± 15 F, UCP error only), it initiates a latching diagnostic. Code **b E7** flashes on the control panel display and the unit is shut down.

Below is a list of some of the circumstances that can result in a "high motor temperature" diagnostic:

1. inaccurate sensor response or open sensor (i.e., check the sensors and micro module 1U3);

2. plugged motor cooling orifice;



3. plugged motor cooling drain lines;

4. "low voltage" condition, resulting in over-amperage; and,

5. motor operation in excess of the RLA.

To diagnose an occurence of this diagnostic, refer to Figure 20 on the next page.

IS POWER SUPPLY OK?

YES → REPLACE MICRO MODULE 1U3

NO

REPLACE BAD POWER SUPPLY COMPONENT

b E8
Differential Oil Pressure Switch

One of the UCP695 control panel's safety features requires micro module 1U3 to check the status of the differential oil pressure switch (1S2) between compressor starts: it must open after each compressor shutdown. If switch 1S2 does not open before the UCM initiates oil pump operation during the next unit start sequence, a latching diagnostic occurs. Code **b E8** flashes on the display and the chiller start sequence is aborted. This diagnostic condition will occur if the oil pump switch (i.e., on the control panel front) is set at "On" when a start-up is attempted. To diagnose an occurence of this diagnostic, refer to Figure 21 on the next page.

To check for proper operation of switch 1S2, monitor terminals 1TB4-1 and 1TB4-2 while manually starting and stopping the oil pump with the oil pump switch. If 1S2 is functioning correctly, the differential oil pressure switch will close when the pressure differential rises to 15 psid and open when it falls to 9 psid. Before condemning micro module 1U3, ensure that the contacts of switch 1S2 are clean and dry, and that there are no wiring errors (e.g., a strand crossover at the terminal strip).

Note: Diagnostic **b E8** normally occurs only during the chiller start sequence. It does not occur when a low oil pressure condition is detected. (See "b F2: Low Oil Pressure".)

b E9
Stop Relay

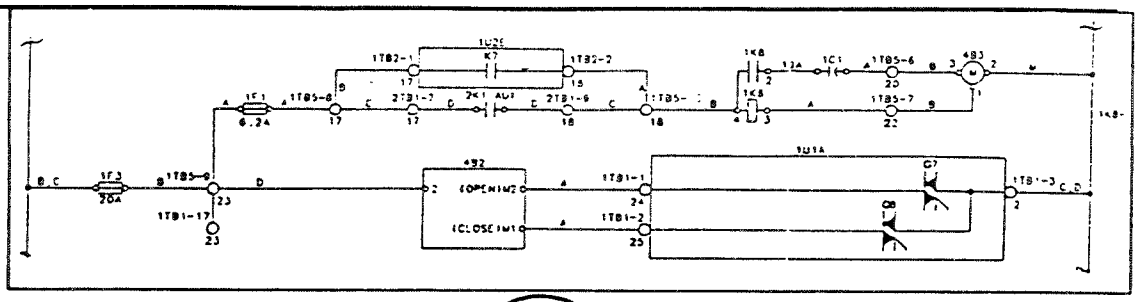
This latching diagnostic is generated if you attempt to shut down the chiller, but the UCM continues to detect current; when this situation occurs, the UCM takes the chiller off-line by opening the overload relay.

During the normal stop sequence, the micro module opens both the stop relay (1U2K2) and the overload relay (1U2K3), which interrupts the "run" signal to the starter. If the motor current does not drop to zero when the "run" signal is interrupted, the micro module will display the latching diagnostic **b E9**.

Probable causes for a **b E9** diagnostic include:

a. failure of starter pilot relay 2K5;
b. failure of main starter contactors 2K1 and 2K2;
c. failure of control modules 1U3 and/or 1U2.

Note: The **b E9** diagnostic indicates a serious problem with the control system. If the module is displaying the **b E9** diagnostic and the chiller is still running, operation will have to be interrupted using the main disconnect switch. Use caution when opening the disconnect as they generally are not designed to interrupt large current flows.



1. With the main disconnect open, inspect the starter contactors 2K1, 2K2, 2K3, 2K4 and 2K5. If any of these contactors are in the closed position, determine what caused the failure and correct it. Be certain that none of the contactors are closed or can pass current through their contacts before continuing.

WARNING: To prevent personal injury or death due to electrocution, be certain that contacts of starter contactors are open.

2. Remove Wire #3 from the starter-side of 2TB1-3 in the starter panel. (**Note**: This wire provides the control voltage to the starter circuit through the N.O. 2K5 relay contacts.)

3. With the chiller switch in the STANDBY/RESET position, close the main disconnect switch to energize the control panel.

DIAGNOSTIC b E8 DISPLAYED

RESET DIAGNOSTIC

IS OIL PUMP RUNNING BEFORE A 72?
- YES → CHECK POSITION OF OIL PUMP SWITCH
  - IS SWITCH IN ON POSITION?
    - YES → TURN SWITCH TO AUTO
    - NO → CHECK POSITION OF 2K1 AUXILIARY CONTACTS
      - ARE CONTACTS CLOSED?
        - YES → CHECK OUT STARTER
        - NO → CHECK POSITION OF 1U2-K7 CONTACTS
          - ARE CONTACTS CLOSED?
            - YES → MEASURE DC VOLTAGE AT PLUG 1P4-4, -11
              - IS VOLTAGE BETWEEN 0.85-1.6 VDC?
                - YES → PERFORM "POWER SUPPLY CHECKOUT" ON PG. 105
                - NO → REPLACE 1U2 MODULE
            - NO → CHECK FOR SHORTED WIRES
- NO → MEASURE DC VOLTAGE AT TERMINALS 1TB4-1, -2
  - IS VOLTAGE > 0.7 VDC?
    - YES → PERFORM "POWER SUPPLY CHECKOUT" ON PG. 105
    - NO → CHECK CONDITION OF SWITCH 1S2
      - IS 1S2 CLOSED?
        - YES → REPLACE SWITCH 1S2
        - NO → CHECK FOR SHORTED WIRING

PERFORM "POWER SUPPLY CHECKOUT" ON PG. 105
- IS POWER SUPPLY OK?
  - YES → REPLACE MICRO MODULE 1U3
  - NO → REPLACE BAD POWER SUPPLY COMPONENT

4. Check and record the voltages at the following pins on ribbon connector 1P4:

a. Pin 5 with respect to Pin 14 = should be 0.0-0.1 VDC;
b. Pin 7 with respect to Pin 14 = should be 0.0-0.1 VDC;
c. Pin 8 with respect to Pin 14 = should be 0.85 to 1.6 VDC.

i) If any of the measured voltages are out of range, module 1U3 is bad; replace it.
ii) If the measured voltages are in range, go to Step 5.

5. Check the control voltage at Terminals 1TB2-9 and 1TB2-8 with respect to Terminal 1TB5-3.

i) If control voltage is not present at 1TB2-9, check fuses 1F2 and 1F4, and the power supply transformer 2T4.
ii) If control voltage (115 VAC) is measured at both terminals, 1U2 is bad; replace it.
iii) If control voltage is measured at 1TB2-9 but not at 1TB2-8, go to Step 6.

6. If no problems have been found in the previous steps, the problem may be intermittent. The following items may help isolate the problem:

a. With the start signal disconnected from the starter (as in Step 2), run the chiller through the normal start sequence. Confirm that pilot relay 2K5 pulls in momentarily and then drops out. Non-latching diagnostic **b E2** should be displayed.

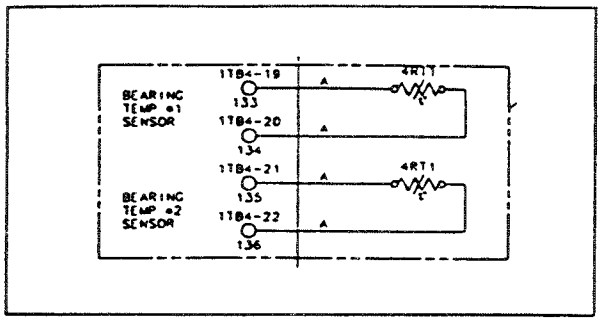
b. Perform the starter "dry run" procedure as described in the "Initial Start-Up Procedure" section of the appropriate service guide. Confirm that all contactors are reacting in the proper sequence. Check the resistance through the main contactors to confirm their proper operation. Repeat the sequence several times.

b EA, Eb
High Bearing Temperature (Optional Sensors # 1, # 2)

The occurrence of latching diagnostic **b EA** or **b Eb** indicates that one of the optional bearing temperature sensors registered a leaving oil temperature (from the motor bearings) exceeding the 180 F trip point.
If the UCP detects a high bearing temperature:

1. Check bearing temperature sensors 4RT8 and 4RT9 for proper operation using the checkout instructions in Figure 17 on page 67.

Note: Determine which bearing (i.e., inboard or outboard) is running hot by noting which sensor tripped. See Table 20 on page 58. Shorting 4RT8 or 4RT9 at the sensor should result in a sensor failure diagnostic (i.e., b AF or b b0). Be sure to allow enough time for the sensor slew rate to "catch up" (i.e., 5 minutes, maximum).



2. Check the oil sump temperature. Normal sump temperature ranges are 140 to 145 F when the unit is off, and 115 to 150 F while the chiller is running.

If the oil sump temperature reading is above the normal range:

a. Check the oil cooler for proper operation (CVHE 036 thru 125 only).
b. Verify that the oil heater control is functioning correctly. (See "b F4: High Oil Temperature".)

Other possible causes of a high bearing leaving oil temperature include: (1) an insufficient flow of oil to the bearings, and (2) a progressive bearing failure. Refer to the diagnostic chart in Figure 22 on the next page.

IS VOLTAGE > 2.159 VDC? — YES → MEASURE RESISTANCE AT TERMINALS 1TB4-19, -20, -21, -22 → DOES RESISTANCE CORRESPOND TO VALUES IN TABLE 20, PAGE 58? — YES → CHECK OUT OIL SUPPLY SYSTEM

NO

NO

PERFORM "POWER SUPPLY CHECKOUT " ON PG. 105

IS POWER SUPPLY OK? — YES → REPLACE MICRO MODULE 1U3

NO

REPLACE BAD POWER SUPPLY COMPONENT

b EC
Running Overload

Latching diagnostic **b EC** is generated by the UCM when the average 3-phase current drawn by the compressor motor exceeds 107% of the RLA. The "time-to-trip" interval graduates from 20 seconds at 107% RLA to 1 second at 140% RLA

Chiller control near the compressor RLA is comprised of a 5-step "corrective action" control sequence designed to minimize the likelihood of overload lockouts caused by normal operating fluctuations in amperage. The 5 steps in this corrective action sequence are: (1) vane opening limited; (2) vane opening prevented; (3) modulated vane closure; (4) "hard" vane closure; and, (5) chiller shutdown on latching diagnostic **b EC**. A motor overload may result from a vane control failure or a motor/bearing failure, though these are not the only possible causes of an overload condition.

b Ed
Chilled Water Flow

Code **b Ed** represents a nonlatching diagnostic condition caused when the chilled water flow interlock circuit opens. A built-in time delay of 2 seconds (i.e., maximum without flow) is designed to eliminate nuisance tripouts caused by a fluttering flow switch.

Because this diagnostic is nonlatching, the chiller automatically attempts to restart when the interlock circuit closes. The **b Ed** code is then stored in the "Last Diagnostic Code" register of the display menu. Manual (i.e., from a remote source) start-up of the chilled water pump(s) is required.

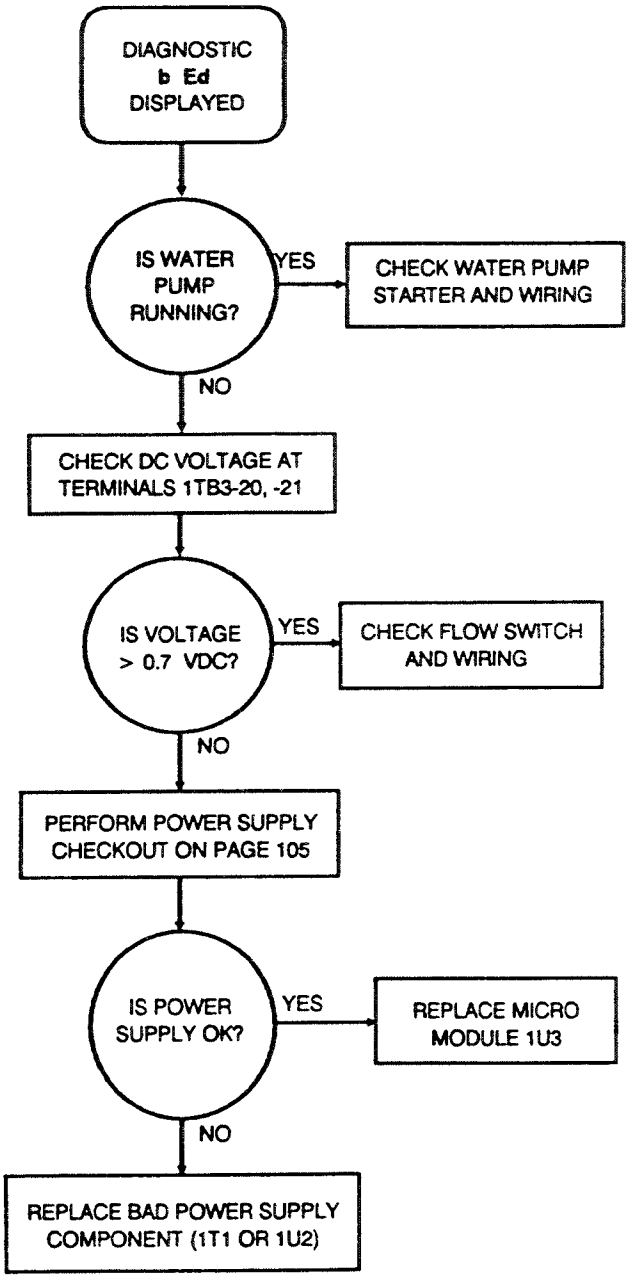
Use the steps outlined below to determine why the chilled water flow diagnostic occurred (Also, refer to the diagnostic chart in Figure 23 on the next page):

1. Verify that the chilled water pump is turned on.

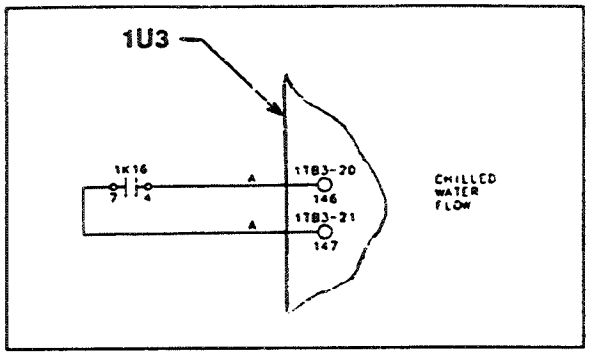
a. If the pump is not running, check for blown fuses, open disconnect switches, etc.
b. If the pump is running, check for closed valves and plugged strainers. Also, ensure that pump capacity is sufficient to handle all of the chillers piped into the chilled water circuit.

2. Check the status of chilled water flow switch 5S2; if it is open, see Step 1b. In addition, be sure that the proper pressure drop is provided to the unit. If the flow rate is correct, flow switch 5S2 may be defective.

3. Check the status of the chilled water pump contactor auxiliary (5K1); it should be closed whenever the pump is running.

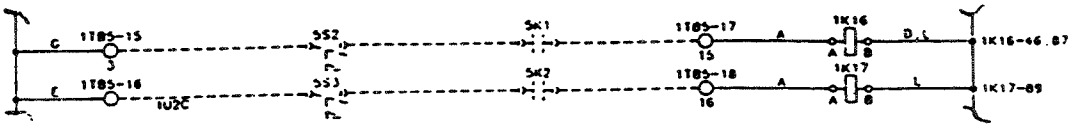


4. Verify that chilled water pump relay 1K16, is energized and that its contacts are closed. Relay 1K16's contacts are connected between terminals 1TB3-20 and 1TB3-21 on micro module 1U3.



5. Determine whether micro module 1U3 is functioning correctly. To do this, install a jumper between terminals 1TB3-20 and 1TB3-21, and set the chiller switch at one of the AUTO positions.

If the **b Ed** diagnostic code is cleared from this display, 1U3 is operating properly. However, if **b Ed** remains on the display, micro module 1U3 is defective and must be replaced.



Caution: To ensure proper chiller protection, never start the unit when the chilled water flow interlock circuit is jumpered! If jumper installation clears the diagnostic, remove the jumper immediately. If the diagnostic does not clear within three (3) minutes, remove the jumper and replace 1U3.

Figure 23 - Diagnostic "b Ed" Chilled Water Flow

Electrical Schematic - Water Pump Interlock Circuit

b EE
Exceeded Maximum Acceleration Time

This latching diagnostic occurs when motor amperage draw does **not** drop to 85% of the compressor RLA within the acceleration time limit. Long acceleration times result from a greater-than-normal load on the compressor during the start sequence. Possible causes for this increased load include--but are not limited to--these:

[ ] Maximum acceleration time setpoint is incorrectly set.
Check the positions of switches 1 through 5 on DIP switch block S3; see "b A5: Maximum Acceleration Time Range".
[ ] Inlet guide vanes are not fully closed.
This may be the result of an improperly adjusted actuator, broken linkage, sheared linkage pins, or inlet vane damage.
[ ] Warm evaporator and a cool condenser.
This condition creates a high differential pressure across the compressor, and forces a greater-than-normal flow of refrigerant gas through it.
[ ] Transition relay K5 (i.e., on power supply output module 1U2) fails to close.

If the compressor motor amperage draw drops below 85% of the RLA during the start sequence but the motor fails to transition, follow the transition relay checkout instructions in on page 96

b F0
Transition

Latching diagnostic **b FO** occurs when the starter fails to complete transition. Micro module 1U3 monitors the status of a normally-open set of auxiliary contacts on the "run".contactor (2K2). (Relay 2K2 is located in the starter panel.) If these contacts do not close within 2 seconds after the transition signal is sent to the starter, the UCM shuts down unit operation on the **b FO** diagnostic. The auxiliary on contactor 2K2 is tied to terminals 2TB1-10 and 2TB1-11 in the starter panel and-- from there--to terminals 1TB4-5 and 1TB4-6 on micro module 1U3 in the unit control panel). Refer to the typical wiring schematics on pages 46 thru 49. Among the possible reasons for a failure to transition are these:

[ ] Faulty wiring or bad connections in the proof-of-transition circuit.

WARNING: To prevent injury or death due to electrical shock, disconnect main starter power supply before checking this circuit.

[ ] Defective "run" contactor auxiliary (2K2).
Check for closure of the 2K2 auxiliary contacts when the main contactor closes.
[ ] Defective compressor transition relay (K5; located on power supply output module 1U2 in the unit control panel).

Note: Micro module 1U3 will not generate a **b FO** diagnostic unless it sees the conditions necessary for transition and initiates the transition signal.

Monitor the status of the K5 relay contacts at terminals 1TB2-5 and 1TB2-6 on power supply output module 1U2. If the K5 contacts do not close, follow the transition relay troubleshooting instructions on page 96. If the K5 contacts do close, the problem lies either in the starter or in the wiring connections to the starter. Use the "Electrical Sequence of Operation" in the unit Operation/ Maintenance manual and the wiring diagrams provided with the starter as a guide for determining proper starter operation.

b F1
Running External Interlock (Optional) or HGBP High Discharge Temperature Switch (4S5)

Units w/o Hot Gas Bypass

The UCM generates latching diagnostic condition **b F1** when the field-supplied and -installed run spare fault switch (5S4) closes during chiller operation. This switch input becomes active 1 second after transition, but is ignored by micro module 1U3 before and during start-up.

In the event that a **b F1** diagnostic occurs, check the electrical connections made at terminals 1TB4-3 and 1TB4-4. Verify that these terminals are not jumpered, and that the device connected to them--if any--is functioning properly. Refer to the diagnostic chart in Figure 24 on the next page.

If the external circuit appears to be okay, remove the wires from 1TB4-3 and 1TB4-4 and operate the chiller. Disappearance of the **b F1** diagnostic indicates that the problem is somewhere in the external circuit, while its reoccurrence implies that micro module 1U3 is defective and must be replaced.

Units w/Hot Gas Bypass

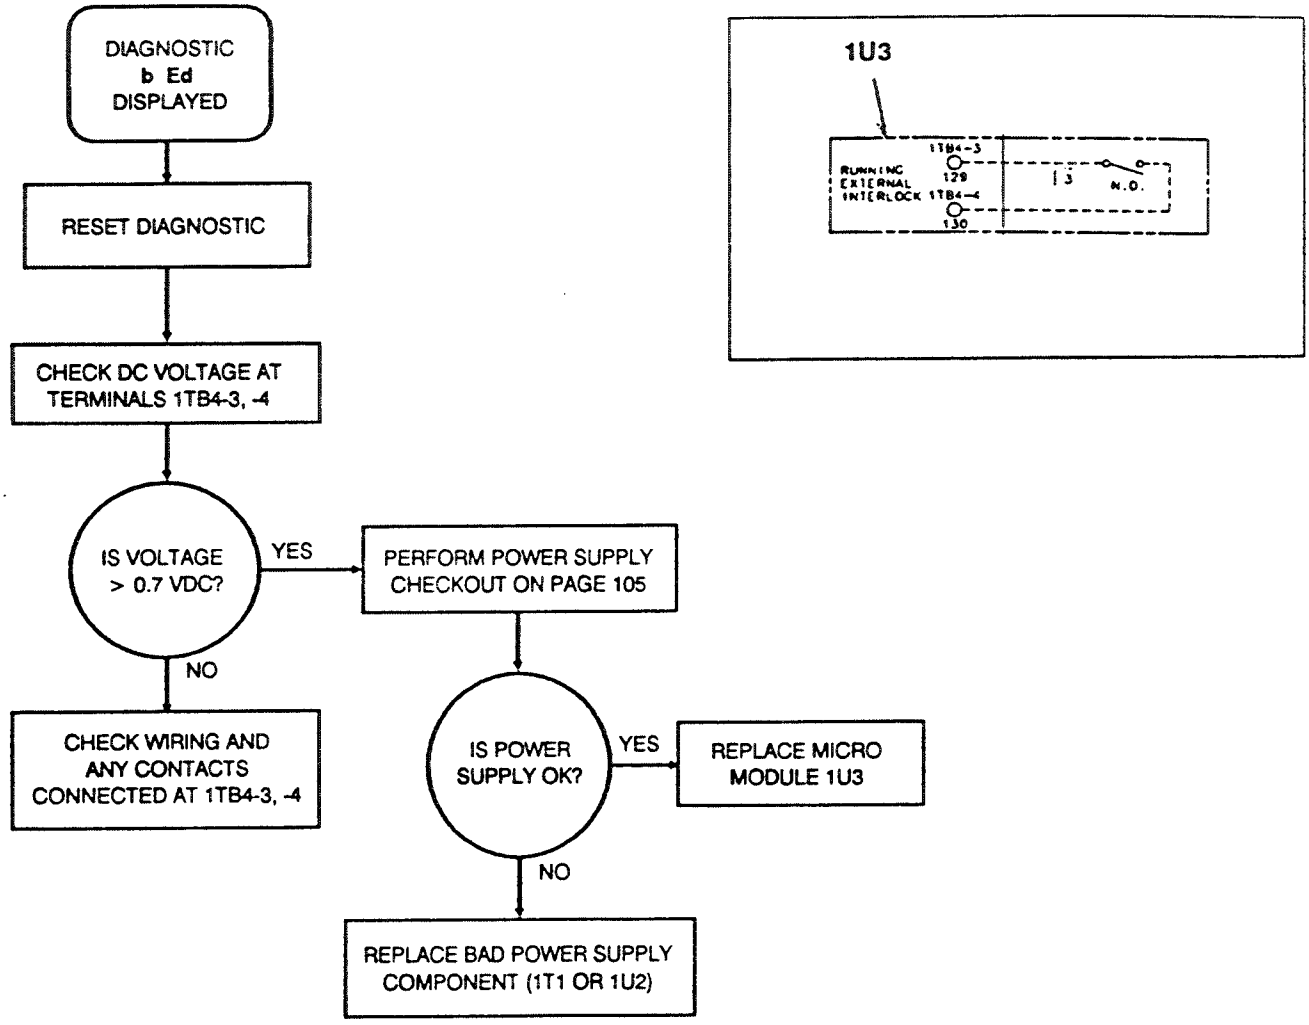
A temperature-monitoring device is located on the compressor discharge line of units equipped with optional hot gas bypass. If the discharge temperature rises above 210 F, this device closes its contacts and causes the chiller to shut down on latching diagnostic **b F1**.

Check the operation and setpoint of high discharge temperature switch 4S5; if the switch is functioning properly, the hot gas bypass valve requires adjustment to correct the high discharge temperature condition.

If unit operation and the external circuit appear to be okay, remove the wires from 1TB4-3 and 1TB4-4 and operate the chiller. Disappearance of the **b F1** diagnostic indicates that the problem is somewhere in the external circuit, while its reoccurrence implies that micro module 1U3 is defective and must be replaced.

Caution: High discharge temperature switch 4S5 must be reconnected into the circuit after test is complete. Unit operation without 4S5 connected can result in serious machine damage.

Note: Refer to Figure 24. Run spare fault switch 5S4 is connected at the same terminals used for the hot gas bypass temperature switch (4S5). A unit cannot be factory-equipped with both of these optional switches, but may be modified in the field so that both 5S4 and 4S5 are wired in parallel to terminals 1TB4-3 and 1TB4-4.



b F2
Low Oil Pressure

Latching diagnostic **b F2** indicates that the UCM detected a problem with the oil pressure either at start-up or during the run mode.

Micro module 1U3 starts the oil pump during the chiller start-up routine by closing the K7 oil pump relay contacts on power supply output module 1U2. 1U3 then monitors the contacts of the differential oil pressure (1S2) for closure; as soon as they close, 1U3 starts a 15-second timer.

If the 1S2 contacts remain closed throughout this 15-second interval, a "start" signal is sent to the starter. However, if the contacts open during this period, the timer is reset to zero and the 1S2 contacts must close again to reactivate the timer. In the event that the 15-second timer is not satisfied within 48 seconds of the initial K7 contact closure, the start sequence is aborted on a **b F2** latching diagnostic.

Figure 24 - Diagnostic "b F1" Running External Interlock

This diagnostic will also occur if the differential oil pressure switch (1S2) opens during any of the run modes of operation.

Note: Switch 1S2 should be adjusted to close on a differential pressure of 15 psid, and open when the pressure differential falls to 9 psid. Also, if 1S2 is wired properly, it is connected between terminals 1TB4-1 and 1TB4-2 on micro module 1U3 in the unit control panel.

To diagnose an occurrence of a **b F2** code, refer to Figure 25 and the following procedure. Determine whether or not the oil pump is operational. If the oil pump motor (4B5) will not run, it may be the result of--but not limited to--one of the malfunctions listed below. (If the oil pump does run but fails to build sufficient pressure, go to Item 3.)

1. Defective oil pump relay (K7).

Verify that oil pump relay K7 on power supply output module 1U2 is functioning correctly. To do this:

a. Remove the wires from terminals 1TB2-1 and 1TB2-2.

WARNING: To prevent injury or death due to electrical shock, open chiller disconnect before removing leads from terminals.

b. Check for continuity between these terminals while switching the oil pump switch (on the control panel front) between the ON and AUTO positions.

c. If the K7 contacts do not close when the oil pump switch is set at ON, check the voltage at pins 4 and 14 on ribbon connector 1P4. These voltage readings should be observed:

Oil Pump Switch "Off" = 0.0 VDC min. to 0.1 VDC max.
Oil Pump Switch "On" = 0.85 VDC min. to 1.6 VDC max.

If these voltages are not obtained, micro module 1U3 is defective and must be replaced.

If these voltages are observed and the (1U2)K7 relay still does not operate, power supply output module 1U2 is defective and must be replaced.

d. If the oil pump runs (and the oil pressure is satisfactory) when the oil pump switch is set at ON (manual mode) but does not operate during the start-up sequence, monitor the K7 relay as described in Step 1c to verify whether 1U3 is sending a "start" signal to the oil pump.

2. Oil pump motor-related problem. Check for:

[ ] a blown oil pump fuse (1F1) in the unit control panel;
[ ] faulty wiring and loose or broken connectors;
[ ] a blown oil pump capacitor (1C1);
[ ] a defective oil pump starter relay (1K8);
[ ] the resistance of the oil pump motor windings with the motor leads removed. Resistance readings obtained should be as follows:

2.2 ohms between terminals 1 and 2 (run);
4.8 ohms between terminals 1 and 3 (start); and,
7.0 ohms between terminals 2 and 3.

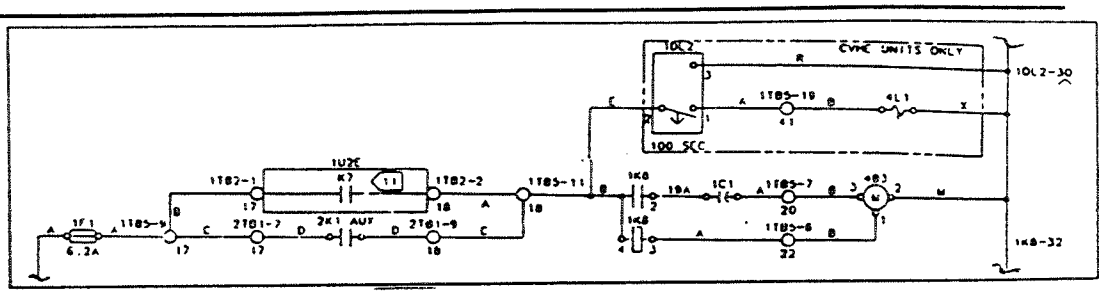
WARNING: To prevent injury or death due to electrical shock, open chiller disconnect switch before reversing motor leads.

Proceed to Items 3 through 7 if a check of the oil pump motor reveals that the oil pump runs but does not build sufficient pressure.

3. Low oil level.

Check the oil level in the sump using the 2 sight glasses provided in the oil sump head. Add oil as necessary to raise the level to better than half of the lower sight glass while the pump is running.

4. Oil sump temperature is out of range.



Check oil temperature at the sump; the temperature should be 140 to 145 F when the chiller is shut down, and 115 to 150 F while the unit is running.

5. Faulty or improperly adjusted oil pressure regulator.

With the unit off, adjust the oil pressure regulator to provide 20 to 22 psid. Then monitor the pressure change during the chiller start and run modes to verify that the reulator is working properly.

6. Defective differential oil pressure switch (1S2).

Figure 25 - Diagnostic "b F2" Low Oil Pressure

DIAGNOSTIC b F2 DISPLAYED

RESET DIAGNOSTIC

DOES OIL PRESSURE DROP < 9 PSI?

YES → MEASURE AC VOLTAGE AT TERMINALS 1TB5-8, -2

IS 115 VAC PRESENT?

YES → CHECK OIL PUMP AND LUBRICATION SYSTEM

NO → MEASURE AC VOLTAGE AT TERMINALS 1TB2-2 & 1TB5-2

IS 115 VAC PRESENT?

YES → CHECK WIRING FROM 1TB2-2 TO OIL PUMP MOTOR

NO → MEASURE AC VOLTAGE AT TERMINALS 1TB2-1 & 1TB5-2

IS 115 VAC PRESENT?

YES → CHECK WIRING AND FUSES 1F1 & 1F3

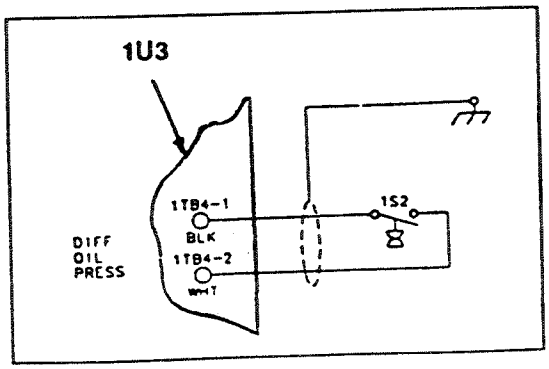
NO → MEASURE DC VOLTAGE AT PLUG 1P4-4, -14

IS VOLTAGE BETWEEN 0.85-1.6 VDC?

YES → REPLACE 1U2 MODULE

NO → MEASURE DC VOLTAGE AT TERMINALS 1TB4-1, -2

IS VOLTAGE > 0.7 VDC?



YES → CHECK DIFFERENTIAL PRESSURE SWITCH AND WIRING

NO → PERFORM POWER SUPPLY CHECKOUT ON PAGE 105

IS POWER SUPPLY OK?

YES → REPLACE MICRO MODULE 1U3

NO → REPLACE BAD POWER SUPPLY COMPONENT (1T1 OR 1U2)

Monitor the status of switch 1S2's contacts while manually starting and stopping the oil pump with the oil pump switch. Check for a broken switch, bad contacts, and plugged pressure- sensing lines.

7. Defective oil pump.

a. Disconnect the high oil pressure gauge and connect a pressure gauge capable of registering 100 psi in its place.

b. Remove and cap bearing oil supply lines (i.e., the oil pump is "deadheaded" except for the relief bypass).

c. Start the oil pump and tighten down the oil pressure regulator adjusting screw completely to increase oil pressure.

d. Check the pressure gauge installed in Step 7a; the oil pressure should exceed 60 psi.

If the oil pressure does not exceed 50 psi--and the regulator is blocking all bypass flow, the oil pump is faulty and must be replaced.

Note: The oil pump is a positive-displacement-type device designed to pump at a rate of 2 to 3 gallons per minute. Since "deadheading" will cause the motor amp draw to rise, run the pump only long enough to complete the test.

b F3
Low Oil Temperature

(This diagnostic provided on CVHE units, "1C" and later design sequences only ; CVHB units, "1D" and later design sequences only; and all CVHF units with UCP695.)

An occurence of this of this non-latching diagnostic indicates that the oil temperature sensor 4RT7 is sensing a temperature less than 100 F. Micro module 1U3 will not allow a chiller start with an existing oil temperature that is lower than 100 F. When oil temperature rises above 100 F, the UCP will initiate a start sequence. In the even that a **b F3** diagnostic occurs, the following steps may be necessary:

1. Wait for oil temperature to rise above 100 F. If temperature does not increase in a reasonable amount of time, check for proper oil heater and control operation as follows (refer to appropriate wiring schematics for the chiller).

a. Check Fuse 1F2.

b. Check condition of oil heater. Check for voltage to the heatrer, burned out heater, loose connections or machanical problem.

c. Determine acutal oil temperature using oil temperature sensor 4RT7, located in the bulbwell at the rear of the oil sump. Read voltages on terminals 1TB3-13, -14 on micro module 1U3. Convert this voltage DC to temperature, using Table 20 on page 58. If the actual temperature does not agree with the measured resistance of if the measured resistance does not agree with the thermistor voltage, perform the power supply checkout procedure on page 105. If the power supply is functioning properly, replace the oil temperature sensor.

d. Check for proper operation of 1U2-K6, and the 1K9 relay. Some UCP micro panels do not use a 1K9 relay.

e. Confirm that the micro issending a signal to the oil heater relay K6. Measure the DC voltage on Pins 2, -14 of ribbon connector 1P4. If oil temperature is less than 100 F, this voltage should be 0.85-1.6 VDC.

b F4
High Oil Temperature

Occurrence of this latching diagnostic indicates that oil temperature thermistor 4RT7 sensed a temperature exceeding 180 F during chiller operation. This sensor is located in a bulbwell at the rear of the oil sump, and its leads are connected to terminals 1TB4-13 and 1TB4-14 on micro module 1U3.

In the event that a "high oil temperature" (**b F4**) diagnostic occurs, refer to Figure 26 on the next page and:

1. Check the oil temperature at the sump to determine if it is normal. Use the checkout instructions in Figure 13 on page 57 to verify that 4RT7 is functioning correctly.

2. If the oil temperature measured in Step 1 is excessive, check the oil heater for proper operation.

a. Oil heater relay K6 (i.e., on power supply output module 1U2) should energize when sump temperature is less than 140 F, and de-energize when it exceeds 145 F.

Note: Oil heater operation is governed by the temperature the UCM "sees" at sensor 4RT7. The temperature observed on the gauge located on the oil sump may not match the temperature measured by 4RT7. When troubleshooting the oil heater circuit, always read the voltage at terminals 1TB4-13 and 1TB4-14 and convert this voltage to a temperature (Table 20 on page 58).

b. If the sump temperature is greater than 145 F and oil heater relay (1U2)K6 is closed, determine: (1) if micro module 1U3 is calling for the contact closure, and (2) whether power supply output module 1U2 is defective.

To do this:

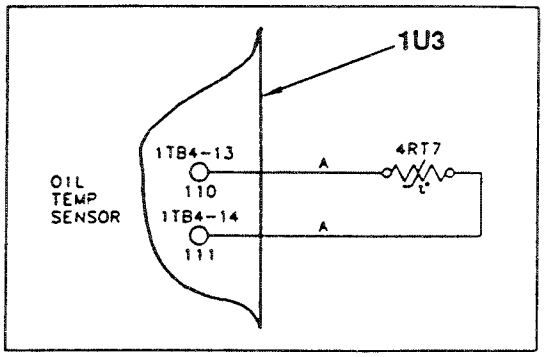
(1) Measure the DC voltage signal at pins 2 and 14 of ribbon connector 1P4. The following voltage readings should be observed:

Relay (1U2)K6's contacts open = 0.0 VDC min. to 0.1 VDC max.
Relay (1U2)K6's contacts closed = 0.85 VDC min. to 1.6 VDC max.

(2) If the status of the K6 relay contacts does not match the voltage signals shown above, power supply output module 1U2 is defective and must be replaced.

If 1U3 is sending a "closed" signal to K6 (i.e., a voltage signal of 0.85 to 1.6 VDC) and sensor 4RT7 is functioning properly--and is reading a temperature above 145 F, then micro module 1U3 is defective and must be replaced.

Note: To "force" micro module control of oil heater relay K6, substitute fixed resistances for oil temperature sensor 4RT7. For example:



Relay (1U2)K6 should open at 2,000 ohms = 151.5 F;
Relay (1U2)K6 should close at 3,000 ohms = 131.5 F.

Be sure to allow sufficient time for micro module 1U3 to respond (i.e., 5 minutes).

Caution: To prevent possible equipment damage, remove fixed resistances and reconnect sensor 4RT7 as soon as the tests are complete.

3. Check for machine operating conditions that could result in an increased oil temperature. (See "b EA, Eb: High Bearing Temperature" for possible causes.)

b F5
High Condenser Pressure

This diagnostic indicates that the condenser high pressure switch (1S1) has closed its N.O. contacts, indicating excessive condenser pressure. 1S1 is located in the control panel and is connected to output module 1U2 via the 1J2 connector cable. Note that all 3 leads from 1S1 (common, N.O. and N.C.) must be connected to 1U2 for proper operation.

1. Check for operating conditions that would drive the condensing pressure upward. These include — but are not limited to:

[ ] air or noncondensibles in the machine (check the purge);
[ ] low condenser water flow;
[ ] condenser water temperature too high;
[ ] fouled condenser tubes.

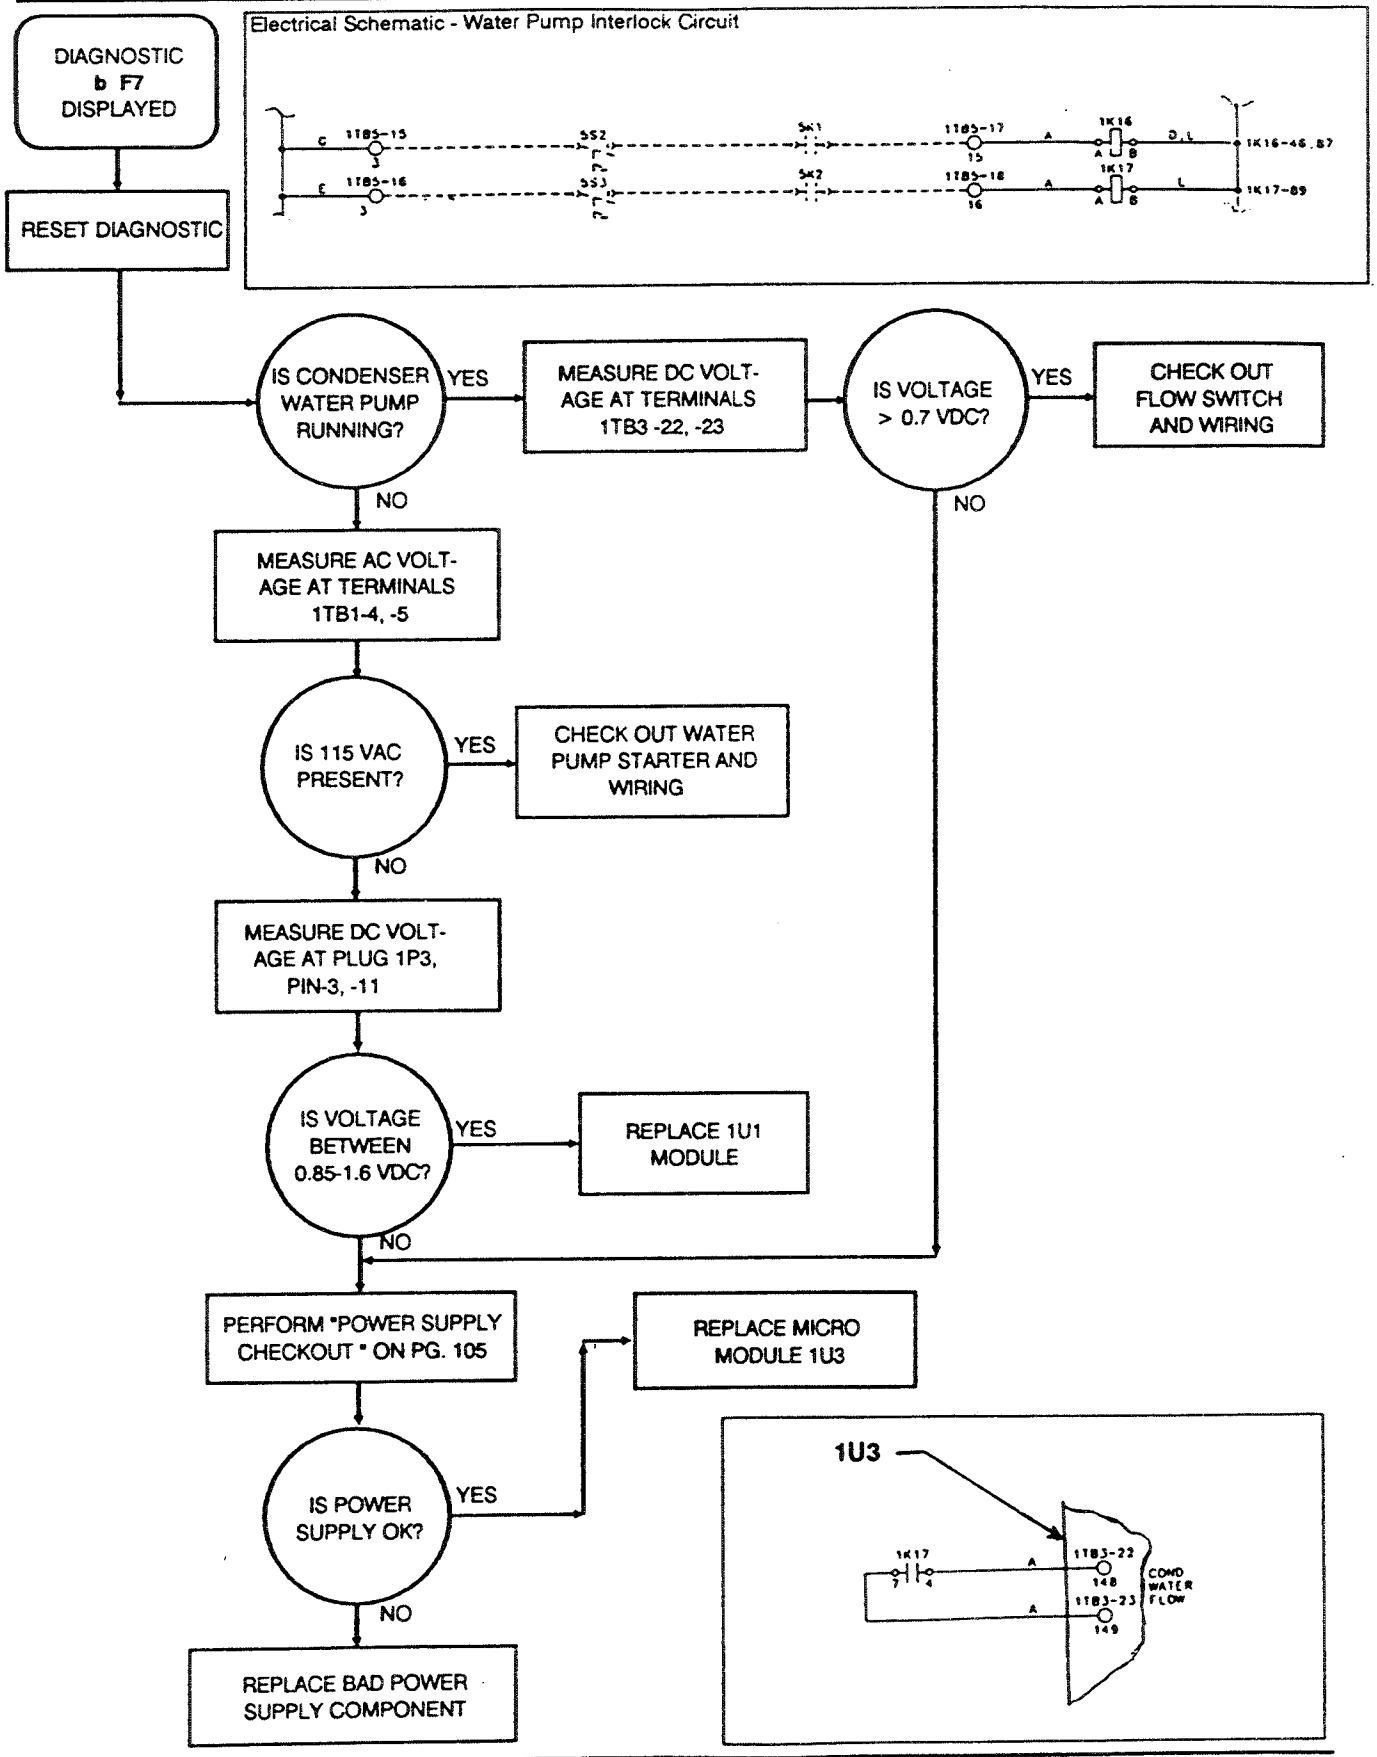
If no operational problems can be found, the pressure switch should be checked for proper operation.

a. Check all wiring connections for accuracy and tightness. See the appropriate wiring diagram.
b. Connect the pressure switch to a source of compressed air or nitrogen through a pressure regulator. Slowly increase the pressure from 0 psi to the trip pressure (15 ± 1 psi standard; 25 ± 1 psi ASME). If the switch does not operate at the trip pressure, recalibrate or replace it.

b F7
Condenser Water Flow

This diagnostic indicates that the condenser water flow interlock circuit opened during chiller operation.

Note: This diagnostic is nonlatching; therefore, chiller restart will be attempted. If condenser water is still not available upon restart, the chiller will shut down on the latching diagnostic **b dC** (condenser water flow overdue).



Start-up of the condenser water pump is normally done by the chiller during the start-up sequence.

Possible causes of a **b F7** diagnostic include:

[ ] closed condenser water valves;
[ ] low condenser water flow;
[ ] plugged condenser water system filters;
[ ] faulty condenser water pump relay (K6);
[ ] faulty condenser water pump contactor (5K2);
[ ] faulty condenser water pump contactor auxiliary (5K2);
[ ] faulty condenser water pump relay (1K17);
[ ] faulty condenser water flow switch (5S3).

To troubleshoot an occurrence of a **b F7** diagnostic, refer to the procedure in Figure 27 on the next page.

Figure 27 - Diagnostic "b F7" Condenser Water Flow

b F8
Improper Unit Identification

This diagnostic indicates that the micro was configured for a different type of chiller than it is installed on. Check the unit I.D. switches on DIP switch S9 for proper position. See "Factory DIP Switch Settings" starting on page 22.

If the switches are set in the correct positions and the diagnostic will not clear, try moving the switches up and down several times. This may clear any oxidation that may have formed on the switches.

If the diagnostic still does not clear, replace micro module 1U3.

b F9
Free Cooling Valves

This diagnostic occurs when the free cooling valves do not close prior to a powered cooling start. Free cooling valves 4B12 and 4B13 have full-closed end switches wired in series and connected to Terminals 1TB3-18 and 1TB3-19 of the 1U3 module. Prior to a powered cooling start, the FC valves are given a "close" signal via the normally-closed contacts of relay 1U1K1. If the valve end switches do not close within the preset 3-minute time period, the **b F9** diagnostic will result.

Possible causes of a **b F9** diagnostic include:

[ ] end switches are not properly adjusted;
[ ] free cooling valves(s) jammed;
[ ] signal to close valves not being sent either because:

- 1U1K1 relay malfunction
- 1U3 not calling for 1U1K1

Troubleshooting the **b F9** diagnostic:

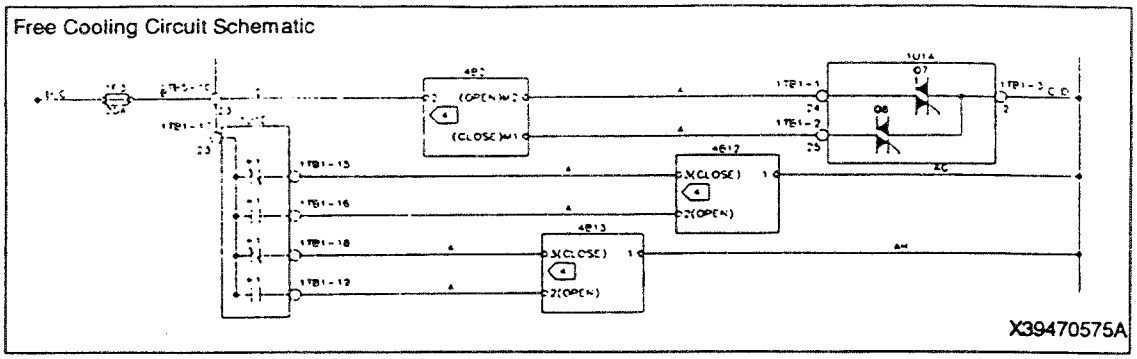
1. Set chiller switch at STANDBY/RESET and free cooling switch at OFF.

2. Check the free cooling valve end switch circuit.

Remove wires 118 and 119 from Terminals 1TB3-18, -19. Check for continuity through the end switch circuit.

a. If continuity exists, then the valves have closed, but the 1U3 module does not recognize the closure. Replace the 1U3 micro module.

Note: Whenever 1U3 replacement is indicated, always perform the power supply checkout procedure.



b. If there is no continuity, go to Step 3.

3. Check for power at Terminal 1TB1-17.

a. If there is no power, check Fuse 1F3 and the power supply wiring.

b. If there is power, go to Step 4.

Figure 28 - Diagnostic "b F9"

NO

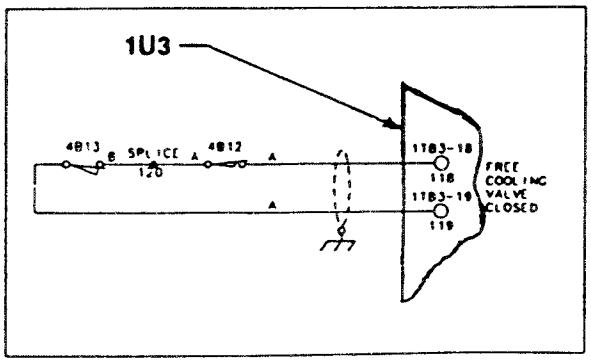
PERFORM POWER SUPPLY CHECKOUT ON PAGE 105



IS POWER SUPPLY OK?

YES

REPLACE MICRO MODULE 1U3

NO

REPLACE BAD POWER SUPPLY COMPONENT (1T1 OR 1U2)

4. Check for power at both terminals, then check the free cooling valves for faulty end switches for incomplete operation.

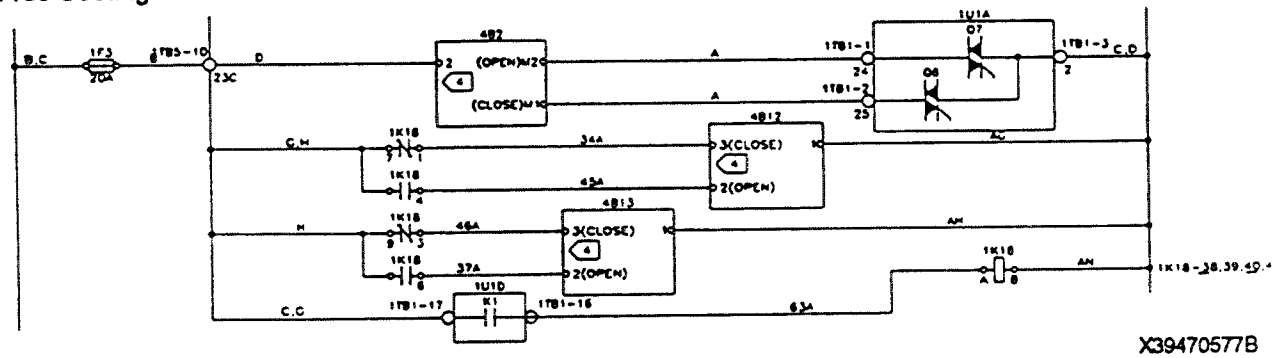
a. If there is power at both terminals, then check the free cooling valves for faulty end switches or incomplete operation.

b. If there is no power at either or both terminals, go to Step 5.

5. Check for a voltage signal at ribbon cable 1P3, Pin 9 (with respect to Pin 11).

a. If voltage is less than 0.1 VDC, then relay output module 1U1 is bad; replace it.

Note: Whenever 1U1 replacement is indicated, always perform the power supply checkout procedure first!



b. If voltage is greater than 0.5 VDC and:

— the chiller switch is in the STANDBY/RESET or AUTO/LOCAL position, and
— the free cooling switch is set at the OFF position;

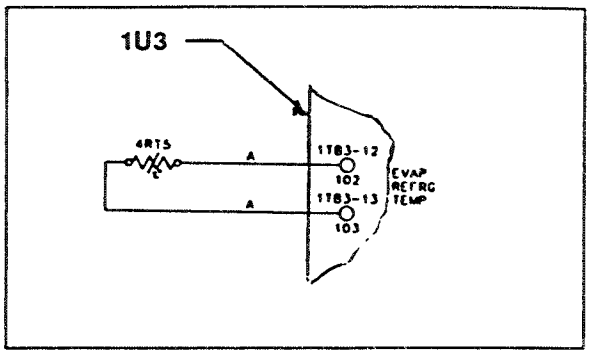
then, micro module 1U3 is bad and must be replaced.

Note: Whenever 1U3 replacement is indicated, always perform the power supply checkout procedure first!

Free Cooling Circuit Schematic

IMPORTANT: After April 1992 the 1K1 relay in the 1U1 module is no longer used to actuate the free cooling valve. The 1K1 relay is now used to close a heavier relay 1K18 as shown above in X39470577B.

b FA
Actuator



Diagnostic **b FA** occurs when the vane actuator (4B2) fails to close during the (powered or free cooling) start sequence.

The start sequence for the unit incudes an "establish condenser flow/close vanes" operating mode (**A 71**). During the **A 71** operating mode, the micro module 1U3 sends a "vanes close" signal to the vane actuator and monitors an end switch on 4B2. If the end switch does not close within the preset 4-minute window, latching diagnostic **b FA** results.

To diagnose an occurrence of this diagnostic, refer to "Vane Control Checkout Procedure" on page 111.

Note: If the **b FA** diagnostic is intermittent, the problem will likely be the vane actuator end switch.

PERFORM POWER SUPPLY CHECKOUT ON PAGE 105

IS POWER SUPPLY OK?

YES → REPLACE MICRO MODULE 1U3

NO

REPLACE BAD POWER SUPPLY COMPONENT (1T1 OR 1U2)

b Fb
Low Evaporator Refrigerant Temperature

Evaporator refrigerant temperature is continuously monitored and compared to the trip point during chiller operation. If the trip point is violated for a period of 30 F-seconds, the chiller will shut down on latching diagnostic **b Fb**. To diagnose an occurrence of a **b Fb** diagnostic, refer to Figure 29 .

Probable causes for a **b Fb** diagnostic include:

[ ] chilled water setpoint too low;
[ ] sensor failure;
[ ] unit low on refrigerant;
[ ] refrigerant stacked in condenser;
[ ] evaporator tubes fouled.

b Fd
External Interlock (Optional)

The UCP (1U3) generates latching diagnostic condition **b Fd** any time the circuit between Terminals 1TB3-16, -17 opens while the control panel is powered. The unit is shipped with a jumper between 1TB3-16, and -17; however, the jumper may have been removed and replaced with a field-supplied interlock circuit.

In the event that a **b Fd** diagnostic occurs, check the electrical connections to Terminals 1TB3-16, -17. If the jumper is installed, verify that the terminals connections are tight. If the diagnostic cannot be reset (cleared) with the input jumpered, micro module 1U3 is bad and must be replaced.

If Terminals 1TB3-16 and -17 are wired to an external circuit, find the remote device that opened the circuit and reset it. Verify that there is continuity through the circuit by removing the wires from 1TB3-16 and -17 and checking for continuity. If the diagnostic cannot be reset after the remote device is reset, remove the external circuit and connect a jumper wire to 1TB3-16 and -17. If the diagnostic still cannot be reset, the problem is with the 1U3 model; replace it. If the diagnostic can be reset, check the contact fo the remote device.

Note: The external interlock circuit is monitored with a low-voltage signal. Contacts in the external circuit must be compatible with a dry circuit, 12 VDC, 45 mA. Gold-plated contact are recommended.

b FF
Unit Controller

The UCP (1U3) runs a continuous self-diagnostic routine that monitors the functions and communications within the micro module (1U3). Latching diagnostic **b FF** is displayed when the self-test routine locates a problem.

The **b FF** diagnostic can also be seen when a noise spike enters the system and disrupts the controller.

Reset (clear) the diagnostic by toggling the chiller switch to STANDBY/RESET and back to one of the AUTO positions. If the diagnostic cannot be reset, power down the control panel for 2 minutes and power it back up with the chiller switch in the STANDBY/RESET position. If the **b FF** diagnostic returns immediately, replace micro module 1U3.

Note: If this condition occurs at initial unit start-up, carefully check all inputs to the low-voltage terminal strips (1TB3, 1TB4, 1TB6) for misconnections and noise interference.

If the **b FF** diagnostic can be reset but recurs frequently, check the low-voltage wiring for proper isolation from noise sources.

Compressor Transition Relay 1U2K5 and Current Transformer Checkout Procedures

(UCP695 Control Panels Only)

Note: The following compressor transition relay and current transformer checkout procedures are only applicable for those CVHE units equipped with UCP695 control panels (i.e., chillers of "K" or later design sequence). Check the tenth digit of the model number stamped on the chiller nameplate to determine its design sequence.

To effectively use the compressor transition relay (1U2K5) and current transformer (2T1, 2T2, 2T3, 2T5, 2T6 and 2T7) checkout procedures described in this section, it is important to first understand the normal operation of the control panel during the start sequence. Review the start sequence outlined below (along with the typical electrical schematic in Figure 9 on pages 46-49) or using the electrical diagrams that shipped with the chiller, before attempting to check the integrity of 1U2K5.

1. Micro module 1U3 initiates a "start" signal.

Once all of the prestart criteria are satisfied (i.e., condenser and chilled water flows proven, oil pressure established, etc.), micro module 1U3 initiates a "start" signal by "telling" the K1, K2, K3 and K4 relay contacts in power supply output module 1U2 to close. See Line 16 of the electrical schematic.

Proper response of all 4 sets of contacts allows control voltage to flow from Terminal 1TB2-9 to 1TB2-7; from there, current passes through Terminal 1TB5-5 (and 2TB1-4) and energizes the coil of pilot relay 2K5 in the starter panel.

2. "Star" windings of chiller compressor motor 4B1 energize.

Once energized, pilot relay 2K5 begins the compressor motor start process by energizing the coil of shorting contactor 2K3; this, in turn, energizes start contactor 2K1. (See Lines 19 and 21 of the schematic). Closure of 2K1's normally-open contacts allows line voltage to flow through the "star" windings of the compressor motor (4B1). Lines 1, 5 and 9.

3. Micro module 1U3 initiates transition.

Milliamp signal inputs at Terminals 1TB4-7 through -12 allow micro module 1U3 to monitor compressor motor amperage draw via 3 pairs of current transformers. (Refer to Lines 1 through 12 of the schematic.)

Keep in mind that 1U3's control logic prevents it from initiating transition unless these 2 conditions are met:

a. first, motor amp draw must exceed 100% of the rated load amps (RLA); and,

b. motor amp draw must then fall below 85% of the RLA.

If both of these requirements are satisfied, 1U3 initiates transition by energizing the compressor transition relay (1U2K5) in the power supply output module (Line 20).

Note: 1U2K5 is energized when the voltage signal at Pin 1 (with respect to Pin 14) on ribbon connector 1P4 is 0.85 to 1.6 VDC.

4. Transition occurs successfully, and compressor motor 4B1 is operating in the normal run configuration.

Closure of the K5 compressor transition relay contacts in 1U2 allows current to reach the coil of the starter panel's transition contactor (2K4). As 2K4 energizes, its normally-closed auxiliary contacts (Line 19) open to de-energize shorting contactor 2K3.

Run contactor 2K2 energizes when 2K3's normally-closed auxiliary contacts (Line 22) reclose. (Notice that the 2K4 transition contactor de-energizes as soon as the normally-open 2K2 auxiliary contacts in the transition circuit--Lines 19 and 20--close.)

When line voltage flows across the now-closed 2K2 contacts to the "delta" windings of 4B1 (Lines 4, 8 and 12), the compressor motor is in its normal "run" configuration.

5. Micro module 1U3 confirms that transition was successfully completed.

Refer to Line 69 of the schematic; notice that a normally-open set of auxiliary contacts on run contactor 2K2 is located in a "proof- of-transition" circuit connected to micro module input Terminals 1TB4-5 and -6.

Closure of these auxiliary 2K2 contacts "tells" micro module 1U3 that transition occurred successfully.

If these contacts do not close within 2 seconds after the transition signal is sent to the starter (see Step 3), micro module 1U3 assumes that the compressor motor failed to transition, and shuts down unit operation on latching diagnostic **b FO**.

Any one (or all!) of the malfunctions listed below can cause micro module 1U3 to abort a start-up attempt with the "transition failure" (**b F0**)--or "exceeded max. accel. time" (**b EE**)-- diagnostic.

[ ] Faulty current-sensing inputs (1TB4-7 thru -12).

Recall that in Step 3 of the preceding start sequence, 1U3 monitors the milliamp signals it receives at input Terminals 1TB4-7 through -12 to determine whether or not compressor motor amp draw exceeds 100%--then falls below 85%--of RLA. Control logic prevents 1U3 from initiating the transition signal unless these prerequisites are met.

Faulty current-sensing inputs may prevent 1U3 from "seeing" this change in amp draw (i.e., causing it to shut down unit operation on either a **b EE** diagnostic, or a **b E2** diagnostic if all 3 inputs are bad).

[ ] Defective micro module (1U3).

Latching diagnostic **b EE** can also occur if micro module 1U3 receives the appropriate current-sensing inputs at Terminals 1TB4-7 through -12, but-- because of an internal malfunction-- either: (1) fails to issue a "close" signal to the normally-open 1U2K5 contacts; or (2) continuously sends this "close" signal.

Review Step 3 of the start sequence again. Notice that the existence of a 0.85 to 1.6 VDC voltage signal at Pin 1P4-1--with respect to Pin 1P4-14--confirms that 1U3 did tell the 1U2K5 contacts to close.)

[ ] Defective power supply output module (1U2).

Even though motor amp draw requirements are satisfied and 1U3 successfully transmits a "transition" signal to the power supply output module (1U2), transition will not occur if 1U2 is defective and fails to close its K5 compressor transition relay contacts.

[ ] Faulty starter component(s) or wiring.

Refer again to Step 4 of the start sequence. Notice that closure of the 1U2K5 contacts should provide current to transition contactor 2K4 (and, ultimately, run contactor 2K2) in the starter panel. If the electrical connections between 1U2 and the starter panel are faulty--or if either 2K4, 2K3 or 2K2 is defective--transition will not occur, and 1U3 will generate a **b F0** or **b EE** diagnostic.

[ ] Faulty "proof-of-transition" circuit.

Keep in mind that the existence of a **b F0** diagnostic may not necessarily mean that the starter failed to transition. It is equally possible that transition was completed successfully, but micro module 1U3 is not receiving "proof of transition" at input Terminals 1TB4-5 and -6. (Lines 69 and 70.) In this situation, either the auxiliary 2K2 contacts are malfunctioning, the "transition complete" electrical circuit is faulty, or 1U3 is defective.

Whenever a **b F0** or **b EE** chiller diagnostic condition exists, use the following checkout procedure to isolate the source of the transition-related failure.

1U2K5 Checkout Procedure

Note: The steps in this procedure were purposely arranged for ease of completion, and do not reflect the sequence of events previously described for a normal, attempted start-up.

WARNING: Use extreme care when performing this checkout procedure while the chiller is energized. Carelessness can result in injury or death.

1. Check the input voltage at ribbon connector Pin 1P4-1 (red VOM lead) with respect to Pin 1P4-14 (black VOM lead) while the unit is not running.

If the voltage measured is 0.85 to 1.6 VDC, module 1U3 is defective and must be replaced.

If the voltage reading is 0.0 to 0.1 VDC, use an ohmmeter to check for continuity between Terminals 1TB2-5 and -6. If the resistance reading obtained indicates that the K5 contacts between these terminals are closed, power supply output module 1U2 is defective and must be replaced.

2. Connect a voltmeter—adjusted to read 115 VAC—to Terminals 1TB2-6 and 1TB5-2; then initiate the chiller start sequence. The voltmeter should initially register 0 VAC until the 1U2K5 contacts close during the start sequence; at that point, the meter should register control voltage (approximately 115 VAC).

If the K5 compressor transition relay contacts do close, and:

a. the 2K4 starter transition contacts pull in but drop out again within 2 seconds (causing 1U3 to trip on **b F0**), then go to Step 3.

b. the starter does not transition at all (causing 1U3 to trip on **b EE**), then the problem lies either in the starter itself, or the wiring connections to the starter. (In this situation, it is not necessary to complete Steps 3 through 9 of this checkout procedure.)

However, if the K5 contacts do not close, complete Steps 4 through 9 to isolate the malfunction at power supply output module 1U2, micro module 1U3, or the current transformers (i.e., 2T1, 2T2, 2T3, 2T5, 2T6 and 2T7).

3. Monitor the status of 1U3's "proof-of-transition" circuit during the chiller start sequence. To do this, connect the black lead of a digital VOM to 1U3 Terminal 1TB4-6 and the red lead to 1TB4-5; then initiate another start-up.

a. Check the voltage between Terminals 1TB4-5 and -6 before the oil pump starts to determine the status of the auxiliary 2K2 contacts (Line 69 of the schematic). Since these contacts should be open at this point in the start sequence, you should obtain a voltage reading of 6.9 to 16.8 VDC.

(If the auxiliary 2K2 contacts are already closed, micro module 1U3 should "lock out" on the **b F0** latching diagnostic for transition.)

b. Recheck the voltage between these terminals when motor amp draw falls below 85% of the RLA. (When this occurs, 1U3 should send a "close" signal to the K5 contacts; the auxiliary 2K2 contacts should then close within 2 seconds.)

Since the auxiliary 2K2 contacts should now be closed, you should see a voltage reading of 0.0 to 0.1 VDC.

If you do obtain the voltage readings just described in (a) and (b) above--but the unit still "locks out" on the **b F0** diagnostic, micro module 1U3 is defective and must be replaced. Otherwise, the problem lies either in the starter or the wiring connections to the starter. (In either case, it is not necessary to complete Steps 4 through 9 of this checkout procedure.)

4. Set a digital VOM to register DC voltage; then connect the black (negative) VOM lead to Pin 1P4-14 and the red lead to Pin 1P4-1.

5. Repeat the chiller start sequence. Verify that compressor motor amp draw actually exceeds 100% of the compressor RLA, and check the VDC signal at Pin 1P4-1 when amp draw falls below 85% of RLA. (Instructions for calculating %RLA are provided in Note 1 of Table 25.)

If the signal measured at Pin 1P4-1 does not increase from 0.0-0.1 VDC to 0.85-1.6 VDC when the amp draw falls below 85% of RLA, go to to Step 6.

Note: If input voltage at Pin 1P4-1 does increase to 0.85-1.6 VDC when amp draw drops below 85% of RLA but the 1U2K5 contacts do not close, power supply output module 1U2 is not functioning properly. Before replacing 1U2, perform the power supply checkout procedure described in the next section of this bulletin. (An improper voltage supply to 1U2 can cause a good module to produce erratic output responses.)

6. Use the unit's design RLA value in conjunction with the data in Table 26 to verify that:

a. the line current transformers (CTs; 2T1, 2T2 and 2T3) are properly sized;

b. each line CT is provided with the correct number of "primary turns" (i.e., number of times that the main power line passes through its CT); and,

c. the DIP switches used to establish the unit's RLA setpoint (i.e., DIP switch block S1, switch nos. 1 through 8) are properly positioned. (A step-by-step, RLA-setpoint verification procedure is provided in the CVHE Service Guide (CTV-SG-2.)

Table 25
Current Transformer Input to Micro Module 1U3 (1)

Primary Current (I1) to Auxiliary CTs 2T5, 2T6 & 2T7	Input Voltage @ 1TB4-11, -12; 1TB4-9, -10; & 1TB4-7, -8 Respectively (Note 3)
0.50 amps RMS	1.34 ± 0.05 volts RMS
1.00 amps RMS	1.83 ± 0.05 volts RMS
1.25 amps RMS	2.06 ± 0.05 volts RMS
1.50 amps RMS	2.28 ± 0.05 volts RMS
1.75 amps RMS	2.51 ± 0.05 volts RMS
2.00 amps RMS	2.73 ± 0.05 volts RMS
2.25 amps RMS	2.95 ± 0.05 volts RMS
2.50 amps RMS	3.17 ± 0.05 volts RMS
2.75 amps RMS	3.39 ± 0.05 volts RMS
3.00 amps RMS	3.62 ± 0.05 volts RMS
3.25 amps RMS	3.84 ± 0.05 volts RMS
3.50 amps RMS	4.06 ± 0.05 volts RMS
3.75 amps RMS	4.28 ± 0.05 volts RMS
4.00 amps RMS	4.51 ± 0.05 volts RMS
4.25 amps RMS	4.71 ± 0.05 volts RMS
4.50 amps RMS	4.93 ± 0.05 volts RMS
4.75 amps RMS	5.14 ± 0.05 volts RMS
5.00 amps RMS	5.37 ± 0.05 volts RMS
5.50 amps RMS	5.80 ± 0.05 volts RMS
6.00 amps RMS	6.24 ± 0.05 volts RMS
8.00 amps RMS	7.96 ± 0.05 volts RMS

Notes:

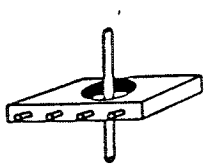
1. To calculate primary current (I1), use the following equation:

$$(I1) = \frac{\text{Line Current}}{\text{CTRA}} \times 5$$

where: (I1) is the primary current to the auxiliary current transformer (CT); the "CTRA" value to for 2T1, 2T2, and 2T3 respectivaly (Table 26); and "Line Current" is the primary current thru the line CTs (2T2, 2T2 and 2T3).

To calculate %RLA, measure line current directly; then use the following equation:

$$\%RLA = \frac{\text{Line Current}}{\text{100\% of Unit RLA Rating}} \times 100\%$$



2. Accuracy of the line CT is ± 1%.
3. Excludes meter error.
4. RMS = root mean square ((i.e., standard AC meter units).

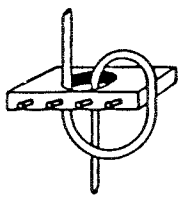


Table 26
Line CT Ratios (2T1, 2T2 and 2T3)

RLA Range	CT Ratio (Note 1)	Line CTRA Value (Note 3)	Primary Turns (PR1; Note 2)	Meter Scale (3)
28.6 to 35.7	150 : 5	150	3	50
35.8 to 42.8	180 : 5	180	3	60
42.9 to 53.5	150 : 5	150	2	75
53.6 to 64.2	180 : 5	180	2	90
64.3 to 71.4	200 : 5	200	2	100
71.5 to 89.2	250 : 5	250	2	125
89.3 to 107.1	150 : 5	150	1	150
107.2 to 128.5	180 : 5	180	1	180
128.6 to 142.8	200 : 5	200	1	200
142.9 to 178.5	250 : 5	250	1	250
178.6 to 214.2	300 : 5	300	1	300
214.3 to 250.0	350 : 5	350	1	350
250.1 to 285.7	400 : 5	400	1	400
285.8 to 357.1	500 : 5	500	1	500
357.2 to 428.5	600 : 5	600	1	600
428.6 to 500.0	700 : 5	700	1	700
500.1 to 571.4	800 : 5	800	1	800
571.5 to 714.2	1000 : 5	1,000	1	1000
714.3 to 857.1	1200 : 5	1,200	1	1200
857.2 to 1071.4	1500 : 5	1,500	1	1500
1071.5 to 1285.7	1800 : 5	1,800	1	1800
1285.8 to 1500.0	2100 : 5	2,100	1	2100
1500.1 to 1785.7	2500 : 5	2,500	1	2500

Notes:
1. The CT ratio represents the size of the current transformers used with the specified RLA range.
2. Each "primary turns" (PRI) value indicates the number of times that the main power line passes through its current transformer.

Examples: PRI = 1 PRI = 2

3.If ampmeters are used with the CTs, their full-scale deflection will equal the "meter scale" values in this table.

Note: Meter Scale = $\frac{\text{Line CTRA}}{\text{PRI Turns}}$

where "Line CTRA" is the first number of the line CT ratio.

7. Calculate the "I1" values for primary current to the auxiliary CTs at 100% and 85% of design RLA using the following equations:

$$I1 \text{ for } 100\% \text{ RLA} = \text{Design RLA} \times \frac{5}{\text{Meter Scale}}$$

$$I1 \text{ for } 85\% \text{ RLA} = 0.85 \times \text{Design RLA} \times \frac{5}{\text{Meter Scale}}$$

where,

"I1" is the primary current to the auxiliary CTs (2T5, 2T6, and 2T7); "Meter Scale" is the effective line CT ratio (see Table 26); and "Design RLA" is the RLA value stamped on the chiller nameplate.

8. Use Table 25 to determine the input voltage values that correspond to the 100% and 85% RLA values calculated in Step 7.

9. Monitor--and record--the micro module's phase current voltage inputs at Terminals 1TB4-7 and -8, 1TB4-9 and -10, and 1TB4-11 and -12, respectively, during the start sequence. Use Table 25 to convert the recorded input voltages to corresponding "I1" values for primary current to the auxiliary CTs.

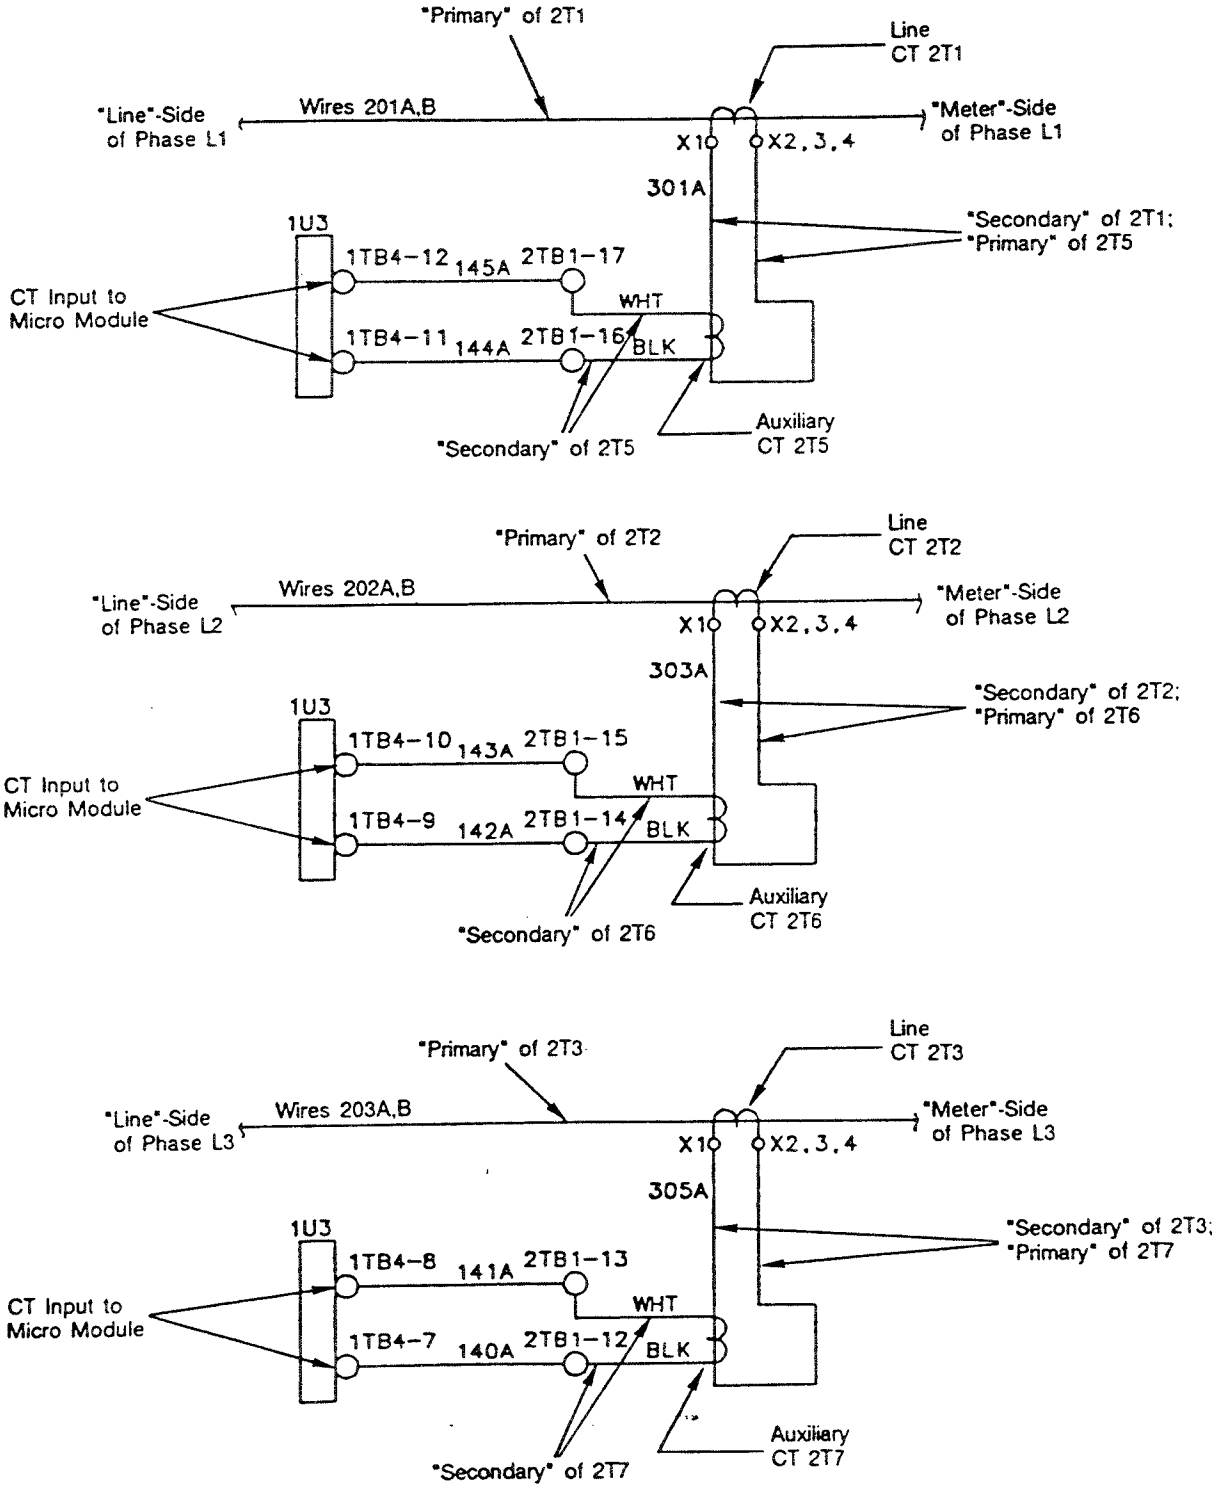
If primary current to the auxiliary CTs drops from more than 100% RLA to less than 85% of RLA (see Step 7 of this procedure)--but the input voltage at Pin 1P4-1 does not increase from 0.0-0.1 VDC to 0.85-1.6 VDC, micro module 1U3 may be defective. Perform the power supply checkout procedure described in the next section of this bulletin before condemning 1U3.

If primary current to the auxiliary CTs does not drop from over 100% to less than 85% RLA, then check the integrity (i.e., including wiring and part numbers) of each current transformer. See "Current Transformer Checkout" that follows.

Current Transformer Checkout

Each phase of the incoming power supply to the compressor motor is provided with line (2T1, 2T2, 2T3) and auxiliary (2T5, 2T6, 2T7) current transformers. All of these CTs are mounted in the starter panel; current transformer connections are shown in Figure 30.

Note: Polarity is critical for proper setup of both line and auxiliary current transformers. Be sure to check each CT for proper polarity--and all CT wiring for faulty connections--before performing the checkout procedure described below. Also, use Table 26 to verify that the correct line CTs are in use, and that the proper terminals are connected.



WARNING: Use extreme care when performing this checkout procedure while the chiller is energized. Carelessness can result in injury or death.

1. Use a series ammeter to monitor the output of Phase L1's line current transformer (2T1).

Note: This check cannot be made reliably with a clamp-on ammeter; always use a series ammeter on the line CT secondary!

2. Check the CT ratio, and verify that the measured input and output values conform to this ratio.

Figure 30
Current Transformer (CT) Connections

If these values do not conform, determine why and make the necessary repairs. (In some cases, the primary winding is wound more than once through the current transformer. This reduces the primary-to-secondary ratio by a factor equalling the number of loops through the transformer. See Table 26.)

Note: In order to check CT input and output voltages, CT line and secondary amp flows must be monitored while the unit is running.

3. Check the voltage at Terminals 1TB4-11 and -12 on micro module 1U3, and compare this value to the corresponding auxiliary CT primary current (I1) value in Table 25 to verify the integrity of 2T5.

4. Repeat Steps 1 through 3 for Phase L2 and Phase L3. Check the integrity of auxiliary CT 2T6 and 2T7 as described in Step 3 by measuring the voltage at Terminals 1TB4-9 and -10, and Terminals 1TB4-7 and -8, respectively.

Power Supply Checkout Procedure

(UCP695 Control Panels Only)

Note: The following power supply checkout procedure is only applicable for those CVHE units equipped with UCP695 control panels (i.e., chillers of "K" or subsequent design). Check the tenth digit of the model number stamped on the chiller nameplate to determine its design sequence.

Overview

Refer to the UCP layout illustration in Figure 7 on page 34. The UCP695 control panel utilizes a power supply transformer (1T1) and power supply output module (1U2) that furnish power to micro module 1U3. The information in this section describes a method for verifying that both of these components (i.e., 1T1 and 1U2) are operating properly. A typical control panel connection diagram is shown in Figure 31. Refer to the electrical schematic in Figure 9 on pages 46-49 or to the electrical diagrams that shipped with the chiller.

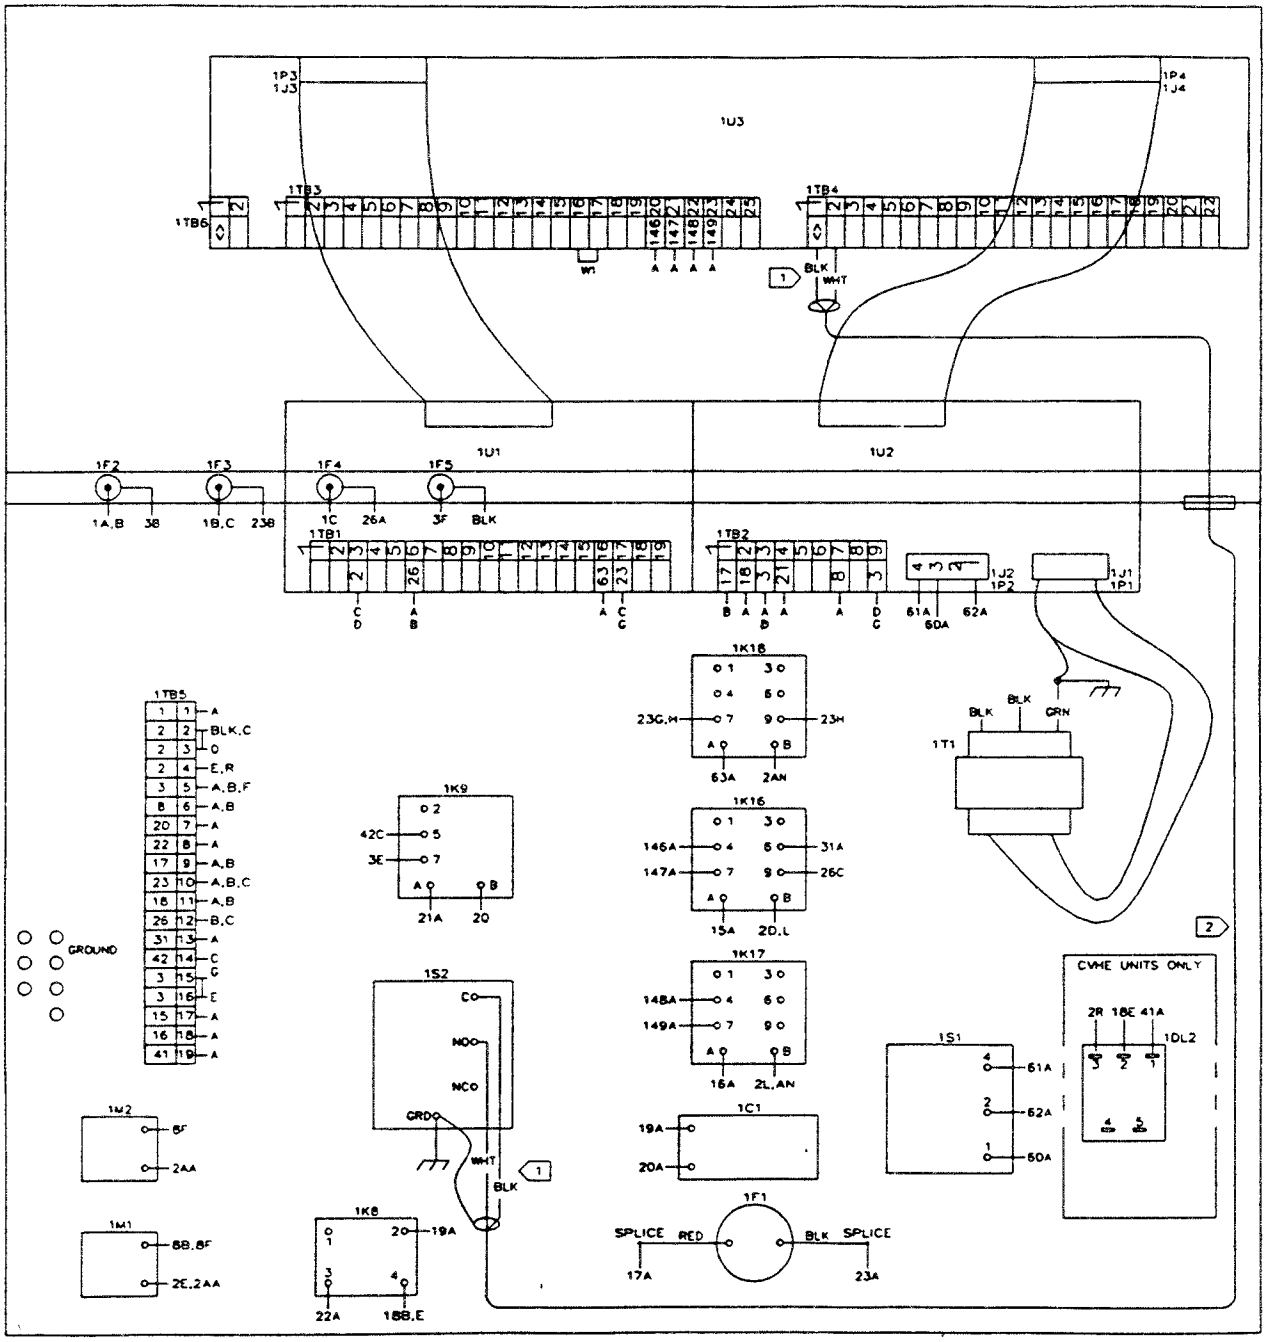
Note: It is good practice to check the power supply components (i.e., 1T1 and 1U2) whenever troubleshooting the micro module. Refer to the procedure illustrated by Figure 32 on the page 106. An improper voltage input to 1U3 can cause a good micro module to produce erratic output responses.

Power Transformer (1T1) Checkout

1. Check branch circuit fuse 1F5 for continuity.

2. Confirm that 120 VAC power is available across the 2 black leads of transformer 1T1.

3. Verify that the output cable (1P1) from power supply transformer 1T1 is firmly and correctly attached to 1J1 on power supply output module 1U2.



Before proceeding to Steps 4, 5 and 6, keep these points in mind when taking the requested measurements: (1) the pins on 1P1 are numbered from right to left; and, (2) be sure that good contact is made with the metal of the pin.

4. Connect the black (negative) lead of a digital VOM--set to measure DC voltage--to Pin 1P1-1 (i.e., chassis common). Then, measure the voltages at Pins 1P1-3, -4 and -5, and compare the measured values with the allowable signal ranges shown in Figure 33.

Note: If any of the voltages measured in Step 4 are out of range--and the voltages measured in Steps 5 and 6 are in range, transformer 1T1 is okay but power supply output module 1U2 may be malfunctioning. Check 1U2's output before replacing either component.

5. Switch the digital VOM to register AC voltage, and--with the black VOM lead still connected to Pin 1P1-1--measure the voltages at Pins 1P1-2, -3, -4 and -6. Compare these measured voltages with the allowable signal ranges indicated in Figure 33.

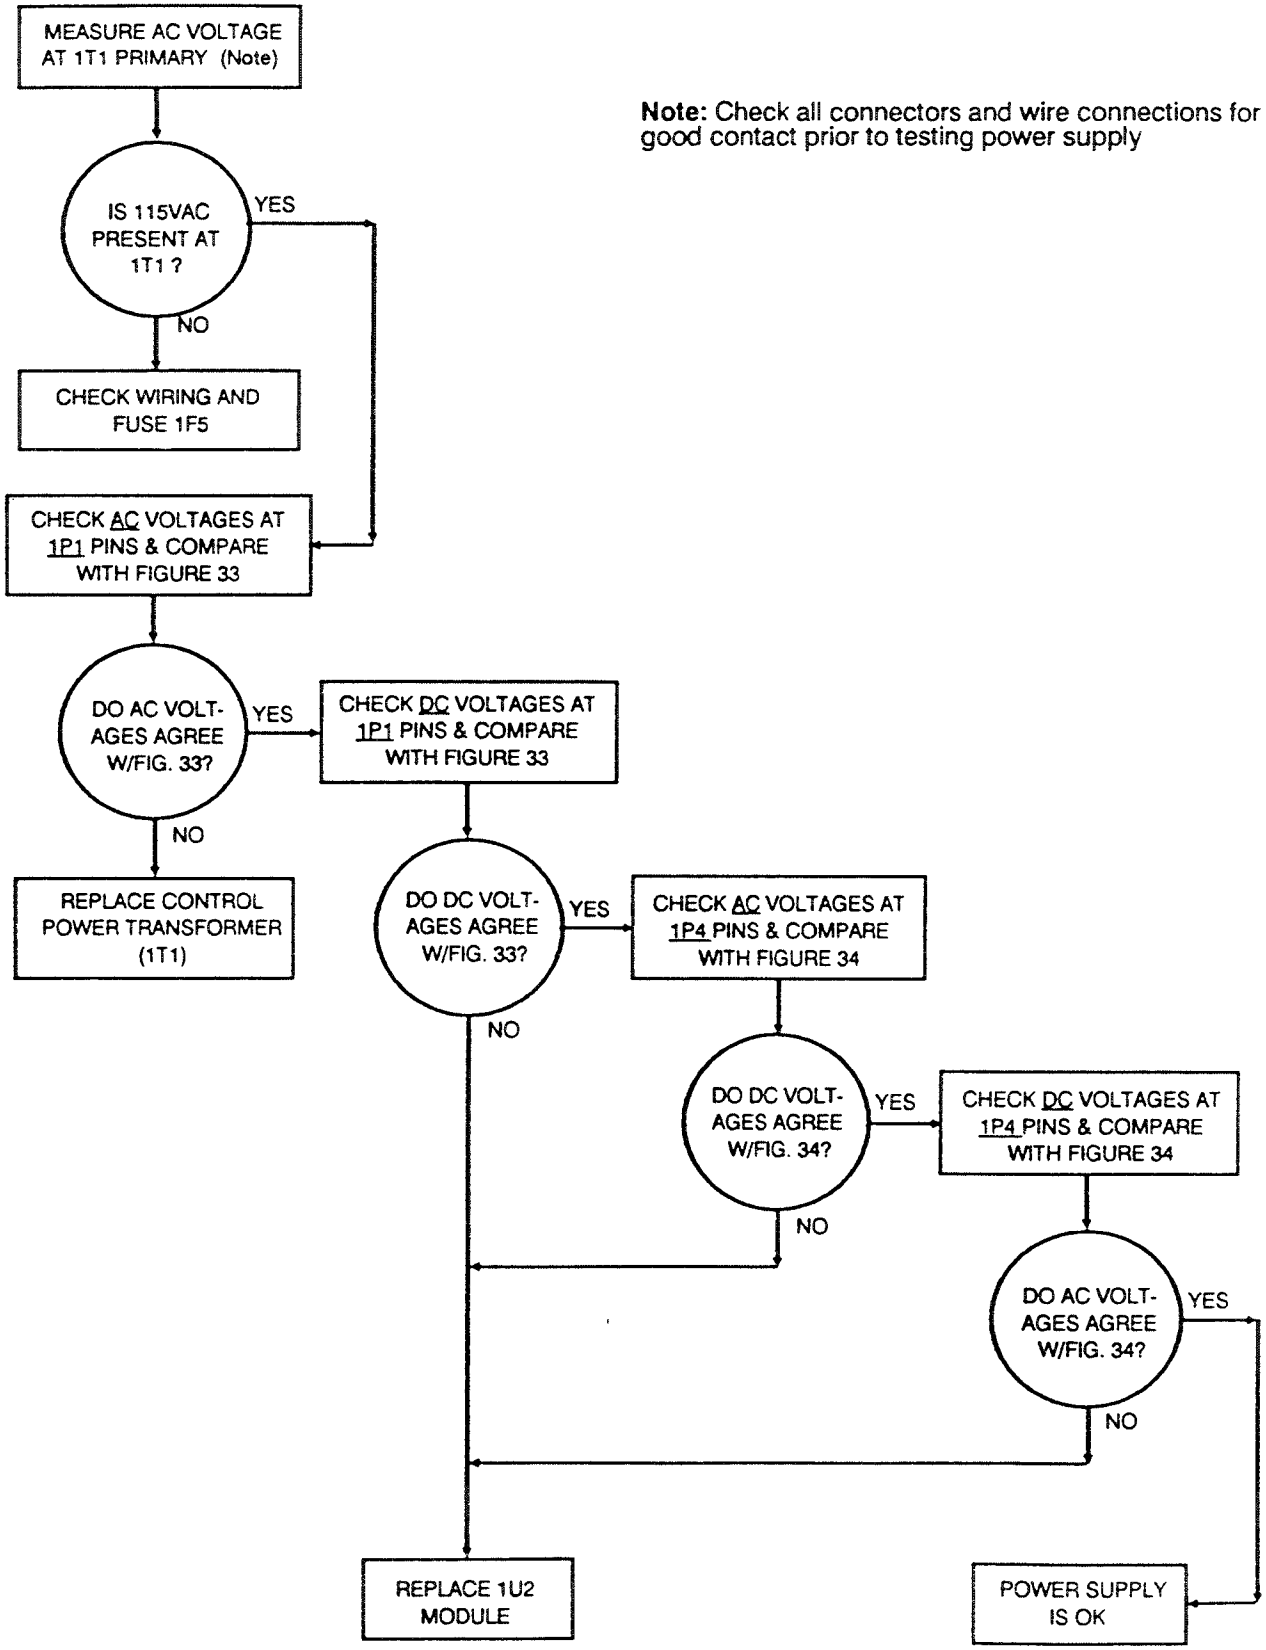


Figure 31
Typical UCP695 Control Panel Connections

Note: This drawing typical of: CVHE - design sequence "1C" and later; CVHB - design sequence "1D" and later; CVHF - all designs w/UCP695. Refer to appropriate wiring manual for earlier designs.

Figure 32 - Power Supply Checkout Procedure

Note: Check all connectors and wire connections for good contact prior to testing power supply

Figure 33
Voltages for Power Supply Transformer
Connector 1P1

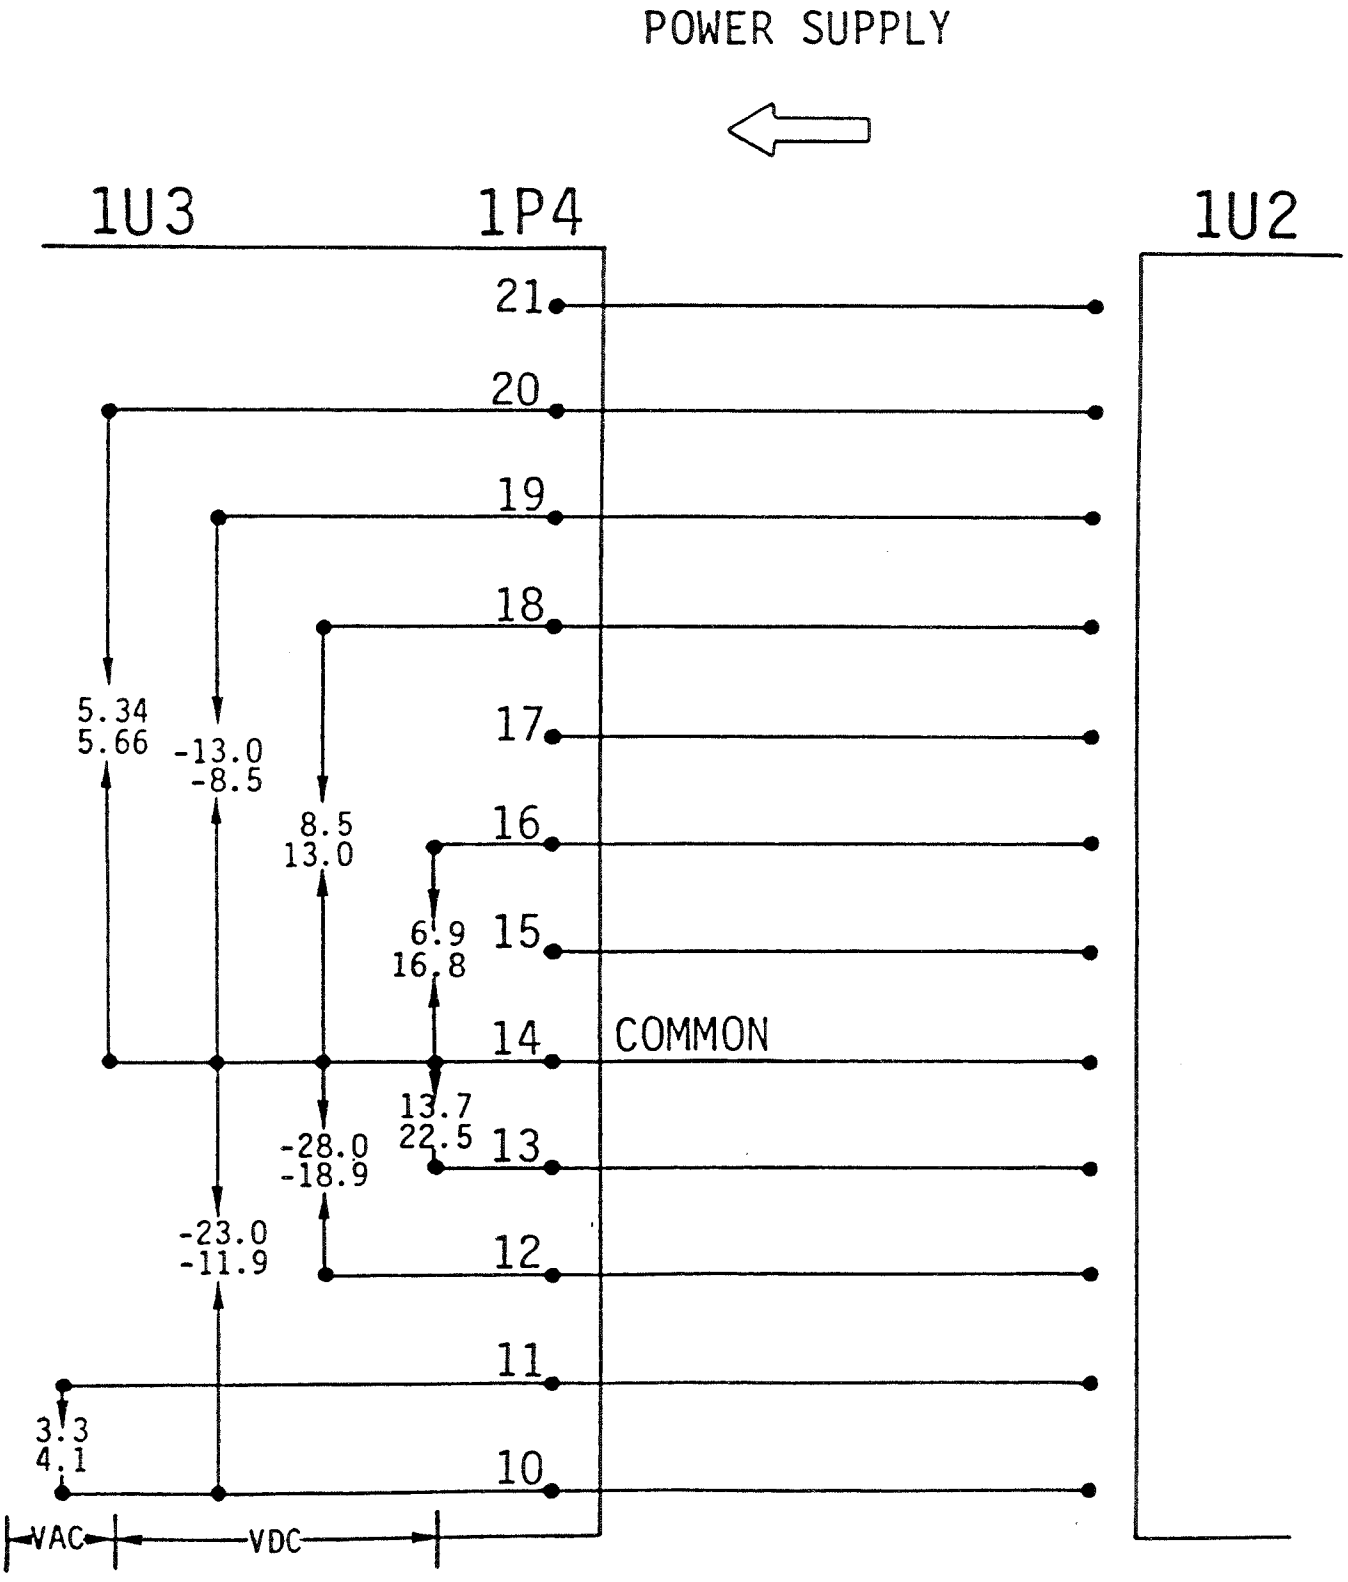
6. Move the black (negative) lead of the VOM to Pin 1P1-7; then measure the voltages at Pins 1P1-8 and -10. Compare the voltage readings obtained with the allowable signal ranges indicated in Figure 33.

Note: If any of the voltages measured in Steps 5 and 6 are out of range, a problem with power supply transformer 1T1 is indicated. Before replacing 1T1, use the blade of a small screwdriver to press the wires of 1J1 firmly into their sockets. Occasionally, the wire insulation is not cut completely when the wires were initially inserted into the connector.

Power Supply Output Module 1U2 Checkout

1. Remove the cover strip located along the top of micro module 1U3, and find ribbon cable connector 1P4. See Figure 31. Verify that ribbon cable 1P4 is firmly and correctly connected to 1J4.

Note: Notice that--in this instance--the pins are numbered from left to right.



2. Using a digital VOM set to register DC voltage signals, connect the black (negative) VOM lead to Pin 1P4-14.

3. Measure the voltages at Pins 1P4-10, -11, -12, -13, -16, -18, -19 and -20. Compare these voltage readings with the allowable voltage signal ranges indicated in Figure 34.

4. Set the VOM to register AC voltage signals; then connect the black VOM lead to Pin 1P4-11 and the red VOM lead to Pin 1P4-10. Measure the voltage between these pins, and compare this value to the "AC component" range shown for Pins 10 and 11 in Figure 34.

Note: If any of the voltages measured in Steps 3 and 4 are out of range--and the power transformer checked out okay, a problem with the power supply output module is indicated.

Figure 34
Voltages for Ribbon Cable Connector 1P4

Checkout Procedure for Vane Control Operation

(UCP695 Control Panels Only)

Note: Use the checkout procedure described in this section when the vane actuator does not respond to the vane control switch on the front of the unit control panel. Keep in mind that this procedure is only applicable for those CVHE units equipped with UCP695 control panels (i.e., chillers of "K" or subsequent design). Check the tenth digit of the model number stamped on the chiller nameplate to determine its design sequence.

Several equipment "fault" conditions can prevent the chiller from controlling properly; these include:

[ ] a blown branch circuit fuse (1F3);
[ ] faulty actuator wiring;
[ ] a mechanically or electrically defective actuator;
[ ] a Triac switch failure in relay output module 1U1; and,
[ ] a micro module (1U3) malfunction.

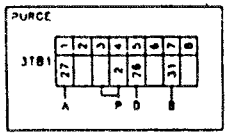
To determine whether or not any of these components are responsible for inhibiting proper chiller control, follow the step-by-step instructions provided below. (Refer to Figure 9 on pages 46-49 for a typical electrical schematic. The UCP695 control panel layout is shown in Figure 31 on page 106.)

1. Verify that branch circuit fuse 1F3 is intact; to do this, check for 115 VAC at Terminal 1TB5-9. See Line 35 in the electrical schematic.

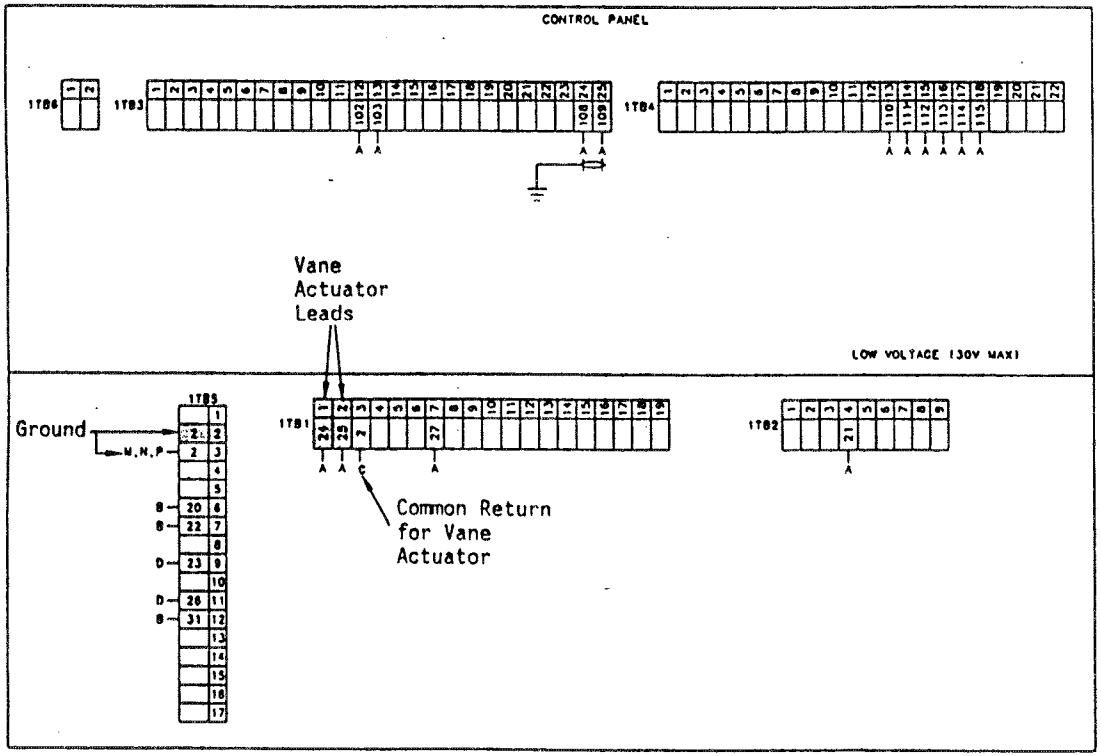
2. Adjust the chiller switch to STANDBY/RESET and the vane control switch to AUTO; then remove power from the vane actuator circuit by removing Fuse 1F3.

WARNING: To prevent injury or death due to electrical shock, lock power supply disconnect open before opening control panel door. Also, remember that terminals connected to remote equipment (e.g., condenser water pump) may remain energized when power is removed from panel. Always check for voltage before disconnecting wires!

3. Disconnect Wire Nos. 24A and 25A from Terminals 1TB1-1 and 1TB1-2, respectively. (Refer to the typical connection diagram in Figure 35 on the next page.)



4. Reinstall Fuse 1F3 and apply power to the UCP695 panel; be sure to exercise care since Wire Nos. 24A and 25A are now "hot" (i.e., each carries 115 VAC).



WARNING: Use extreme care when performing the following checkout procedure with power on; carelessness can result in injury or death due to electrical shock.

5. Check the operation of vane actuator 4B2; to do this:

a. Short Wire No. 24A to ground (Terminal 1TB1-3; see Figure 35), and check for actuator movement. Unless it is already fully open, the actuator should drive open. Proceed to Step 5b.

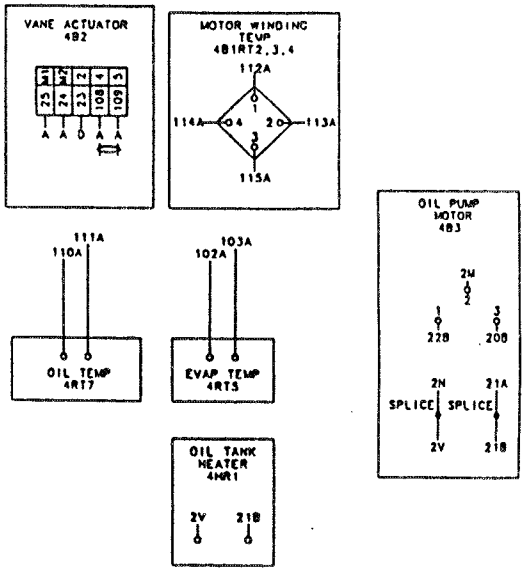


Figure 35
Typical Connection Diagram for Standard CVHE Units

WARNING
Disconnect all electrical power supplies to prevent injury or death due to electrical shock.

Caution
Use copper conductors only to prevent equipment damage.

Drwg. X39470468

If the actuator does not move--and is not already fully open, thoroughly check the vane actuator assembly (including end switches) and actuator wiring for defects. Make sure that the wire connected to Terminal 1TB1-3 is common with the wire connected to Terminal 1TB5-2 (ground). Repair or replace as necessary.

b. Short Wire 25A to ground (Terminal 1TB5-2), and check for actuator movement. The actuator should drive closed unless it is already in the full-closed position.

If the actuator does not move--and is not already fully closed, check the actuator (including end switches) and actuator wiring for defects. Again, verify that the wire connected to Terminal 1TB1-3 is common with the wire connected to Terminal 1TB5-2 (ground). Repair or replace as necessary.

After verifying the integrity of the actuator, complete Steps 6 through 11 to confirm that micro module 1U3 is functioning properly.

Note: If the results obtained in Step 5 indicated a defective actuator or faulty actuator wiring, remove power from the unit and perform the necessary repairs before completing this checkout procedure!

WARNING: To prevent injury or death due to electrical shock, lock power supply disconnect open before servicing unit.

6. With the control panel energized and the chiller switch set at STANDBY/RESET", turn the vane control switch to the HOLD position.

WARNING: Use extreme care when performing this checkout procedure with power on; carelessness can result in injury or death due to electrical shock.

7. Check the voltage at Pin 1--with respect to Pin 11--of the 1P3 post header power supply plug. (Figure 31 on page 106) indicates the relative position of 1P3 in the UCP695 chiller control panel.)

The voltage signal measured at Pin 1 should be 0.0 to 0.06 VDC if micro module 1U3 is functioning properly.

If the measured voltage at Pin 1 is outside this range, 1U3 may be defective. Perform the "Power Supply Checkout Procedure" (pages 105-110) before condemning 1U3!

Note: Whenever micro module replacement is indicated, always perform the "Power Supply Checkout Procedure to confirm that 1U3 is actually defective.

8. Readjust the vane control switch to the UNLOAD position.

9. Again check the voltage at Pin 1-- with respect to Pin 11-- of 1P3; this time, the measured voltage should be 5.1 to 5.6 VDC if micro module 1U3 is operating correctly.

If the measured voltage at Pin 1 is outside this range, 1U3 may be defective. See the "Power Supply Checkout Procedure" on pages 105-110.

10. Adjust the vane control switch to HOLD, and check the voltage at Pin 2--with respect to Pin 11--of 1P3. If micro module 1U3 is operating properly, the measured voltage should be 0.0 to 0.06 VDC.

If the voltage reading obtained is outside this range, 1U3 may be defective. See the "Power Supply Checkout Procedure" on pages 105-110.

11. Turn vane control switch back to LOAD, and again check the voltage at Pin 2--with respect to Pin 11--of 1P3. This time, the measured voltage should be 5.1 to 5.6 VDC if micro module 1U3 is functioning correctly.

If the meter indicates a voltage outside outside this range, 1U3 may be defective. See the "Power Supply Checkout Procedure" on pages 105-110.

Vane position is governed by two Triac switches (1U1Q7, "vanes open"; 1U1Q8, "vanes closed") inside relay output module 1U1. See Lines 35 and 36 of the electrical schematic. To verify whether or not both of these Triacs are operational, complete Steps 12 through 16.

Note: If the results obtained in Steps 6 through 11 indicate a defective micro module (1U3)--and completion of the "Power Supply Checkout Procedure" (pages 105-110) confirms this diagnosis, remove power from the unit and replace 1U3 before completing this checkout procedure!

WARNING: To prevent injury or death due to electrical shock, lock power supply disconnect open before servicing unit.

12. With the control panel energized and the chiller switch set at STANDBY/RESET, adjust the vane control switch to the HOLD position (i.e., both Triac switches should now be open).

WARNING: Use extreme care when performing this checkout procedure with power on; carelessness can result in injury or death due to electrical shock.

Note: Review Steps 13 through 17 below. In each of these steps, be sure to remove Branch Circuit Fuse 1F3 before disconnecting or reconnecting Wire No. 24A or 25A.

13. Connect Wire No. 24A to Terminal 1TB1-1; see Figure 35. (Remember that both Wire No. 24A and Wire No. 25A were disconnected in Step 3.)

Check for actuator movement. If the actuator drives open (assuming that it is not already fully open), the "vanes open" Triac switch (1U1Q7) is shorted; since 1U1Q7 is an integral part of the relay output module, 1U1 is defective and must be replaced.

14. Disconnect Wire No. 24A from Terminal 1TB1-1, and connect Wire No. 25A to Terminal 1TB1-2; again, check for actuator movement.

If the actuator drives closed (assuming that it is not already fully closed), the "vanes closed" Triac switch (1U1Q8) is shorted; since 1U1Q8 is an integral part of the relay output module, 1U1 is defective and must be replaced.

15. With Wire No. 25A still connected to Terminal 1TB1-2, readjust the vane control switch to the UNLOAD position and check for actuator movement.

If the actuator does not drive closed--and it is not already in the full-closed position, Triac switch 1U1Q8 failed open; replace relay output module 1U1.

16. Disconnect Wire No. 25A from Terminal 1TB1-2 and set the vane control switch at LOAD; then connect Wire No. 24A to Terminal 1TB1-1 and check for actuator movement.

If the actuator does not drive open--and it is not already in the full-open position, Triac switch 1U1Q7 failed open; replace relay output module 1U1.

17. Remove power from the UCP695 control panel and complete any repairs indicated in Steps 12 through 16; then:

a. Connect Wire No. 24A to Terminal 1TB1-1 and Wire No. 25A to Terminal 1TB1-2.

b. Adjust the vane control switch to the AUTO position.

c. Set the chiller switch at either AUTO/LOCAL or AUTO/ REMOTE, as desired.

d. Restore power to the UCP695 control panel.

CVHE-SB-23 (4/90) – Original issue of bulletin.

Subject: Mandatory Return For CNT-1091 Surge Arrestors (MOV's) On CVHE/CVHB Units With In-Warranty Motor Failures

Introduction:

During September of 1988, Trane initiated factory installation of two surge protective devices (M.O.V.'s) on all 600-volt or lower-voltage CVHE and CVHB motors. These devices are connected between the six motor leads and to ground. They are mounted through the motor terminal box enclosure on direct-ship starter units and through the motor-to-starter housing on units equipped with unit-mounted starters (UMS-type units).

Discussion:

Both MOV's on each 600-volt or lower-voltage CVHE or CVHB unit that has a motor failure within the warranty period of the unit, must be returned to La Crosse.

Note: If the MOV's are on a CenTraVac unit that is out of warranty, return the MOV's only if they are on the "Return Exception List".

Each returned MOV will be analyzed to determine its condition and to help establish the most likely cause of the motor failure.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Units Affected:

All Model CVHE and CVHB units 600-volts or lower voltage equipped with MOV voltage surge protectors (manufactured during September of 1988 and thereafter).

Recommended Action:

Disconnect MOV leads and mark each lead with its' corresponding motor terminal-stud designator (i.e., T-1 thru T-6). Remove both MOV's from the unit and tag each MOV "set" with the following information:

- Job Name;
- CVHE/CVHB Model Number;
- CVHE/CVHB Serial Number;
- Motor Failure Date;
- Motor Serial Number;
- ACS Claim Number.

Return tagged MOV sets to:

The Trane Company
Q.C. Lab Bldg-15
2512 So. 21st Place
La Crosse, WI 54601

Note: Do not send MOV's back to the motor manufacturer. Two new MOV's must be installed to replace the one's being returned.

Parts Ordering Information:

Order two MOV's for each motor failure occurence:

Trane Part No. = CNT-1091 MOV Surge Protector.
(Contains one MOV surge protector per each part no. ordered.)

Order from La Crosse, "Ship from 31"

Note: This service bulletin is informational only and does not authorize parts or labor.

Literature Changes:
CVHE-SB-24 (6/90) -- Original issue of bulletin.

Subject: CVHE Vane-Actuator Motor Limit-Switch Gear Replacement Kit

Introduction:

The purpose of this service bulletin is to advise the field of the availability of a replacement kit for the gear assembly of the vane-actuator motor limit switch used on CVHE units with the UCP-695 control panel.

Discussion:

A kit is now available for replacing the plastic worm-gear assembly in the CVHE vane-actuator motor limit switch. This kit is part number **GER-0315**. The vane-actuator motor has failed on several occasions due to stripped gears in the limit switch.

Units Affected:

All Model CVHE units with UCP-695 micro-control panel.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

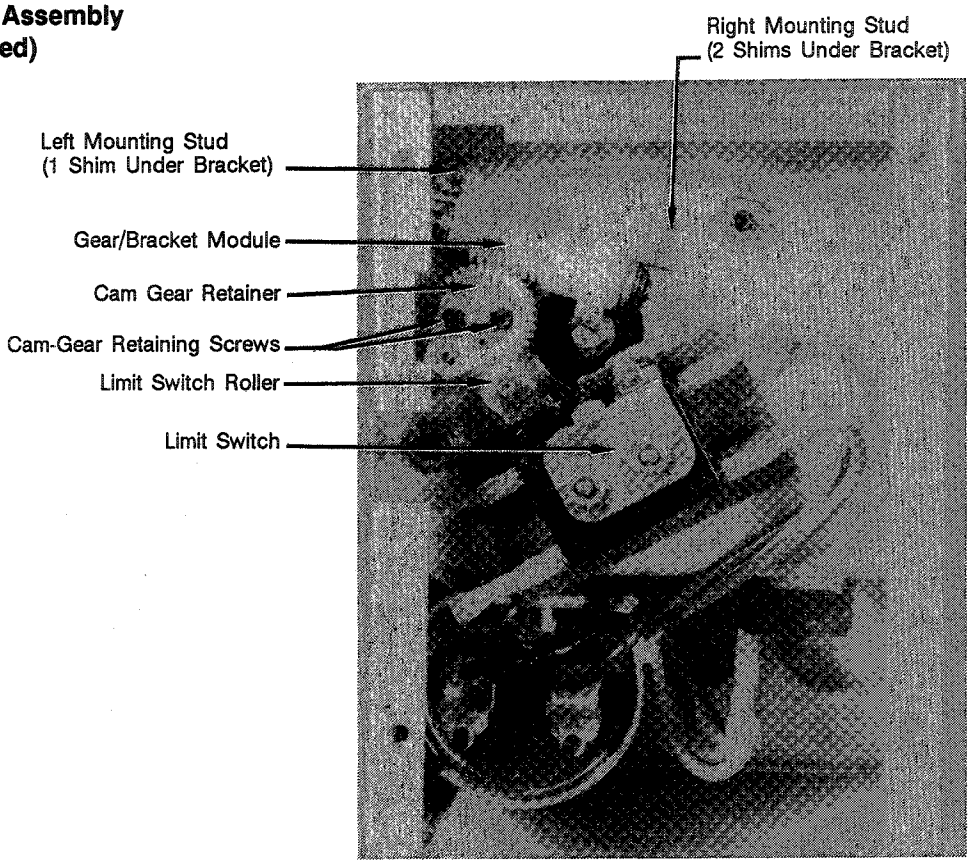
Recommended Action:

Use the following procedure to replace the gear assembly in the vane actuator motor limit switch:

1. Disconnect power to the vane-actuator motor.

WARNING: To prevent injury or death due to electrical shock, open and lock all disconnects before servicing the unit.

2. Remove and set aside the eight retaining screws from the actuator conduit-box cover. Remove the conduit box cover, exposing the limit-switch gear assembly. See Figure 1.



3. Remove and discard the gear/bracket module, the two gear/bracket mounting nuts, and the three shims (washers) located under the gear-bracket.

4. Remove and discard the snap ring and worm gear (on the motor shaft).

5. Mount the new worm gear (provided in the kit) on the motor shaft with hex-end toward actuator motor. Kit components are shown in Figure 2. The snap-ring groove should be exposed. Install the new snap ring (provided in the kit) in the groove. Check the worm gear to be sure it is secure on the motor shaft.

It is not usually necessary to replace the cam gears. If they require replacement, however, remove and discard the cam retaining screws, the cam retainer, and the old cam gears. Install the new cam gears and retainer using the new screws provided in the kit. Cams should be installed on left side of the cam roller as shown in Figure 1. Start but do not fully tighten the cam-retaining screws at this time.

Figure 1
Vane-Actuator Limit Switch Assembly
(Conduit Box Cover Removed)

 © American Standard Inc. 1990

6. Place one new shim (Figure 2) on the left gear/bracket mounting stud (Figure 1) and place two new shims over the right gear/bracket mounting stud (Figure 1).

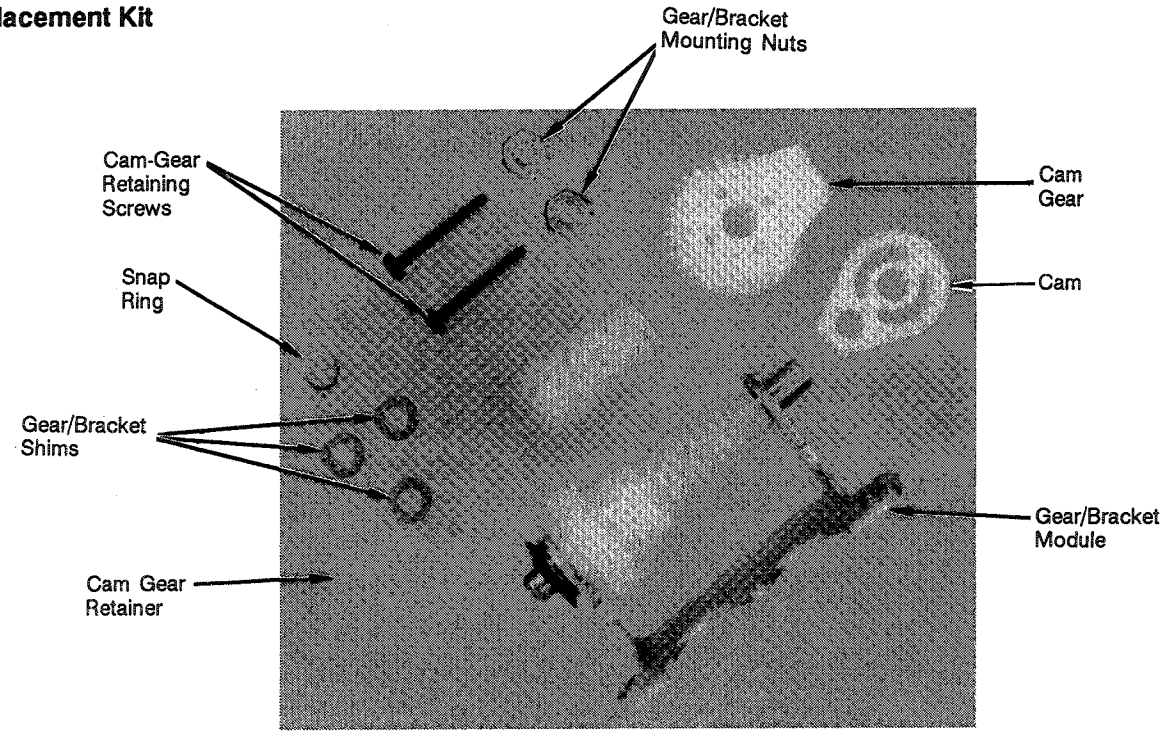
7. Position the new gear/bracket module (provided in the kit) over the mounting studs and install the new mounting nuts (provided in the kit) on the studs. Do not tighten the nuts fully at this time. Adjust position of gear/bracket module to engage both gear sets; then tighten the mounting nuts.

8. Then, check both gear sets for backlash. Gears should rotate slightly, but not excessively. Movement should be restricted to .005 to .010 inches.

Caution: Too much or too little backlash will shorten gear life.

9. Remove mounting pin from actuator extension tube.

10. Restore power to the actuator motor and retract the actuator until the limit switch shuts down the actuator. The extension tube may rotate during this process. Rotate the extension tube (if necessary) until the dimension between the mounting holes (center-to-center) is 16.63 to 16.75 inches.



WARNING: To prevent injury or death due to electrical shock, exercise extreme caution when servicing unit with electrical circuits energized.

While preventing the extension tube from rotating, extend the actuator until the stroke length between the mounting holes (center-to-center) is 21.44 to 21.94 inches. The cam gear retaining screws should be loose enough to allow the cam gear to turn. Turn the cam to engage the limit switch roller. Keep turning the cam until the limit switch makes with an audible "click". Then, tighten the cam gear retaining screws to 4 in./lbs.

11. Replace the mounting pin and cycle the actuator to check limit switch function and stroke length.

12. Replace conduit box cover.

Figure 2
Vane-Actuator Motor Limit Switch Gear Replacement Kit

Parts Ordering Information:

Order one vane-actuator limit switch gear kit for each vane-actuator failure occurence due to stripped limit switch gears. Specify the part number listed below:

Trane Part No. = **GER-0315**

Each kit contains:
(1) Motor worm gear;
(1) Snap-ring;
(1) Gear/bracket module;
(2) Gear/bracket module mounting nuts;
(3) Gear/bracket module shims;
(2) Cam gears;
(1) Cam-gear retainer;
(2) Cam-gear retainer screws.

Order from La Crosse, "Ship from 31".

Note: This service bulletin is informational only and does not authorize parts or labor.

Literature Changes:
CVHE-SB-25 (6/90) – Original issue of bulletin.

Subject: CVHE 5000-Frame Low-Voltage Motor Cooling

Introduction:

A potential reliablity problem has been identified for 5000-frame, low-voltage Reliance motors typically used on CVHE units, sizes 056 thru 1250 shipped before November 30, 1989. The tightly-bundled lead wires on these motors may overheat under certain conditions. Since motor-lead failure will require replacement of the entire compressor motor, all units equipped with motors affected by this bulletin must be identified and repaired. All operating units must be repaired immediately. Repair of units that have not been started must be accomplished at the time of start-up.

Discussion:

Under certain load conditions (i.e., high load, low head), the tightly-bundled lead-wires on 5000-frame low-voltage Reliance motors may not receive sufficient cooling. Over a period of time, the leads may eventually fail due to a repeated overheating condition. The required repair consists of providing additional cooling to the motor leads by installing a cooling line to the motor.

Units Affected:

All Model CVHE units equipped with 5000-frame, 380 thru 600-volt (512 KW and larger) Reliance motors shipped prior to November 30, 1989. A manufacturing design change has been implemented to correct this condition on all units that shipped after this date.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Corrective Action:

All units affected by this bulletin must be retrofitted with a cooling line to provide additional cooling to the motor-lead bundle. To accomplish this, install a 1/2-inch copper line from the refrigerant feed line up to the motor stator housing at the location where the motor leads exit the motor-coil end turns as follows:

Note: Use of the repair procedure that follows is recommended to minimize refrigerant loss, joint leaks and the possibility of bearing damage.

1. Follow the procedures provided in the CVHE Service Guide (CTV-SG-2) to shut the unit down and secure it for service.

2. Following the procedures provided in the CVHE Service Guide (CTV-SG-2), bring the unit internal pressure up to one (1) psig.

3. Perform the remaining retrofit procedure while maintaining a slight positive pressure (1 psig) within the unit.

IMPORTANT: Be sure to maintain positive pressure in the unit, since the retrofit procedure is accomplished with the refrigerant charge in the unit.

4. Braze a 1/2-inch flare plug (modified Mueller Part No. A-123) to the motor refrigerant feed line as illustrated in Figure 1.

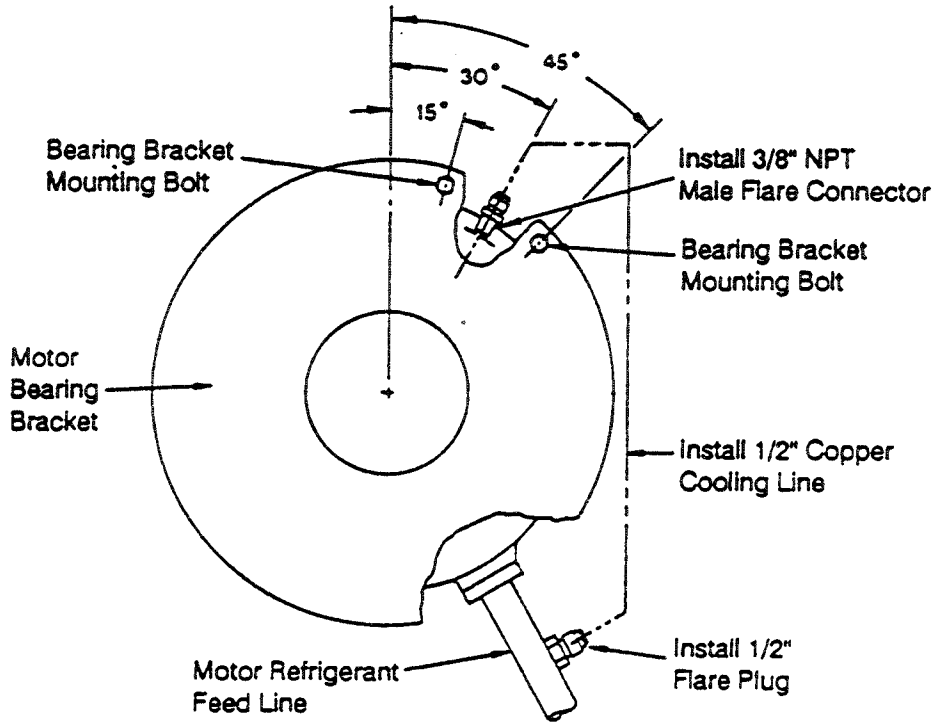
Note: The flare plug is provided with the letter of retrofit notification to the Territorial Service Manager.

5. Drill a 3/8-inch hole through the bottom of the flare plug and continue drilling through the wall of the refrigerant feed line. Install a 1/2-inch flare cap on the flare plug to hold the refrigerant in the unit.

6. Identify the 12th digit of the unit model number (on the unit nameplate). This KW designator will be the letter U, V, W, X, Y or Z. By referring to Table 1, use this KW designator to determine Dimension "A" shown in Figure 1. Dimension "A" is the distance from the end of the stator housing to the proper entry point on the housing for the new cooling line.

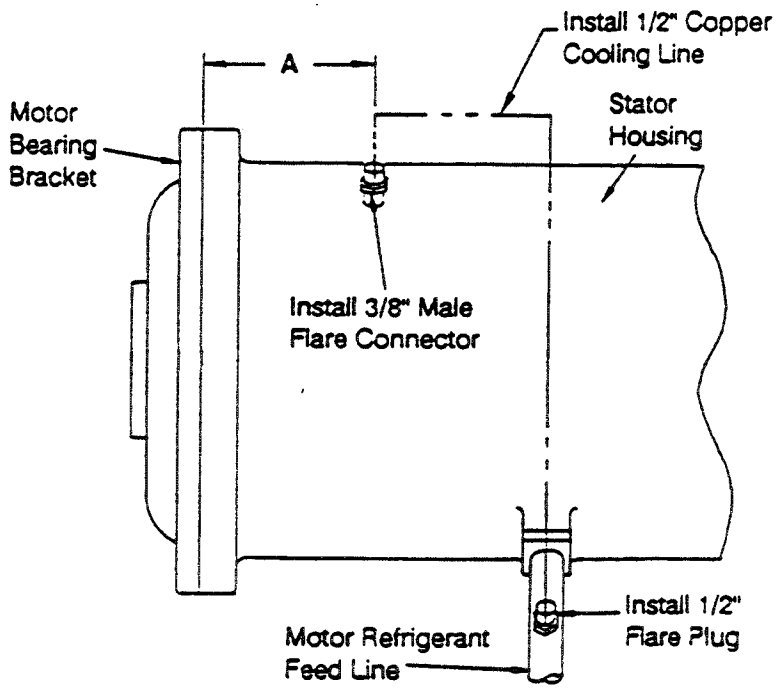
Caution: Be certain that Dimension "A" is properly identified, since the new coolant line must enter the stator housing at the proper location.

Table 1
Drilling Locator Dimension "A" Identification



KW Nameplate Designator (1)	Motor HP	Motor KW	Motor Code	Dimension "A"
U	650	512	X70551316-23 thru 27	9-1/2"
V	743	588	X70551316-43 thru 47	8-13/64"
	743	588	X70551317-23 thru 27	8-13/64"
W	832	653	X70551317-43 thru 47	7-13/64"
	832	653	X70551317-23 thru 27	7-13/64"
X	946	745	X70551317-63 thru 67	5-11/16"
Y	1088	856	X70551317-73 thru 77	4-13/64"
Z	1220	957	X70551317-83 thru 87	2-11/16"

Notes:
1. CVHE nameplate designator is 12th digit of model number as shown on unit nameplate.



© American Standard Inc.

Figure 1
Motor Lead Cooling Line Installation

End View

Side View

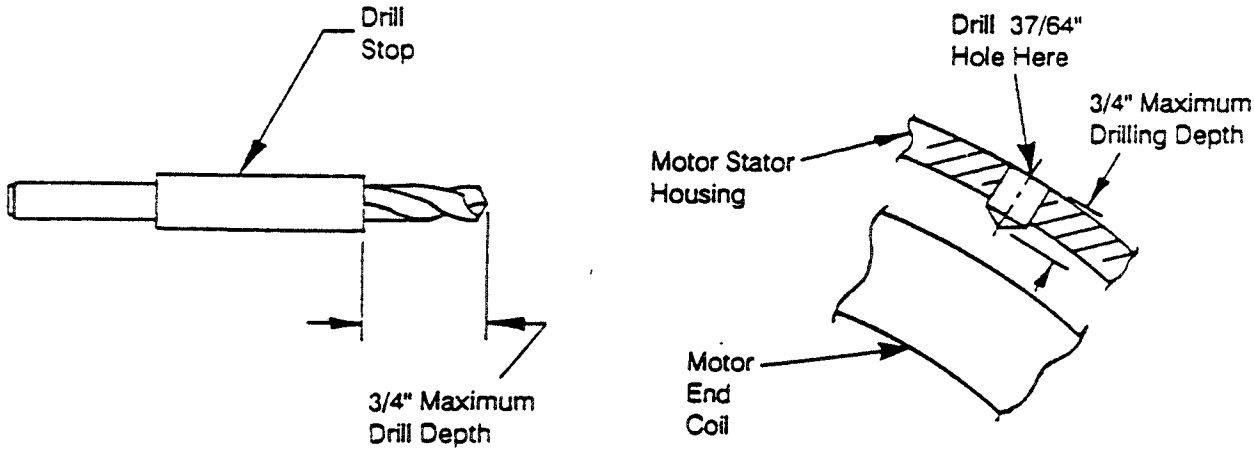
7. Using Dimension "A", locate and mark the proper drilling location at a point 30-degrees from top dead center on the stator housing as shown in Figure 1. This point is midway between the first and second bearing bracket mounting bolts, moving clockwise from top dead center; as viewed from the end of the motor.

8. Drill a 37/64" hole, 3/4-inch deep at this point. Tap this hole for 3/8" NPT. Remove drill chips during drilling with a vacuum or small pencil magnet.

Caution: Do not drill any deeper than 3/4-inch into the stator housing. Use a positive stop on the drill bit to prevent penetration over 3/4-inch (Figure 2).

WARNING! Wear safety glasses to prevent possible eye injury during drilling operation.

9. Screw a 3/8" NPT X 1/2" flare male connector into the tapped hole (Mueller Part No. A334; Trane Part No. X17050029). Install a cap on the flare connection.



Note: The flare connector is provided with the letter of retrofit notification to the Territorial Service Manager.

10. Make up a suitable-length 1/2-inch copper line (refrigerant-grade, Type L) with female flare connectors for each end. Connect the line at the male flare connections on the motor refrigerant feed line and on the stator housing.

11. Leak-test all new fittings and connections.

12. Follow the procedures provided in the CVHE Service Guide (CTV-SG-2) to purge and restart the unit.

Figure 2
Drilling Cooling Line Connection In
Stator Housing

Caution: To prevent damage to motor-end coil, do not allow drill to penetrate deeper than 3/4".

Parts Information:

No parts should be ordered for this procedure.

The parts that follow are provided to the Territorial Service Manger with the letter of retrofit notification. Each service manager will receive the appropriate number of parts required for the units located within his respective territory.

Quantity	Part Description	Part Identification
1	1/2" Flare Plug	(Modified Mueller Part No. A-123)
1	3/8" NPT X 1/2" Flare Male Connector	(Mueller Part No. A-334; Trane Part No. X17050029)

The parts listed below that are required to perform this retrofit procedure are to be obtained locally:

Quantity	Part Description	Part Identification
1	1/2" Type L Copper Tubing (Variable length, depending on unit.)	----------
2	1/2" Female Flare Connectors	----------

Subject: CVHE Oil Loss

(This is an informational Service Bulletin Only.)

Introduction:

We have received reports of excessive oil loss some on CVHE units, varying in age and design sequence. The purpose of this service bulletin is to discuss oil loss and available corrective action.

Discussion:

CVHE oil-loss can occur due to a sudden reduction in oil tank pressure. Oil-loss sypmptoms are most likely to occur during these operating conditions:

- Start up after a long shut down;
- Start up with a warm evaporator;
- Shut down at high load (especially with high condensing pressure), and;
- During load shedding.

These operating conditions normally produce sudden reductions in oil tank pressure that can cause the refrigerant dissolved in the oil to out-gas. If this pressure reduction is rapid enough, the out-gassing is not contained in the oil tank, allowing oil to be carried out through oil tank vent line.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Each CVHE installation is unique. Oil loss and return efficiency will depend upon system conditions and controls being applied. Oil loss may be a very dynamic event that is difficult to isolate and is not apparent during normal operation. Symptoms of oil loss problems are:

- Three or more gallons of oil are added to the unit and the oil level has not stabilized. The optimum operating oil level is visible in the lower half of the bottom oil-sump sight glass. During unit start-up and shutdown, it is normal for the oil level to drop. The oil level should return, however, after a period of sustained operation.

Note: Trane OIL-22 is the only oil recommended for use in CVHE units. The proper oil charge for all unit sizes is seven (7) gallons.

- The unit loses oil to the point of tripping on low oil pressure.

- Oil tank pressure is more than 6-7 inches of mercury greater than evaporator pressure.

Root Cause:

The root cause of oil loss is: High oil-tank pressure relative to evaporator pressure. The oil tank is vented to the suction cover behind the first stage guide vanes, which is the lowest pressure area in the unit (at or below evaporator pressure). Oil tank pressure is established by:

- The amount of leakage that occurs through the seals, and;
- The amount of oil tank line-loss in the oil tank vent line.

Oil tank pressure tends to follow evaporator pressure, but may be low at part load and even lower at low-load operation, depending on head conditions.

During start-up and shut down, oil-tank pressure moves closer to evaporator pressure. If oil-tank pressure is too high, the pressure drop causes out-gassing and oil loss through the vent line. Rapid changes in operating conditions can also cause sudden oil-tank pressure drop, with resultant oil loss.

A secondary result of high oil tank pressure is, that the oil reclaim system is not effective. The reclaim system relies on the eductor to pump oil out of the suction cover to the oil tank. If a large pressure differential exists between the suction cover and the oil tank, eductor oil return rate is reduced. At high heads and low loads, the normally high oil-tank pressure makes the eductor's ability to return oil marginal.

Units Affected:

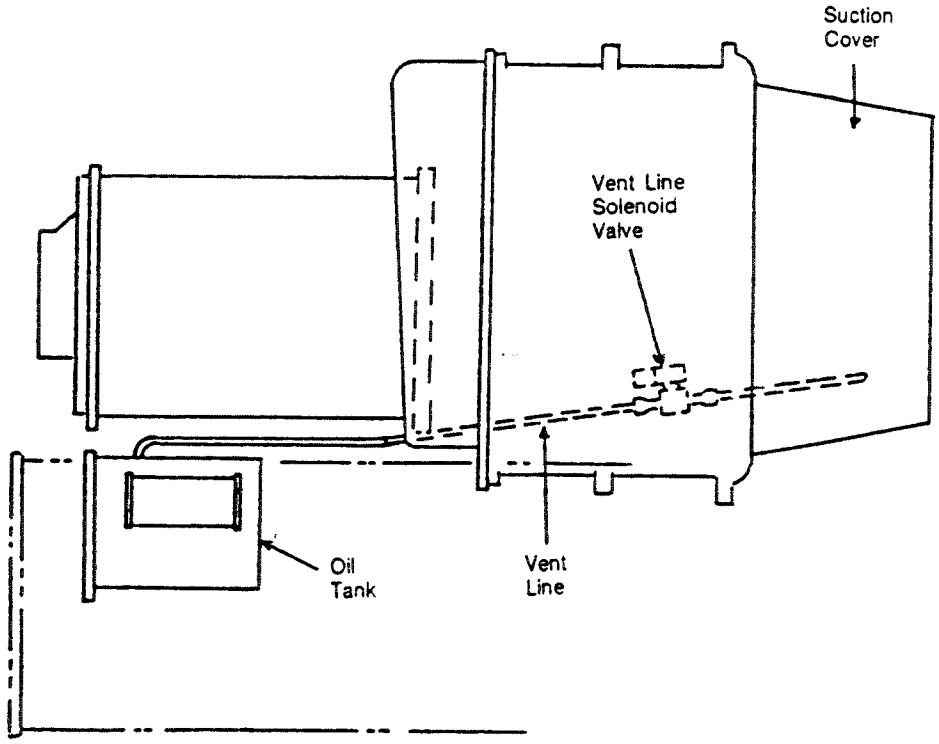
All CVHE units.

Corrective Action:

Since each job tends to be unique, a comprehensive evaluation must be made for that jobsite. The first step is to verify that the unit has a full operating refrigerant charge. Secondly, record an accurate system operating log to determine where the unit is operating (as compared to the design specifications) and to determine the degree of oil loss at those actual conditions. Pay particular attention to evaporator pressure versus low oil-tank pressure (be sure that all gauges are properly calibrated). The greater the pressure differential, the greater the oil-loss potential is, and the more likely the chance that the oil recovery system will not adequately reclaim oil. Once it has been determined that an oil loss condition exits, the following corrective action is available:

1a. Increase the vent line (Figure 1) size to 1-1/8". The line is 7/8" on units manufactured through September of 1990. Cut off the 7/8" line as close as possible to the oil tank and use a 1-1/8" x 7/8" reducing coupling. At the suction cover, cut the line and remove the screw-in fitting. Replace it with a 90-degree elbow (Mueller No. W2164) or straight adaptor (Mueller No. W1164), whichever is appropriate for the job. Both are 1-1/8" solder vs. 3/4" NPT. The bent tube in the old suction cover fitting is not required.

1b. Next, install a new ALCO vent-line solenoid valve (Trane Part No. VAL-3217) at the location shown in Figure 1.



1c. Finally, install a second eductor (Trane Part No. TEE-0077) on the 1/4" valve on the evaporator. Tee a 3/8" line from the condenser supply to the eductor, 1/4" line to the evaporator and 3/8" line to the oil tank.

If the oil loss problem persists after performing these steps., contact the CenTraVac and Absorption Systems Business Unit Technical Service Department in La Crosse, Wisconsin.

Special Note:

When a CVHE teardown is performed for any reason, pay particular attention to the third-stage labyrinth seal clearance, (SEL-0366, SEL-0367.) Total clearance should be .004" to .007". Replace the seal if this clearance exceeds .007".

Figure 1
CVHE Vent Line and Vent-Line Solenoid Valve Location

Parts Information:

This service bulletin is informational only and does not authorize any parts or labor. The parts listed below are required to complete the procedures described under "Corrective Action":

Obtain the parts listed below locally:
- 1-1/8" Copper Tubing (field supplied);
- (1) 90-Degree Elbow **(Mueller No. W2164)**; or,
- (1) Straight Adaptor **(Mueller No. W1164).**

Order the parts listed below from La Crosse, "Ship from 31", and specify the following part numbers:

VAL-3217 - ALCO Vent-Line Solenoid Valve;
TEE-0077 - Oil Eductor.

Other Service Bulletins Referencing Oil Loss:

CVHE-SB-20 - "CVHE Oil Pressure Loss During Startup".
CTV-SB-68 - "CenTraVac Oil Recovery System".

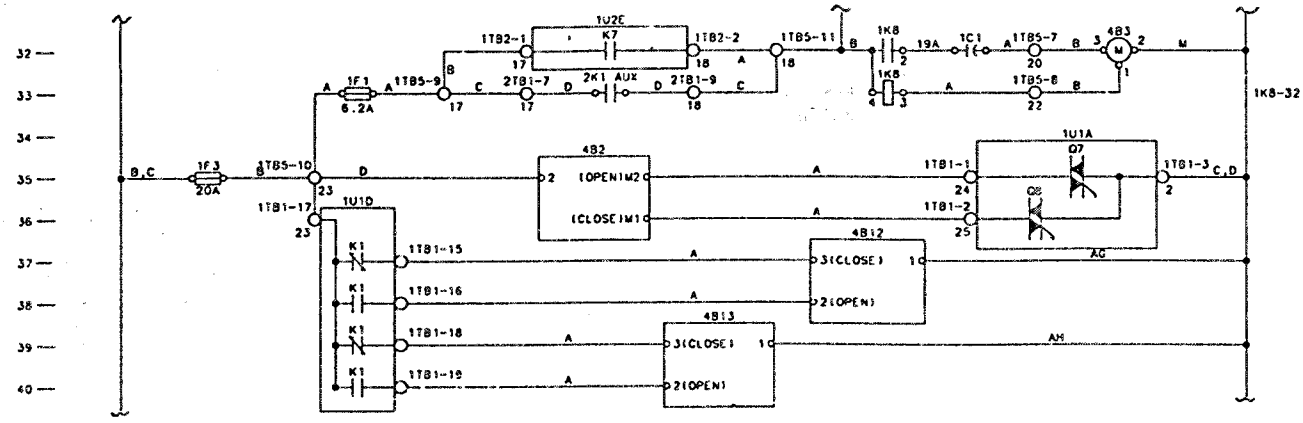
Subject: CVHE/CHVB Free-Cooling K1 Relay Malfunction

Introduction:

A potential reliability problem has been identified with the K1 (free-cooling) relay located in the 1U1 module of all CVHE and CVHB units equipped with UCP695 micro-control panels and the free-cooling option. This bulletin provides details and instructions for corrective action to be taken if the contacts of relay K1 fail. The procedures presented in this bulletin should be performed only if this failure occurs.

Discussion:



A potential problem has been identified with free-cooling relay 1K1 on the 1U1D output module of the UCP. Refer to Figure 1. There have been occurrences where one of the normally-open contacts of 1K1 have welded closed. This has happened during free cooling valve actuator motor operation, but also may occur if a fluttering water flow switch causes the K1 contacts to chatter, since the relay cannot withstand the resultant arcing between the contacts.

Units Affected:

All CVHE and CVHB free-cooling units equipped with the UCP695 microprocessor control panel that do not have auxiliary free-cooling valve relay 1K18 in the panel are susceptible to this problem. The affected units were all manufactured prior to April 15, 1992.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Figure 1
Typical Free-Cooling Relay (1U1D) and Valve Actuator Wiring

X39470561A

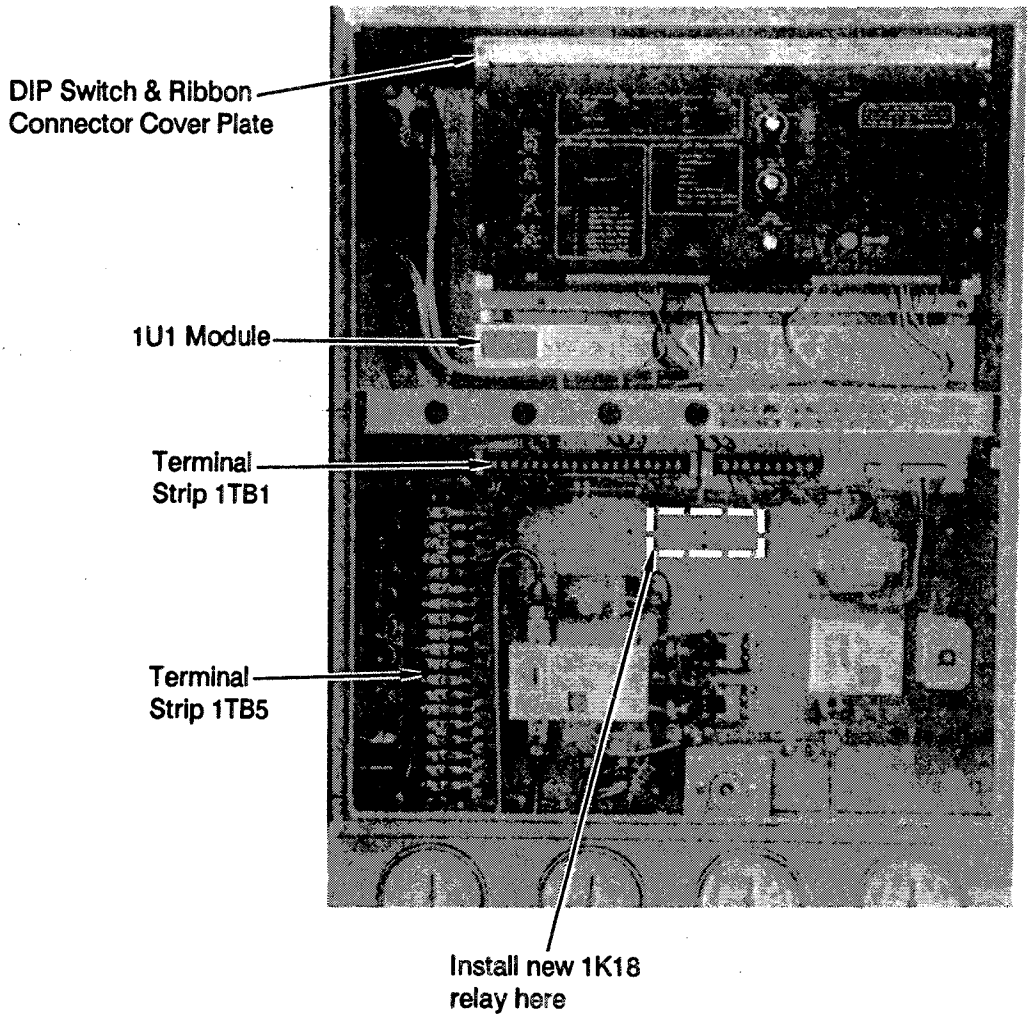
Current Production:

To alleviate this problem, a manufacturing change is being made for free cooling units to provide an additional relay (1K18) in the UCP, using heavier-duty contacts to drive the free-cooling valve actuator motors.

Corrective Action:

Any chiller that exhibits a history of K1 relay contact failures should be repaired. The repair consists of installing auxiliary free-cooling valve relay 1K18 in the UCP. The existing components of the 1U1 module do not change. The normally-open contacts of the K1 relay in the 1U1 module (between terminals 1TB1-16 and 1TB1-17) that are presently used to drive a free-cooling valve actuator motor, will be used to power the new relay (1K18). Refer to "1K18 Installation Procedure". The heavier-duty contacts of the new 1K18 relay will be used to drive the actuator motors.

Note: The diagrams illustrated in this bulletin are typical. Refer to the wiring diagrams that shipped with the chiller for specific information.



1K18 Installation Procedure

1. Mount the new 1K18 relay in the UCP at the location shown in Figure 2 using a 6-32 x .38 thread-forming screw. The relay location is the same as the hot gas bypass valve relay (1K15) location when the chiller is equipped with the hot gas bypass option. Use one of the mounting holes provided in the back of the panel.

WARNING! To prevent injury or death due to electrical shock, lock power supply disconnect open before opening UCP door. The terminals connected to remote equipment (e.g. condenser water pump) may remain energized even when power is removed from the panel. Always check for voltage before disconnecting wires!

 ©American Standard Inc. 1992

Figure 2
Installing 1K18 in UCP

2. Disconnect the following wires from their corresponding 1U1 module terminals (refer to Figure 1):

Wire No.	Terminal No.
34A	- 1TB1-15
45A	- 1TB1-16
23C	- 1TB1-17
46A	- 1TB1-18
37A	- 1TB1-19

3. Check the condition of the K1 contacts in the 1U1D relay as follows:

With power off to the control panel, check continuity between terminals 1TB1-16 and 1TB1-17. If continuity exists between these terminals, replace the 1U1 module. Contact the CenTraVac Technical Service Department in La Crosse WI for information on obtaining a replacement 1U1 module (MOD0028).

WARNING! When servicing the machine, disconnect electrical power source to prevent injury or death due to electrical shock.

4. Check K1 relay operation as follows:

a. Remove the DIP switch and ribbon connector cover plate located across the top of the 1U3 module (Figure 2). Apply power to the control panel. Monitor DC voltage on terminals 1P3-9, -11 (Figure 3). Turn chiller switch to AUTO/LOCAL position. Switch free cooling switch to ON. DC voltage on 1P3-9, -11 should increase to between 0.85 and 1.6 volts.

Note: If voltage does not fall within this range, perform the "Power Supply Checkout Procedure" as described in the chiller service guide or in "CVHE-SB-22".

WARNING! Use extreme caution when performing checkout procedures with power on; carelessness can result in injury or death due to electrical shock.

b. Check continuity again between 1TB1-16, -17. With the free cooling switch in the ON position, there should now be continuity between 1TB1-16, -17. Operate the free cooling switch 2-3 times to ensure proper K1 relay operation. If the K1 relay operates properly, do not replace the 1U1 module.

WARNING! Use extreme caution when performing checkout procedures with power on; carelessness can result in injury or death due to electrical shock.

5. Disconnect power from the UCP. Referring to Figures 3 and 4, reconnect the wires in the UCP as shown in Table 1 below:

WARNING! When servicing the machine, disconnect electrical power source to prevent injury or death due to electrical shock.

Table 1
Wire Connection Points for Free-Cooling Relay 1K18 Installation

Wire No.	Connects From	Connects To
23C	1TB5-10	1TB1-17

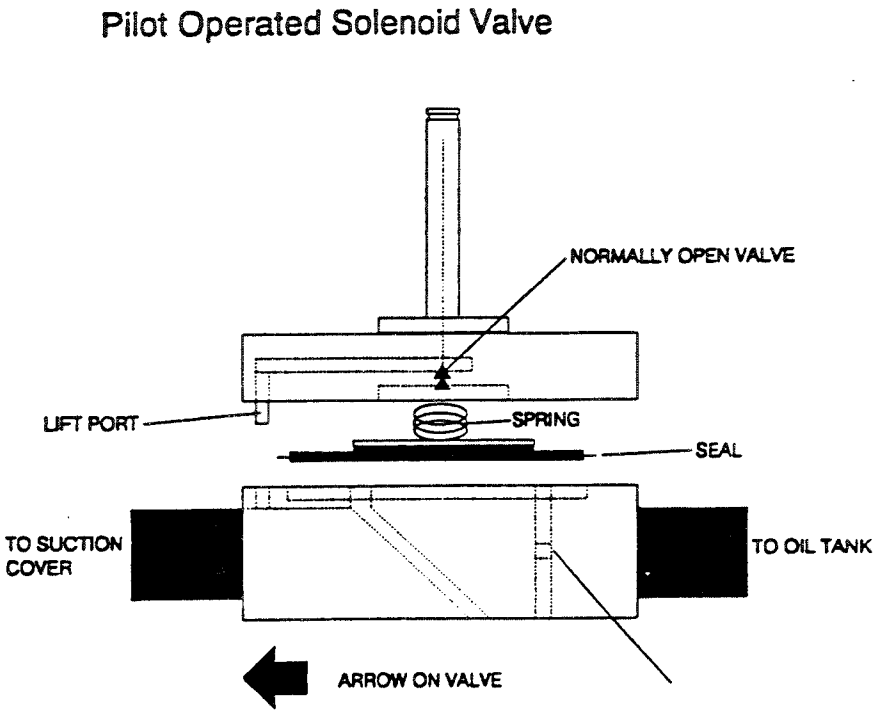
Subject: CVHE Vent Line Solenoid Valve Malfunction (This is an informational service bulletin only)

Introduction:

We have received reports of malfunctioning vent line solenoid valves (Trane part no. VAL-3217) on some CVHE units. The purpose of this service bulletin is to discuss proper check-out of the solenoid valve before condemning it as defective.



Discussion:

The CVHE vent line solenoid valve (Figure 1) is a pilot operated valve and is normally open with the coil de-energized. It should be noted that a bleed hole (3/16" diameter) is provided in the valve body so that a metered gas flow is present even when the valve is closed during coil energization. To bench test the valve, the bleed hole is plugged and air pressure is supplied to the valve inlet. The air should flow through the valve until the coil is energized, at which time a definite click should be heard and the air flow should cease. When the coil is de-energized, the air flow should resume through the valve.

Several vent line solenoid valves, minus the coil, were returned to La Crosse as defective. The complaint was that the valve would not close when the coil was energized. These valves were bench tested using a new 120 volt coil and were found to function normally. No binding or sticking was found.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Figure 1
CVHE Vent Line Solenoid Valve

It is important to make sure the coil is functioning before condemning a valve as defective. This can be done with a simple test while the coil is mounted on the valve as follows: With the coil energized, place a small iron object, such as a screw driver blade, on top of the coil retaining cap. If a magnetic field is present, the coil is functioning. If no magnetic field can be detected, remove power from the coil and remove the coil from the valve. Place a screwdriver through the coil and energize the coil. A strong magnetic field should be felt. If no magnetic field is present, the coil is bad and must be replaced. Make sure the power provided to the coil is the same as the coil nameplate. Do not apply power to a solenoid coil when no plunger or armature is present as the coil will over-heat and burn out.

Units Affected

All CVHE Units are affected. If the coil functions properly but the valve will not work, replace the vent line solenoid valve with Trane Part No. VAL-3217 and return the defective valve, including the coil to:

The Trane Company

Literature Changes:
CVHE-SB-29 (1/8/93) - Original date of bulletin

Subject: DRV5-1740 Louis Allis Motor Replacement on CVHE 035 through 050

Introduction

This service bulletin discusses an operational problem experienced by some replacement Louis Allis DRV5-1740 motors supplied by Trane ServiceFirst.

Discussion

The DRV5-1740 motor is nominally rated at 321 BHP and is used in CVHE 035 through CVHE 050. The original motor liquid feed line orifice is a number two with an inside diameter of .312 inches.

There have been occasions where a replacement motor has operated with end turn temperature in excess of the motor temperature control trip point of 265°F.

Investigation of the problem revealed an excessive pressure drop across the liquid feed line orifice which results in flashing and turbulence around the stator. This effectively reduces the flow of liquid through the liquid feed ports in the stator with resultant high end turn temperature.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Corrective Action

When a DRV5-1740 Louis Allis motor is replaced or is used as a replacement for a Reliance motor, replace the orifice with a number three or enlarge the number two orifice to a .390 inch diameter. The enlarged orifice will provide improved liquid refrigerant flow to the motor.

Units Affected

All CVHE 035 through CVHE 050 units are affected if a DRV5-1740 Louis Allis motor is replaced or is used as a placement for a Reliance motor.

Parts Information

This service bulletin is informational only and does not authorize any parts or labor.

Supersedes	

Literature History:
CVHE-CSB-31 (11/94)–Original Issue of Bulletin.

Subject: Starter Line Side Fuses CVHE/CVHF UCP2 200-575 Volt Units - Fix-On-Fail

Introduction:

The purpose of this Confidential Service Bulletin is to provide information on Line Side Fuses (2F1, 2F2 and 2F3) that may fail. This is a fix on fail bulletin and not mandatory.

We have experienced some situations on the CVHE and CVHF 200-575 Volt Units where one or more of the starter line side fuses have failed at powerup. The fuse failure occurs after the disconnect to the unit is closed and the fuse fails to handle the inrush current of the 2T5 3KVA control power transformer.

Discussion:

The fuse that we have been using is a Littelfuse Type Fuse, as detailed in Service Alert No. 144 and No. 145. If you have a unit that has experienced a Littelfuse failure at powerup, you may order and install a new kit. The kit contains a new larger fuse block, fuses and instructions to replace the smaller fuses. Production changes are in process.

Labor Authorization:

This service bulletin authorizes 1.0 man-hours per unit on affected units. No travel authorized. All claims must be submitted on the "Service Warranty Sales Allowance Claim" (Form No. 1-30-09-2) within 30 days of the repair. Any exceptions to the guidelines established in this service bulletin must be authorized by the Centrifugal Technical Service department.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Material Authorization:

This service bulletin authorizes one kit per unit at no charge. The appropriate kit can be ordered from Cutler Hammer per the following address or you may telephone or fax the order.

	Kit Number	Cutler-Hammer
200/208 Volt	2A92583G02	Attn: Gene Weinand
380/415 Volt	2A92583G03	4201 N. 27th Street
460/480 Volt	2A92583G04	Milwaukee, Wisconsin 53216
575/600 Volt	2A92583G05	Telephone: (414)-449-6801 (Fax: (414)-449-7093

Corrective Action:

Installation instructions are in the kit. Remove the Littelfuse and install the new larger fuse block and fuses. The fuse block comes with a bracket that will attach to the 3KVA transformer in the starter.

Material Disposition:

The material does not require return to headquarters and can be scrapped in the field.

Expiration date:

The effective cut-off date of this bulletin is July 31, 1995. All claims must be submitted no later than August 31, 1995.

Problem Description	No.	Page
Approach Temperature reads -40°F.	1	6
Auto X-former Starter: Runs (3) seconds and trips. Unit will not transition.	2	6
Bearing Temperatures 1 and 2 Locations.	3	6
Capacity Limited by High Current when the phase current as read from the Compressor report reads zero amps. Getting this message during the run mode.	4	6
Chiller Loss of Communication with Circuit module and IGV overdriving close.	5	6
Check Clock (IFW) Informational Warning Diagnostics. On a loss of power the clock does not keep time, if there is an extended power loss (greater than 15 seconds).	6	6
Chiller Loss of Communication with Purge and the IGV calibrates	7	7
Circuit Loss of Communication with Starter or Circuit Loss of Communication with Chiller Diagnostics	8	7
Clear Language Display won't go into Demo mode.	9	7
Communication diagnostic; none or degraded communications.	10	7
Loss of Communication with Starter Diagnostics at Start-up with no Inlet Guide Vane action. Mode is "Resetting" and can move through the menus.	11	7
Loss of Communications or Intermittent Communication between the Tracer and the UCMs.	12	8
No Communication, on a power up, get message "No Communication, Data Not Valid" and no action in the IGV.	13	9
No Communication, on a power up, get message "No Communication, Data Not Valid" but the Inlet Guide Vane calibrates.	14	9
Starter Loss of Communication with Chiller. No other diagnostic.	15	9
TCI Loss of Communication with Chiller.	16	9
Cond. Pressure 2-10 VDC output will not work.	17	10
Cond. Refrig. Temp. Sensor diagnostic, when the displayed Cond. Refrig. Temp is reading fine.	18	10
Condenser and Evaporator entering and leaving water temps. changing rapidly and reading incorrectly, i.e. -25°F to 90°F.	19	10
Condenser Water Flow lost diagnostic. Unit will not restart until manually reset.	20	10
Custom menu - Unwanted items that you did not install and you cannot remove.	21	10
Display is locked up. No communication, Data Not Valid Diagnostic.	22	10
Display on the CLD is flashing.	23	11
External Chilled Water Setpoint does not work.	24	11
Evaporator Water Temperatures are reversed. 2 pass units only.	25	11
2F1, 2F2 and 2F3 Fuses blow - On 200-575 volt units when switching the starter disconnect from OPEN to CLOSED.	26	11

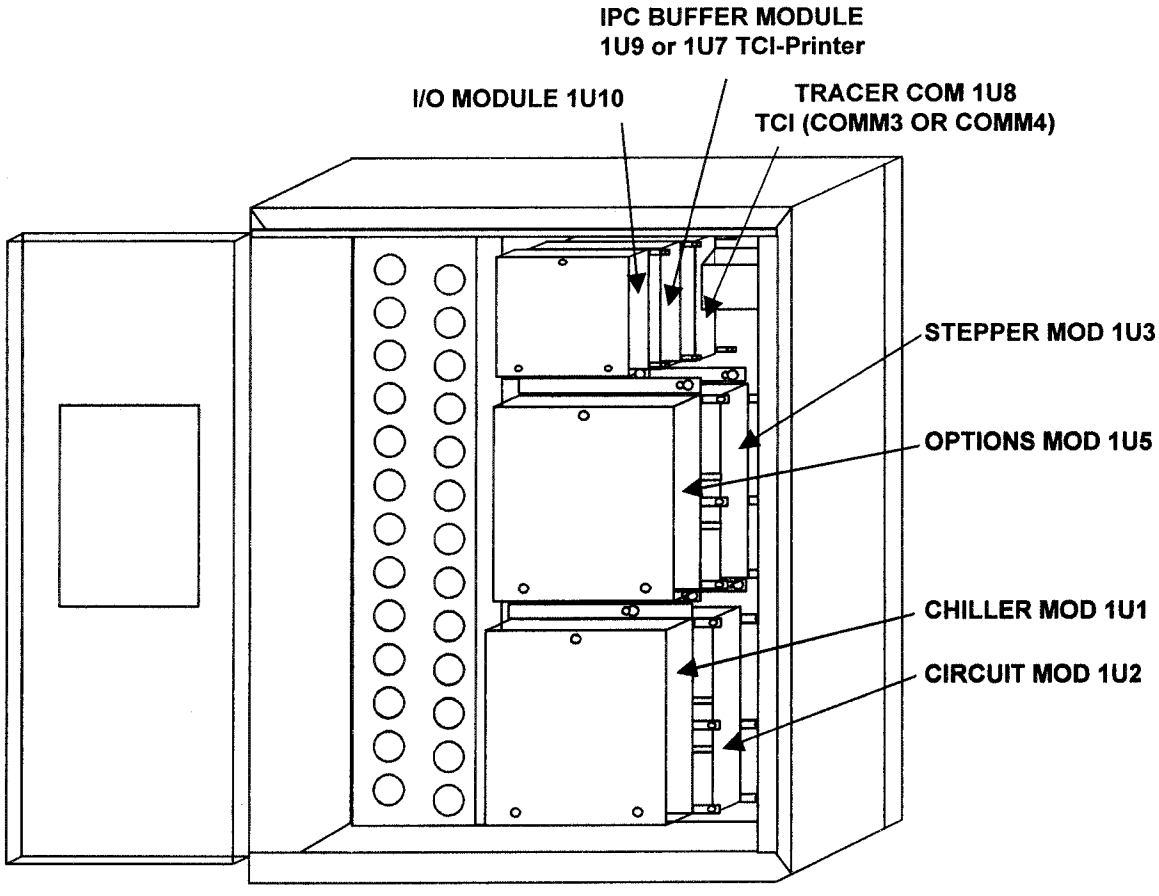
General Troubleshooting Index

Problem Description	No.	Page
Hot Gas Bypass does not work.	27	12
IGV will not move in the Service Test Manual mode.	28	12
IPC Buffer Diagnostics	29	12
KW reads high by a factor of 3, with optional PT installed.	30	12
Loading Problems	31	13
Momentary Power Loss	32	13
Motor winding temperatures changing rapidly and randomly.	33	13
Differential Oil Pressure Calibration Diagnostic following post lube. Secondary problem may be the oil pump will not shut off after post lube.	34	14
Differential Oil Pressure Overdue Diagnostic immediately following a Remote Reset.	35	14
Oil Pump Discharge Pressure Sensor Diagnostic and Oil Pressure Calibration.	36	14
Over/Under Voltage Diagnostic on Startup.	37	14
Phase Loss	38	14
Phase Reversal	39	15
Printer will not work.	40	15
Purge Compressor will not run in the manual "ON" mode.	41	15
Transition resistors stay in too long.	42	16
Setpoints are not being stored, service tests will not work and we are calling many diagnostics on the CLD.	43	16
Starter Contactor Interrupt Failure Diagnostic when powering up the UCP.	44	16
Starter Dry Run Test Diagnostic upon entering a Starter Dry Run Test.	45	16
Starter Dry Run will not work.	46	16
Stepper motor is humming.	47	17
Pressure Transducer shift in calibration. Diagnostics will be sensor calibration related such as sensor failure or oil pressure sensor calibration.	48	17
Rapid Time of Day Scrolling or Date jumps back one day.	49	17
Unit did not Transition diagnostics.	50	17
Unit Tons Read-out on CLD does not work	51	18
High Vacuum Lockout. The UCP2 looks at the oil tank pressure via the oil tank pressure transducers. On R-123 units, if the pressure is -11.6 PSIG (3.1 PSIA) or greater, we get the high vacuum lockout. On R-11 units it is -10.9 (3.8 PSIA).	52	18

UCP2 Control Panel and Module Description

Unit Control Panel

Safety and operating controls are housed in the UCP2 Unit Control Panel, the Starter Panel and the Purge Control Panel (Control Panel layout is illustrated in Figure 1).



The UCP2 control consists of a modular design partitioned by major function or group of functions. All modules communicate with each other through the IPC circuit.

Major components within each of these control groups are described below.

Unit-mounted temperature sensors, pressure transducers and functional switches provide analog and binary inputs to the various modules.

The "microprocesser-based" modules are described as below: All wiring to the modules is to pluggable terminal blocks.

Figure 1
UCP2 Control Panel

UCP2 Control Panel and Module Description

Chiller Module

The Chiller Module is the Master-of-the-Chiller communicating commands to other modules and collecting data/status/diagnostic information from other modules over the IPC (Inter Processor Communications Link). The Chiller Module performs the leaving chilled water temperature and limit control algorithms arbitrating capacity against any operating limit the chiller may find itself working against. The Chiller Module checks for valid setpoints and contains non-volatile memory (NOVRAM), to retain them on any power loss. Inputs and Outputs are chilled water system level such as, but not limited to, evaporator and condenser water temperatures, evaporator and condenser water pump control, status and alarm relays, and external auto/stop.

Circuit Module

The Circuit Module serves as an input/output expander and is assigned inputs and outputs associated with the refrigerant and lubrication circuits. The Circuit Module also receives a 4-20mA signal from an external refrigerant level monitoring device. UCP2 then converts the signal to ppm for display at the Clear Language Display.

Stepper Module

The Stepper Module is designed to drive the stepper motor inlet guide vane actuator on CenTraVac chillers. On CenTraVac chillers the Stepper Module receives from the Chiller Module the direction and distance to drive the inlet guide vanes and then generates the appropriate signals to operate the stepper motor. The Stepper Module also has other I/O capabilities used to support functions on the stepper module and/or just I/O expansion. These are Evap. temperature, Cond. discharge, Bearing temperature and Cond. temperature.

Starter Module

The Starter Module physically resides in the Compressor Motor Starter Panel providing control of the starter when starting, running and stopping the motor. The Starter Module provides interface to and control of Y-Delta, X-Line, P-Reactor, A-Transformers, Solid State Starters and Trane® Adaptive Frequency Drive. The Starter Module also provides protection to both the motor and the compressor in the form of running overload, phase reversal, phase loss, phase unbalance, momentary power loss, and compressor surge, in addition to others.

Purge Module

The Purge Module provides control of the purge used on R11 and R123 low pressure CenTraVac models. The Purge Module provides all the inputs and outputs to control the purge optimizing both purge and chiller efficiency. The Purge Module resides in the purge control panel and communicates with the Chiller Module over the IPC (Inter processor Communications Link) uploading set points and downloading data and diagnostics.

Local Clear Language Display

The Local CLD (Clear Language Display) resides at the Chiller providing a display of chiller data and access to operator/serviceman controls, set points and chiller setup information. All information is stored in non-volatile memory in the Chiller Module. The Local Clear Language Display and the Chiller Module work together to display and store information requiring non-volatility.

Remote Clear Language Display Panel and Remote Clear Language Display Interface Module

As an option, the Remote Clear Language Display permits the operator to remotely operate 1-4 chillers. The Remote Clear Language Display Panel works like the Local Clear Language Display with two exceptions, (1) a Local Stop command takes precedence over all other remote or external devices, and (2) the Remote Clear Language Display's Custom Report and display language are independent of the Local Clear Language Display Panel.

UCP2 Control Panel and Module Description

Options Module

The Options Module satisfies control or interface requirements for a number of options. Some of these options are stand alone, such as Generic BAS Interface; other options support either additions or modifications to the chiller itself, such as Free Cooling. Features supported by the Options Module include Ice-Making, Heat Recovery, External Chilled Water Setpoint, and External Current Limit Setpoint.

Tracer Communications Interface

TCI COMM 3 is an optional module that provides a 1200 baud bi-directional serial communications link to Tracer 100/100i/CPM/Monitor BAS panels.

TCI COMM 4 (Tracer Summit) is an optional module that is also now available.

Printer Interface Module

The Printer Interface module provides a pre-formatted chiller log to a printer. The Printer Interface can be programmed via the Clear Language Display to print a chiller log on command, at the time of a diagnostic, and/or on a periodic basis. Each printed event is time and date stamped.

The preferred printer to be used is **OKIDATA Microline 184 Turbo**. It has been assigned a Trane number of 4150 2066.

Secondary Printer Options

Epson: Not all Epson printers support serial communications. For a low cost printer that does support serial communications, Epson recommends the LX810 Printer with the Serial interface option (C823032).

IBM ProPrinters: Use either the "2380" + or the "2390+" along with the Serial interface option "1363110".

Other: Any printer/computer with 232 capabilities should be capable interfacing with the TCI Printer module (allowing for different cables and jumper configurations).

General Troubleshooting Information

Problem 1. *Approach Temperature reads -40°F*

Corrective Action:

A CLD X13650448-04 or newer is required with a chiller module X13650450-04 or newer.

Problem 2. *Auto X-former starter: Runs (3) seconds and trips. Unit will not transition.*

Corrective Action:

Verify Starter Module. If -07 or later, it requires transition circuit.
No voltage on transition complete J4 circuit. Trace circuit path. Reference CVHE-SB-36.

Problem 3. *Bearing Temperatures 1 and 2 Locations.*

Corrective Action:

- Bearing temperature 1 (Stepper module J5-5, 6) goes to the front Journal bearing.
- Bearing temperature 2 (Stepper module J5-7, 8) goes to the rear Thrust bearing.

Problem 4. *Capacity Limited by High Current when the phase current as read from the Compressor report reads zero amps. Getting this message during the run mode.*

Note: This is what is happening: The Chiller module takes the three phase currents as sent by the Starter module, selects the highest one and limits based on this.

Corrective Action:

- Check the phase currents as displayed in the Compressor Report.
- Check the Active Current Limit Setpoint. It is possible it is a very low value or even zero amps is loaded in.
- If the current limit source is the external current limit setpoint, check this input on the Options module.

Problem 5. *Chiller Loss of Communication with Circuit module and IGV overdriving close.*

Corrective Action:

- IPC to Circuit module disconnected or reversed.
- Circuit module not powered
- Verify that a good ground exists between all modules including the CLD that needs a dedicated green wire ground.

Problem 6. *Check Clock (IFW) Informational Warning Diagnostics. On a loss of power the clock does not keep time, if there is an extended power loss (greater than 15 seconds).*

Corrective Action:

- This diagnostic is shown in active diagnostic menu.
  Note: If you clear this IFW diagnostic while the machine is running, you will shut down the unit. Wait to clear the diagnostic when the unit is off.

General Troubleshooting Information

Problem 7. *Chiller Loss of Communication with Purge and the IGV calibrates.*

Corrective Action:

- IPC to Starter module disconnected or reversed.
- Starter module not powered up
- Verify that a good ground exists between all modules including the CLD that needs a dedicated green wire ground.

Problem 8. *Circuit Loss of Communication with Starter or Circuit Loss of Communication with Chiller Diagnostics*

Corrective Action:

- The 120 VAC side of the 3KVA transformer should be grounded at only one spot and it is in the Starter. Both the 120 VAC and the 24 VAC in the UCP should not be grounded.
- Verify the IPC wire is shielded twisted pair between the Starter and Chiller module and its shield is grounded at the J1-6.
- Verify there is a dedicated ground between the remote starter and the chiller.
- Verify that a good ground exists between all modules including the CLD that needs a dedicated green wire ground.

Problem 9. *Clear Language Display won't go into Demo mode.*

Corrective Action:

You must press Custom report and Compressor report at the same time while the display is showing software part number on power-up. If it still does not go into the Demo Mode, check the IPC communication.

Problem 10. *Communication diagnostic; none or degraded communications.*

Corrective Action:

- Starter module must have the A phase on pin 2 of J2 24 vac
- IPC wires must be connected
- IPC wires must have correct (+ -) polarity on J1.
- The TCI and CLD modules have LEDs to indicate the sending and receiving of chiller packets.
- On TCI Green (RxA) is receive and should be blinking constantly. Red (TxA) is send and blinks every 1-2 seconds.

Problem 11. *Loss of Communication with Starter Diagnostics at Startup with no Inlet Guide Vane action. Mode is "Resetting" and can move through the menus.*

Corrective Action:

- IPC to Starter module disconnected or reversed
- Starter module not powered up.
- Verify that a good ground exists between all modules including the CLD that needs a dedicated green wire ground

General Troubleshooting Information

Problem 12. *Loss of Communication or Intermittent Communication between the Tracer and the UCMs. (If the TCI loses communication with the Tracer for 15 continuous minutes then you will get the "Tracer Communications Lost" message).*

Corrective Action:

- Verify that a TCI COM 3 is installed.
- Verify the Chiller and CLD versions are compatible with Tracer. Reference CTV-CSB-90 and CTV-CSB-92.
- ICS address at CLD should match with Tracer
- Are the DIP switches set correctly. They should be all off for COM 3.
- In the Tracer Module, verify the IPC LEDs near J1 are blinking. Red LED is transmit and should be blinking constantly showing lots of IPC action (even if not for the TCI). The green LED is for receive and should only be blinking rapidly in a row once every 1-2 seconds which is the IPC cycle time.
- Verify the COM 3 LEDs near J3 are blinking. Red LED is transmit and should be blinking showing lots of COM 3 action (even if not for the TCI). The green LED is for receive and should only be blinking rapidly in a row once every minute which is the Tracer cycle time.
- The Starter module or other modules are not grounded well. The IPC needs the modules to be grounded together.
- Go to service test menu and verify that Chiller thinks a TCI 4 is installed.
- Look at the voltage of each line with respect to ground. A logic 0 should be .5 V or less, a logic 1 should be 4.5 volts or more.
- For COM 3 lines less that 1000 Ft., a 300 Ohm terminating resistor put across the two wires is needed. Install the resistor first at the chiller end of the link.
- Radio frequencies generated from sources like airplanes and TV/radio towers may be inducing noise in the communication lines. Tie matched capacitors of around 200pF at either ends or both ends from each line to ground.
- TCI option is self installed. No need to enable it manually. If you do enable it manually and no TCI Tracer module on the line, then a loss of communication with TCI will be called. If installing TCI option, then IPC side diagnostics are called i.e. Loss of Communication with TCI. No Tracer diagnostics are called.
- De-install TCI option and power up and see it self install within 10 seconds. If not, something is wrong in TCI module.
- De-install Tracer option and power up and see if it self installs within three minutes. If not, something is wrong with the Tracer side.
- Tracer option is self installed. No need to enable it manually. If enabled manually and no Tracer on the communication line, then a Loss of Communication with Tracer will be called. If a Tracer is put on communication line, then communication side diagnostics are called Loss of Communication with Tracer.

General Troubleshooting Information

Problem 13. *No Communication, on a power up, get message "No Communication, Data Not Valid" and no action in the IGV.*

Corrective Action:

- Chiller module not powered up
- IPC to Chiller module not connected
- IPC shorted
- Disconnect all modules from the IPC to CLD except the Chiller module. If a communication is received back, then try plugging one of the other modules one at a time, do a power up and if it then fails, this is the module that is pulling down the line.
- Check the LEDs at the rear of the CLD. The left one is "TEST" and should be on if all is normal.
- The second LED from the left is the "+5VDC" and should be on all the time if all is normal.
- The third LED from the left is the transmit and should only blink rapidly every 2 seconds when the CLD talks on the line.
- The fourth LED from the left is the receive and should be blinking rapidly all the time since there is constant buss action.
- Verify that the CLD is grounded to the other modules.
- Module Grounding Problem. On the Starter module DO NOT ground the IPC. IPC is grounded at the Chiller module.

Problem 14. *No Communication, on a power up, get message "No Communication, Data Not Valid" but the Inlet Guide Vane calibrates.*

Corrective Action:

- IPC to the Local Clear Language Display reversed
- IPC to Local Clear Language Displaydisconnected
- Verify that a good ground exists between all modules including the CLD which needs a dedicated green wire ground.

Problem 15. *Starter Loss of Communication with Chiller. No other diagnostic.*

Corrective Action:

- Verify IPC connections are good to Starter module and cable is shielded. Chiller module X13650450-01 is not compatible with Starter module X13650453-02 and later. X13650453-02 and later request chiller packet 20. Chiller module X13650450-01 does not support packet 20. All later Chiller modules do.

Problem 16. *TCI Loss of Communication with Chiller.*

Corrective Action:

Need a X13650460-02 or newer TCI module.

General Troubleshooting Information

Problem 17. *Cond. Pressure 2-10 VDC output will not work.*

Corrective Action:

The Chiller module must be a X13650450-04 or later. Earlier versions did not support this option.
Check wiring between transducer (located near the purge) and the circuit module J7.
Faulty transducer - follow transducer checkout procedure on page 58.

Problem 18. *Cond. Refrig. Temp. Sensor diagnostic, when the displayed Cond. Refrig. Temp. is reading fine.*

Corrective Action:

Chiller software found in X13650450-01 Rev. D or earlier mis-diagnose Cond. Refrig. Press.
Replace with new Chiller module.

Problem 19. *Condenser and Evaporator entering and leaving water temps. changing rapidly and reading incorrectly, i.e. -25° F to 90° F.*

Corrective Action:

Bad Chiller module, it must be replaced.

Problem 20. *Condenser Water Flow lost diagnostic. Unit will not restart until manually reset.*

Corrective Action:

Phase A and B Chiller module software were actually an MMR. Phase C (X13650450-04) changed to a MAR. Time changed from 3 minutes to 4-1/4 minutes.

Problem 21. *Custom menu - Unwanted items that you did not install and you cannot remove.*

Corrective Action:

- The initial problem was if you had installed an option, put it in the Custom menu, then de-installed it without first removing it from the Custom menu.
- Problem corrected on CLD X13650448-02, Rev. E.

Problem 22. *Display is locked up. No communication, Data Not Valid Diagnostic.*

Corrective Action:

1. Check the (4) LEDs on the back of the CLD. Left to right.
   - #1 is the Test Light and should be on all the time.
   - #2 is the 5VDC and should be on all the time.
   - #3 is the Transmit and should blink every 2 seconds.
   - #4 is the Receive and should blink continuously.
2. There probably is a IPC communication problem with one of the boards. Disconnect the IPC from all modules except leave the IPC connected from the CLD to Chiller module. Start connecting the IPC at one at a time until we find which one is the problem.
3. Check the Chiller module 24 VDC, 5 VDC and 24 VAC.
4. Check the CLD (Clear Language Display) grounding. It has to be grounded from the clear language display to the chassis/back panel.
5. Starter Module IPC should not be grounded. Ground is on the Chiller module end. A double ground will lock up the display.

Problem 23. *Display on the CLD is flashing.*

Corrective Action:

- The inductor in the switching power supply may be shorted to its core. The switch is going in and out of thermal shut down.
- The +5V LED should also be flashing.
- Verify the 24 VAC delivered to the CLD is within range of 20-28 VAC. Disconnect the IPC to verify it is not causing this.

Problem 24. *External Chilled Water Setpoint does not work.*

Corrective Action:

1. Polarity must be (minus) (plus)
2. If the 4-20 MA and the 2-10 VDC are out of range, the active chilled water setpoint source reverts back to front panel and does not work.
3. Setpoints
   - SW3-1 should be:
     OFF for 2-10 VDC
     ON for 4-20 MA
   - Chilled Water Reset type is Disabled
   - Chilled Water Setpoint source is External
   - Setpoint source override is None.
   - External Chilled Water Setpoint is Install.

Problem 25. *Evaporator Water Temperatures are reversed. 2 pass units only.*

Corrective Action:

Reverse the sensor leads at the module.

Problem 26. *2F1, 2F2 and 2F3 Fuses blow - On 200-575 volt units when switching the starter disconnect from OPEN to CLOSED.*

Corrective Action:

See manual CVHE-CSB-31.

Problem 27. *Hot Gas Bypass Does Not Work.*

Corrective Action:

1. Module Compatibility:
   Chiller must be X13650450-04 or newer
   CLD module must be X13650448-05 or newer
   Option module is a X13650452-01 or newer.
2. Hot Gas Bypass Option must be installed in the machine configuration
3. Hot Gas Valve Control in the service test menu must be in the Auto Mode.
4. Hot Gas Bypass Control enabled in field startup
5. The Inlet Guide Vane must be closed or at a minimum to go into Hot Gas.
6. The Chilled Water Setpoint minus the actual chilled water temperature must be 0.6 F or greater, i.e., Setpoint of 45° F and leaving temperature of 44° F for more than 20 seconds would show the need for Hot Gas.
7. Verify the Hot Gas Timer is installed and max HGBP time is greater than zero.
8. Verify that the module software numbers are being displayed in the Service Test Menu.
9. Verify that the IPC Communications wire is connected to J1 of all modules and we have good 24 VAC, 24 VDC and 5VDC.

Problem 28. *IGV will not move in the Service Test Manual mode.*

Corrective Action:

1. Verify the CLD LED comes on solid. Verify there are no Stepper module diagnostics.
2. Verify we are in a Stop mode, Diagnostic Stop mode, or Run mode.
   All other modes the Manual Vane Control will not work.
3. Is the IGV travel percentage increasing? If so there is a problem with the motor or Stepper Module drive circuit.
4. Are we in a "Stop" mode after being in a Limit mode. The limit bit may be set so do a power down to clear.
5. Will not work in post lube or initialization in preparing to start.
6. On power up, does the Stepper module do a BPI search. If not, the Stepper module could be held up in the Initialize mode internally. On a power up, the Stepper module looks for communication with the Chiller, Starter and Circuit modules. If it doesn't hear from any one of them, it stays in the Initialize mode and will not do BPI or Manual Vane Control. If no BPI, check the IPC wiring. Also, if trying to start the chiller, the mode will stay in initialize.

Problem 29. *IPC Buffer Diagnostics*

Corrective Action:

Clear Language Display is not communicating. Replace the CLD or the Chiller module is not communicating and needs replacing.

Problem 30. *KW reads high by a factor of 3, with optional PT installed.*

Corrective Action:

Software change made 11/93 to CLD. X13650448-02 Rev. E or later corrects the problem.

General Troubleshooting Information

Problem 31. *Loading Problems*

Corrective Action:

1. Unit is in External Stop and when released, requires 3.5 minutes to get the vanes to desired point of operation (typically 50 degrees). This is close to the maximum rate that the compressor can load because the fastest the vanes will move is 1250 steps every 5 seconds.
2. If Soft Load Control is Enabled, the Soft Control parameters can be adjusted to meet the requirements of the system. If the chiller is allowed to ramp up faster than needed it could over shoot the leaving chilled water temperature setpoint and potentially be current limited. If this overshoot is too rapid and causes excessive current draw, the adaptive control will force an unload to approximately 70 %. This could cycle several times before stabilizing.
3. If Soft Load Control is Disabled or the loading is not from initial startup, The LWT Control Proportional, Integral and Derivative gains can be adjusted to allow system adjustment to properly follow the load. Typical changes should be small. 1-2% proportional gain change or 0.01 % integral gain changes. Always adjust proportional gain first. This is the coarse adjustment, while integral is the fine and derivative is the micro adjustment.
4. Item 1 reference the mechanical limitation of the stepper motor while the software limitation is a pulldown rate of 5 F/minute of the leaving water temperature. This maximum cannot be overridden.

Problem 32. *Momentary Power Loss*

Corrective Action:

1. MPL is active for the Run mode. Not in the Start mode.
2. CT wiring on J5 of the Starter module must be wired White-Black per print and Phase A must be on Terminals 1 and 2, Phase B on 3 and 4 and Phase C on 5 and 6.
3. Check phasing of the supply voltage. The "A" phase must be delivered to J2-2 or 4 of the Starter module.
4. Look at the voltage on J2 for noise. J2 should be a smooth 24 VAC sign wave. If we get electrical noise from things such as inverters or high frequency generators, you will see noise blips off the sign wave.
5. Verify the polarity of the CT circuit is correct. For single CT circuits the White wire must be connected to J5-5 with the dot on the CT facing the line. For dual CTs. The "HI" polarity dot on the line CT must be facing the line, the Brown wire from the X13650266 transformer primary connected to X1 and the White wire from X13650266 secondary connected to J5-5.
6. Verify that there is voltage delivered to the J6 terminal, if not check the HPC circuit, circuit breaker or Starter Interlock.
7. Check for loose wires.
8. Check the wiring from J8 to 2K1 Coil and Auxiliary.
9. Two wiring errors will allow you to start and go out on Momentary Power Loss when the unit loads up. The CTs and 24 VAC may be wired up improperly. As the loading is changed due to vane movement, then MPL may be called.
10. If the unit trips on Momentary Power Loss, vanes stay where they were and then restarts without going through a Vane Closure or BPI search, (2) modules need to be changed:
    1. Chiller module needs to be a X13650451-04 or newer.
    2. Stepper module must be X13650455-04 or newer.

Problem 33. *Motor winding temperatures changing rapidly and randomly.*

Corrective Action:

Electrical noise problem in the circuit module. X13650451-04 Rev. D or later corrects the problem by adding a filtering circuit.

Problem 34. *Differential Oil Pressure Calibration Diagnostic following post lube. Secondary problem may be the oil pump will not shut off after post lube.*

Corrective Action:

1. Diagnostics is active in all non-running modes and the unit has been off for 5 minutes. The UCP2 calibrates the oil pressure sensors and if an error is found greater than 3 PSID a diagnostic is called out.
   (1.1) Sensors
   (1.2) Changing system pressures caused by such things as a pressure or changing water temperatures.
2. If the oil pump is running and will not shut off in post lube, the problem is a wiring error on the starter module. One or both of the following apply.
   (2.1) 115 VAC is connected to terminal J6-3 of the Starter module. Check to see if it was connected incorrectly to Terminal J3-1.
   (2.2) Terminal J8 on the Starter module. J8-1 (Wire #13) goes to the 2K1 Contactor. J8-2 (Wire #15) goes to 2K1 Auxiliary. Check to see if Wire #13 and Wire #15 are reversed.

Problem 35. *Differential Oil Pressure Overdue Diagnostic immediately following a Remote Reset.*

Corrective Action:

- The Circuit module was clearing the 3 minute oil pressure establish timer during a remote RESET. This would result in a Oil Pressure Overdue diagnostic.
- Exists for Circuit modules X13650451-06 and earlier.

Problem 36. *Oil Pump Discharge Pressure Sensor Diagnostic and Oil Pressure Calibration.*

Corrective Action:

Chiller is in a high vacuum where one or both of the transducers read -14.9 PSIG. This is out of range and thus a sensor diagnostic is being called. The diagnostic may be cleared once the chiller is charged.

Problem 37. *Over/Under Voltage Diagnostic on Startup.*

Corrective Action:

You may get the diagnostic with the following Setup Sequence.

1. Unit Line Voltage enabled in Machine Configuration.
2. Under/Over Voltage is enabled in Field Startup.
3. If you then disable Unit Line Voltage, the Under/Over Voltage screen disappears but is still active. You have to then re-enable Unit Line Voltage in Machine Configuration and disable Over/Under Voltage.
4. Over/Under Voltage is used only with PTs installed. If you enable the option with "No" PTs installed you will get the diagnostics.
5. When the Line Voltage Sensing Option is not installed, the Unit Line Voltage menu item is not displayed nor is the Under/Over Voltage option installed.

Problem 38. *Phase Loss*

Corrective Action:

1. CT hooked incorrectly relative to incoming power.
2. Defective Primary CT.
3. 120 VAC missing from the Stop Relay circuit on J6 of Starter module.
4. Defective High Pressure switch. Wire may be off.
5. Problem in the Start Relay circuit on J8 of Starter module. Check all connections and circuit.
6. Verify currents are over 10% RLA.

7. Check the Starter Wiring diagram for other components i.e., power monitoring devices that may be taking us off.
8. The Starter contactors may be too slow to respond to the Start signal. Disabling the phase rotation will give us more time by taking out the 0.7 highly aggressive circuit but keeping in the primary phase protection. For Starter software X13650453-04 Rev. K , the time for detection of the highly aggressive circuit changed from 0.3 to 0.7 seconds.

Problem 39. Phase Reversal

Corrective Action:

Phase Rotation Protection is based on clockwise ABC Phasing. UCP2 picks up current phasing through the Starter Module Terminal J5.

Three possible causes are:

1. Phases actually revised
2. Noise on the Link which may inject an illegal state
3. Current imbalance, higher impedance on (1) phase caused by:
   - Bad Contactor
   - All the lighting on (1) circuit/phase
4. (2) of the CT wires revised on J5.

Problem 40. *Printer will not work.*

Corrective Action:

1. Verify Printer is compatible with a serial 9 pin RS232.
2. Verify printer setup in the CLD is correct
   - Machine Configuration Menu:
     Printer Option is Installed
   - Service Settings Menu:
     Set Baud Rate, Parity, Data Bits, Stop Bits, Handshaking
     For Handshaking: XON/XOFF is recommended.
3. Verify the printer settings match the CLD setup
   - Baud Rate, Parity, Dat Bits, Stop Bits, and Handshaking must be the same as in the CLD
4. Verify the printer interface is working properly
   - Verify there is IPC communication
     - RxA (Green LED near J1) is IPC *receive* and should be blinking
     - TxA (Red LED near J1) is IPC *transmit* and should not be blinking
     - Diagnostic LED (Red) is OFF
     - Check DIP switches, they should be OFF-OFF-ON
   - RxB (Green LED near J3) is printer receive and should be OFF
   - TxB (Red LED near J3) is printer transmit and blinks only when printing
5. Check the printer cable
   - Usually a 9-25 pin cable with RX (receive) to Rx, and Tx (transmit) to Tx connections
6. Try to print manually (in Operator Settings menu)

Problem 41. *Purge Compressor will not run in the manual "ON" mode.*

Corrective Action:

1. In the Operator Setting menu, select "ON" for Purge Operating Mode. Note that "ON" means that the purge compressor and condenser fan will run. The pumpout motor will run only when the Purge Suction temperature gets below 17° F and turns off when the temperature gets above 25° F.
2. If you get "Purge Pumpout Rate Exceeded" message then go to the Service Settings menu, go to Field Startup Group and set "Purge Service Excessive Pumpout Outride Timer" to the amount of time you would like the pump-out motor to run without it incrementing the pumpout rate.
   The maximum allowed time is 72 hours. When this time is reached, you will get the "Max Pumpout Rate Exceeded" message.
3. Clear all purge diagnostics.

General Troubleshooting Information

Problem 42. *Transition resistors stay in too long.*

Corrective Action:

- If the J8 terminal on the Starter module is loose, the control does not latch in and extends the timing keeping the resistors in longer.
- Reference Service Bulletin CVHE-CSB-35.

Problem 43. *Setpoints are not being stored, service tests will not work and we are calling many diagnostics on the CLD.*

Corrective Action:

- IPC to Starter module disconnected or reversed.
- Starter module not powered up.
- One wire of the IPC is not connected.

Problem 44. *Starter Contactor Interrupt Failure Diagnostic when powering up the UCP.*

Corrective Action:

1. Starter module is sensing motor current greater than 10% RLA when motor should be OFF on a power up or in OFF state.
2. Starter module is sensing motor current greater than 10% RLA .68 Sec. after initiating a shutdown.
3. Look at phase currents as read in the Compressor Report.
4. If power factor correction capacitors are used, these capacitors should be placed on the motor side of the 2K1 and 2K2 contactors so as to be disconnected from the line when the motor is off.

Problem 45. *Starter Dry Run Test Diagnostic upon entering a Starter Dry Run Test.*

Corrective Action:

The Starter module is sensing either the presence of line voltage from the PTs or line current from the CTs.

Problem 46. *Starter Dry Run will not work.*

Corrective Action:

1. If the PTs are installed they sense voltage and prevent dry run
2. A major diagnostic is present
3. Unit is not in Stop mode
4. Starter senses the presence of currents
5. There is a (MMR) diagnostic present

Problem 47. *Stepper motor is humming.*

Corrective Action:

While in the hold mode, the stepper motor is driven with 1.0 amps. This is the case even if the actuator is fully closed. The humming is normal.

Problem 48. *Pressure Transducer shift in calibration. Diagnostics will be sensor calibration related such as sensor failure or oil pressure sensor calibration.*

Corrective Action:

1. Wired incorrectly. Check diagram.
2. Corrosion on X-ducer contacts
3. Bad transducer
4. Disregard diagnostics when the unit is a deep vacuum prior to charging.

Problem 49. *Rapid Time of Day Scrolling or Date jumps back one day.*

Corrective Action:

1. Problem one is rapid time of day and year scrolling. The problem is in the CLD software when we reach December 29, 30 and 31. Fix: Replace the CLD (Local Clear Language Display) with a X13650448-03 or newer. To stop the scrolling press Enter to get a valid date and set before or after Dec. 29/30.
2. Problem two is when the date jumps back one day. The date of January 4, 1995 is set and it jumps back to January 3, 1995. This is because 1996 is a leap year and the problem only exists on the year prior to leap year. Replace the CLD with a X13650448-03 or newer.

Problem 50. *Unit did not Transition diagnostics.*

Corrective Action:

1. Do a Starter Dry Run Test.
2. Check for 24 VAC input to all modules
3. Check for 24 VDC and 5VDC on the Starter module
4. Check all wiring and connections
5. Check for 120 VAC on the Starter module J4-1 and 2. J4 is an OPTO input circuit that recognizes transition complete. If there is no signal on J4, the unit will not transition.
6. Could have a bad Starter module.

General Troubleshooting Information

Problem 51. *Unit Tons Read-out on CLD does not work.*

Corrective Action:

- Verify that the condenser solenoid is connected to the condenser.
- Verify that the entering port of the solenoid goes to the entering water line.
- Verify that the leaving port of the solenoid goes to the leaving water line.
- With the solenoid de-energized, the entering water line is monitored.
- Verify that the Evaporator Solenoid is connected to the evaporator.

Problem 52. *High Vacuum Lockout. The UCP2 looks at the oil tank pressure via the oil tank pressure transducers. On R-123 units, if the pressure is -11.6 PSIG (3.1 PSIA) or greater, we get the high vacuum lockout. On R-11 units it is -10.9 (3.8 PSIA).*

Corrective Action:

- In Machine Configuration make sure the correct refrigerant is selected.
- If the unit has a "PREVAC" installed and you get a high vacuum lockout at Startup, contact La Crosse Technical Service. A special Circuit Module chip may be required.

Module Compatibility

UCP2 Module Compatibility

1. Chiller modules X13650450-02 or greater when installed in a system with a CLD of X13650448-01 will call out a diagnostic of (Unknown Diagnostic 905). The machine requires a CLD of X136504489-02 or greater.

2. Starter module X13650453-02 and greater requires Chiller Packet 20.
   Chiller module X13650450-01 does not support Packet 20. You need a Chiller module of X13650450-02 or greater along with the Starter module X13650453-02 through 6 or you will get a diagnostic of starter loss of communication with chiller. Beginning with Starter module X13650453-07, the Starter module no longer expects to receive Chiller Packet 20.

3. Chiller module X13650450-03 and earlier do not have the bit that the Stepper module looks for to determine if it should do an inlet vane motor BPI search on startup. These modules will do a BPI search on each startup.

4. TCI COM3 module X13650460-01, the TCI packet time to receive the information from Tracer is 15 seconds. The information is sent out every 10 seconds and you may get repeat (IFW) informational warning diagnostics filling up the diagnostic logs. TCI COM3 module X13650460-02 or greater is required.

5. To read evaporator approach temperature, you need a CLD of X13650448-04 and later along with a Chiller module of X13650450-04 and later.

Description of UCP2 Options

1. **TRACER COMMUNICATIONS INTERFACE MODULE (COM 3 MODULE)**
   This option must be ordered if the chiller is to communicate over a serial communication link to a TRACER 100.

2. **TRACER COMMUNICATIONS INTERFACE MODULE (COM 4 MODULE)**
   This option must be ordered if the chiller is to communicate over a serial communication link to a TRACER Summit.

3. **REMOTE CLEAR LANGUAGE DISPLAY MODULE**
   Enables the UCP2 to communicate serially with the remote CLD.
   The remote CLD panel (COPT:RCPL) communicates serially with 1-4 UCP2 equipped chillers that have the optional remote CLD. The local CLD stop command function has precedence over the remote function. The Custom Report and display language at the local CLD and remote CLD are independent.

4. **OPTIONS MODULE**
   The Options module is required to implement any/all of the following Control options. Some require additional sensor/transducers.

   4.1 Chilled water setpoint by external/remote source. Allows a remote source to set the chilled water setpoint via 4-20 Ma or 2-10 Vdc signal. The range is 0 F to 65 F.

   4.2 Current limit setpoint by external source. Allows a remote source to set the current limit setpoint via a 4-20 MA or 2-10 VDC SIGNAL. Range is 40% to 120%.

   4.3 Compressor percent (%) RLA output. Allows a remote system to receive a 2-10 VDC signal proportional to the chillers % RLA. Range is 0% TO 120%.

   4.4 Head relief request output. Allows a remote system to receive a binary signal for use with compressor surge protection and condenser limit by requesting lower entering cond. water temp. This option requires an additional transducer on the condenser.

   4.5 Maximum capacity output. Allows a remote system to receive a binary signal indicating the chiller is at maximum capacity.

   4.6 Heat recovery/auxiliary condenser entering and leaving water temperatures. This option includes the Option module. Allows UCP2 to monitor the entering and leaving heat recovery or auxiliary cond. water temps which are displayed at the local CLD.

   4.7. Free cooling machine mode enable/disable and valve control. Allows a remote source to re-enable/disable the chillers free cooling.

Description of UCP2 Options

5. **PRINTER INTERFACE MODULE**
   This option must be ordered if the UCP2 is to have a direct connect serial printer. The printer and cable must be ordered separately. This option includes ASHRAE Guideline 3 Report.

6. **CHILLED WATER RESET - OUTDOOR AIR TEMPERATURES**
   Provides for outdoor air temperature reset of the UCP2 front panel chilled water setpoint. Includes display of outdoor air temperature.

7. **WATER PRESSURE SENSORS FOR EVAP AND COND SYSTEM PRESSURE LESS THAN 150 PSIG.**
   Includes sensing of the entering and leaving water pressures of the evaporator and condenser, factory mounted in the water boxes. The Options module is not required. The following data will be shown:
   - Entering/leaving evaporator & condenser water pressure (PSIG)
   - Evaporator and condenser differential water pressure (PSID)
   - Evaporator/condenser GPM
   - Evaporator tons (Approximate)

   WATER PRESSURE SENSORS FOR EVAP AND COND SYSTEM GREATER THAN 150 PSIG
   Includes sensing of the differential evaporator and condenser water pressures. The Options module is included and required. The following data will be shown:
   - Evaporator and condenser differential water pressure (PSID)
   - Evaporator/condenser GPM
   - Evaporator tons (Approximate)

8. **BEARING OIL TEMPERATURE SENSORS**
   Includes factory installed sensors and safety cutouts (On high temp) to monitor the leaving bearing oil temperature: Sensor (1) monitors the Journal bearing temperature and Sensor (2) monitors the Thrust bearing temperature.

9. **PHASE VOLTAGE SENSORS**
   Includes factory installed potential transformers in the starter for monitoring/displaying phase voltage and this provides over/under voltage protection. The following is displayed:
   - Compressor phase voltage; Kilowatts Power Factor.

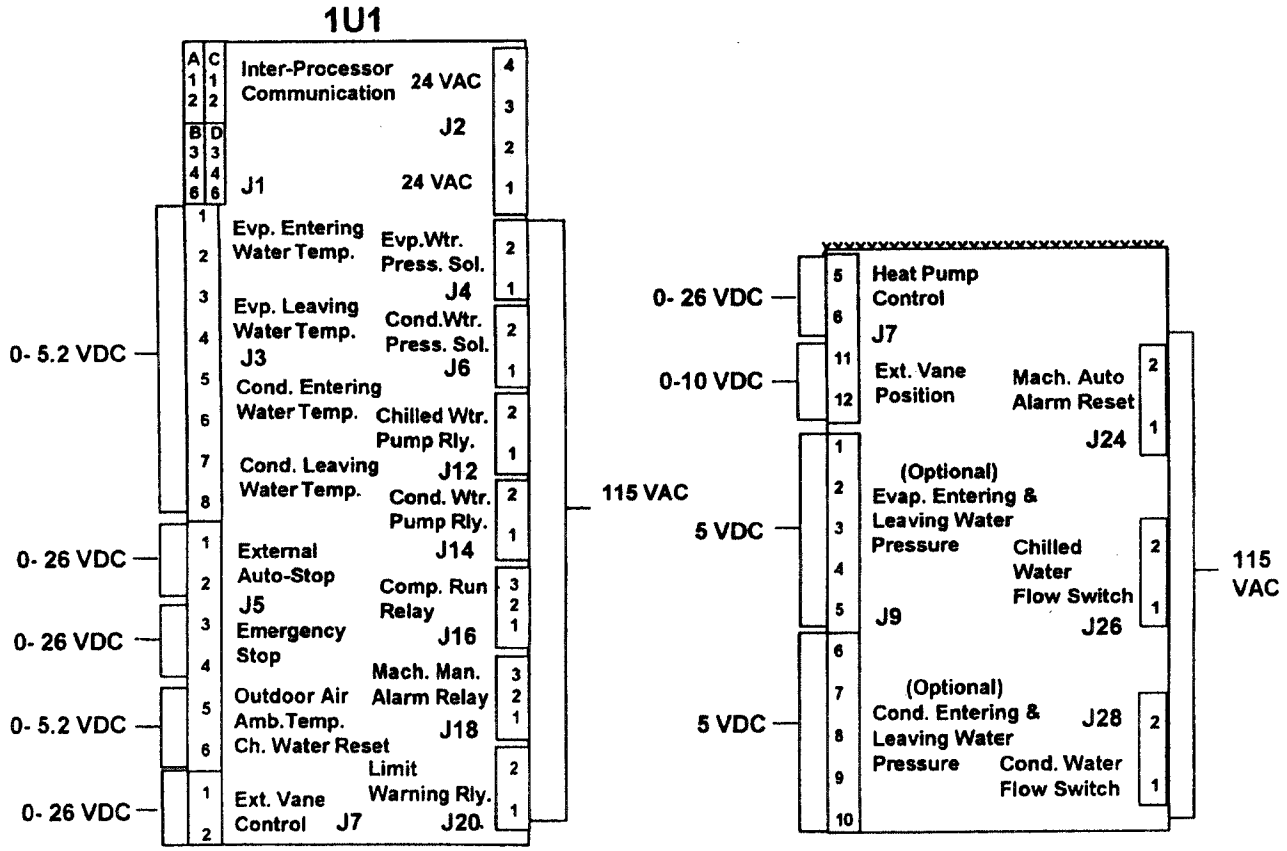
10. **ENHANCED CONDENSER LIMIT**
    Includes factory installed cond pressure tranducer, piping and wiring.
    Provides enhanced high pressure cut-out over cond limit which is standard.
    The head relief request relay will energize when cond. limit is approached. The Options module is included.

11. **DISCHARGE TEMP SENSOR**
    Includes a factory installed sensor and safety cutout on high compressor discharge temp. Allows the UCP2 to monitor compressor discharge temperature. When the chiller is selected with hot gas bypass this sensor is included.

12. **STARTER BY OTHERS**
    When the starter is being furnished by others, Trane furnishes the Starter module in the UCP2, and other wiring/components as needed. The starter must be built per Trane starter specifications.

Module Voltages

Chiller Module



- 1U1 is the "Master module", collecting data, status conditions, diagnostic information, etc. from modules (over the IPC link) from sensors and remote contacts and in turn communicating commands to other modules.

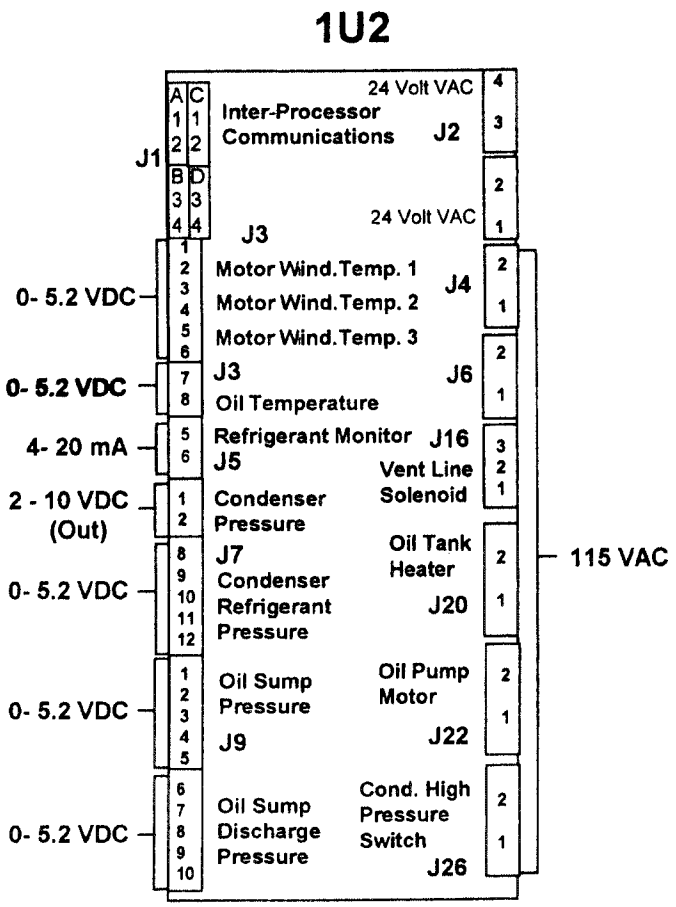
- 1U1 performs leaving water temperature and limits control algorithms, trading off chiller capacity against various "limits" that the chiller may be working against.

- 1U1 checks for valid setpoints and identifies unit type for other modules.

- Low Voltage (<30VAC) Inputs:
- 24 VAC, IPC Links to Internal, to Purge and to Starter Modules; Evap. Ewt and Lwt; Cond. Ewt and Lwt; External Auto Stop; Emergency Stop; Ambient Air CWR; Heat Pump Control; Evap. Water Delta P; Cond. Water Delta P
- High Voltage (>30VAC) Outputs:
- Evap. Water Pressure Solenoid; Cond. Water Pressure Solenoid; Evap. Water Pump Relay; Cond. Water Pump Relay; Compressor Run Relay; MMR Alarm Relay; MAR Alarm Relay; Limit Warning Relay

Figure 2
Chiller Module

Module Voltages



Circuit Module

- 1U2 assigned functions associated with compressor motor, lubrication system and refrigerant monitoring.

- Low Voltage (<30VAC) Inputs:
- 24VAC; IPC link;
  Compressor motor winding temp. sensors 1, 2, 3;
  Oil tank temperature;
  Refrigerant monitor equipment room ppm level:
  Condenser refrigerant pressure;
  Oil sump pressure;
  Oil discharge pump pressure;

- High Voltage, High Amperage (120VAC) Inputs:
- High Condenser Pressure
- High Voltage, High Amperage (120VAC) Outputs:
- Vent line solenoid valve; oil tank heater; oil pump motor

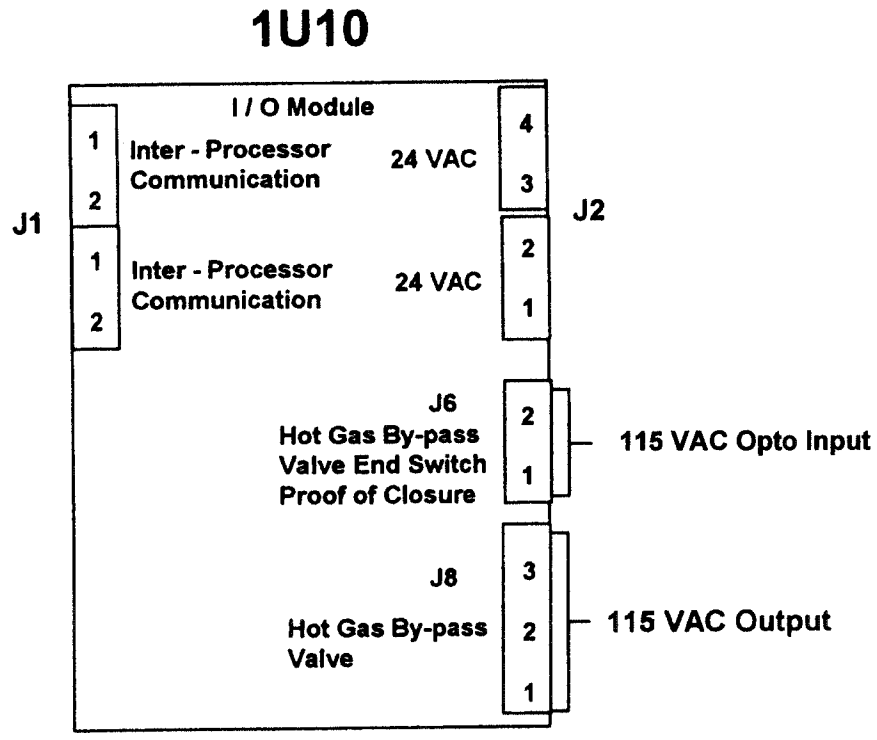


Figure 3
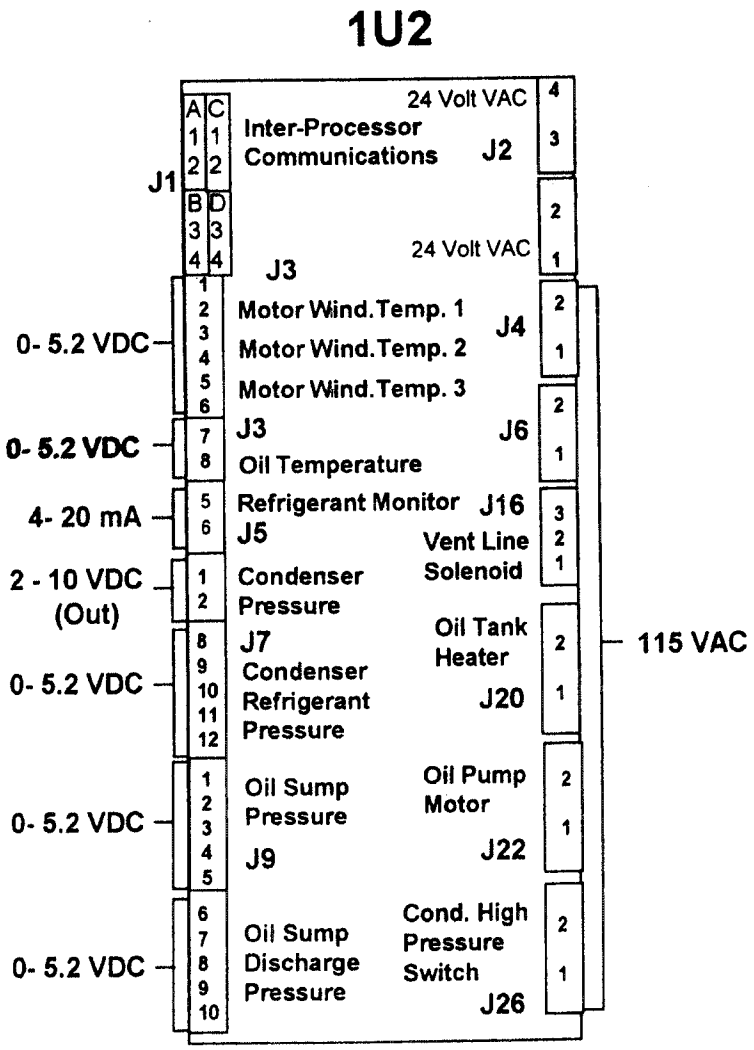
Circuit Module

Input/Output Module

- Provided only when chiller is equipped with Hot Gas Bypass (HGBP) option.
- The I/O Module (1U10) operates the Hot Gas Bypass valve on CVHE and CVHF units in response to signals from stepper module 1U3.
- The module also receives input on HGBP valve position from the HGBP valve end switch.
- Low Voltage (<30VAC) Inputs
- 115 V HGBP valve drive signal
- High Voltage (>30VAC) Inputs
- 110 V HGPB valve proof-of-closure signal from valve end switch
- High Voltage (>30VAC) Outputs
- HGBP Open Triac
- HGBP Close Triac

Figure 4:
Input/Output Module

Module Voltages



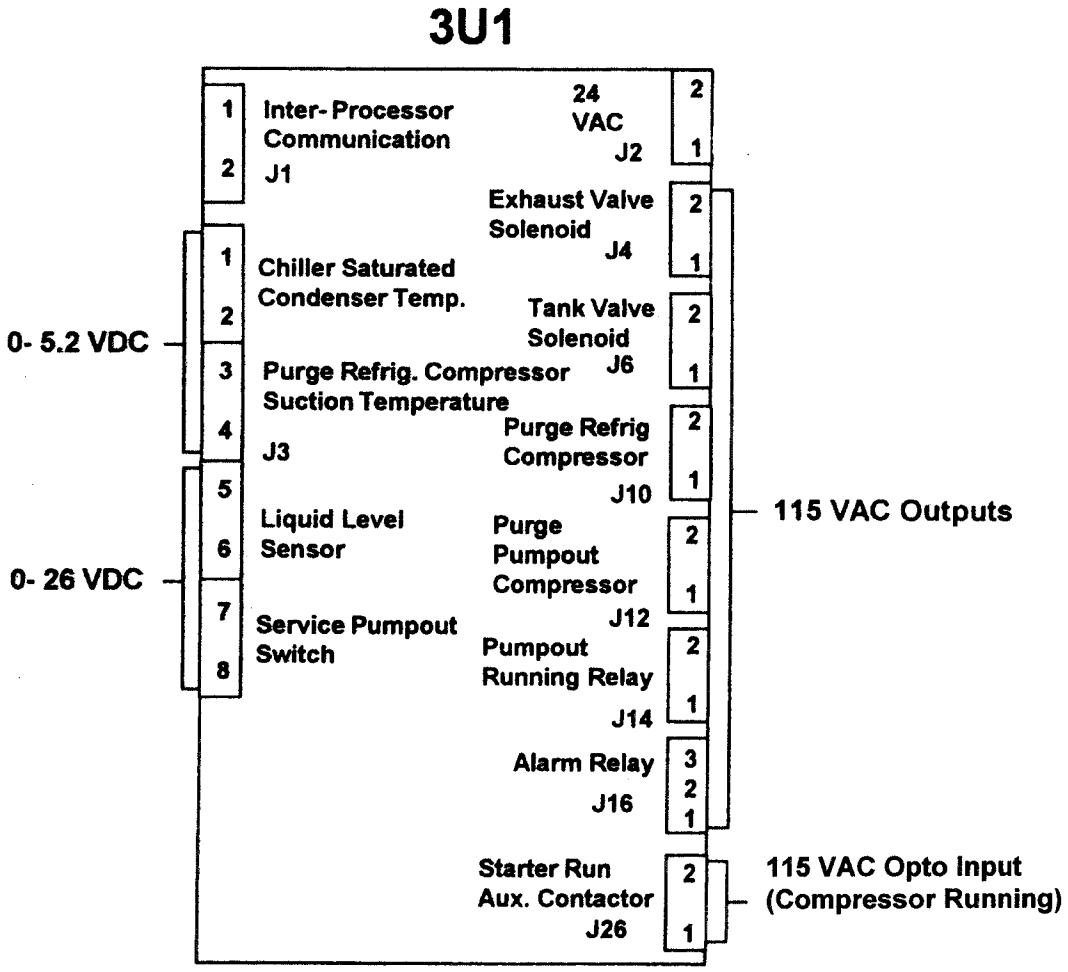
Options Module

- As its name indicates, 1U5 provides the control or interface requirements for many of the options available with the UCP2.

- Low Voltage (<3OVAC) Outputs:
  - Heat Recovery Actuator
    % RLA Compressor

- High Voltage (>3OVAC) Outputs:
- Ice-Making Relay; Head Relief Request Relay; Max. Capacity Relay;
  Free Cooling Actuator Relay I (Liquid Line Valve);
  Free Cooling Auxiliary Relay;
  Free Cooling Actuator Relay 2 (Gas Line Valve)

Figure 5
Options Module



Module Voltages

Purge Module

- The purge module (3U1) is provided with the Trane Model PGRC Purifier Purge on CVHE and CVHF chillers. It is located in the purge control panel at the purge. It provides all inputs and outputs for the UCP2 to control purge operation.
- Low Voltage (<30VAC) Inputs:
- 24 VAC; IPC link to Chiller module
  Purge refrigeration compressor suction temperature;
  Purge tank liquid level sensor
  Service pumpout switch

- High Voltage (>3OVAC) Outputs:
- Exhaust valve solenoid; tank valve solenoid;
  Purge refrigerant compressor purge pumpout compressor;
  Purge pumpout running (Tracer); purge alarm

Figure 6
Purge Module

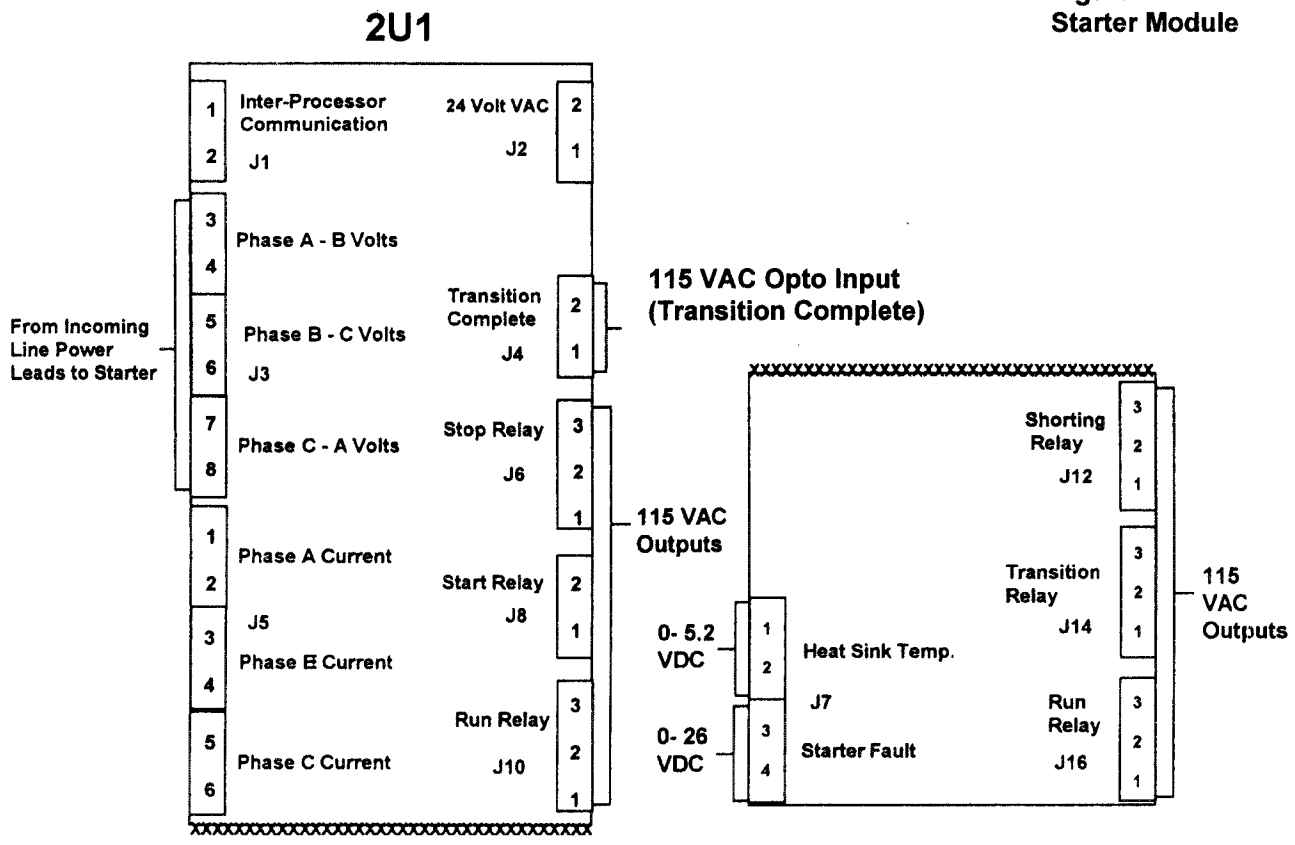
Module Voltages

Starter Module Values

- The starter module (2U1) is present in all Trane-provided starter panels, whether unit-mounted or remote. For CTV's, if no Trane starter is provided and the customer is providing the starter instead, 2U1 is mounted in an extension of the unit control panel. It is still designated as 2U1.

- 2U1 controls the starter when starting, running and stopping compressor motor and provides an interface to all types of starters and AFD's (adjustable frequency drives).

- 2U1 provides compressor motor protection for running overload, phase reversal, phase loss, phase unbalance and momentary power loss.



- Low Voltage (<30VAC) Inputs:
  - 24 VAC; IPC link to chiller module; phase voltages (optional); phase currents; solid-state heat sink temperature (optional); starter driver fault.

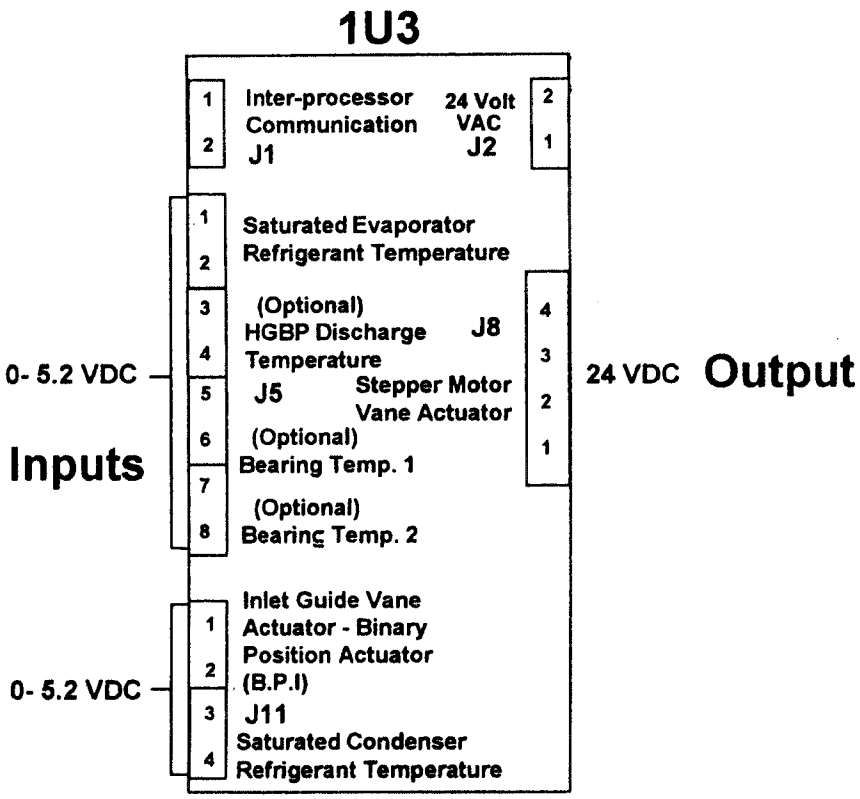
- Low Voltage (<30VAC) Outputs:
  - Speed signal output (0-10 VDC - optional)

- High Voltage (>30VAC) Inputs:
  - Transition complete (CTV only)

- High Voltage (>30VAC) Outputs:
  - Stop relay; starter relay; run relay; shorting relay; transition relay, shunt trip relay.

Figure 7
Starter Module

Module Voltages



Stepper Module

- The main function of 1U3 is to drive the Inlet Guide Vane Stepper motor (CTV) along with other functions. It does this in response to signals received from Chiller module 1UI.

- Low Voltage (<30VAC) Inputs:
- 24VAC; IPC link;
  Evaporator saturated refrigerant temperature;
  Compressor discharge temperature (optional);
  Bearing temps, 1 and 2;
  Inlet guide vane actuator; Binary position indicator
  Condenser saturated refrigerant temperature;

- Low Voltage, High Amperage (<30VAC) Outputs:
- Vane actuator stepper motor

Figure 8
Stepper Module

Module Dip Switch Settings

UCP2 Board Dip Switch Settings

Several of the UCP2 modules have dip switch settings on them, used to set up the board for 2-10 VDC or 4-20 MA signal inputs and/or outputs of the boards. The following are the various switch settings.

Chiller Module

	Switch	0-10V	4-20MA
External Vane Position	SW2-1	OFF	ON (SW2-2 and SW2-3 are not used)

Options Module

BOTH INPUTS MUST BE THE SAME TYPE. - (4 to 20 mA) (2 to 10 volts)

	Switch	0-10V	4-20MA
External Current Limit	SW2-1	OFF	ON(SW2-2 and SW2-3 are not used).
External Chilled Water	SW3-1	OFF	ON (SW3-2 and SW3-3 are not used)

Tracer COM 3

Switch	-1	-2	-3
SW1	OFF	OFF	OFF

Tracer COM 4

Switch	-1	-2	-3
SW1	OFF	ON	OFF

IPC BUFFER

Switch	-1	-2	-3
SW1	OFF	OFF	ON

PRINTER

Switch	-1	-2	-3
SW1	OFF	OFF	ON

Diagnosing A Non-Working Stepper Module

Method to Troubleshoot a UCP2 Stepper Module and Actuator

I. Overview

The UCP2 Stepper Module is used to drive a Stepper Motor, which is used to open and close a valve or actuator. The big difference between a Stepper Motor and other types of motors, is that instead of just making the motor turn, you can control the angular position of the rotor inside the motor, and therefore control the position of your valve or actuator.

The Stepper Motor has two windings inside. To distinguish between the two, we call them Winding 1 and Winding 2. The Stepper Module contains one drive circuit for each winding. Most of the failures you will probably deal with will result in the two internal fuses, FI and F2, inside the Stepper Module to open. These fuses protect the motor from damage, and are not easily accessible. Replacing these fuses in the field right now is not an acceptable option, because the original fuses have been through some special UL testing. We cannot guarantee safety to the customer if a blown fuse is replaced with another of a different type.

The Stepper Motor three states: Moving, Holding and Off:

1. In the moving state, current flows bi-directionally through each of the two windings. The frequency and amount of current is electronically controlled by the Stepper Module.

2. In the Holding State, current flows one way through each of the two windings. The amount of current is electronically controlled by the Stepper Module.

3. The Off state occurs only when the Stepper Module power is cycled. Until the Stepper receives an order from the Chiller Module to move, no current flows through the Stepper Motor windings.

II. Quick Test of Stepper Board

A. This section will show how to test the main power points of the Stepper Board to get an idea of where the problem is.

   1. If the UCP2 Control Panel is unpowered, unplug the J2 connectors from the Stepper board and continue to Section III to check motor and wiring resistance's.

   2. If the UCP2 Control Panel is powered, measure and compare the Power Input (J2) and the 4 Test Points at the right side of the Stepper board with Table 1.

Diagnosing A Non-Working Stepper Module

Table 1: UCP2 Stepper Module Test Point Voltage Limits

Connector		Vac	Vdc
J2 - (1 to 2) or (3 to 4)		20.4 to 33.12 Vac	=0 Vdc
J2 - (1 to case) or (2 to case)		10 to 17 Vac	13.12 to 21.81 Vdc
TP2: 5V to ground	≅	0 Vac	4.8 to 5.2 Vdc
TP4: 24 V to ground	≅	0 Vac	23.2 to 25.1 Vdc
TP3: 14 V to ground	≅	0 Vac	11.45 to 15.75 Vdc
TP1: 35 V to ground		100 m Vac to 72 m Vac	26 to 48 Vdc

If any of the voltages are out of range, there is a malfunction on the Stepper Board.
The majority of these malfunctions may be diagnosed by using Table 2. The ones marked with a star have been seen in the field before:

Table 2: UCP2 Stepper Module Troubleshooting

Condition(s)	Possible Problem	Possible Cause(s)	(Solution(s)
Voltage at Test Points TP1-TP4 on Stepper Module ≅0. Motor winding resistance check pin to conduit ≅0. Motor does not move.	Wiring between Stepper Module and actuator motor is shorted to ground.	1. Wire insulation bared inside conduit. 2. Wire insulation bared or pinched inside motor junction box.	1. Seal wire or run new wire through conduit. 2. Seal wire, or restrip and rewire motor junction box. See Table 4 for wiring diagram.

Diagnosing A Non-Working Stepper Module

Continuation of Table 2: UCP2 Stepper Module Troubleshooting

Condition(s)	Possible Problem	Possible Cause(s)	Solution(s)
Voltage at Test Points TP1-TP4 on Stepper Module ≅0. Motor winding restance check pin to pin fails. Motor does not move.	Wiring shorted together inside conduit between Stepper Module and actuator motor.	Insulation bared.	Seal wire or run new wire through conduit. See Table 4 for wiring diagram.
	Wiring shorted together at board edge connector J6 or J8	*1. metal shavings from drilling into UCP2 Panel form bridge. 2. Loose wire strands form bridge.	1. Inspect J6 and J8 connectors. Remove any metal shavings bridging the wires before powering module. 2. Restrip and rewire the board edge connector.
	Wires shorted together inside motor junction box.	Insulation bared.	Seal wire or run new wire through conduit. See Table 4 for wiring diagram.
Stepper Module TP1 - TP4 OK. Motor winding resistance check OK. Motor does not move.	Motor does not move and steps display does not change on CLD when using manual vane control.	UCP2 is not in Stop Mode and Chiller Module is overriding manual vane control.	Hit stop button on CLD, and try again.

Continuation of Table 2: UCP2 Stepper Module Troubleshooting

Condition(s)	Possible Problem	Possible Cause(s)	Solution(s)
Stepper Module TP1 - TP4 OK. Motor winding resistance check OK. Motor runs backward.	Motor runs backwards.	Motor is miswired.	Unplug the motor connector (J6 or J8) from the Stepper Module. Use Table 3 and Table 4 to swap wire pairs (1, 3) or (2, 4) so that the motor is wired properly.
Stepper Module TP1 - TP4 OK. Motor winding resistance check of W1 or W2 open circuit. CLD shows steps are changing in manual mode. Motor does not move.	1. Open circuit in wiring to motor. 2. Open in one or both of the two actuator windings.	*1. Loose or disconnected wireat J6 or J8 connector, or at Motor terminal. 2. Wiring from Stepper to Motor is open-circuited. 3. Winding 1 or 2 open inside motor.	1. Check wiring with Table 4. Reconnect any loose wires. 2. Check wiring with Table 4. Replace any open wires. 3. Replace motor.

III. Check Stepper Motor and Wiring for Shorts and Opens

A. During this stage, motor winding and wire resistance's will be measured to ensure proper continuity.

1. If the unit is powered, hit the stop button on the CLD and use manual mode in the service tools menu to step the actuators all the way to position 0.

2. Unplug power (J2 connector) from the Stepper Module.

3. Unplug J6 and J8 from the board.

4. Measure the DC resistance of one of the motor windings by measuring between what would be Pin (1,3) or Pin (2,4) on the Stepper Board at the unplugged connector (See Table 3).

5. If the resistance is lower than the limits in Table 3 there is a short in the wiring between the Stepper Module and the motor or the in motor winding. Note that nominal values are not including wire resistance's.

6. If the resistance is higher than the limits in Table 3 the wiring between the Stepper Module and the motor or a winding is open. Note that nominal values are not including wire resistance's.

Table 3: Motor Winding Resistance

J6 or J8 Connector Pin	Acceptable DC Resistance Range	CTV Nominal Resistance
(4 to 3)	Open Circuit	NA
(4 to 2): W1	50 mOhm to 5 Ohm	1.68 Ohm
(4 to 1)	Open Circuit	N/A
(3 to 2)	Open Circuit	N/A
(3 to 1): W2	50 mOhm to 5 Ohm	1.68 Ohm
(2 to 1)	Open Circuit	N/A
(4 to conduit)	Open Circuit	N/A
(3 to conduit)	Open Circuit	N/A
(2 to conduit)	Open Circuit	N/A
(1 to conduit)	Open Circuit	N/A

7. If the winding resistance is in the range, plug the j connector back into the appropriate socket.

8. Perform steps 3-7 for each winding of the motor on the Stepper Module.

9. If there is a short or an open, you will need to check the wiring to the motor, and then check the motor.

10. If the windings resistance check passes, and you have not measured the Stepper Module voltages while it is powered, then plug J2 back into the module and go back to Section II, Quick Test of Stepper Board.

B. If you need to disconnect the wires going to the motor for any reason, Table 4 is a wiring table you can use to reconnect them.

Table 4: Stepper Motor Connections

J6 or J8 Connector Pin# on Stepper	Motor Winding Output Signal Name	Stepper Motor Terminal Connection
4	1+	3
3	2+	5
2	1-	1
1	2-	4

IV. Motor Voltages for CTV Stepper Motor

A. With the motor connector J6 (or J8) connected to the Stepper Board, and the Stepper powered, measure the AC and DC voltages of the connector pins, and compare to Table 5 and 6.

Table 5: Motor Voltages with Actuator Holding

Connector Pin	AC Voltage	DC Voltage
J6 - (4 to 3)	≅ 0 or (5.8 - 10)	- 400 m V to +400 m V
J6 - (4 to 2)	5.8 - 8.2	≅ ± 400 m V, but not 0 m V
J6 - (3 to 1)	≅ 0 or (5.8 - 10)	- 400 m V to +400 m V
J6 - (3 to 2)	≅ 0 or (5.8 - 10)	- 400 m V to +400 m V
J6 - (3 to 1)	5.8 to 8.2	≅ ± 400 m V, but not 0 m V
J6 - (2 to 1)	≅ 0 or (5.8 - 10)	- 400 m V to +400 m V
J6 - (4 to conduit)	≅ 0 or (5.8 - 8)	(0.3 - 0.43) or (1.04 - 1.135)
J6 - (3 to conduit)	≅ 0 or (5.8 - 8)	(0.3 - 0.43) or (1.04 - 1.135)
J6 - (2 to conduit)	≅ 0 or (5.8 - 8)	(0.3 - 0.43) or (1.04 - 1.135)
J6 - (1 to conduit)	≅ 0 or (5.8 - 8)	(0.3 - 0.43) or (1.04 - 1.135)

Table 6: Motor Voltages with Actuator Moving

Connector Pin	AC Voltage	DC Voltage
J6 - (4 to 3)	(16.6 - 25.9)	-720 m V to +720 m V
J6 - (4 to 2)	(20.8 - 27.5)	-720 m V to +720 m V
J6 - (4 to 1)	16.6 - 25.9)	-720 m V to +720 m V
J6 - (3 to 2)	16.6 - 25.9)	-720 m V to +720 m V
J6 - (3 to 1)	20.8 - 27.5)	-720 m V to +720 m V
J6 - (2 to 1)	(16.6 - 25.9)	-720 m V to +720 m V
J6 - (4 to conduit)	(11.4 - 17.3)	(9.1 - 10.1)
J6 - (4 to conduit)	(11.4 - 17.3)	(9.1 - 10.1)
J6 - (4 to conduit)	(11.4 - 17.3)	(9.1 - 10.1)
J6 - (4 to conduit)	(11.4 - 17.3)	(9.1 - 10.1)

External Current Limit Setpoint

- Option Module J7-11, -12 (-, +)

- Isolated 2-10 Vdc or 4-20 ma

- UCP2 shall accept either a 2-10 Vdc or 4-20 ma analog input suitable for customer connection to set the unit external current limit setpoint. 2-10 Vdc and 4-20 ma shall each correspond to a 40 to 120% RLA range. CTV UCP2 will limit the maximum ECLS to 100%.

- The following must be "Set".

1. SW2-1 OFF for 2-10 Vdc
   ON for 4-20 ma
2. Current Limit Setpoint Source: External Source

3. External Current Limit Setpoint: Installed

4. External Setpoint Inputs: 2-10 Vdc or 4-20 ma.

Module Set-Up Procedures For:

Refrigerant Monitor Input

- Analog type input
  4-20ma input signal to the Circuit module J5-5 and J5-6. This represents 0-100 ppm.
  Under machine configuration "Refrigerant Monitor Type" is '01' for Analog.
  Typical input if using an RMWC generation Monitor.

- IPC Monitor (Requires RMWD monitor with Version 2 Software)
  Direct communication to the CLD via the IPC.
  Under Machine Configuration "Refrigerant Monitor Type" is '02' for IPC Monitor.
  Also allows monitor calibration and setup. Please note that the monitor cannot have a local display and communicate with the UCP2. If the customer requires a local display, he can connect an RMWD style monitor up like an analog type previously described.

Load Indication Output

- Options Module J7-3,-4

- 2-10 Vdc

- As an option, the UCM shall provide a 0-10 Vdc analog output to indicate % RLA. The transfer function shall be 2 to 10 Vdc corresponding to 0 to 120% RLA.

Module Set-Up Procedures For:

External Chilled Water Setpoint

GENERIC INTERFACE, ALLOWS THE CUSTOMER TO CHANGE THE CHILLED WATER SETPOINT FROM A REMOTE LOCATION.

UCP2 SHALL ACCEPT EITHER A 2-10 VDC OR 4-20 MA ISOLATED ANALOG INPUT SUITABLE FOR CUSTOMER CONNECTION TO SET THE UNIT LEAVING CHILLED WATER SETPOINT. THE 2-10 VDC AND
4-20 MA ANALOG INPUT EACH CORRESPONDS TO A 0 TO 65 F (- 17.8 TO 18.3 C) CWS RANGE.
SEE LINEAR RELATIONSHIP ON CHART.

THE ISOLATED ANALOG INPUT SHOULD BE CONNECTED AT THE J9 PLUG, PINS 4 (NEG) AND 5 (POS) ON THE OPTIONS MODULE.

THE FOLLOWING ITEMS NEED TO BE "SET".

1. SW3-1 OFF FOR 2-10 VDC.
   ON FOR 4-20 MA.

2. CHILLED WATER RESET TYPE:
   DISABLE - OPERATOR SETTINGS GROUP

3. CHILLED WATER SETPOINT SOURCE :
   EXTERNAL - OPERATOR SETTINS GROUP

4. SETPOINT SOURCE OVERRIDE :
   NONE - OPERATOR SETTINGS GROUP

5. EXTERNAL CHILLED WATER SETPOINT :
   INSTALLED - SERVICE SETTINGS GROUP
   - MACHINE CONFIGURATION

Analog Input Table Abbreviations

The information below is an explanation of abbreviations used in Analog Input Tables which are shown in this section.

-- Oil Pressures

-- Water Pressures

A1: Entering and Leaving Evap Temp.
Purge Compressor Suction Temp.

A2: Oil Temp.
Entering and Leaving Condenser
Aux HR Entering and Leaving Temp.
Compressor Discharge Ref Temp.
Bearing Temps 1 and 2
Saturated Cond. Refrigerant Temp.
Outdoor Air Temperature.

A4: Saturated Evap Temp.

A6: Compressor Motor Winding Temp 75 Ohm

Note: A1, A2 and A4 are the same sensor.

Note:

1. Min. Res. and Max. Res. = Minimum and Maximum Resistance in Ohms.
2. Min Vterm. and Max. Vterm = Minimum and Maximum DC Voltage measure at the appropriate module terminal.

Table 7: Pressure vs Voltage for Oil Pressures

Oil Pressure (PSIG)	Differential Voltage (DC)		
	Min	Nom	Max
-15	-0.0017	0.0000	0.0017
-10	0.0033	0.0050	0.0067
-5	0.0083	0.0100	0.0117
-4	0.0093	0.0110	0.0127
-3	0.0103	0.0120	0.0137
-2	0.0113	0.0130	0.0147
-1	0.0122	0.0140	0.0158
0	0.0132	0.0150	0.0168
1	0.0142	0.0160	0.0178

Transducer
Checkout Procedure

QUICK TEST PROCEDURE FOR MEDIAMATE WATER PRESSURE TRANSDUCER

1. Set regulated power supply to 5 VDC. Connect 5 VDC to Pins 2 and 4 on the Transducer.

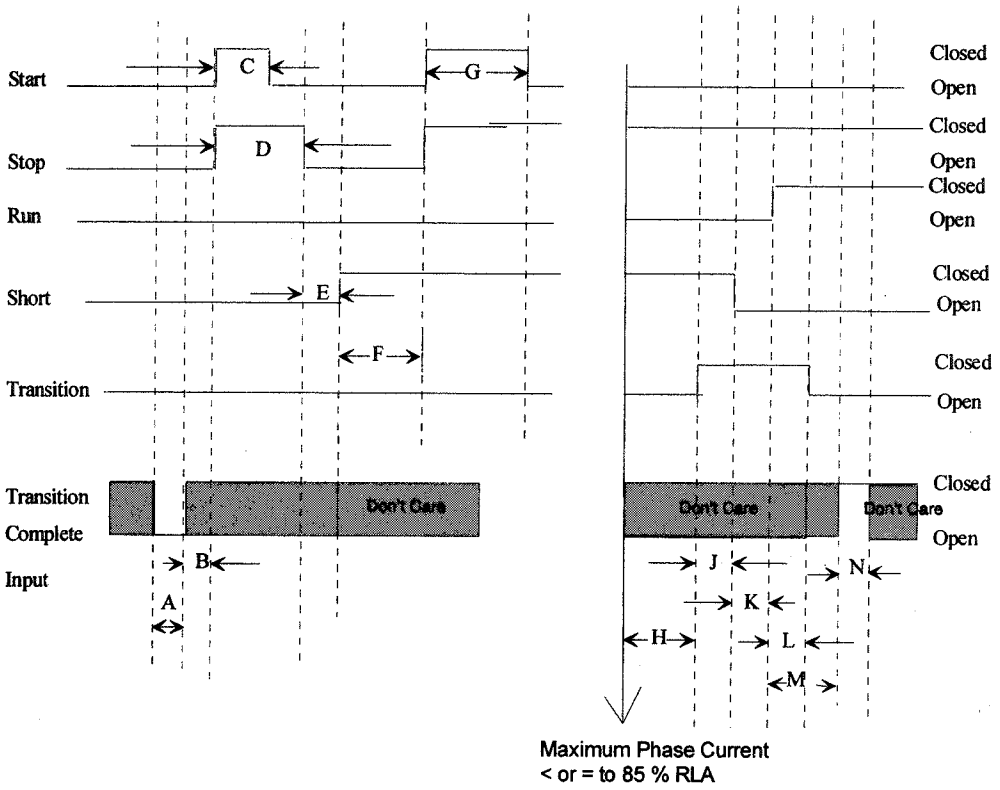
2. Check zero balance at ambient pressure by attaching Transducer lead wires of a Digital Volt Meter to Pin 1 and Pin 3 of the Transducer.

Pin 4:	+ Excitation	(Supply)	> Connect 5 VDC Power Supply
Pin 2:	- Excitation	(Supply)	
Pin 1:	+ Signal		> Connect Volt Meter
Pin 3:	- Signal		

(A cable assembly with a mating Hirschmann connector could be made up and used for all tests.)
Allow transducer to stabilize under power (approximately 15 - 30 seconds).

Readings:

1. Transducer used for Condenser Pressure, Oil Discharge Pressure and Oil Sump.
   Trane Part Number TDR0272. A good Transducer reading is: 15 mV ± 1mV



2. Evaporator and Condenser Water Flow Transducer and Part Number TDR0274
   A good Transducer reading is: 0 mV ± 1mV.

4. Insert a Q-Tip or small wooden dowel into the pressure port and gently apply force to the diaphragm and watch the DVM for a corresponding change in output.

Starter
Contactor Sequence

Implemented in CTV Upgrade 2, Phase C release X13650453-07

Timing requirements to operate the "Stop", "Start", "Short", "Transition", and "Run" contact closure outputs are shown below. Prior to closing the "Short" contact, the transition complete input shall be verified to be open, otherwise an MMR diagnostic shall be generated.

Interval	Minimum	Maximum	Units	Actual
A. (Test for transition complete input open)				120 to 180 msec
B. (Just delay time)				20 msec
C. Close 1M (2K1) Contactor and test for no current.) (Starter integrity test)				500 msec
D.				1 sec
E. (Open 1M (2K1)				200 msec
F. (Close Shorting Contactor (2K3) and test for no current, then wait for Start command) (Starter integrity test)	100 (1)			1.0 sec (Min.)
G. (Close 1M (2K1))	2.0		sec	2 sec
H. (Wait 1.5 sec after phase currents drop to 85%)	1	2	sec	1.5 sec
J. (Close 2K4 Transition Contactor)	85	100	msec	100 msec
K. (Open S (Shorting) Contactor	250	300	msec	260 msec
L. (Close 2M (2K2) Contactor)				140 msec
M. (Wait to look for Transition complete)	(2)		msec	2.32 to 2.38sec
N. (Filtering time on Transition complete input)	(2)		msec	120 to 180 sec

(1) This timer period must long enough to verify the absence of phase currents caused by the closing of the "Short" contacts.

(2) The sum of intervals M and N are designed to be 2.5 seconds.

Note: The transition complete contact closure is expected to be an auxiliary contact to the "Run Contactor" (2K2).

Starter Module
CT Voltage and Currents

There are two configurations of CT's used. One is the single stage, the other is the dual stage. A different transfer function exists depending on whether a single or dual stage configuration is used. The two configurations appear the same to the UCP2 by normalizing each. Thus a different equation is used to take the actual line current and convert it to a common 'Normalized Line Current' that may be used in Table 19. Note that the 'Terminal Volts' is the AC voltage seen at the current input terminal pairs of the Starter module. These pairs are J5-1,2, J5-3,4 and J5-5,6.

For a single stage CT:

$$\text{Normalized Line Current (\%)} = \frac{\text{Actual Line Current(Amps)*100\%*Primary Turns}}{\text{CT Rated Primary Current (Amps)}}$$

For a two stage CT:

$$\text{Normalized Line Current (\%)} = \frac{\text{Actual Line Current(Amps)*138.89\%*Primary Turns}}{\text{Line CT Rated Primary Current (Amps)}}$$

Table 19 - Current Input Transfer Function

Normalized Line Current %	Terminal Input Current (mA RMS)	Terminal Volts (V RMS) (± 5%)	Normalized Line Current %	Terminal Input Current (mA RMS)	Terminal Volts (V RMS) (± 5%)
0	0	0	115	115	4.23

TRANE

General Service Bulletin

CVHE-SB-32A

Library	**Service Literature**
Product Section	**Refrigeration**
Product	**Centrifugal Liquid Chiller, Water-Cooled**
Model	**CVHE, F, G**
Literature Type	**General Service Bulletin**
Sequence	**32A**
Date	**August 1999**
File No.	**SV-RF-CVHE-SB-32A**
Supersedes	**CVHE-SB-32**

Literature History: CVHE-SB-32 (8/95)—Original Issue of Bulletin.

Subject: Troubleshooting and Checkout Procedures For CVHE/F/G Units with UCP2 Controls

Introduction:

The purpose of this service bulletin is to provide troubleshooting information on CVHE/F/G Centrifugal Chillers with UCP2 Control Panel. Additional UCP2 information is found in the following manuals:

CVHE-OM-8, Operation/Maintenance Manual

CVHE-IN-9,10,11, Installation Manual

CVHE-W-8A, Wiring Manual

CVHE-CLD-1A, Clear Language Display Manual

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and designs without notice. The installation and servicing equipment referred to into this booklet should be done by qualified experienced technicians.

General Troubleshooting Information ... 9

Problem 1: AFD (adaptive frequency drive) diagnostics 9
Problem 2: Failure to accelerate or did not accelerate 9
Problem 3: Approach Temperature reads -40°F 9
Problem 4: Auto X-former starter: Runs (3) seconds and trips. Unit will not transition. 9
Problem 5: IGV BPI not found or low 9
Problem 6: Bearing Temperatures 1 and 2 Locations 10
Problem 7: Capacity Limited by High Current when the phase current as read from the Compressor report reads zero amps. Getting this message during the run mode. 10
Problem 8: Current Overload 10
Problem 9: Chiller Loss of Communication with circuit module and IGV overdriving close 10
Problem 10: Check Clock (IFW) Informational Warning Diagnostics. On a loss of power, the clock does not keep time if there is an extended power loss (greater than 15 seconds) 10
Problem 11: Chiller Loss of Communication with Starter and the IGV calibrates. 11
Problem 12: Chiller Loss of Communication with Starter or Circuit Loss of Communication with Chiller Diagnostics 11
Problem 13: Clear Language Display won't go into Demo mode 11
Problem 14: Communication diagnostic; None or Degraded Communications 11
Problem 15: Loss of Communication with Starter Diagnostics at Startup with no Inlet Guide Vane action. Mode is "Resetting" and can move through the menus 11
Problem 16: Loss of Communication or Intermittent Communication between any of the modules. (Chiller, Starter, Tracer, Circuit, Stepper, Options, Purge, etc.) 12
Problem 17: No Communication, on a power up, get message "No Communication, Data Not Valid" and no action in the IGV. 13
Problem 18: No Communication, on a power up, get message "No Communication, Data Valid" but the Inlet Guide Vane calibrates 13
Problem 19: Starter Loss of Communication with Chiller. No other diagnostic 13
Problem 20: TCI Loss of Communication with Chiller. 13
Problem 21: High compressor Discharge temperature, The compressor discharge temperature exceeded 200°F. 13
Problem 22: Cond. Pressure 2-10 VDC output will not work 14
Problem 23: Condenser Pressure Delta-pressure output does not show up. 14
Problem 24: Cond. Refrig. Temp. Sensor diagnostic, when the displayed Cond. Refrig. Temp. is reading fine 14
Problem 25: Condenser and Evaporator entering and leaving water temps. changing rapidly and reading incorrectly, i.e. -25°F to 900°F. 14
Problem 26: Condenser Water Flow lost diagnostic. Unit will not restart until manually reset. 14
Problem 27: Capacity limited by current limit 14
Problem 28: Custom menu - Unwanted items that you did not install and you cannot remove 14

Problem 29: Display is locked up. No communication, Data Not Valid Diagnostic. 15
Problem 30: Display on the CLD is flashing. 15
Problem 31: External Chilled Water Setpoint Problems. 15
Problem 32: External Current Limit setpoint does not work. 16
Problem 33: Fault Relay open on an AFD (air cooled adaptive frequency Drive) 16
Problem: 34 Fault relay open on Solid State Starter (SSS) 16
Problem 35: Free cooling (FC) operation problems. 16
Problem 36: Evaporator Water Temperatures are reversed (2 pass units only). 17
Problem 37: Low Evaporator refrigerant temperature 17
Problem 38: 2F1, 2F2 and 2F3 Fuses blow - On 200-575 volt units when switching the starter disconnect from OPEN to CLOSED. 17
Problem 39: GPM/Tonnage option problems 17
Problem 40: High Vacuum Lockout 17
Problem 41: Hot Gas Bypass (HGBP) Does Not Work. 18
Problem 42: Ice Making 18
Problem 43: IGV will not move in the Service Test Manual mode. 19
Problem 44: IPC Buffer Diagnostics 19
Problem 45: KW reads high by a factor of 3, with optional PT installed. 19
Problem 46: Loading Problems 19
Problem 47: Memory Error 20
Problem 48: Momentary Power Loss (MPL) 20
Problem 49: Motor winding temperatures changing rapidly and randomly 21
Problem 50: Differential Oil Pressure Calibration Diagnostic following post lube. Secondary problem may be the oil pump will not shut off after post lube. 21
Problem 51: Differential Oil Pressure 21
Problem 52: Oil temperature High. 22
Problem 53: Oil temperature Low (Startup) 22
Problem 54: Low Oil Temperature (Running) 22
Problem 55: Enhanced oil temperature function not working. 22
Problem 56: Oil Pump Discharge Pressure Sensor Diagnostic and Oil Pressure Calibration. Corrective Action. 22
Problem 57: Over/Under Voltage Diagnostic on Startup. 23
Problem 58: Phase Loss 23
Problem 59: Severe Phase Unbalance 25
Problem 60: Phase Reversal 25
Problem 61: Printer will not work. 25
Problem 62: Purge Compressor will not run in the manual "ON" mode. 26
Problem 63: Sensor errors 26
Problem 64: Transition resistors stay in too long. 26
Problem 65: Setpoints are not being stored, service tests will not work and we are calling many diagnostics on the CLD. 26
Problem 66: Starter Contactor Interrupt Failure Diagnostic when powering up the UCP. 27
Problem 67: Starter Dry Run Test Diagnostic upon entering a Starter Dry Run Test. 27
Problem 68: Starter Dry Run will not work. 27
Problem 69: Starter Fault type 1, 2 or 3 27
Problem 70: Stepper motor is humming. 27
Problem 71: Extended surge 28
Problem 72: Pressure Transducer shift in calibration. Diagnostics will be sensor calibration related such as sensor failure or oil pressure sensor calibration. 28
Problem 73: Rapid Time of Day Scrolling or Date jumps back one day. 28
Problem 74: Unit did not Transition diagnostics. 28
Problem 75: Tracer Diagnostics e.g.,Tracer loss of comm with options, starter, etc. as well as other Tracer related diagnostics. 29
Problem 76: Unit Tons Read-out on CLD does not work. 29
Problem 77: Unknown diagnostics 1217 informational warning. 29

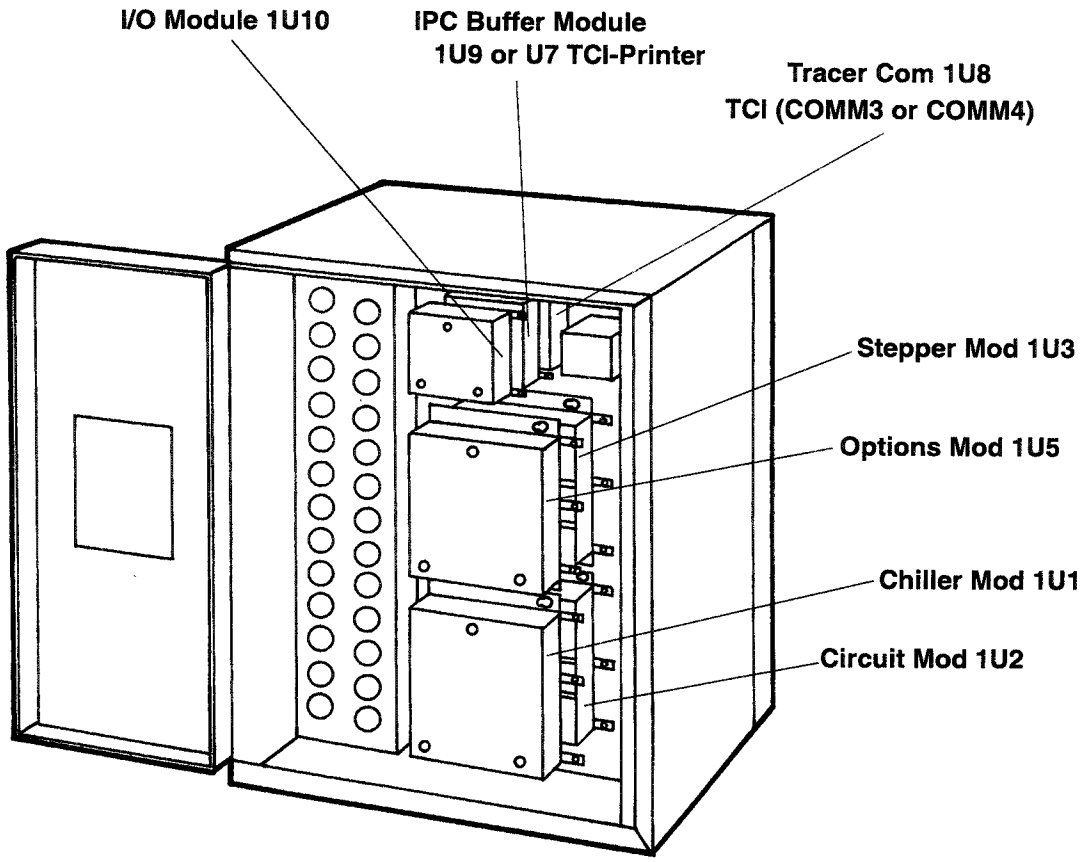
UCP2 Control Panel and Module Description

Unit Control Panel

Safety and operating controls are housed in the UCP2 Unit Control Panel, the Starter Panel and the Purge

Control Panel (Control Panel layout is illustrated in Figure 1).



The UCP2 control consists of a modular design partitioned by major function or group of functions. All modules communicate with each other through the IPC circuit.

Major components within each of these control groups are described below.

Unit-mounted temperature sensors, pressure transducers and functional switches provide analog and binary inputs to the various modules.

The "microprocessor-based" modules described are shown below. All connections to the modules are made with pluggable phoenix connectors.

Figure 1
UCP2 Control Panel

UCP2 Control Panel and Module Description

Chiller Module

The Chiller module is the Master-of-the-Chiller communicating commands to other modules and collecting data/status/diagnostic information from other modules over the IPC (Interprocessor Communications Link). The Chiller module performs the leaving chilled water temperature and limit control algorithms arbitrating capacity against any operating limit the chiller may find itself working against. The Chiller module checks for valid setpoints and contains non-volatile memory (NOVRAM), to retain them on any power loss. Inputs and Outputs are chilled water system level such as, but not limited to, evaporator and condenser water temperatures, evaporator and condenser water pump control, status and alarm relays, and external auto/stop.

Circuit Module

The Circuit module serves as an input/output expander and is assigned inputs and outputs associated with the refrigerant and lubrication circuits. The Circuit module also receives a 4-2OmA signal from an external refrigerant monitor and converts the signal to ppm for display at the Clear Language Display.

Module Setpoints relating to the circuit module.

1. condenser refrigerant pressure output: (J7 1,2) 2-10 VDC; 2 V = 0 psia (14.7 psig); 10 V = 14.7 psia (29.7 psig)

2. Refrigerant monitor input. (J5 5,6) 4-20 mA input suitable for factory or field connection. 4-20 mA range is 0 to 100 ppm.

Stepper Module

The Stepper module is designed to drive the stepper motor inlet guide vane actuator on CenTraVac chillers. On CenTraVac chillers the Stepper module receives from the Chiller module the direction and distance to drive the inlet guide vanes and then generates the appropriate signals to operate the stepper motor. The Stepper module also has other I/O capabilities used to support functions on the stepper module and/or just I/O expansion. These are Evap. temperature, Cond. discharge, Bearing temperature and Cond. temperature.

Starter Module

The Starter module physically resides in the Compressor Motor Starter Panel providing control of the starter when starting, running and stopping the motor. The Starter module provides interface to and control of Y-Delta, X-Line, P-Reactor, A-Transformers, Solid State Starters and Trane® Adaptive Frequency Drive. The Starter module also provides protection to both the motor and the compressor in the form of running overload, phase reversal, phase loss, phase unbalance, momentary power loss, and compressor surge, in addition to others.

Purge Module

The Purge module provides control of the purge used on R-11 and R-123 low pressure CenTraVac models. The Purge module provides all the inputs and outputs to control the purge optimizing both purge and chiller efficiency. The Purge module resides in the purge control panel and communicates with the Chiller module over the IPC (Interprocessor Communications Link) uploading set points and downloading data and diagnostics.

Local Clear Language Display

The Local CLD (Clear Language Display) resides at the Chiller providing a display of chiller data and access to operator/serviceman controls, set points and chiller setup information. All information is stored in non-volatile memory in the Chiller module. The Local Clear Language Display and the Chiller module work together to display and store information requiring non-volatility.

Remote Clear Language Display Panel and Remote Clear Language Display Interface Module

As an option, the Remote Clear Language Display permits the operator to remotely operate 1-4 chillers. The Remote Clear Language Display Panel works like the Local Clear Language Display with two exceptions, (1) a Local Stop command takes precedence over all other remote or external devices, and (2) the Remote Clear Language Display's Custom Report and display language are independent of the Local Clear Language Display Panel.

Options Module

The Options module satisfies control or interface requirements for a number of options. Some of these options are stand alone, such as Generic BAS Interface; other options support either additions or modifications to the chiller itself, such as Free Cooling. Features supported by the Options module include Ice-Making, Heat Recovery, External Chilled Water Setpoint, and External Current Limit Setpoint.

Module Setpoints relating to the options module:

1. %RLA compressor output (J7 3,4) 2-10 VDC out; 2 VDC = 0% RLA; 10 VDC = 120% RLA

2. External current limit input (J7 11,12) 2-10 VDC or 4-20 mA in; The range is 40% to 120% RLA.

3. External chilled water setpoint. Input (J9 4,5) 2-10 VDC or 4-20 mA in; The range is 0 to 65°F.

Tracer Communications Interface

TCI COMM 3 is an optional module that provides a 1200 baud isolated communications link to TRACER.

TCI COMM 4 (Tracer Summit) is an optional module that provides a 9600 baud non-isolated link to Summit.

Printer Interface Module

The Printer Interface module provides a pre-formatted chiller log to a printer. The Printer Interface can be programmed via the Clear Language Display to print a chiller log on command, at the time of a diagnostic, and/or on a periodic basis. Each printed event is time and date stamped.

The *preferred* printer to be used is Okidata Microline 184 Turbo. Serial cables required are (DB25 male to DB9 Female). The maximum distance allowed between the printer module and the printer is 50 feet.

Secondary Printer Options

Epson: not all Epson printers support serial communications. For a low cost printer that does support serial communications, Epson recommends the LX810 Printer with the Serial interface option (C823032).

IBM ProPrinters: Use either the "2380' + or the "2390+' along with the Serial interface option "1363110".

Other: Any printer/computer with 232 capabilities should be capable interfacing with the TCI Printer module (allowing for different cables and jumper configurations).

Duplex Control Module (DCM)

Duplex control is accomplished by the Duplex Control module that resides in the downstream Unit Chiller "A". It's tasks are setpoint control (chilled water and current limit) and compressor staging. All other setpoints are controlled at each individual compressor UCP2 Clear Language Display panel. Each unit can be reset or stopped separately through each CLD. The dip switch setting on the board is ON-OFF-ON. IPC communication with the downstream chiller "A" panel connects to J1, 1 & 2. IPC communication with the upstream chiller "B" panel connects to J3, 1 & 2.

General Troubleshooting Information

Problem 1: AFD (adaptive frequency drive) diagnostics

Corrective Action:

1 Correctly input all AFD parameters called out and specified in the AFD Operation Maintenance manuals, such as AFDA-OM-1 and AFDB-OM-1.

2 Review and follow the specific trouble shooting sections of the appropriate drive.

Problem 2: Failure to accelerate or did not accelerate

Corrective Action:

1 Set the appropriate acceleration Timers 1 and 2 in machine configuration menu.

2 Set correct starter type in machine configuration menu.

3 Replace defective CTs.

4 Defective Starter module, ct input. Replace Starter module.

5 Defective IGV linkage.

6 Defective Stepper module.

7 Fast Restart. Change Starter to a X-13650453-16 or newer and Chiller modules. For X-13650450-15 or newer, reference Trane *CVHE-SB-46.*

Problem 3: Approach Temperature reads -40°F

Corrective Action:

1 A CLD X-13650448-04 or newer is required with a Chiller module X-13650450-04 or newer.

Problem 4: Auto X-former starter: Runs (3) seconds and trips. Unit will not transition.

Corrective Action:

1 Verify Starter module. If X-13650453-07 or later, it requires transition circuit.

2 No voltage on transition complete J4 circuit. Trace circuit path. Reference Trane *CVHE-SB-36.*

Problem 5: IGV BPI not found or low

Corrective Action:

1 BPI switch location may have changed. Reposition/calibrate BPI switch.

2 Defective BPI switch and/or wire.

3 Incorrect Stepper motor wiring.

4 Replace the Stepper module.

5 Correctly program the BPI maximum travel setpoint in service settings.

Problem 6: Bearing Temperatures 1 and 2 Locations.

Corrective Action:

1 Bearing temperature I (Stepper module J5-5, 6) goes to the front Journal bearing.

2 Bearing temperature 2 (Stepper module J5-7, 8) goes to the rear Thrust bearing.

Problem 7: Capacity Limited by High Current when the phase current as read from the Compressor report reads zero amps. Getting this message during the run mode.

Note: The Chiller module takes the three phase currents as sent by the Starter module, selects the highest one and limits based on this.

Corrective Action:

1 Check the phase currents as displayed in the Compressor Report.

2 Check the Active Current Limit Setpoint. It is possible it is a very low value or even zero amps is loaded in.

3 If the current limit source is the external current limit setpoint, check this input on the Options module.

Problem 8: Current Overload

Corrective Action:

1 Correctly program in the overload information in the machine configuration menu.

2 Defective CTs.

3 Check CT wiring and polarity.

4 Check for the correct number of turns through the CTs.

Problem 9: Chiller Loss of Communication with Circuit module and IGV overdriving close.

Corrective Action:

1 IPC to Circuit module disconnected or reversed.

2 Circuit module not powered.

3 Verify that a good ground exists between all modules including the CLD that needs a dedicated green wire ground.

Problem 10: Check Clock (IFW) Informational Warning Diagnostics. On a loss of power, the clock does not keep time if there is an extended power loss (greater than 15 seconds).

Corrective Action:

This diagnostic is shown in active diagnostic menu.

Note: If you clear this IFW diagnostic while the machine is running, you will shut down the unit. Wait to clear the diagnostic when the unit is off.

Problem 11: Chiller Loss of Communication with Starter and the IGV calibrates.

Corrective Action:

1 IPC to Starter module disconnected or reversed.

2 Starter module not powered up.

3 Verify that a good ground exists between all modules including the CLD that needs a dedicated green wire ground.

Problem 12: Chiller Loss of Communication with Starter or Circuit Loss of Communication with Chiller Diagnostics

Corrective Action:

1 The 120 VAC side of the 3KVA transformer should be grounded at only one spot and it is in the Starter. Both the 120 VAC and the 24 VAC in the UCP should not be grounded.

2 Verify the IPC wire is shielded twisted pair between the Starter and Chiller modules and its shield is grounded at J1-6.

3 Verify there is a dedicated ground between the remote starter and the chiller.

4 Verify that a good ground exists between all modules including the CLD that needs a dedicated green wire ground.

Problem 13: Clear Language Display won't go into Demo mode.

Corrective Action:

1 You must press Custom report and Compressor report at the same time while the display is showing software part number on power-up. It will not go into Demo mode if there is IPC communication.

Problem 14: Communication diagnostic; None or Degraded Communications.

Corrective Action:

1 Starter module must have the A phase on pin 2 of J2 24 Vac

2 IPC wires must be connected

3 IPC wires must have correct (+ -) polarity on J1.

4 The TCI and CLD modules have LEDs to indicate the sending and receiving of chiller packets. Green (RxA) is receive and should be blinking constantly. Red (TxA) is send and blinks every 1-2 seconds.

Problem 15: Loss of Communication with Starter Diagnostics at Startup with no Inlet Guide Vane action. Mode is "Resetting" and can move through the menus.

Corrective Action:

1 IPC to Starter module disconnected or reversed

2 Starter module not powered up.

3 Verify that a good ground exists between all modules including the CLD that needs a dedicated green wire ground

Problem 16: Loss of Communication or Intermittent Communication between any of the modules. (Chiller, Starter, Tracer, Circuit, Stepper, Options, Purge, etc.)

Corrective Action:

1 Verify the Chiller and CLD versions are compatible with Tracer.

2 Reference Trane *CTV-CSB-90* and *92* for module compatibility numbers.

3 ICS address at CLD should match with Tracer.

4 Are the DIP switches set correctly? They should be all off for COM 3; OFF-ON-OFF for Comm 4.

5 In the Tracer module, verify the IPC LEDs near J1 are blinking. Red LED is transmit and should be blinking constantly showing lots of IPC action (even if not for the TCI). The green LED is for receive and should only be blinking rapidly in a row once every 1-2 seconds which is the IPC cycle time.

6 Verify the COM 3 LEDs near J3 are blinking. Red LED is transmit and should be blinking showing lots of COM 3 action (even if not for the TCI). The green LED is for receive and should only be blinking rapidly in a row once every minute which is the Tracer cycle time.

7 The Starter module or other modules are not grounded well. The IPC needs the modules to be grounded together.

8 Go to service test menu and verify that Chiller thinks a TCI 4 is installed.

9 Look at the voltage of each line with respect to ground. A logic 0 should be .5 V or less; a logic 1 should be 4.5 volts or more.

~ For COM 3 lines less that 1000 Ft., a 300 Ohm terminating resistor put across the two wires is needed. Install the resistor first at the chiller end of the link.

~ Radio frequencies generated from sources like airplanes and radio towers may be inducing noise in the communication lines. Tie matched capacitors of around 200pF at either ends or both ends from each line to ground.

10 De-install TCI option and power up and see it self install within 10 seconds. If not, something is wrong in TCI module.

11 De-install Tracer option and power up and see if it self installs within three minutes. If not, something is wrong with the Tracer side.

12 Tracer option is self-installed. No need to enable it manually. If enabled manually and no Tracer on the communication line, then a Loss of Communication with Tracer will be called. If a Tracer is put on communication line, then communication side diagnostics are called: Loss of Communication with Tracer.

Problem 17: ***No Communication, on a power up, get message "No Communication, Data Not Valid" and no action in the IGV.***

Corrective Action:

1 Chiller module not powered up.

2 IPC to Chiller module not connected.

3 IPC shorted.

4 Disconnect all modules from the IPC to CLD except the Chiller module. If a communication is established, try plugging one of the other modules one at a time. When it then fails, this module is pulling down the line.

- ~ Check the LEDs at the rear of the CLD. The left one is "TEST and should be on if all is normal.
- ~ The second LED from the left is the "+5VDC" and should be on all the time if all is normal.
- ~ The third LED from the left is the transmit and should only blink rapidly every 2 seconds when the CLD talks on the line.
- ~ The fourth LED from the left is the receive and should be blinking rapidly all the time since there is constant bus action.
- ~ Verify that the CLD is grounded to the other modules.
- ~ Module Grounding Problem. On the Starter module DO NOT ground the IPC. IPC is grounded at the Chiller module.

Problem 18: ***No Communication, on a power up, get message "No Communication, Data Not Valid" but the Inlet Guide Vane calibrates.***

Corrective Action:

1 IPC to the Local Clear Language Display reversed.

2 IPC to Local Clear Language Display disconnected.

3 Verify that a good ground exists between all modules including the CLD which needs a dedicated green wire ground.

Problem 19: ***Starter Loss of Communication with Chiller. No other diagnostic.***

Corrective Action:

1 Verify IPC connections are good to Starter module and cable is shielded. Chiller module X-13650450-01 is not compatible with Starter module X-13650453-02 and later.

Problem 20: ***TCI Loss of Communication with Chiller.***

Corrective Action:

1 Need a X-13650460-02 or newer TCI module.

Problem 21: High compressor Discharge temperature
The compressor discharge temperature exceeded 200°F.

Corrective Action:

1 Check unit operating conditions for something that would generate high gas discharge temperatures, such as condenser water flow.

2 Extended operation in hot gas bypass. Set the hot gas bypass timer lower.

Problem 22: ***Cond. Pressure 2-10 VDC output will not work.***

Corrective Action:

1 The Chiller module must be a X-13650450-04 or later. Earlier versions did not support this option.

2 Check wiring between transducer (located near the purge) and the Circuit module J7.

3 Faulty transducer (See ***Transducer Checkout procedure)***.

Problem 23: Condenser Pressure Delta-pressure output does not show up.

Corrective Action:

1 In the service settings menu, enable% condenser.

2 The Circuit module must be X-13650451-10 or greater.

3 The chiller module must be X-13650450-09 or greater.

4 Clear language display must be X-13650448-09 or greater.

Problem 24: Cond. Refrig. Temp. Sensor diagnostic, when the displayed Cond. Refrig. Temp. is reading fine.

Corrective Action:

1 Chiller software found in X-13650450-01 Rev. D or earlier mis-diagnosed Cond. Refrig. Press. Replace with new Chiller module.

Problem 25: Condenser and Evaporator entering and leaving water temps. changing rapidly and reading incorrectly, i.e. -25°F to 900°F.

Corrective Action:

1 Bad Chiller module; it must be replaced.

Problem 26: Condenser Water Flow lost diagnostic. Unit will not restart until manually reset.

Corrective Action:

1 Phase A and B Chiller module software were actually an MMR. Phase C (X-13650450-04) changed to a MAR. Time changed from 3 minutes to 4-1/4 minutes.

Problem 27: Capacity limited by current limit

Corrective Action:

1 Correct overload settings.

2 Check for correct number of turns through the CTs.

3 Starter module ct input bad.

4 Defective CT.

Problem 28: Custom menu - Unwanted items that you did not install and you cannot remove.

Corrective Action:

1 The initial problem was if you had installed an option, put it in the Custom menu, then de-uninstalled it without first removing it from the Custom menu.

Problem corrected on CLD X-13650448-02, Rev. E.

Problem 29: Display is locked up. No communication, Data Not Valid Diagnostic.

Corrective Action:

1 Check the (4) LEDs on the back of the CLD. Left to right.

- ~ #1 is the Test Light and should be on all the time.
- ~ #2 is the 5VDC and should be on all the time.
- ~ #3 is the Transmit and should blink every 2 seconds.
- ~ #4 is the Receive and should blink continuously.

2 There may be a IPC communication problem with one of the boards. Disconnect the IPC from all modules except leave the IPC connected from the CLD to Chiller module. Start connecting the IPC at one at a time until we find which one is the problem.

3 Check the Chiller module 24 VDC, 5 VDC and 24 VAC.

4 Check the CLD (Clear Language Display) grounding. It has to be grounded from the clear language display to the chassis/back panel.

5 Starter module IPC should not be grounded. Ground is on the Chiller module end. A double ground will lock up the display.

Problem 30: Display on the CLD is flashing.

Corrective Action:

1 The +5V LED should also be flashing.

2 Verify the 24 VAC delivered to the CLD is within range of 20-28 VAC. Disconnect the IPC to verify it is not causing this.

Problem 31: External Chilled Water Setpoint Problems.

Corrective Action:

1 Polarity must be (minus) (plus) on J9 4,5 of the Option module.

2 If the 4-20 MA and the 2-10 VDC are out of range, the active chilled water setpoint source reverts back to front panel and does not work. The 4-20 mA and 2-10 VDC corresponds to 0 to 65°F.

3 Setpoints: SW3-1 should be: OFF for 2-10 VDC and ON for 4-20 mA

4 Chilled Water Reset type is Disabled.

5 Chilled Water Setpoint source is External.

6 Setpoint source override is None.

7 External Chilled Water Setpoint is Installed in machine configuration.

8 Clear any active options module diagnostics.

9 Input type must be selected in the field start-up menu.

10 May need to install an isolation device (DC to DC converter),

11 Set to 2-10 VAC and hook an 8-volt battery to the input to verify the module works.

Problem 32: External Current Limit setpoint does not work.

1 Polarity must be (-, +) on the option module J7 11,12.

2 Isolated 2-10 VDC or 4-20 mA analog input is required. The 2-10 VDC and 4-20mA corresponds to 40% to 120% RLA.

3 SW2,1: OFF for 2-10 VDC and ON for 4-20 mA.

4 Current limit setpoint source: set to external.

5 External current limit setpoint: set to installed.

6 Setpoint type: 2-10 VDC or 4-20 mA. Input type must be selected in the field start-up menu.

7 May need to install an isolation device (DC to DC converter),

8 Set to 2-10 VAC and hook an 8-volt battery to the input to verify the module works.

Problem 33: Fault Relay open on an AFD (air cooled adaptive frequency Drive)

Corrective action:

1 In machine configuration, check for correct starter type.

2 Wiring problem on the drive.

3 2U2 logic module problem.

4 Starter module.

Problem: 34 Fault relay open on Solid State Starter (SSS)

Corrective action:

1 Bad SSS fault input on Starter module. Replace Starter module.

2 Wiring problem to Starter module.

3 Program correct starter type in machine configuration.

4 Set the correct HPC setting in machine configuration.

5 Replace the HPC.

6 Replace the Circuit module. Faulty HPC input.

Problem 35: Free cooling (FC) operation problems.

Free cooling can be controlled manually from the front panel or automatically via a on/off binary input (called external free cooling switch) at the Options module.

Corrective action:

1 Free cooling can be entered via an on/off switch manually at the front panel automatically via an on/off switch input called external free cooling switch on the Options module J3 5,6

2 Free cooling cannot be entered if the unit is in the stop mode, it has to be entered from the auto mode. You cannot use the Manual vane control in free cooling.

3 If the chiller is in auto, and not running the UCP2 will start the condenser water pump just as with the powered cooling.

4 Once the condenser water pump is running and confirmed. The FC valve relays #1 & #2 and the FC aux relay are all energized. If the FC valve-closed limit switches do not close within 3 minutes, a MMR diagnostic will be generated.

5 If the chiller is in auto and running powered cooling, the chiller will do a normal friendly shutdown when the FC command is given before going into FC.

6 FC can be terminated from either the front panel, external switch input or Tracer.

7 Enable free cooling in machine configuration menu.

8 Install compatible modules.

9 Connect power and IPC to the options module.

10 Defective Options module.

11 Free cooling actuator.

Problem 36: Evaporator Water Temperatures are reversed (2 pass units only).

Corrective Action:

1 Reverse the sensor leads at the module.

Problem 37: Low Evaporator refrigerant temperature

Corrective action:

1 Defective Stepper module.

2 Missing or incorrect wiring to Stepper module.

3 Defective sensor.

4 Unit charge.

Problem 38: 2F1, 2F2 and 2F3 Fuses blow - On 200-575 volt units when switching the starter disconnect from OPEN to CLOSED.

Corrective Action:

See Trane manual *CVHE-CSB-31*

Problem 39: GPM/Tonnage option problems

Corrective action:

1 Correct Flow Coefficients and Exponents settings.

2 Reference Trane service bulletin *CHVE-CSB-45C*. For upgrade modifications, CLD X-13650782-01 or newer is required to see all new screens. Updated chiller module X-13650450-15 or newer is required.

3 Install GPM/tonnage option in machine configuration.

4 Debris in the strainers.

5 Defective transducer.

6 Defective Chiller module.

7 Automatic calibration performed.

Problem 40: High Vacuum Lockout

Corrective action:

1 Select correct refrigerant type in machine configuration.

2 Check and correct oil sump pressure transducer wiring.

3 Program correct local atmospheric pressure.

4 Replace the oil sump pressure transducer.

5 Replace the Circuit module, bad oil sump pressure input.

6 Replace Circuit module. Software improvement in modules X-13650451-12 and greater.

Problem 41: Hot Gas Bypass (HGBP) Does Not Work.

Corrective Action:

1 Module Compatibility:

- ~ Chiller must be X-13650450-04 or newer
- ~ CLD module must be X-13650448-05 or newer
- ~ Option module is X-13650452-01 or newer.

2 Hot Gas Bypass Option must be installed in the machine configuration. Installing HGBP control sets up the display features associated with HGBP.

3 Hot Gas Valve Control in the service test menu must be in the Auto Mode.

4 Hot Gas Bypass Control enabled in the field startup group. With this enabled, the IGV target% screen comes up along with the HGBP timer. Enable and Maximum HGBP time.

5 IGV target% has a default of 10%. This is a good place to start. The goal is to keep the unit out of surge.

6 The Inlet Guide Vane must be closed or at a minimum to go into Hot Gas. Set the guide vane travel stop in the service settings. ROM default is 0%.

7 The Chilled Water Setpoint minus the actual chilled water temperature must be 0.6°F or greater, i.e., Setpoint of 45°F and leaving temperature of 44°F for more than 20 seconds would show the need for Hot Gas.

8 Verify the Hot Gas Timer is installed and max HGBP time is greater than zero.

9 Verify that the module software numbers are being displayed in the Service Test Menu.

10 Verify that the IPC Communications wire is connected to J1 of all modules and we have good 24 VAC and 5 VDC.

Problem 42: *Ice Making*

UCP2 will accept a contact closure (Options module J3 7,8) input to initiate Ice building. When in ice making the compressor will be fully loaded.

Corrective action:

1 Enable ice making in machine configuration.

2 Binary input required on the Options module J3 7,8. If you enter ice making externally or a remote communicated input (Tracer) to initiate ice building.

3 Operator settings:

- ~ Ice building enable. DO NOT enable this or you will not be able to exit ice building. ROM default is disable. *NOTE: This is typically used by Service to manually enable ice making.*
- ~ Set Front panel ice termination setpoint. ROM default is 27°F
- ~ Set the ice making to normal cooling transition timer. ROM Default is 5 min.

4 Ice building shall be able to be terminated by one of three methods:

- ~ Opening the external ice contacts/remote communicated (Tracer)
- ~ Satisfying an evaporator entering water temperature setpoint
- ~ Surging for 15 minutes.

Problem 43: IGV will not move in the Service Test Manual mode.

Corrective Action:

1 Verify the CLD LED comes on solid. Verify there are no Stepper module diagnostics.

2 Verify we are in a Stop mode, Diagnostic Stop mode, or Run mode. All other modes the Manual Vane Control will not work.

3 Is the IGV travel percentage increasing? If so there is a problem with the motor or Stepper module drive circuit.

4 Are we in a "Stop" mode after being in a Limit mode. The limit bit may be set so do a power down to clear.

5 Will not work in post lube or initialization in preparing to start.

6 On power up, does the Stepper module do a BPI search? If not, the Stepper module could be held up in the Initialize mode internally. On a power up, the Stepper module looks for communication with the Chiller, Starter and Circuit modules. If it doesn't hear from any one of them, it stays in the Initialize mode and will not do BPI or Manual Vane Control. If no BPI, check the IPC wiring. Also, if trying to start the chiller, the mode will stay in initialize.

Problem 44: IPC Buffer Diagnostics

Corrective Action:

1 Clear Language Display is not communicating. Replace the CLD or the Chiller module is not communicating and needs replacing.

Problem 45: KW reads high by a factor of 3, with optional PT installed.

Corrective Action:

1 Software change made 11/93 to CLD. X-13650448-02 Rev. E or later corrects the problem.

Problem 46: Loading Problems

Corrective Action:

1 Unit is in External Stop and when released, requires 3.5 minutes to get the vanes to desired point of operation (typically 50 degrees). This is close to the maximum rate that the compressor can load because the fastest the vanes will move is 1250 steps every 5 seconds.

2 If Soft Load Control is Enabled, the Soft Control parameters can be adjusted to meet the requirements of the system. If the chiller is allowed to ramp up faster than needed it could over shoot the leaving chilled water temperature setpoint and potentially be current limited. If this overshoot is too rapid and causes excessive current draw, the adaptive control will force an unload to approximately 70%. This could cycle several times before stabilizing.

   If Soft Load Control is Disabled or the loading is not from initial startup, The LWT Control Proportional, Integral and Derivative gains can be adjusted to allow system adjustment to properly follow the load. Typical changes should be small. 1-2% proportional gain change or 0.01% integral gain changes. Always adjust proportional gain first. This is the coarse adjustment, while integral is the fine and derivative is the micro adjustment.

3 Item 1 reference the mechanical limitation of the stepper motor while the software limitation is a pulldown rate of 5°F/minute of the leaving water temperature. This maximum cannot be overridden.

Problem 47: Memory Error

Corrective action

1 Replace the Chiller module.

Problem 48: Momentary Power Loss (MPL)

Momentary power losses are temporary interruptions in the power being delivered to the motor. The UCP2 monitors MPL by measuring currents from phase A and C and by monitoring the 24 VAC input power to the Starter module (terminals J2 1,2. Since the UCP2 is looking at actual power flow into the motor, it needs the relationship of voltage and current. MPL is active anytime the compressor is running, but not on startup.

Corrective Action:

1 MPL is active for the Run mode, not in the Start mode.

2 CT wiring on J5 of the Starter module must be wired White-Black per print and Phase A must be on Terminals 1 and 2, Phase B on 3 and 4 and Phase C on 5 and 6. CT polarity must be correct.

3 Wrong CTs installed.

4 Check phasing of the supply voltage. The "A" phase must be delivered to J2-2 of the Starter module. 24 volt AC polarity must be correct.

5 Look at the voltage on J2 for noise. J2 should be a smooth 24 VAC sine wave. If we get electrical noise from things such as inverters or high frequency generators, you will see noise blips off the sine wave.

6 Verify the polarity of the CT circuit is correct. For single CT circuits the White wire must be connected to J5-5 with the dot on the CT facing the line. For dual CTs. The "HI" polarity dot on the line CT must be facing the line, the Brown wire from the X-13650266 transformer primary connected to XI and the White wire from X-13650266 secondary connected to J5-5.

7 Verify that there is voltage delivered to the J6 terminal, if not check the HPC circuit, circuit breaker or Starter Interlock.

8 Check for loose wires.

9 Check the wiring from J8 to 2K1 Coil and Auxiliary.

10 Two wiring errors will allow you to start and go out on Momentary Power Loss when the unit loads up. The CTs and 24 VAC may be wired up improperly. As the loading is changed due to vane movement, then MPL may be called. If the unit starts and runs for a period of time before tripping on MPL (on a regular basis), you probably have one of two issues. Either 2 wiring errors (i.e., polarity on J2 and CT wiring error) or line noise on the incoming J2 24 VAC.

11 Defective HPC (high pressure control).

12 PFCCs installed incorrectly.

13 If the unit trips on Momentary Power Loss, vanes stay where they were and then restart without going through a Vane Closure or BPI search, two modules need to be changed:

- ~ Chiller module needs to be a X-13650450 -04 or newer.
- ~ Stepper module must be X-13650455-04 or newer.

14 Starter module X-13650453-13 and greater have a less sensitive MPL diagnostic trip point.

Problem 49: Motor winding temperatures changing rapidly and randomly.

Corrective Action:

1 Electrical noise problem in the Circuit module. X-13650451-04 Rev. D or later corrects the problem by adding a filtering circuit.

Problem 50: Differential Oil Pressure Calibration Diagnostic following post lube. Secondary problem may be the oil pump will not shut off after post lube.

Corrective Action:

1 Diagnostics are active in all non-running modes and the unit has been off for 5 minutes. The UCP2 calibrates the oil pressure sensors and if an error is found greater than 3 PSID a diagnostic is called out.

- ~ Sensors
- ~ Changing system pressures caused by such things as a pressure or changing water temperatures.

2 If the oil pump is running and will not shut off in post lube, the problem is a wiring error on the Starter module. One or both of the following apply.

- ~ 115 VAC is connected to terminal J6-3 of the Starter module. Check to see if it was connected incorrectly to Terminal J3-1.
- ~ Terminal J8 on the Starter module. J8-1 (Wire #13) goes to the 2K1 Contactor. J8-2 (Wire #15) goes to 2K1 Auxiliary. Check to see if Wire #13 and Wire #15 are reversed.

Problem 51: Differential Oil Pressure

On Circuit module revision X-13650451-13 and newer, has a positive oil pressure trip at 2/3 the setpoint with a default setpoint 12 psig and a minimum of 9 psig setpoint.

Corrective Action:

1 The Circuit module was clearing the 3 minute oil pressure establish timer during a remote RESET. This would result in an Oil Pressure Overdue diagnostic. (Exists for Circuit modules X-13650451-06 and earlier).

2 Faulty oil pump motor.

3 Faulty 1F2 fuse.

4 Faulty Circuit module relay output.

5 Faulty oil pump capacitor.

6 Faulty oil pump sensor and/or wiring.

7 Clogged oil filter.

8 Faulty oil pressure regulator.

9 Differential oil pressure when the unit is off. The unit sees current due to Feedback via the PFCCs or CTs. We get a starter interrupt failure. The UCP2 thinks the motor is running and brings on the oil pump and logs differential oil pressure diagnostics.

Problem 52: Oil temperature High.

Corrective action:

1 Check oil temperature setpoint in service settings.

2 Bad Circuit module heater relay output.

3 Defective oil temperature sensor.

4 Compressor bearings.

5 Oil cooler.

Problem 53: Oil temperature Low (Startup)

Corrective Action:

1 Defective Circuit module relay output.

2 Oil temperature sensor.

3 Replace oil heater.

4 Raise the oil temperature setpoint.

5 Excessive refrigerant in the oil. Check the oil eductor valve. It should be 2 turns open.

Problem 54: Low Oil Temperature (Running)

Corrective Action:

1 The refrigerant pump shaft seal is leaking. Remove the refrigerant pump volute and impeller. Check and replace the shaft seal.

2 The oil tank is being flooded with excessive refrigerant. Check the oil eductor valve (evaporator to oil tank line) at the evaporator. Close it and open 2 turns. If the chiller is exposed to outside ambient/cold temperatures, it may be overcooling the oil/tank, in which case the tank needs insulating.

3 The oil tank heater is off when the unit is running (*Trane Service Alert 206*). A UCP2 software change was made 6/98 so that the chiller is allowed to operate at a condition of saturated evaporator temperature plus 30°F. Take this into consideration when diagnosing this problem. Look at the saturated evaporator temperature to see where your are in operation.

Problem 55: Enhanced oil temperature function not working.

Correction Action:

1 Enable enhanced oil temperature in the service setting menu (the default is enabled.) If enhanced oil temperature is disabled, you will get two additional screens to set oil temperature setpoint and low oil temperature setpoint.

2 Chiller module X-13650450-12 or greater is required.

3 Circuit module X-13650451-13 or greater is required.

4 CLD X-13650448-11 or greater is required.

Problem 56: Oil Pump Discharge Pressure Sensor Diagnostic and Oil Pressure Calibration.

Corrective Action.

Chiller is in a high vacuum where one or both of the transducers reads -14.9 psig.

This is out of range and thus a sensor diagnostic is being called. The diagnostic may be cleared once the chiller is charged.

Problem 57: Over/Under Voltage Diagnostic on Startup.

Overvoltage is a + 10% must hold and +15% must trip. Undervoltage is a must hold –10% and must trip –15%.

Corrective Action:

1 Check main power supply and wiring.

2 You may get the diagnostic with the following Setup Sequence.

- ~ Unit Line Voltage enabled in Machine Configuration.
- ~ Under/Over Voltage is enabled in Field Startup.
- ~ If you then disable Unit Line Voltage, the Under/Over Voltage screen disappears but is still active. You have to then re-enable Unit Line Voltage in Machine Configuration and disable Over/Under Voltage.

3 Over/Under Voltage is used only with PTs installed. If you enable the option with "No" PTs installed you will get the diagnostics.

4 When the Line Voltage Sensing Option is not installed, the Unit Line Voltage menu item is not displayed nor is the Under/Over Voltage option installed.

Problem 58: Phase Loss

There are 2 variations of this diagnostic:

Less than 10% current was sensed on one or more of the current Transformer inputs. Time to trip is 1 second minimum, 3 seconds maximum. This is a MMR diagnostic.

A second and less common method of receiving phase loss diagnostic is via the phase reversal protection circuit of the Starter module. Phase rotation protection is enabled and either the Phase A current signal or the Phase C current is less than 5% of the CT rating, then phase loss will be called out. Time to trip is 0.7 seconds for CTV during start.

Corrective Action:

1 CT hooked incorrectly relative to incoming power.

2 Defective Primary CT (See ***CT Checkout Procedure***).

3 120 VAC missing from the Stop Relay circuit on J6 of Starter module.

4 Defective High Pressure switch. Wire may be off.

5 Problem in the Start Relay circuit on J8 of Starter module. Check all connections and circuit.

6 Verify currents are over 10% RLA.

7 Check the current overload settings.

8 Defective Starter module.

9 Turns through the CTs may be incorrect.

Table 1
CT's for more than 600V or more than 936A systems:

Motor RLA	CT Part Number	CT Terminal Connections	Number of primary turns
8.0-11.9	X-13580272-01		3
12.0-17.9	X-13580272-01		2
18.0-23.9	X-13580272-02		2
24.0-35.9	X-13580272-01		1
36.0-47.9	X-13580272-02		1
48.0-72.0	X-13580272-01		1
24-36 A	X-13580048-01	X1 to X2	3
28-43 A	X-13580048-01	X1 to X3	3
36-54 A	X-13580048-01	X1 to X2	2
43-64 A	X-13580048-01	X1 to X3	2
48-72 A	X-13580048-01	X1 to X4	2
60-90 A	X-13580048-02	X1 to X2	2
72-108 A	X-13580048-01	X1 to X2	1
86-129 A	X-13580048-01	X1 to X3	1
96-144 A	X-13580048-01	X1 to X4	1
120-180 A	X-13580048-02	X1 to X2	1
144-216 A	X-13580048-02	X1 to X3	1
168-252 A	X-13580048-02	X1 to X4	1
192-288 A	X-13580048-03	X1 to X2	1
240-360 A	X-13580048-03	X1 to X3	1
288-432 A	X-13580048-03	X1 to X4	1
336-504 A	X-13580048-04	X1 to X2	1
384-576 A	X-13580048-04	X1 to X3	1
480-720 A	X-13580048-04	X1 to X4	1
480-720 A	X-13580047-02	X1 to X2	1
576-864 A	X-13580048-05	X1 to X2	1
576-864 A	X-13580047-02	X1 to X3	1
720-1080 A	X-13580048-05	X1 to X3	1
720-1080 A	X-13580047-02	X1 to X4	1
864-1296 A	X-13580047-01	X1 to X2	1
1008-1512 A	X-13580047-01	X1 to X3	1
1200-1800 A	X-13580047-01	X1 to X4	1

10 Defective SCR in a solid state starter.

11 Clean or replace contactor contacts

12 Check the Starter Wiring diagram for other components i.e., power monitoring devices that may be causing phase loss.

13 The Starter contactors may be too slow to respond to the Start signal. Disabling the phase rotation will give us more time by taking out the 0.7 highly aggressive circuit but keeping in the primary phase protection. For Starter software X-13650453-04 Rev. K, the time for detection of the highly aggressive circuit changed from 0.3 to 0.7 seconds.

Problem 59: Severe Phase Unbalance

Three currents supplied to the Starter module are monitored for unequal Amp draw. An imbalance in the motor amp draw can cause the motor windings to heat up. This protection can not be disabled or removed. The Starter module phase unbalance protection was made less aggressive in starter module X-13650453-09 or later, when the current unbalance trip point was increased from 25% to 30%.

Corrective Action:

1 Check for defective or incorrect CTs.

2 Replace Starter module with improved software with X-13650453-08.

3 Replace Starter module, for possible bad CT input.

4 Local power company problem.

Problem 60: Phase Reversal

Corrective Action:

Phase Rotation Protection is based on clockwise ABC Phasing. UCP2 picks up current phasing through the Starter module Terminal J5. Four possible causes are:

1 Phases actually reversed

2 Noise on the Link which may inject an illegal state

3 Bad contactor or all the lighting on (1) circuit/phase or (2) of the CT wires reversed on J5.

4 Two of the CT wires reversed on J5.

Problem 61: Printer will not work.

Corrective Action:

1 Verify printer is compatible with a serial 9 pin RS232.

2 Verify printer setup in the CLD is correct. Machine Configuration Menu: Printer Option is Installed. Service Settings Menu: Set Baud Rate, Parity, Data Bits, Stop Bits, Handshaking. For Handshaking: XON/XOFF is recommended.

3 Verify the printer settings match the CLD setup. Baud Rate, Parity, Data Bits, Stop Bits, and Handshaking must be the same as in the CLD.

4 Verify the printer interface is working properly.

- ~ Verify there is IP communication
  - ~ RxA (Green LED near J1) is IPC receive and should be blinking
  - ~ TxA (Red LED near J1) is IPC transmit and should not be blinking

- ~ Diagnostic LED (Red) is OFF
- ~ Check DIP switches, they should be OFF-OFF-ON
- ~ RxB (Green LED near J3) is printer receive and should be OFF
- ~ TxB (Red LED near J3) is printer transmit and blinks only when printing

5 Check the printer cable. Usually a 9-25 pin cable with RX (receive) to Rx, and Tx (transmit) to Tx connections.

6 Try to print manually (in Operator Settings menu).

Problem 62: Purge Compressor will not run in the manual "ON" mode.

Corrective Action:

1 In the Operator Setting menu, select "ON" for Purge Operating Mode. Note that "ON" means that the purge compressor and condenser fan will run. The pumpout motor will run only when the Purge Suction temperature gets below 18°F and turns off when the temperature gets above 22°F.

2 If you get "Purge Pumpout Rate Exceeded" message then go to the Service Settings menu, go to Field Startup Group and set "Purge Service Excessive Pumpout Outride Timer" to the amount of time you would like the pump-out motor to run without it incrementing the pumpout rate. The maximum allowed time is 72 hours. When this time is reached, you will get the "Max Pumpout Rate Exceeded" message.

3 Clear all purge diagnostics.

Problem 63: Sensor errors

You may get sensor errors such as: evaporator water temperature, condenser water temperature, outdoor air temperature, condenser or evaporator refrigerant temperature sensor.,motor temperature, discharge temperature, oil temperature or purge suction temperature.

Corrective Action:

1 Check sensor installation.

2 Replace sensor.

3 Check all sensor wiring and connections. Depending on the sensor and which module it connects to, you may have a bad module such as the Chiller, Stepper Circuit Or Purge.

Problem 64: Transition resistors stay in too long.

Corrective Action:

1 If the J8 terminal on the Starter module is loose, the control does not latch in and extends the timing keeping the resistors in longer. Reference *Trane Service Bulletin CVHE-CSB-35.*

Problem 65: Setpoints are not being stored, service tests will not work and we are calling many diagnostics on the CLD.

Corrective Action:

1 IPC to Starter module disconnected or reversed.

2 Starter module not powered up.

3 One wire of the IPC is not connected.

Problem 66: Starter Contactor Interrupt Failure Diagnostic when powering up the UCP.

Corrective Action:

1 Starter module is sensing motor current greater than 10% RLA when motor should be OFF on a power up or in OFF state.

2 Starter module is sensing motor current greater than 10% RLA .68 Sec. after initiating a shutdown.

3 Look at phase currents as read in the Compressor Report.

4 If power factor correction capacitors (PFCCs) are used, these capacitors should be placed on the motor side of the 2K1 and 2K2 contactors so as to be disconnected from the line when the motor is off.

5 Replace the Starter module. Could be a software problem or bad module.

6 Contactor or contactor wiring problem.

Problem 67: Starter Dry Run Test Diagnostic upon entering a Starter Dry Run Test.

Corrective Action:

The Starter module is sensing either the presence of line voltage from the PTs or line current from the CTs.

Problem 68: Starter Dry Run will not work.

Corrective Action:

1 If the PTs are installed, they sense voltage and prevent dry run.

2 A major diagnostic is present.

3 Unit is not in Stop mode.

4 Starter senses the presence of currents.

5 There is a MMR diagnostic present.

Problem 69: Starter Fault type 1, 2 or 3

Corrective Action:

1 Program the correct starter type in the machine configuration menu.

2 Repair or replace contactors.

3 Replace Starter module. Possible faulty relay output.

4 Starter panel wiring.

5 Check CT connections to the Starter module.

Problem 70: Stepper motor is humming.

Corrective Action:

While in the hold mode, the stepper motor is driven with 1.0 amps. This is the case even if the actuator is fully closed. The humming is normal.

Problem 71: Extended surge

Corrective action:

1 Unit operation conditions resulting in surge, such as: high head, air in the unit, condenser tube fouling, low water flow, low charge and condenser water temperature vs. design. Unit operation conditions is the most likely cause.

2 Replace Starter module. Faulty CT input.

3 Stepper motor and/or linkage.

4 Replace options module. Bad head relief request relay.

5 Guide vane linkage.

6 Replace Starter module with more sensitive one (X-13650453-17 or greater).

Problem 72: Pressure Transducer shift in calibration. Diagnostics will be sensor calibration related such as sensor failure or oil pressure sensor calibration.

Corrective Action:

1 Wired incorrectly. Check diagram.

2 Corrosion on transducer contacts.

3 Bad transducer.

4 Disregard diagnostics when the unit is a deep vacuum prior to charging.

Problem 73: Rapid Time of Day Scrolling or Date jumps back one day.

Corrective Action:

1 Problem one is rapid time of day and year scrolling. The problem is in the CLD software when we reach December 29, 30 and 31. Fix: Replace the CLD (Local Clear Language Display) with a X-13650448-03 or newer. To stop the scrolling, press Enter to get a valid date and set before or after Dec. 29/30.

2 Problem two is when the date jumps back one day. The date of January 4,1995 is set and it jumps back to January 3, 1995. This is because 1996 is a leap year and the problem only exists on the year prior to leap year. Replace the CLD with a X-13650448-03 or newer.

Problem 74: Unit did not Transition diagnostics.

Corrective Action:

1 Do a Starter Dry Run Test.

2 Check for 24 VAC input to all modules.

3 Check for 24 VDC and 5VDC on the Starter module.

4 Check all wiring and connections.

5 Check for 120 VAC on the Starter module J4-1 and 2. J4 is an OPTO input circuit that recognizes transition complete. If there is no signal on J4, the unit will not transition.

6 Replace bad Starter module.

Problem 75: Tracer Diagnostics e.g.,Tracer loss of comm with options, starter, etc. as well as other Tracer related diagnostics.

1 Check the IPC wiring connections on the related module with diagnostics.

2 Check tracer to UCP wiring/connections.

3 Make sure the Tracer module is installed, wired correctly and powered up.

4 Set the chillers ICS to match Tracer. Check the Tracer dip switch settings: Tracer Comm 3 should be: "OFF OFF OFF" and Tracer Comm 4 should be: "OFF ON OFF"

Problem 76: Unit Tons Read-out on CLD does not work.

Corrective Action:

1 On the original design up to mid-1998 (with the reversing solenoid valve and plastic piping):

- ~ Verify that the condenser solenoid is connected to the condenser.
- ~ Verify that the entering port of the solenoid goes to the entering water line.
- ~ Verify that the leaving port of the solenoid goes to the leaving water line.
- ~ With the solenoid de-energized, the entering water line is monitored.
- ~ Verify that the Evaporator Solenoid is connected to the evaporator.

2 With the new electronic version mid-1998 on (does not have the reversing valve or plastic piping): reference *Trane Service Bulletin CVHE-CSB-45B.*

- ~ Check for fault transducer.
- ~ Check y-strainer.
- ~ Check wiring.
- ~ Check coefficients in the service settings menu.
- ~ For an open system, follow special procedures in *Trane CVHE-CSB-45B*

Problem 77: Unknown diagnostics 1217 informational warning.

Corrective action:

1 You have a newer Chiller and Starter module and an OLD clear language display (CLD). Install a new CLD to read the diagnostics.

CVHE/F/G Trim Balance Procedure

This procedure outlines the modifications necessary to the Starter module to allow operation of the motor in the Wye configuration during test runs.

1 Unplug the connector from J10 to prevent the run contactor from coming in.

2 Unplug J14 to prevent transition from occurring.

3 Install a jumper on J12 between terminals 1 & 3 to maintain the shorting contactor closed.

4 Install a jumper through an on/off switch across J6 1,3 to start and stop the motor.

Run Procedure:

1 Lockout power to the chiller to prevent startup, until ready.

2 When ready for the run test, energize power to the chiller. The shorting contactor should close. The motor will be controlled by the Auto push-button on the UCP2 Clear Language Display. Stop will be controlled by the switch on J6.

3 Program the inlet guide vanes to zero target.

4 With the chiller in the "panic stop" mode, press Auto.

Start sequence:

1 Go to the service test menu and put the oil pump to the ON position. This will assure lubrication while the stop signal is bypassed via the J6 Switch.

2 Normal start.

3 During acceleration, close the switch across J6.

Stop/Reset sequence

1 Open the switch across J6.

2 Allow the chiller to coast down.

3 Lockout the chiller.

4 Restore the oil pump to Auto.

Sensor And Transducer Operating Ranges

Temperature range on sensors: 140°F to 212°F ± 2.5°F

Transducer range: 0 to 35 psig.

Temporary Forced Unload Setup

The following will work if you have the need to temporarily unload the unit for a specific requirement.

1 Set the front panel current limit setpoint at your requirements, (say 40%)

2 Set the current limit setpoint source to external source.

3 Provide a 10 VDC or 20 mA input signal to J7 11,12.

4 Provide a binary switch to enable/disable the input to J7.

5 With the binary switch closed the unit will operate with a 100% current limit.

6 With the binary switch open the unit will operate with a 40% current limit.

Communications Test

A communications test is included in the CLD to check the Chiller-to-CLD communications.

To access the communications test:

1 Press the 'Service Test' key.

2 For the password, press 'Next' and '+' keys at the same time.

This screen can be used as a debugging tool when CLD-Chiller IP communications are suspect. The first line on the screen indicates which Chiller packets the CLD is checking. The second line on the screen indicates how many times in a 15 second interval the particular packet was received by the CLD. If a packet is received more than 9 times in the interval, a '+' is displayed. The counters are reset to 0 every 15 seconds. Hitting any key while on this screen will cause an exit.

Packet #:	2 3 4 5 6 7 8 9 10 11 12 14 15
Received:	x x x x x x x x x x x x x x x

Troubleshooting IPC Communication Diagnostics

1 Check the IPC connections to all modules. Make sure the twisted pair wires that plug into each modules' J1 connector are making good contact with the wire. Be sure each connector is not clamping down on the wire insulation.

2 Verify that the polarity of the IPC link is correct. The twisted pair IPC link is two color twisted pair wire. Be sure the same color wire is on top for each twisted pair connection.

3 Using a voltmeter set to AC volts, measure the voltage at the J2 connector on each module. It should read between 20 and 28 VAC. Also check the green connector to make sure it is securely plugged into the module. Inspect each screw terminal to be sure they are not clamping down on the wire insulation.

4 Most of the UCP2 modules have 24 VDC and 5 VDC test points on the board. They are clearly labeled and accessible without removing the sheet metal covers. For the Starter and I/O modules, the test points are located in the upper left hand corner of the module. For the other modules, they are located on the upper right hand corner of the module.

Using a voltmeter set to DC volts, measure the 5 volt test point. It should be between 4.75 VDC and 5.25 VDC. Measure the 24 volt test point. It should be between 23 VDC and 25 VDC. **Note: The I/O module's 24 VDC test point will read 0 VDC.** If any of the voltage measurements are not within the acceptable range, replace the module.

5 Verify that a good ground exists between all modules. The CLD requires a dedicated green wire ground. Verify this is in place, and has a good connection. Paint may need to be scraped away to insure a good connection.

6 **For remote starters only:** It is very important that a good ground exists between the starter panel and the chiller control panel. Use a continuity checker to verify a good ground exists between the two panels. If there is not a good ground, run a dedicated ground wire between the starter panel and the control panel.

For a "No Communication, Data Not Valid" message on the Clear Language Display:

1 Perform the above checkout procedure.

2 If the message still did not go away, unplug all of the IPC connections from the Chiller module except for the IPC link that goes to the Clear Language Display.

3 Establish communication with only the Chiller module and then plug the other IPC connections back onto the Chiller module one at a time. If the "No Communication, Data Not Valid" message suddenly reappears when you plug one of the connections back in, you have identified the IPC link that is causing the fault. Carefully check that link for a lead to lead short or a short to ground.

For a "Loss of comm with Stepper" diagnostic:

1 Make sure the wiring to the stepper motor is correct. If the wiring is not correct it will destroy the power supply on the module, and a loss of comm with Stepper will result.

The Correct stepper wiring follows:

Table 2
Stepper Motor Connections

J6 or J8 Connector Pin# on Stepper Module	Motor Winding Output Signal Name	RTH 34X1BEHH Motor Terminal Connection	CTV, ABS M091-FD8109 Motor Terminal Connection
4	1+	1	3
3	2+	3	5
2	1-	2	1
1	2-	4	4

Heat Sink Temperature

This temperature is monitored on the Cutler-Hammer Solid State Starters Only. The Starter module monitors the Solid State Starters Heat Sink Temperature, displays it in the compressor report on the Clear Language Display, and provides a Heat Sink Temperature Start Inhibit mode. The Start Inhibit Temperature is ROM based (Not adjustable at the Human Interface) by Solid State Starter, and Chiller size.

Chiller Nameplate RLA	SSS Heat Sink High Temp. Start Inhibit
0-200 Amps	67°C (152.6°F)
201-360 Amps	77°C (170.6°F)
361-560 Amps	77°C (170.6°F)
561-700+ Amps	78°C (172.4°F)

On a call for cooling if the heat sink temperature is above the value shown in the table above the unit shall enter the Heat Sink Temperature Start Inhibit mode until either the heat sink temperature drops 1.8°F (1°C) below the Start Inhibit Temperature, at which time the unit will complete the pre-start procedures and start, or there is no longer a call for cooling.

The heat sink temperature sensor connects to Starter module terminals J7-1 and J7-2.

Module Compatibility

UCP2 Module Compatibility

1 Chiller modules X-13650450-02 or greater when installed in a system with a CLD of X-13650448-01 will call out a diagnostic of (Unknown Diagnostic 905). The machine requires a CLD of X-136504489-02 or greater.

2 Starter module X-13650453-02 and greater requires Chiller Packet 20.

3 Chiller module X-13650450-01 does not support Packet 20. You need a Chiller module of X-13650450-02 or greater along with the Starter module X-13650453-02 through 6 or you will get a diagnostic of starter loss of communication with chiller. Beginning with Starter module X-13650453-07, the Starter module no longer expects to receive Chiller Packet 20.

   Chiller module X-13650450-03 and earlier do not have the bit that the Stepper module looks for to determine if it should do an inlet vane motor BPI search on startup. These modules will do a BPI search on each startup.

4 TCI COM3 module X-13650460-01, the TCI packet time to receive the information from Tracer is 15 seconds. The information is sent out every 10 seconds and you may get repeat (IFW) informational warning diagnostics filling up the diagnostic logs. TCI COM3 module X-13650460-02 or greater is required.

5 To read evaporator approach temperature, you need a CLD of X-13650448-04 and later along with a Chiller module of X-13650450-04 and later.

6 See *Trane service bulletins CVHE-SB-90 and 91* for additional module compatibility information.

Description of UCP2 Options

1. Tracer Communications Interface Module (Com 3 Module)

This option must be ordered if the chiller is to communicate over a serial communication link to a TRACER 100.

2. Tracer Communications Interface Module (Com 4 Module)

This option must be ordered if the chiller is to communicate over a serial communication link to a Tracer Summit.

3. Remote Clear Language Display Module

Enables the UCP2 to communicate serially with the remote CLD.

The remote CLD panel (COPT:RCPL) communicates serially with 1-4 UCP2-equipped chillers that have the optional remote CLD. The local CLD Stop command function has precedence over the remote function. The Custom Report and display language at the local CLD and remote CLD are independent.

4. Options Module

The Options module is required to implement any/all of the following control options. Some require additional sensor/transducers.

(a)Chilled water setpoint by external/remote source. Allows a remote source to set the chilled water setpoint via 4-20 mA or 2-10 VDC signal. The range is 0°F to 65°F.

(b)Current limit setpoint by external source. Allows a remote source to set the current limit setpoint via a 4-20 mA or 2-10 VDC SIGNAL. Range is 40% to 120%.

(c)Compressor percent (%) RLA output Allows a remote system to receive a 2-10 VDC signal proportional to the chillers % RLA. Range is 0% TO 120%.

(d)Head relief request output. Allows a remote system to receive a binary signal for use with compressor surge protection and condenser limit by requesting lower entering cond. water temp. This option requires an additional transducer on the condenser.

(e)Maximum capacity output. Allows a remote system to receive a binary signal indicating the chiller is at maximum capacity.

(f) Heat recovery/auxiliary condenser entering and leaving water temperatures. This option includes the Options module. Allows UCP2 to monitor the entering and leaving heat recovery or auxiliary cond. water temps which are displayed at the local CLD.

(g)Free cooling machine mode enable/disable and valve control. Allows a remote source to re-enable/disable the chillers free cooling.

5. Printer Interface Module

This option must be ordered if the UCP2 is to have a direct connect serial printer. The printer and cable must be ordered separately. This option includes ASHRAE Guideline 3 Report.

6. Chilled Water Reset Outdoor Air Temperatures

Provides for outdoor air temperature reset of the UCP2 front panel chilled water setpoint. Includes display of outdoor air temperature.

7. Water Pressure Sensors For Evap And Cond System Pressure Less Than 150 Psig.

Includes sensing of the entering and leaving water pressures of the evaporator and condenser, factory-mounted in the water boxes. The Options module is not required. The following data will be shown:

- ~ Entering/leaving evaporator & condenser water pressure (psig)
- ~ Evaporator and condenser differential water pressure (psid)
- ~ Evaporator/condenser GPM
- ~ Evaporator tons (Approximate)

Water Pressure Sensors For Evap And Cond System Greater Than 150 Psig includes sensing of the differential evaporator and condenser water pressures. The Options module is included and required. The following data will be shown:

- ~ Evaporator and condenser differential water pressure (PSID)
- ~ Evaporator/condenser GPM
- ~ Evaporator tons (Approximate)

8. Bearing Oil Temperature Sensors

Includes factory installed sensors and safety cutouts (On high temp) to monitor the leaving bearing oil temperature: Sensor (#1) monitors the journal bearing temperature and Sensor (#2) monitors the Thrust bearing temperature.

9. Phase Voltage Sensors

Includes factory installed potential transformers in the starter for monitoring/displaying phase voltage and this provides over/under voltage protection. The following is displayed: Compressor phase voltage, Kilowatts, Power Factor.

10. Enhanced Condenser Limit

Includes factory installed cond pressure tranducer, piping and wiring.

Provides enhanced high pressure cut-out over cond limit which is standard.

The head relief request relay will energize when cond. limit is approached. The Options module is included.

11. Discharge Temp Sensor

Includes a factory installed sensor and safety cutout on high compressor discharge temp. Allows the UCP2 to monitor compressor discharge temperature. When the chiller is selected with hot gas bypass this sensor is included.

12. Starter By Others

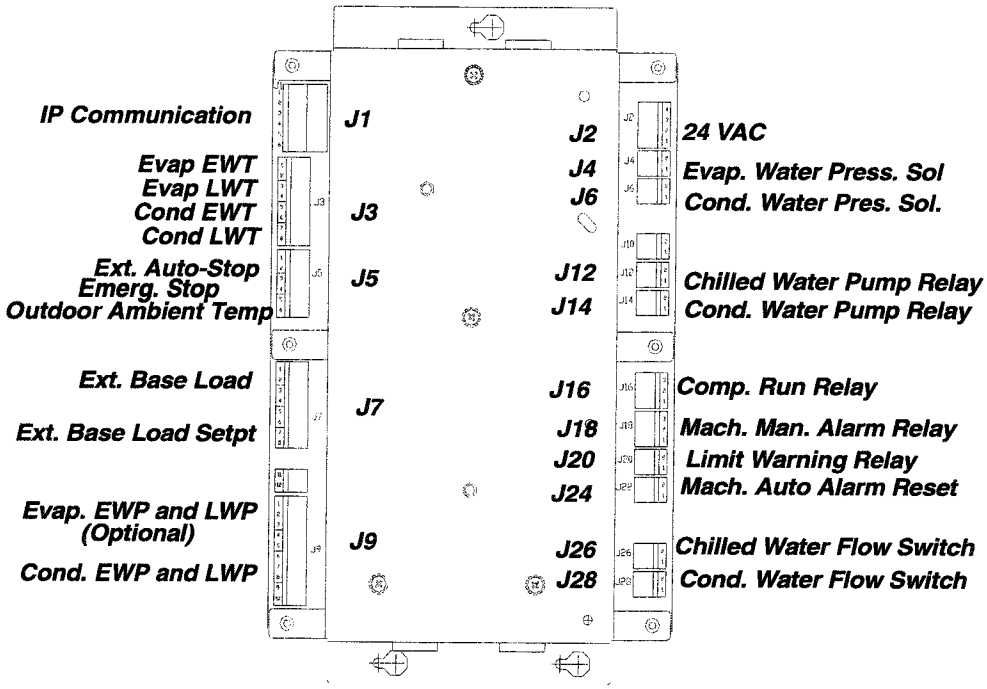
When the starter is being furnished by others, Trane furnishes the Starter module in the UCP2, and other wiring/components as needed. The starter must be built per Trane starter specifications.

UCP2 Modules

Chiller Module

1U1 is the "Master module," collecting data, status conditions, diagnostic information, etc. from modules (over the IPC link) from sensors and remote contacts and, in turn, communicating commands to other modules.

1U1 performs leaving water temperature and limits control algorithms, trading off chiller capacity against various "limits" that the chiller may be working against. 1U1 checks for valid setpoints and identifies unit type for other modules.



Low Voltage (<30VAC) Inputs:

24 VAC, IPC Links to Internal, to Purge and to Starter modules; Evap. EWT and LWT; Cond. EWT and LWT; External Auto Stop; Emergency Stop; Ambient Air CWR; Heat Pump Control; Evap. Water Delta P; Cond. Water Delta P

High Voltage (>30VAC) Outputs:

Evap. Water Pressure Solenoid; Cond. Water Pressure Solenoid; Evap. Water Pump Relay; Cond. Water Pump Relay; Compressor Run Relay; MMR Alarm Relay; MAR Alarm Relay; Limit Warning Relay

Figure 2
Chiller Module

Circuit Module

1U2 assigned functions associated with compressor motor, lubrication system and refrigerant monitoring.

Low Voltage (<30VAC) Inputs:

24 VAC, IPC link

Compressor motor winding temp. sensors 1, 2, 3

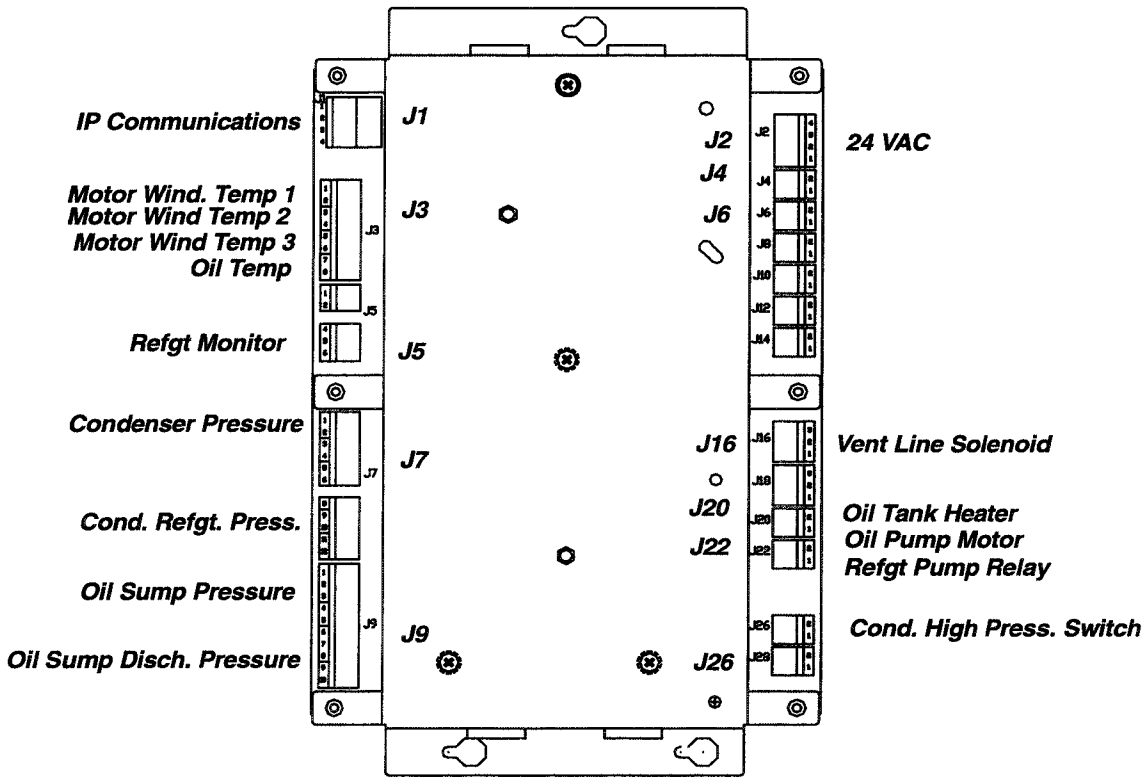
Oil tank temperature

Refrigerant monitor equipment room ppm level

Condenser refrigerant pressure

Oil sump pressure

Oil discharge pump pressure



High Voltage, High Amperage (120 VAC) Inputs:

High Condenser Pressure

High Voltage, High Amperage (120 VAC) Outputs:

Vent line solenoid valve; oil tank heater; oil pump motor

Figure 3
Circuit Module

Input/Output Module

Provided only when chiller is equipped with Hot Gas Bypass (HGBP) option.

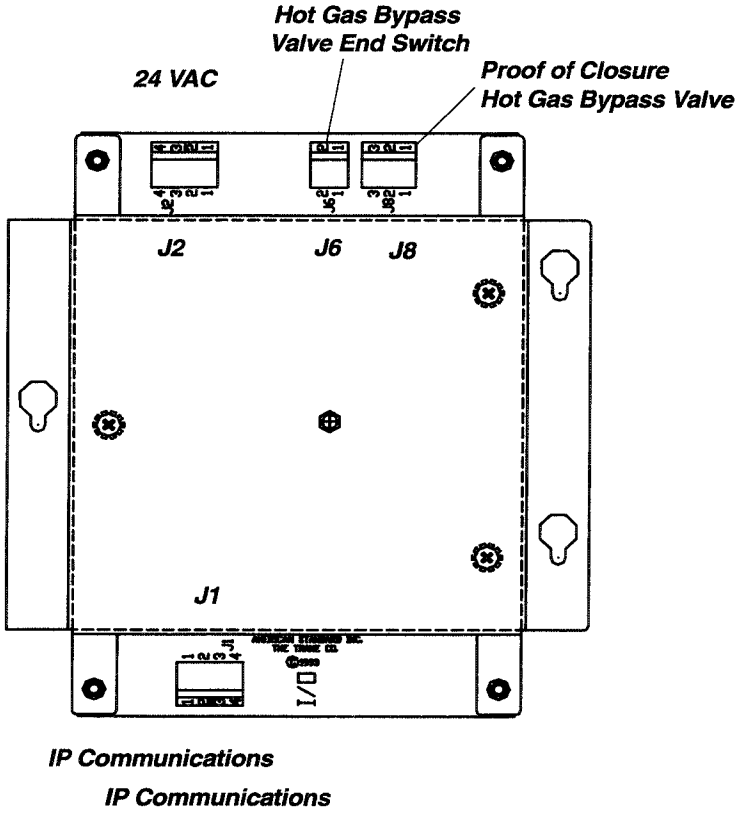
The I/O module (1U10) operates the Hot Gas Bypass valve on CVHE and CVHF units in response to signals from stepper module 1U3.

The module also receives input on HGBP valve position from the HGBP valve end switch.

Low Voltage (<30VAC) Inputs:

115 V HGBP valve drive signal

High Voltage (>30VAC) Inputs



10 V HGPB valve proof-of-closure signal from valve end switch

High Voltage (>30VAC) Outputs:

HGBP Open Triac

HGBP Close Triac

Figure 4
Input/Output Module

Options Module

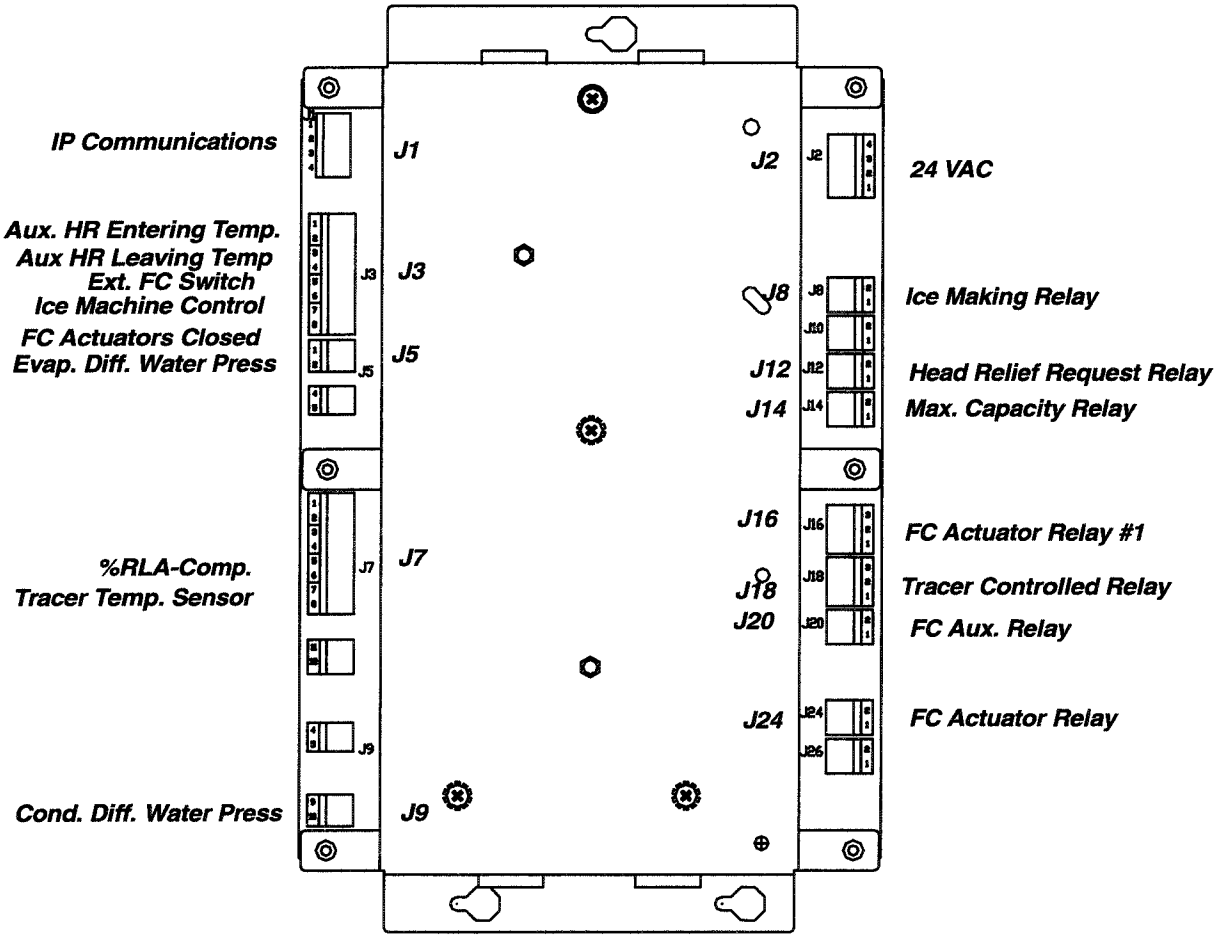
As its name indicates, 1U5 provides the control or interface requirements for many of the options available with the UCP2.

Low Voltage (<30VAC) Outputs:

Heat Recovery Actuator

% RLA Compressor

High Voltage (>3OVAC) Outputs:



Ice-Making Relay; Head Relief Request Relay; Max. Capacity Relay

Free Cooling Actuator Relay 1 (Liquid Line Valve)

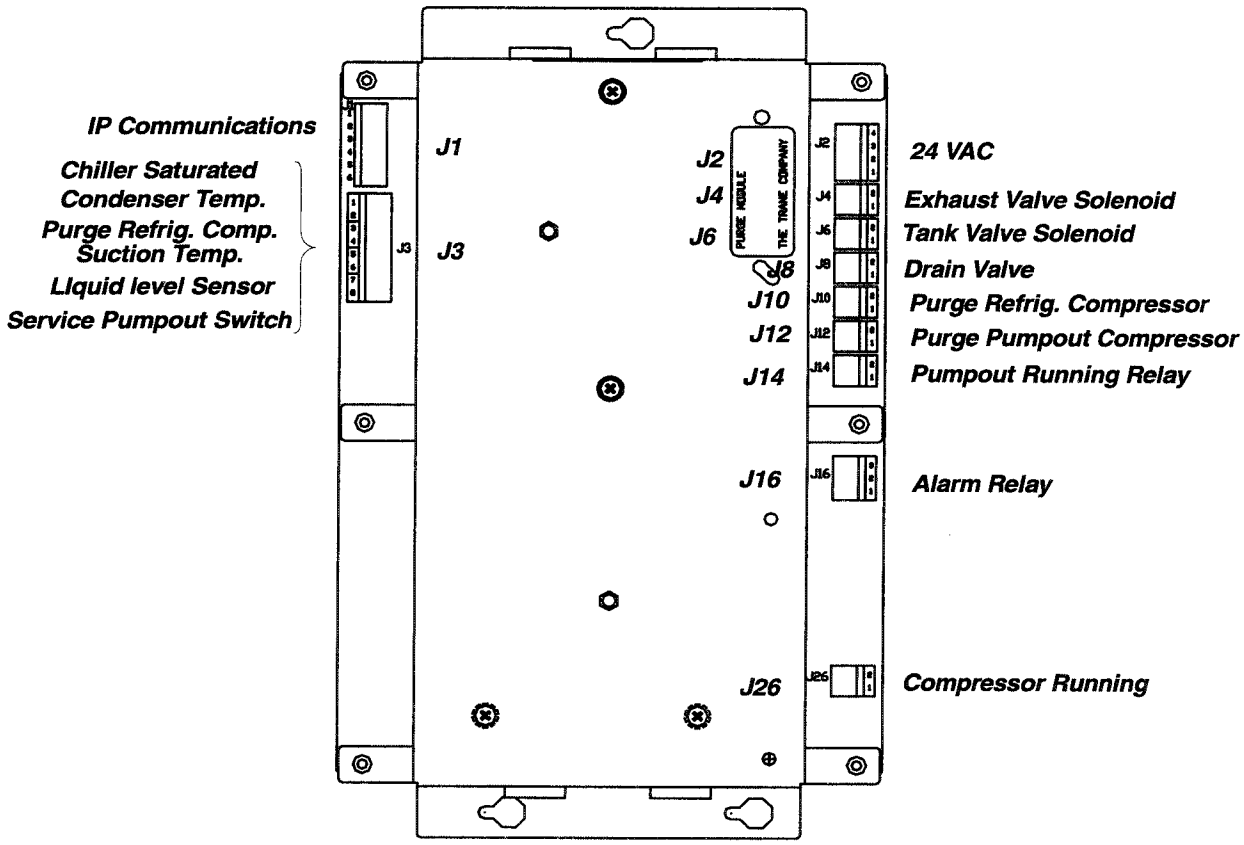
Free Cooling Auxiliary Relay

Free Cooling Actuator Relay 2 (Gas Line Valve)

Figure 5
Options Module

Purge Module

The purge module (3U1) is provided with the Trane Purifier Purge on CVHE and CVHF chillers. It is located in the purge control panel at the purge. It provides all inputs and outputs for the UCP2 to control purge operation.



Low Voltage (<30VAC) Inputs:

- 24 VAC; PC link to Chiller module
- Purge refrigeration compressor suction temperature
- Purge tank liquid level sensor
- Service pumpout switch

High Voltage (>30VAC) Outputs:

- Exhaust valve solenoid; tank valve solenoid
- Purge refrigerant compressor purge pumpout compressor
- Purge pumpout running (Tracer); purge alarm

Figure 6
Purge Module

Starter Module Values

The starter module (2U1) is present in all Trane-provided starter panels, whether unit-mounted or remote. For CTVs, if no Trane starter is provided and the customer is providing the starter, 2U1 is mounted in an extension of the unit control panel. It is still designated as 2U1.

2U1 controls the starter when starting, running and stopping compressor motor and provides an interface to all types of starters and AFDs (adjustable frequency drives).

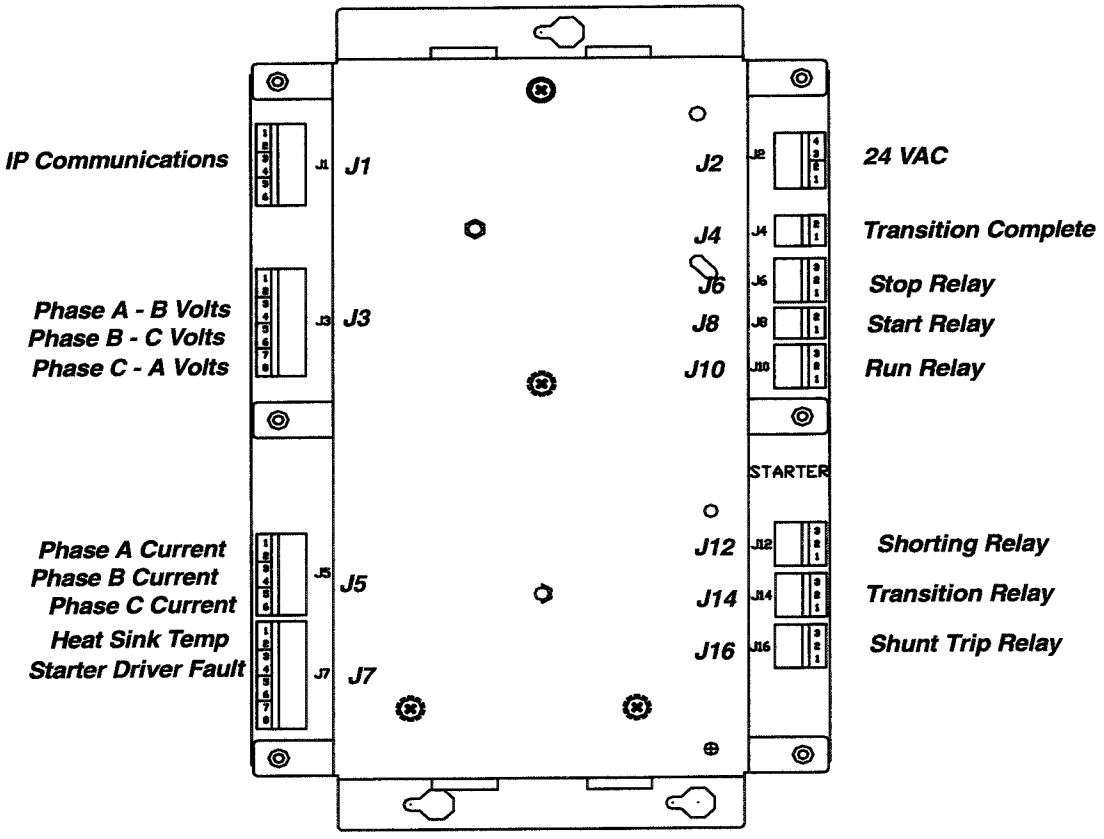
2U1 provides compressor motor protection for running overload, phase reversal, phase loss, phase unbalance and momentary power loss.

Low Voltage (<30VAC) Inputs:

24 VAC; IPC link to chiller module; phase voltages (optional); phase currents; solid-state heat sink temperature (optional); starter driver fault.

Low Voltage (<30VAC) Outputs:

Speed signal output (0-10 VDC - optional)



High Voltage (>30VAC) Inputs:

Transition complete CTV only)

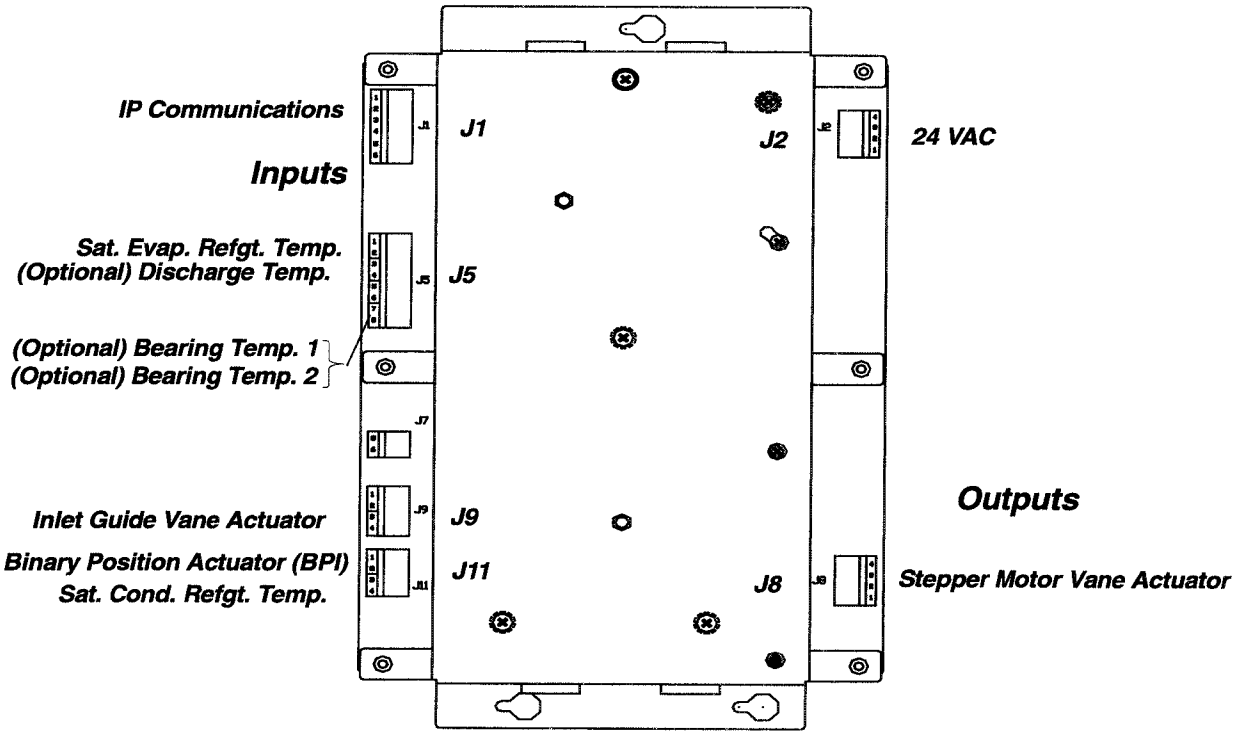
High Voltage (>30VAC) Outputs:

Stop relay; starter relay; run relay; shorting relay; transition relay, shunt trip relay.

Figure 7
Starter Module (Wye-Delta)

Stepper Module

The main function of 1U3 is to drive the Inlet Guide Vane Stepper motor (CTV) along with other functions. It does this in response to signals received from Chiller module 1U1.



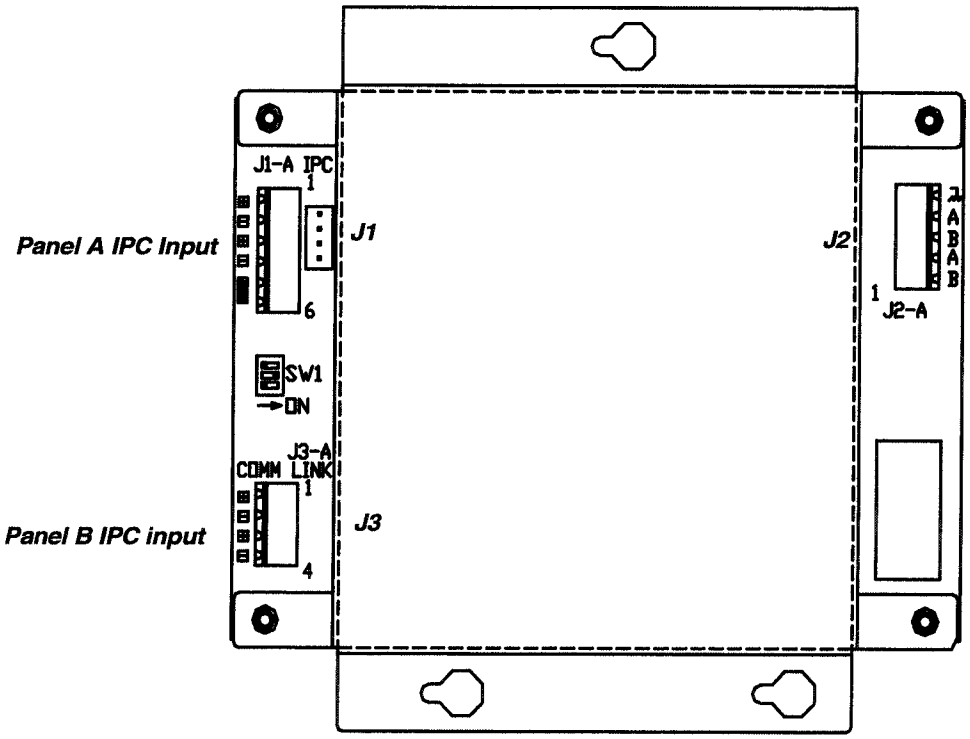
Low Voltage (<30VAC) Inputs:

- 24VAC; IPC link
- Evaporator saturated refrigerant temperature
- Compressor discharge temperature (optional)
- Bearing temps, 1 and 2
- Inlet guide vane actuator Binary position indicator
- Condenser saturated refrigerant temperature

Low Voltage, High Amperage (30 VAC) Outputs:

- Vane actuator stepper motor

Figure 8
Stepper Module



Duplex Module

The Duplex Chiller control is accomplished by the Duplex Control Module (DCM). The DCM is a Trane Communications Interface (TCI) based module. Its two main tasks are setpoint control and compressor staging/control

The DCM will actually control two separate UCP2 panels ("Panel A" and "Panel B"). These panels are for the most part identical and know nothing of each other. All coordination between panels is handled with the DCM.

Figure 9
Duplex Module

Module Dip Switch Settings

UCP2 Board Dip Switch Settings

Several of the UCP2 modules have dip switch settings on them, used to set up the board for 2-10 VDC or 4-20 mA signal inputs and/or outputs of the boards. The following are the various switch settings.

Chiller Module

	Switch	0-10V	4-20mA
External Base Loading	SW2-1	OFF	ON (SW2-2 and SW2-3 are not used)

Options Module

	Switch	0-10V	4-20mA
External Current Limit	SW2-1	OFF	ON (SW2-2 and SW2-3 are not used)
External Chilled Water	SW3-1	OFF	ON (SW3-2 and SW3-3 are not used)

Tracer COM 3

Switch	-1	-2	-3
SW1	OFF	OFF	OFF

Tracer COM 4

Switch	-1	-2	-3
SW1	OFF	ON	OFF

IPC Buffer

Switch	-1	-2	-3
SW1	OFF	OFF	ON

Duplex Control Module (DCM)

Switch	-1	-2	-3
SW1	ON	OFF	ON

Printer

Switch	-1	-2	-3
SW1	OFF	OFF	ON

The printer settings in the service settings menu must be set exactly the same on the printer being used. This includes:

- ~ printer baud rate
- ~ printer parity
- ~ printer data bits
- ~ printer stop bits
- ~ printer handshaking

The above settings are usually configured on a printer by DIP switches. The dip switch settings can be found in the manufacturers information provided with the printer.

Dip switch settings for the Okidata Microline 184 turbo printer follow:

Table 3
Switch Bank1

Parity Type odd parity even parity	Switch 1 on off
Parity No parity With parity	Switch 2 on off
Data Bits 8 bits 7 bits	Switch 3 on off

Diagnosing A Non-Working Stepper Module

Method to Troubleshoot a UCP2 Stepper Module and Actuator

I. Overview

The UCP2 Stepper module is used to drive a Stepper Motor, which is used to open and close a valve or actuator. The big difference between a Stepper Motor and other types of motors, is that instead of just making the motor turn, you can control the angular position of the rotor inside the motor, and therefore control the position of your valve or actuator.

The Stepper Motor has two windings inside. To distinguish between the two, we call them Winding 1 and Winding 2. The Stepper module contains one drive circuit for each winding. Most of the failures you will probably deal with will result in the two internal fuses, F1 and F2, inside the Stepper module to open. These fuses protect the motor from damage, and are not easily accessible. Replacing these fuses in the field is not an acceptable option, because the original fuses have been through some special UL testing. We cannot guarantee safety to the customer if a blown fuse is replaced with another of a different type.

The Stepper Motor three states: Moving, Holding and Off:

1. In the Moving state, current flows bi-directionally through each of the two windings. The frequency and amount of current is electronically controlled by the Stepper module.
2. In the Holding State, current flows one way through each of the two windings. The amount of current is electronically controlled by the Stepper module.
3. The Off state occurs only when the Stepper module power is cycled. Until the Stepper receives an order from the Chiller module to move, no current flows through the Stepper Motor windings.

II. Quick Test of Stepper Board

A.This section will show how to test the main power points of the Stepper Board to get an idea of where the problem is.

1. If the UCP2 Control Panel is unpowered, unplug the J2 connectors from the Stepper board and continue to Section III to check motor and wiring resistances.
2. If the UCP2 Control Panel is powered, measure and compare the Power Input (J2) and the 4 Test Points at the right side of the Stepper board with Table 5 .

Table 5
UCP2 Stepper Module Test Point Voltage Limits

Connector	VAC	VDC
J2 -(1 to 2) or (3 to 4) J2 -(1 to case) or (2 to case) TP2: 5V to ground	20.4 to 33.12 VAC	0 VDC
	10 to 17 VAC	13.12 to 21.81 VDC
	0 VAC	4.8 to 5.2 VDC
TP4: 24V to ground	0 VAC	23.2 to 25.1 VDC
TP3: 14V to ground	0 VAC	11.45 to 15.75 VDC
TP1: 35V to ground	100m VAC to 72m VAC	26 to 48 VDC

If any of the voltages are out of range, there is a malfunction on the Stepper Board.

The majority of these malfunctions may be diagnosed by using . The ones marked with an asterisk have been seen in the field before:

Table 6
UCP2 Stepper Module Troubleshooting

Condition(s)	Possible Problem	Possible Cause(s)	(Solution(s)
Voltage at Test Points TP1-TP4 on Stepper module	Wiring between Stepper module and actuator motor is shorted to ground.	1. Wire insulation bared inside conduit.	1. Seal wire or run new wire through conduit.
Motor winding Resistance check Pin to conduit Motor does not move.		2. Wire insulation bared or pinched inside motor junction box.	2. Seal wire, or restrip and rewire motor junction box. See Table 4 for wiring diagram.
Voltage at Test Points TP1-TP4 on Stepper module Motor winding resistance check pin to pin fails. Motor does not move.	Wiring shorted together inside conduit between Stepper module and actuator motor.	Insulation bared.	Seal wire or run new wire through conduit. See Table 4 for wiring diagram.

Table 6
UCP2 Stepper Module Troubleshooting (Continued)

Condition(s)	Possible Problem	Possible Cause(s)	(Solution(s)
	Wiring shorted together at board edge connector J6 or J8	*1. metal shavings from drilling into UCP2 Panel form bridge. 2. Loose wire strands form bridge.	1. Inspect J6 and J8 connectors. Remove any metal shavings bridging the wires before powering module. 2. Restrip and rewire board edge connector.
	Wires shorted together inside motor junction box.	Insulation bared.	Seal wire or run new wire through conduit. See Table 4 for wiring diagram.
Stepper module TP1 - TP4 OK. Motor winding resistance check OK. Motor does not move.	Motor does not move and steps display does not change on CLD when using manual vane control.	UCP2 is not in Stop Mode and Chiller module is overriding manual vane control.	Hit stop button on CLD, and try again.
Stepper module TP1 - TP4 OK. Motor winding resistance check OK. Motor runs backward.	Motor runs backward	Motor is miswired.	Unplug motor connector (J6 or J8) from the Stepper module. Use Tables 3 and 4 to sway wire pairs (1, 3) or ((2, 4) so the motor is wired properly.

II. Check Stepper Motor and Wiring for Shorts and Opens

A. During this stage, motor winding and wire resistances will be measured to ensure proper continuity.

1 If the unit is powered, hit the stop button on the CLD and use manual mode in the service tools menu to step the actuators all the way to position 0.

2 Unplug power (J2 connector) from the Stepper module.

3 Unplug J6 and J8 from the board.

4 Measure the DC resistance of one of the motor windings by measuring between what would be Pin (1,3) or Pin (2,4) on the Stepper Board at the unplugged connector (See Table 7).

5 If the resistance is lower than the limits in Table 7 there is a short in the wiring between the Stepper module and the motor or the in motor winding. Note that nominal values are not including wire resistances.

6 If the resistance is higher than the limits in Table 7 the wiring between the Stepper module and the motor or a winding is open. Note that nominal values are not including wire resistances.

Table 7
Motor Winding Resistance

J6 or J8 Connector Pin	Acceptable DC Resistance Range	CLV Nominal Resistance
(4 to 3)	Open Circuit	NA
(4 to 2): WI	50 mOhm to 5 Ohm	1.68 Ohm
(4 to 1)	Open Circuit	N/A
(3 to 2)	Open Circuit	N/A
(3 to 1):W2	50 mOhm to 5 Ohm	1.68 Ohm
(2 to 1)	Open Circuit	N/A
(4 to Conduit)	Open Circuit	N/A
(3 to Conduit)	Open Circuit	N/A
(2 to conduit)	Open Circuit	N/A
(1 to conduit)	Open Circuit	N/A

7 If the winding resistance is in the range, plug the J connector back into the appropriate socket.

8 Perform steps 3-7 for each winding of the motor on the Stepper module.

9 If there is a short or an open, you will need to check the wiring to the motor, and then check the motor.

10 If the windings resistance check passes, and you have not measured the Stepper module voltages while it is powered, then plug J2 back into the module and go back to Section II, Quick Test of Stepper Board.

B. If you need to disconnect the wires going to the motor for any reason, Table 8 is a wiring table you can use to reconnect them.

Table 8
Stepper Motor Connections

JB or J8 Connector Pin# on Stepper	Motor Winding Output Signal Name	Stepper Motor Terminal Connection
4	1+	3
3	2+	5
2	1-	1
1	2-	4

IV. Motor Voltages for CTV Stepper Motor

A. With the motor connector J6 (or J8) connected to the Stepper Board, and the Stepper powered, measure the AC and DC voltages of the connector pins, and compare to Table 9 and Table 10 .

Table 9
Motor Voltages with Actuator Holding

Connector Pin	AC Voltage	DC Voltage
J6 - (4 to 3)	0 or (5.8 to 10)	- 400 mV to +400 mV
J6 - (4 to 2)	5.8-8.2	+ 400 mV, but not 0mV
J6 - (3 to 1)	0 or(5.8-10)	- 400 mV to +400 mV
J6 - (3 to 2)	0 or(5.8-10)	- 400 mV to +400 mV
J6-(3 to 1)	5.8 to 8.2	+400 mV, but not 0 mV
J6- (2 to1)	0 or (5.8-10)	- 400 mV to +400 mV
J6 -(4 to conduit)	0 or (5.8-8)	(0.3-0.43) or (1.04- 1.135)
J6 -(3 to conduit)	0 or (5.8-8)	(0.3-0.43) or (1.04- 1.135)
J6 -(2 to conduit)	0 or (5.8-8)	(0.3-0.43) or (1.04- 1.135)
J6 -(1 to conduit)	0 or(5.8 -8)	(0.3-0.43) or (1.04- 1.135)

Table 10
Motor Voltages with Actuator Moving

Connector Pin	AC Voltage	DC Voltage
J6 - (4 to 3)	(16.6-25.9)	-720 mV to +720 mV
J6 - (4 to 2)	(20.8-27.5)	-720 mV to +720mV
J6 - (4 to 1)	16.6-25.9)	-720mVto +720mV
J6 - (3 to 2)	16.6-25.9)	-720mV to +720mV
J6 - (3 to 1)	20.8-27.5)	-720mV to+720mV
J6 - (2 to 1)	(16.6 - 25.9)	-720 mV to +720mV
J6 - (4 to conduit)	(11.4 - 17.3)	(9.1 -10.1)
J6 - (4 to conduit)	(11.4 - 17.3)	(9.1 -10.1)
J6 - (4 to conduit)	(11.4 - 17.3)	(9.1 -10.1)
J6 - (4 to conduit)	(11.4 - 17.3)	(9.1 -10.1)

Procedures For Module Set-Up

External Current Limit Setpoint

Option module J7-11, -12 (-, +)

Isolated 2-10 VDC or 4-20 mA

UCP2 will accept either a 2-10 VDC or 4-20 mA analog input suitable for customer connection to set the unit external current limit setpoint. 2-10 VDC and 4-20 mA shall each correspond to a 40 to 120% RLA range. UCP2 will limit the maximum ECLS to 100%.

The following must be "Set'.

1 SW2-1 OFF for 2-10 VDC
ON for 4-20 mA

2 Current Limit Setpoint Source: External Source

3 External Current Limit Setpoint: Installed Machine Configuration menu

4 External Setpoint Inputs: 2-10 VDC or 4-20 mA (Machine Configuration menu)

Refrigerant Monitor Input

Analog type input

4-20 mA input signal to the Circuit module J5-5 and J5-6. This represents 0-100 ppm.

Under machine configuration "Refrigerant Monitor Type" is '01' for Analog.

Typical input if using an RMWC generation Monitor.

IPC Monitor (Requires RMWD monitor with Version 2 Software) Direct communication to the CLD via the IPC.

Under Machine Configuration "Refrigerant Monitor Type" is '02' for IPC Monitor.

Also allows monitor calibration and setup. Please note that the monitor cannot have a local display and communicate with the UCP2. If the customer requires a local display, he can connect an RMWD style monitor up like an analog type previously described.

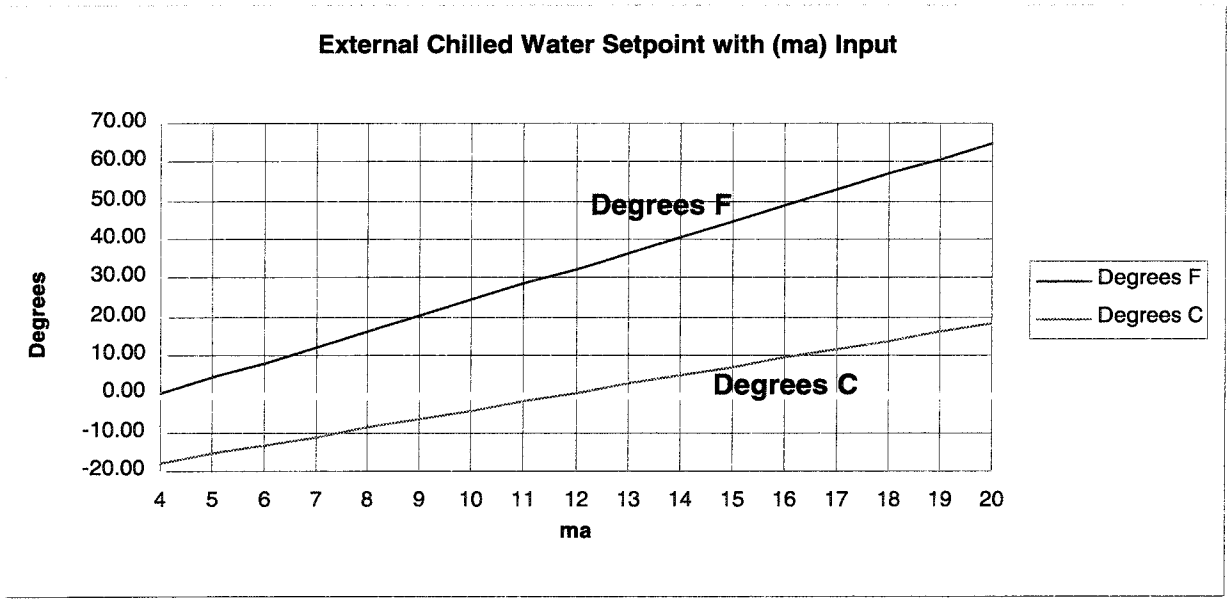
% RLA Output

Options module J7-3,-4

-2-10 VDC

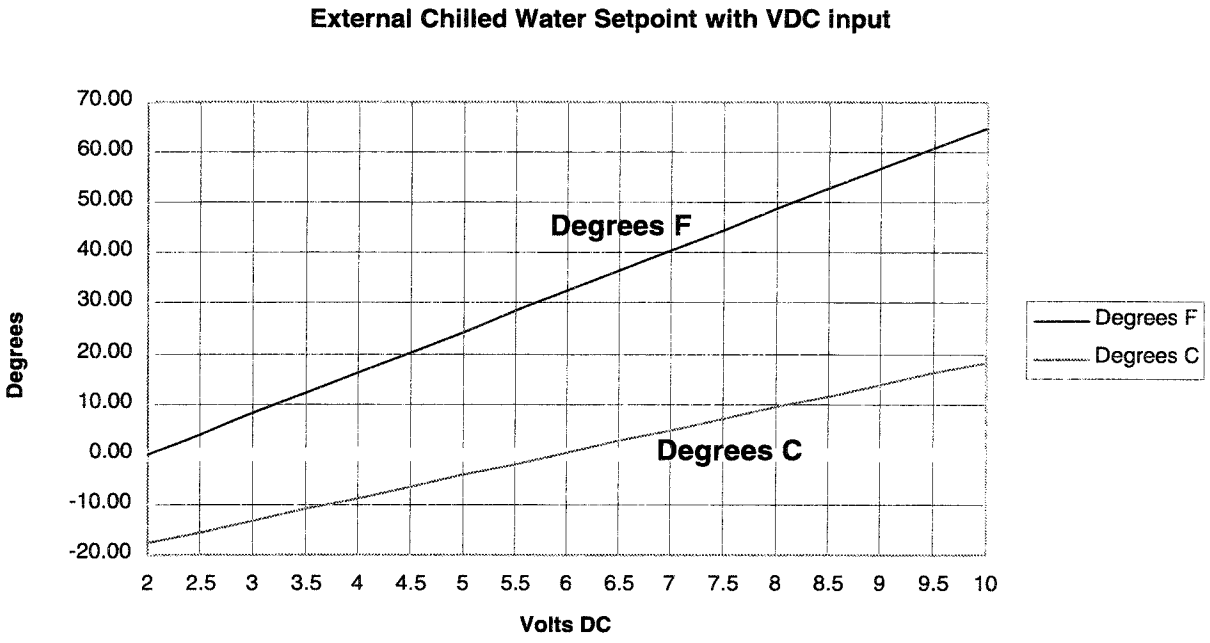
As an option, the UCM shall provide a 0-10 VDC analog output to indicate % RLA. The transfer function shall be 2 to 10 VDC corresponding to 0 to 120% RLA.

External Chilled Water Setpoint



The External Chilled Water Setpoint allows a customer to change the chilled water setpoint from a remote location. The External Chilled Water Setpoint is found on Options module terminals J9-4 and J9-5.

UCP2 accepts either a 2-10 VDC or 4-20 mA analog input suitable for customer connection to set the unit leaving chilled water setpoint. 2-10 VDC and 4-20 mA shall each correspond to a 0 to 65°F (-17.8 to 18.3°C) CWS range. For input signals beyond the 2-10 VDC or 4-20 mA range, an information diagnostic is called and the active chilled water setpoint will default to the front panel.



UCP2 uses the following equations:

	Voltage Signal	Current Signal
As generated from external source	VDC=.12308*(°F)+2	mA=.24615(°F)+4
As processed by UCP2	°F=8.125*(VDC)-16.25	°F=4.0625(mA)-16.25

The following graph shows External Chilled Water Setpoint with a 4-20 mA input:

The following graph shows External Chilled Water Setpoint with a 2-10 VDC input:

The following items need to be set:

1 SW3-1 OFF for 2-10 VDC, ON for 4-20 mA.

2 Chilled Water Reset type: Disable - Operator Settings Group

3 Chilled Water Setpoint Source: External - Operator Settings Group

4 Setpoint Source Override: None - Operator Settings Group

5 External Chilled Water Setpoint: Installed - Service Settings Group Machine Configuration

6 In Machine Configuration, set to 4-20 mA or 2-10 VDC; 4-20 is default

7 Grounding of the BAS and UCP2 systems may be different. To clear this, connect a 9 VDC battery to J9 (4, 8). This acts as an isolated source and you should read 9 VDC. If you do not read 9 VDC, a grounding problem exists.

External Auto-Stop:

The external Auto-Stop input allows the operator to enable and disable chiller operation through a remotely located set of contacts.

A binary input to the UCP2 is provided that will enable the chiller to operate when it is closed and disable operation when it is open. An indication is displayed on the front panel when the chiller is disabled through the remote Auto-Stop.

The Auto-Stop input allows the operator to use a remote signal, such as a time clock or a generic BAS, to signal the start of the chiller. Disabling the chiller through this input will not result in a diagnostic since it is an expected routine shutdown.

UCP2 accepts an isolated contact closure input suitable for customer connection to put the unit in either AUTO or STOP from a remote device. This input has priority over the unit switch when the unit switch is in AUTO. This input does not have priority over the unit switch when the unit switch is in STOP. The input is closed for external AUTO operation and open to put the unit in external STOP. The external stop is a friendly shutdown, i.e. the chiller will unload before the stop command is given.

The External Auto-Stop input is located on Chiller module terminals J5-1 and J5-2.

Analog Input Table Abbreviations

The information below is an explanation of abbreviations used in Analog Input Tables that are shown in this section.

Oil Pressures

Water Pressures

A1: Entering and Leaving Evap Temp. Purge Compressor Suction Temp.

A2: Oil Temp.

Entering and Leaving Condenser

Aux HR Entering and Leaving Temp.

Compressor Discharge Ref Temp.

Bearing Temps 1 and 2

Saturated Cond. Refrigerant Temp.

Outdoor Air Temperature.

A4: Saturated Evap Temp.

A6: Compressor Motor Winding Temp 75 Ohm

NOTE: *A1, A2 and A4 are the same sensor.*

NOTE:
1. Min. Res. and Max. Res. = Minimum and Maximum Resistance in Ohms.
2. Min Vterm. and Max. Vterm = Minimum and Maximum DC Voltage measure at the appropriate module terminal.

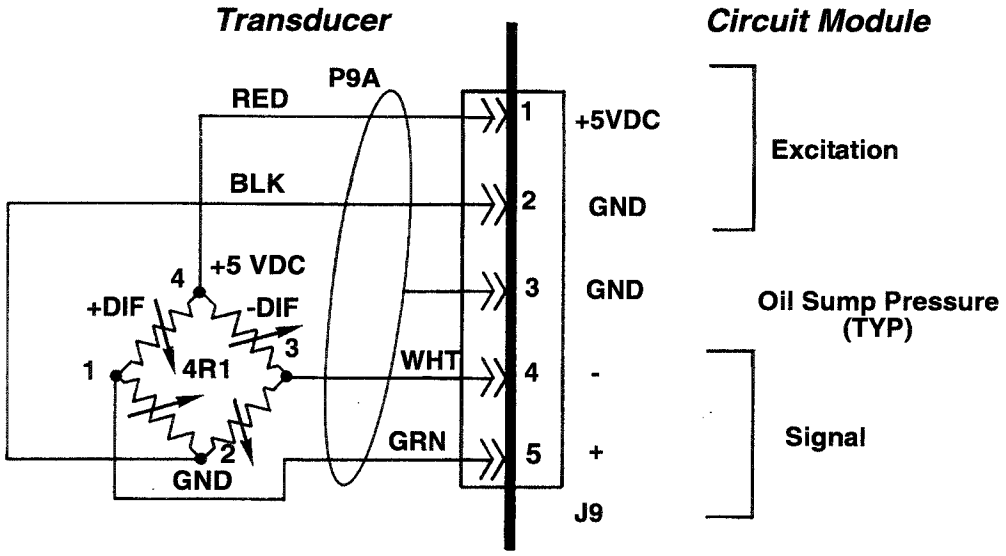
Information on the Oil Pressure Sensor Calibration Diagnostic

UCP2 uses two pressure sensors (one in the sump, one in the discharge) to detect oil flow. When the oil pump has been off for at least 5 minutes, the sump and discharge pressures are compared. If the absolute difference between the sensors is less that 3 psid, the difference is zeroed. If the absolute difference is greater than 3 psid, a sensor calibration diagnostic is called out.



Changes made to -11 Circuit Software (X-13650451-09 hardware) to improve Prevac performance:

The 3 psid calibration check was modified to require 90 consecutive seconds of greater than 3 psid before a diagnostic is issued.

During Prestart, the calibration check is stopped when the evaporator flow is first sensed. Previously the calibration calculation and diagnostic check were terminated when the oil pump turned on. The change was implemented to avoid nuisance pressure fluctuations caused by the start of evaporator water flow and the guide vanes bpi search.

Suspend calling out the oil pressure sensor calibration diagnostic until evaporator water has been flowing for a minimum of 5 minutes.

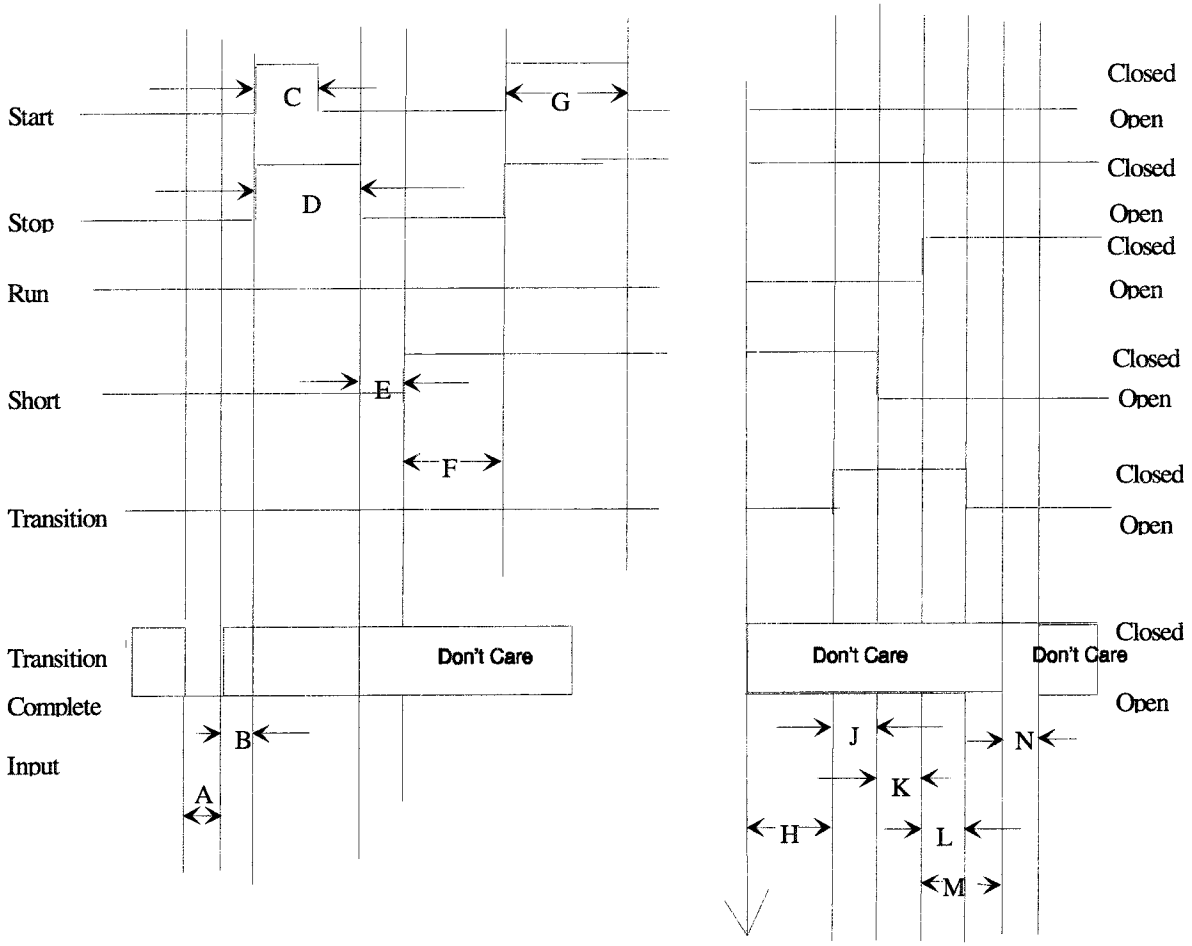
Transducer Checkout Procedure

Quick Test Procedure For Mediamate Water Pressure Transducer

1. Set regulated power supply to 5 VDC. Connect 5 VDC to Pins 2 and 4 on the Transducer.
2. Check zero balance at ambient pressure by attaching Transducer lead wires of a Digital Volt Meter to Pin 1 and Pin 3 of the Transducer.
   - ~ Pin 4 Excitation (Supply) > Connect 5 VDC Power Supply
   - ~ Pin 2: Excitation (Supply)
   - ~ Pin 1: Signal Connect Volt Meter
   - ~ Pin 3: Signal

(A cable assembly with a mating Hirschmann connector could be made up and used for all tests.) Allow transducer to stabilize under power (approximately 15 - 30 seconds).

Readings:



1 Transducer used for Condenser Pressure, Oil Discharge Pressure and Oil Sump. Trane Part Number TDR0272. A good Transducer reading is: 15 mV ± 1mV

2 Evaporator and Condenser Water Flow Transducer and Part Number TDR0274 A good Transducer reading is: 0 mV ± 1 mV.

3. Insert a Q-Tip or small wooden dowel into the pressure port and gently apply force to the diaphragm and watch the DVM for a corresponding change in output.

Starter Contactor Sequence

Timing requirements to operate the "Stop," "Start," "Short," "Transition," and "Run" contact closure outputs are shown below. Prior to closing the "Short" contact, the transition complete input is verified to be open, otherwise a MMR diagnostic is generated.

Maximum Phase Current
< or = to 85 % RLA

Key:

Interval	Units	Actual
A. (Test for transition complete input open)		160 to 240 msec
B. (Just delay time)		20 msec
C. Close 1M (2K1) Contactor and test for no current.) (Starter integrity test)		500 msec
D.		1 sec
E. (Open1M (2K1)		200 msec
F. (Close Shorting Contactor (2K3) and test for no current, then wait for Start command) (Starter integrity test)		1.0 sec (Min.)
G. (Close 1M (2K1)	sec	2sec
H. (Wait 1.5 sec after phase currents drop to 85%)	sec	1.5 sec
J. (Close 2K4 Transition Contactor)	msec	100 msec
K. (Open S (Shorting) Contactor	msec	260 msec
L. (Close 2M (2K2) Contactor)		140 msec
M. (Wait to look for Transition complete) N. (Filtering time on Transition complete input)	msec	2.32 to 2.38sec
N. (Filtering time on Transition complete input)	msec	160 to 240 sec

Note: The transition complete contact closure is expected to be an auxiliary contact to the "Run Contactor' (2K2).

Starter Module CT Voltage and Currents

There are two configurations of CTs used. One is the single stage, the other is the dual stage. A different transfer function exists depending on whether a single or dual stage configuration is used. The two configurations appear the same to the UCP2 by normalizing each. Thus a different equation is used to take the actual line current and convert it to a common 'Normalized Line Current' that may be used in Table 23 . Note that the 'Terminal Volts' is the AC voltage seen at the current input terminal pairs of the Starter module. These pairs are J5-1,2, J5-3,4 and J5-5,6.

For a single stage CT:

$$\text{Normalized Line Current (\%)} = \frac{\text{Actual Line Current(Amps)*100\%*Primary Turns CT-Rated}}{\text{Primary Current (Amps)}}$$

For a two stage CT:

$$\text{Normalized Line Current (\%)} = \frac{\text{Actual Line Current(Amps)*138.89\%*Primary Turns Line CT}}{\text{Rated Primary Current (Amps)}}$$

Table 23-Current Input Transfer Function

Normalized Line Current	Terminal Input Current (mA RMS)	Terminal Volts (V RMS) (± 5%)	Normalized Line Current%	Terminal Input Current (mA RMS)	Terminal Volts (V RMS) (± 5%)
0	0	0	115	115	4.23
5	5	1.19	120	120	4.36
10	10	1.37	125	125	4.49
15	15	1.53	130	130	4.62
20	20	1.67	135	135	4.75
25	25	1.81	140	140	4.88
30	30	1.95	145	145	5.02
35	35	2.09	150	150	5.15
40	40	2.23	160	160	5.41
45	45	2.36	170	170	5.67
50	50	2.50	180	180	5.94
55	55	2.63	190	190	6.20
60	60	2.77	200	200	6.46
65	65	2.90	210	210	6.72
70	70	3.03	220	220	6.99
75	75	3.17	230	230	7.25
80	80	3.30	240	240	7.51
85	85	3.43	250	250	7.77
90	90	3.57	260	260	8.03
95	95	3.70	270	270	8.29
100	100	3.83	280	280	8.56
105	105	3.96	290	290	8.82
110	110	4.10		300	9.08

The Current Transformers should conform to the following resistance tables:

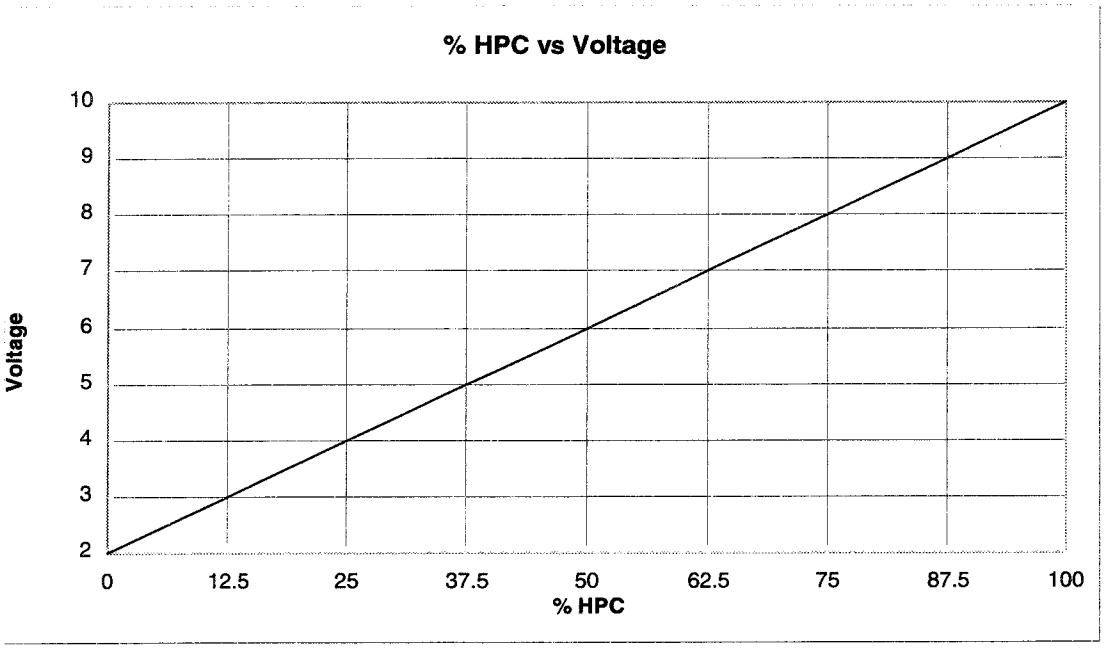
For Single Stage CTs:

Part Number	CT Size	Winding Resistance (±10%)
X-13580253-01	100 A	23 Ω
X-13580253-02	150 A	35 Ω
X-13580253-03	200 A	46 Ω
X-13580253-04	275 A	67 Ω
X-13580253-05	400 A	68 Ω
X-13580253-06	500 A	84 Ω
X-13580253-07	700 A	128 Ω
X-13580253-08	1000 A	235 Ω
X-13580253-09	50 A	12 Ω
X-13580253-10	75 A	17 Ω

Two-Stage CTs:

Two-stage CTs are used on systems that have primary voltages in excess of 600 VAC or line currents higher than 936 amps. The first-stage CT part numbers are in the X-13580047 and X-13580048 families. The second stage is a custom current transformer (X-13580266-01) which has a transformation ratio of 3.6A:0.1A. The secondary of this transformer is then applied to the Starter module.

Trane Part Number	Resistance in Ohms		
X-13580266-01	Primary: 0.020 red and brown leads	Secondary: 5.5 black and white leads	
X-13580047-01	X1 to X4 0.468	X1 to X3 0.374	X1 to X2 0.312
X-13580047-02	X1 to X4 0.697	X1 to X3 0.565	X1 to X2 0.502
X-13580048-01	X1 to X4 0.031	X1 to X3 0.028	X1 to X2 0.023
X-13580048-02	X1 to X4 0.076	X1 to X3 0.065	X1 to X2 0.054
X-13580048-03	X1 to X4 0.104	X1 to X3 0.086	X1 to X2 0.069
X-13580048-04	X1 to X4 0.170	X1 to X3 0.136	X1 to X2 0.119
X-13580048-05	X1 to X3 0.255	X1 to X2 0.204	N/A
X-13580271-01		0.026	
X-13580272-01		0.031	
X-13580272-02		0.044	



Troubleshooting The Percent Condenser Output:

1 While the unit is running, hook up a DC Volt meter between Circuit module terminals J7-1 and J7-2

2 Select '% cond' for the Rfgt Pressure Output Option in the Field Startup menu.

3 View the High Pressure cutout setting in the machine configuration menu.

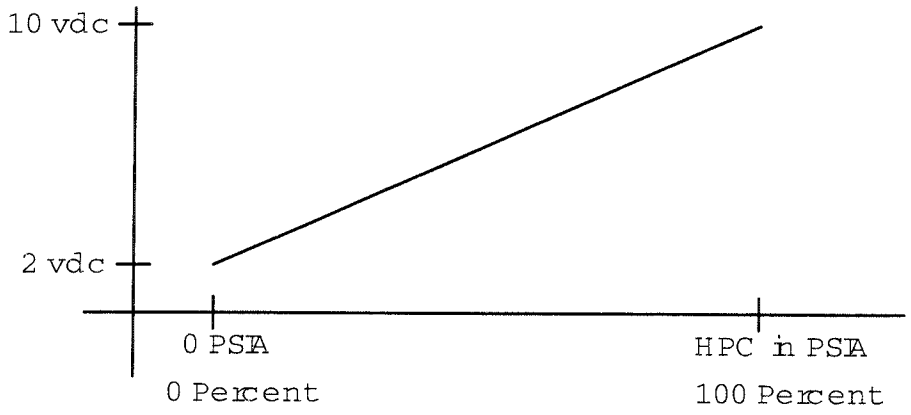
4 View the condenser refrigerant pressure in the refrigerant report.

5 The voltage reading on the voltmeter should correspond to the following graph within 5 percent.

Note: *The zero point on the graph corresponds to 0 PSIA.*

The transfer function is 2 to 10 VDC corresponding to 0 Psia to the HPC setting (psig) plus the local atmospheric pressure setting or, said another way, 0 Psia to HPC in psia. The Percent Condenser Pressure indication output is based on the Condenser Refrigerant Pressure sensor if the Condenser Pressure Option is selected as 'Installed' at the CLD. The Percent Condenser Pressure indication output is based on the Saturated Condenser Refrigerant Temperature sensor if the Condenser Pressure Option is selected as ' Not Installed' at the CLD.

From UCP2 Initial Release (July 93) to 10/21/96 Software Release:



When a Temperature Sensor Only is Used and A Temperature to Pressure Conversion is Made: If the Condenser Saturated Temperature Sensor goes out of range due to an open or short, a pressure sensor diagnostic will be called and the output will also go to the respective out of range value. That is, for an out of range low on the sensor, the output will be limited to 2.0 VDC. For an out of range high on the sensor, the output will be limited to 10.0 VDC.

When a Condenser Pressure Sensor is Used (Optional): If the Condenser Pressure sensor goes out of range, like due to an open or short, a pressure sensor diagnostic will be called

and the output will go to end of range low. That is, for an out of range low on the sensor, the output will be limited to 2.0 VDC. For an out of range high on the sensor, the output will be limited to 2.0 VDC.

As of the 10/21/96 Software Release Including Fastpak and UCP2 Enhancements:

When a Temperature Sensor Only is Used and A Temperature to Pressure Conversion is Made, or When a Condenser Pressure Sensor is Used (Optional): If the Temperature Sensor (or Condenser Pressure sensor) goes out of range due to an open or short, a Temperature Sensor (or Pressure Sensor) diagnostic will be called and the output will go to end of range low. That is, for an out of range low on the sensor, the output will be limited to 2.0 VDC. For an out of range high on the sensor, the output will be limited to 2.0 VDC.

Refrigerant Differential Pressure Indication

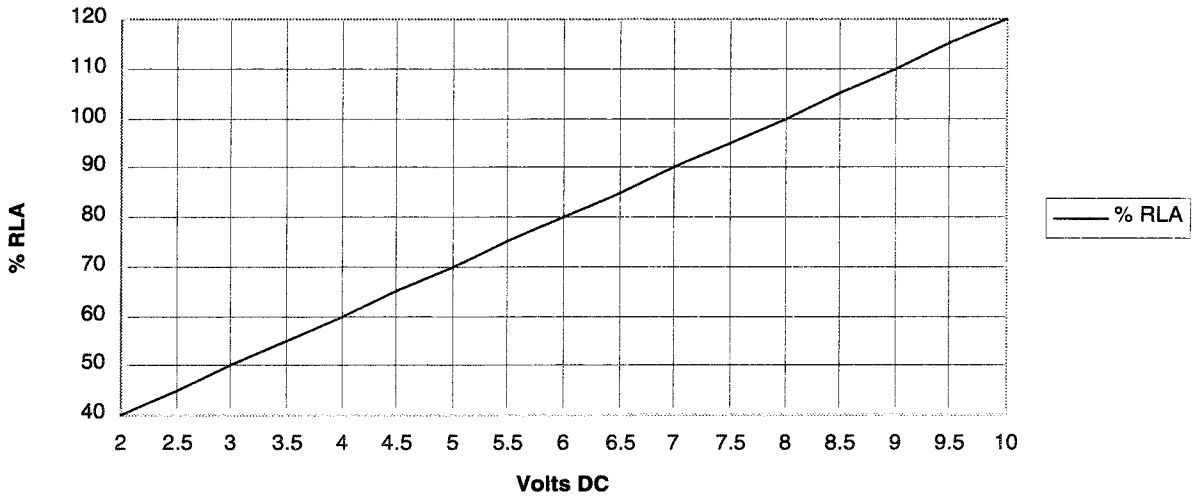
The transfer function is 2 to 10 VDC corresponding to the menu entered "Min Delta Pressure Calibration" setting to the menu entered "Max Delta Pressure Calibration" setting. The Min Delta Pressure Calibration setting has a range of 0-400 psid (0-2758 kPa) in increments of 1 psid (1 kPa). The Max Delta Pressure Calibration setting has a range of 1-400 psid (7-2758 kPa) in increments of 1 psid (1 kPa). The condenser refrigerant pressure is based on the Condenser Refrigerant Pressure sensor if the Condenser Pressure Option is selected as 'Installed' at the CLD. The condenser refrigerant pressure is based on the Saturated Condenser Refrigerant Temperature sensor if the Condenser Pressure Option is selected as 'Not Installed' at the CLD. The evaporator refrigerant pressure is based on the Saturated Evaporator Refrigerant Temperature Sensor.

The Percent Condenser Pressure/Refrigerant Differential Pressure Indication Output is located on the Circuit module at J7-1,2

If the saturated condenser temperature is used to determine condenser pressure, it takes about 11.5 seconds for UCP2's % condenser pressure output to respond to a step change in saturated condenser temperature.

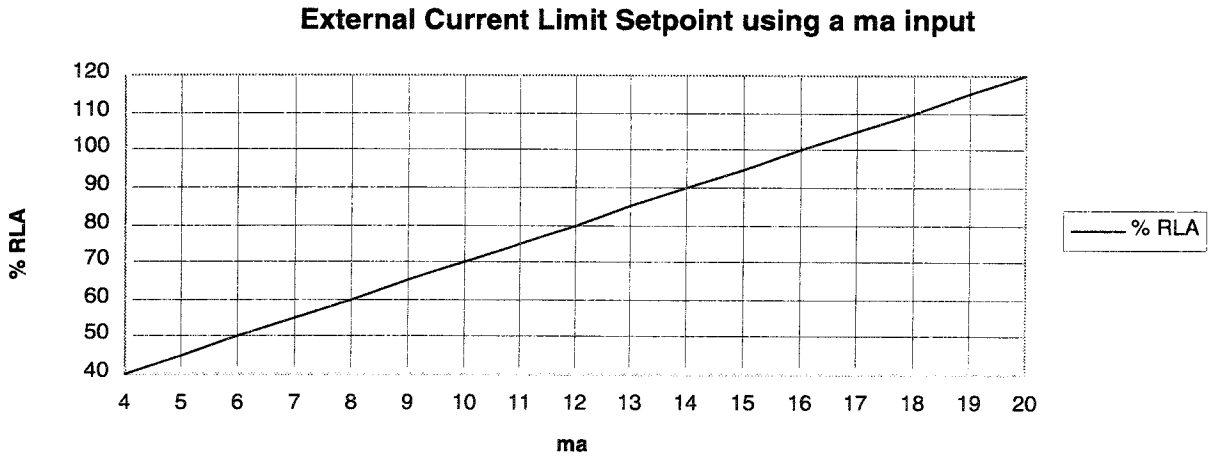
The Percent Condenser Pressure output can source a maximum of 30mA of current.

External Current Limit Setpoint



External Current Limit is an option that allows the customer to change the current limit setpoint from a remote location. The External Current Limit Setpoint is found on Options module terminals J7-11 and J7-12.

UCP2 accepts either a 2-10 VDC or 4-20 mA analog input to set the chillers external current limit setpoint. 2-10 VDC and 4-20mA each correspond to a 40 to 120% RLA range.

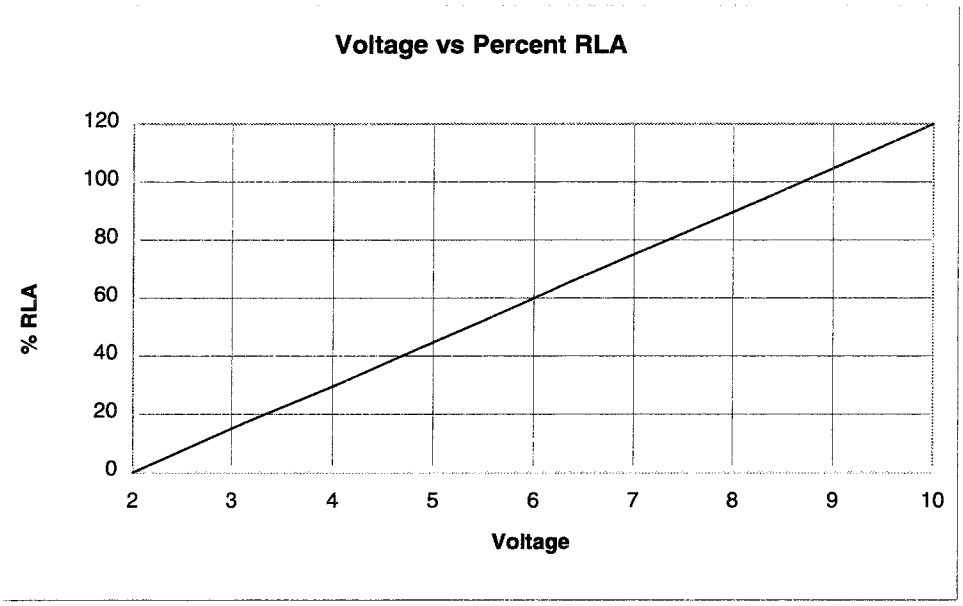


The following equations are what UCP2 uses:

	Voltage Signal	Current Signal
As generated from external source	VDC=.10*(%)-2.0	mA=.20(%)-4.0
As processed by UCP2	%=10.0*(VDC)+20.0	%=5.0(mA)+20.0

The following graph shows External Current Limit Setpoint with a 2-10 VDC input:

The following graph shows External Current Limit Setpoint with a 4-20 mA input:



The Options module DIP switches control what type of input is used. To use a 2-10 VDC signal switch 2-1 should be in the off position. To use a 4-20 mA signal, switch 2-1 should be in the on position.

The user must also specify the type of External Setpoint Input (4-20 mA or 2-10 VDC) in the machine configuration menu.

Percent RLA Output

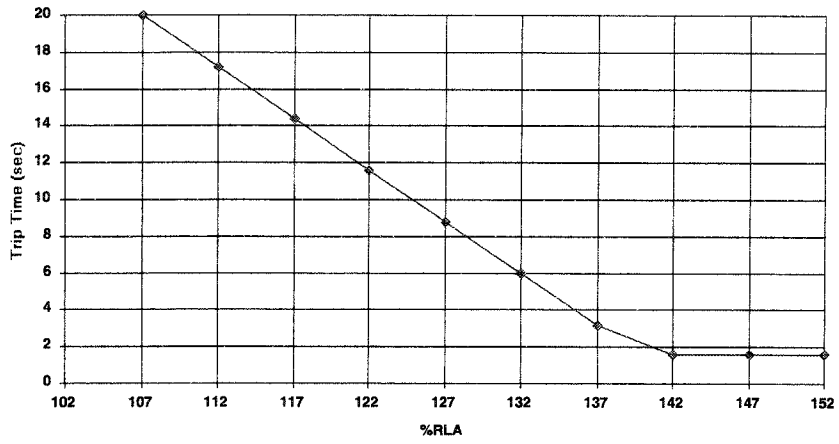
UCP2 provides a 2-10 VDC analog output to indicate % RLA. The transfer function shall be 2 to 10 VDC corresponding to 0 to 120% RLA with a resolution of 0.146%

The following graph illustrates the output:

The % RLA output is found on the Options module terminals J7-3 and J7-4. The % RLA output is polarity sensitive.

J7-3 is +

J7-4 is -



The % RLA output's maximum source capability is 30mA.

Current Overload Protection:

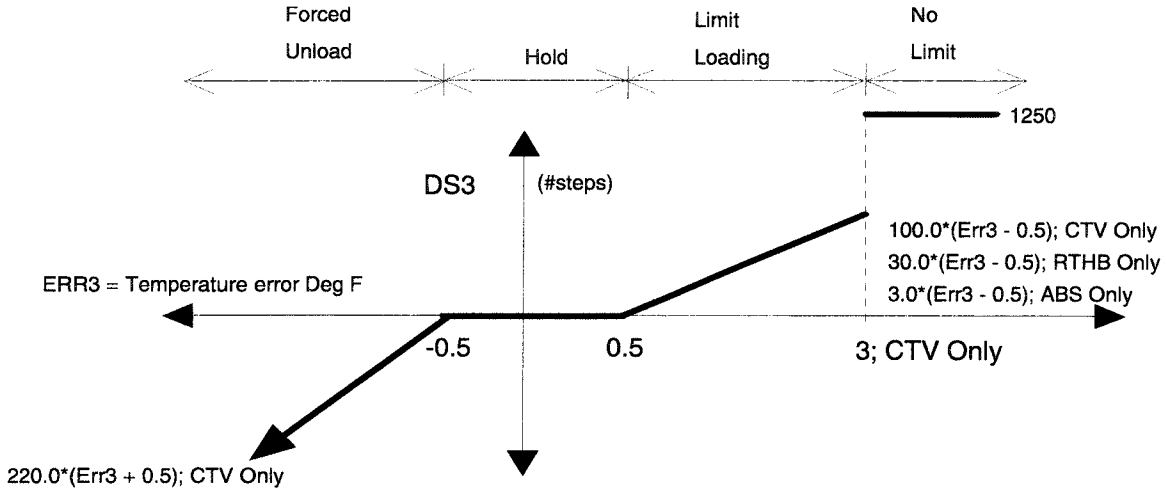
In the run mode, a "time-to-trip" curve is looked at to determine if a diagnostic should be called. UCP2 continuously monitors the compressor current to provide running overcurrent and locked rotor protection. Overcurrent protection is based on the phase with the highest current. It will trigger a manually resettable diagnostic shutting down the compressor when the current exceeds the time-trip curve. The compressor overload is based on unit RLA.

The time-trip curve follows:

Figure 10
Overload Trip Time vs % RLA

Evaporator Refrigerant Temperature Limit

The Evaporator Refrigerant Temperature Limit is a multistage control that acts to prevent chiller shutdown when the evaporator refrigerant temperature approaches the cutout setpoint by reducing chiller capacity. Chiller capacity is reduced by the following steps, providing increasingly aggressive action as the trip point is approached:



1 Limit requests for capacity increases.

2 Prohibit requests for capacity increases.

3 Initiate stepped capacity reduction.

4 Initiate maximum capacity reduction.

The purpose of this limit is to provide maximum capacity while preventing chiller shutdown due to low evaporator refrigerant temperatures.

The Low Refrigerant Temperature Cutout setpoint is found in the Field Startup menu.

Design:

Lowest standard chilled water setpoint (CWS) = 37°F

Lowest standard low refrig. temp. cutout (LRTC) = 28.5°F

Lowest standard refrig. temp. limit setpoint (LRTLS) (28.5 + 2) = 30.5°F

Minimum differential between LRTC and CWS = 6.0°F

Condenser Refrigerant Pressure Limit

Prevents chiller shutdown due to High Condenser Pressure.

Explanatory Comments:

This is a multistage control that acts to prevent chiller shutdown when the condenser refrigerant pressure approaches the cutout setpoint by reducing chiller capacity. Chiller capacity is reduced via the following steps, providing increasingly aggressive action as the trip point is approached:

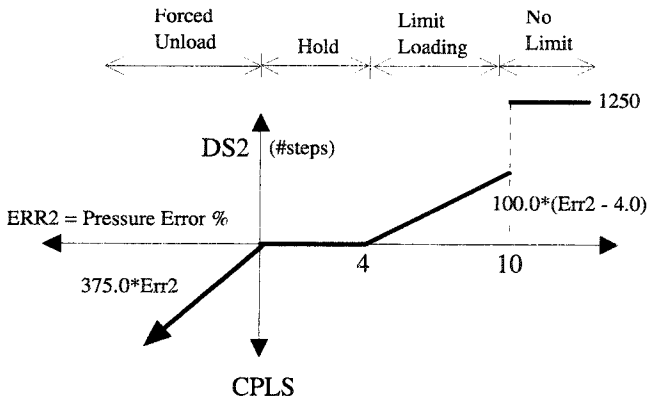
1 Limit requests for capacity increases.

2 Prohibit requests for capacity increases.

3 Initiate stepped capacity reduction.

4 Initiate maximum capacity reduction.

The intent of this control is to provide maximum capacity while preventing chiller shutdown due to high condenser pressures.



The condenser pressure limit function is based on the Condenser Pressure sensor if the Condenser Pressure sensor option is selected as 'Installed' on the CLD. The limit is based on the Saturated Condenser Refrigerant Temperature if the Condenser Pressure sensor is selected as 'Not Installed' on the CLD.

Setpoint (CPLS) range: (80 - 120)% HPC (Factory set to 93% HPC)

Figure 11 provides a graphical representation of the condenser pressure limit control regions for an arbitrary setpoint and the condenser pressure limit control output Ds2.

Where ERR2 = CPLS(% HPC) - actual pressure (% HPC)

Figure 11
Condenser Pressure Limit Control Regions for an Arbitrary Setpoint

Head Relief Request

Keeps chiller on line and/or signals operator when the chiller experiences high head.

This output relay provides the customer with a "hook" into UCP2 to signal the Tower that the current tower temperature is too high. A customer may use this relay to energize multiple fans to reduce the tower water temperature.

UCP2 provides a relay output (Options module terminals J12-1 and J12-2) that can be used to operate some function in the condenser cooling system. Contacts should be compatible with a 115/240VAC control circuit.

For CTV units, the Head Relief Request relay is energized anytime the unit is in condenser limit. In addition, the Head Relief Request relay is energized anytime a surge condition is detected.

The Head Relief Request relay is accessible by Tracer such that Tracer can command it on and off if one of the above criteria is not already energizing the relay.

> *NOTE: The Head Relief Request relay is energized based only on the mode of the chiller. For example, the relay will follow either the condenser limit mode or the surge mode. In the case of condenser limit, the relay is not directly dependent on pressure; again, it is only dependent on mode.*
>
> *It is recommended that an adjustable off-delay relay be used to provide some control adjustment. It is not recommended that a tower fan be turned on and off solely based on the condenser limit mode; excessive cycling may result.*

Free Cooling Relay Checkout

1 Disable Free Cooling in the Operator Settings menu.

2 Unplug the free cooling relay connectors from J-16 and J24 on the Options module.

3 Using a DVM, measure the resistance between J16-3 and J16-2. Record in the table below.

4 Measure and record the resistance between J16-3 and J16-1.

5 Measure and record the resistance between J24-3 and J24-2.

6 Measure and record the resistance between J24-3 and J24-1.

7 Enable Free Cooling in the Operator Settings menu.

8 Using a DVM, measure the resistance between J16-3 and J16-2. Record in the table below.

9 Measure and record the resistance between J16-3 and J16-1.

10 Measure and record the resistance between J24-3 and J24-2.

11 Measure and record the resistance between J24-3 and J24-1.

12 If any of the recorded resistances are out of the specified values, the free cooling relays are not functioning properly.

Terminals	Recorded Resistance	Value when Free Cooling is Disabled	Value when Free Cooling is Enabled
J16-3 to J16-2		Less than 5 Ohms	Greater Than 1M Ohm
J16-3 to J16-1		Greater Than 1M Ohm	Less than 5 Ohms
J24-3 to J24-2		Less than 5 Ohms	Greater Than 1M Ohm
J24-3 to J24-1		Greater Than 1M Ohm	Less than 5 Ohms

UCP2 provides Free Cooling control as follows:

1 The Options module shall provide the following Binary Inputs/Outputs:

- ~ Class II Binary Input: External Free Cooling Switch
- ~ Class II Binary Input: FC Actuators Closed FC valve closed limit switches are wired in series to this input.
- ~ Class I Form C Binary Output: FC Actuator Relay #1 Operates first FC valve.
- ~ Class I Form A Binary Output: FC Aux. Relay Customers choice.
- ~ Class I From C Binary Output: FC Actuator Relay #2 Operates second FC valve

2 The operator has the ability to control Free Cooling On/Off manually at the Front Panel, Automatically via a On/Off binary input (called External Free Cooling Switch) at the Options module, and from a command from Tracer. At the binary input at the Options module, an open shall command Free Cooling Off, and a Short will command Free Cooling On.

3 For display and mode purposes, the FC mode shall be displayed when the FC valves are open. That is, when the FC valve relays are energized and the FC valve limit switches open the FC mode shall be displayed. Likewise, when the FC valve relays are de-energized and the FC valve limit switches close, the FC mode shall be terminated.

4 FC cannot be entered if the chiller is in STOP; FC can only be entered from AUTO. Either setting the FP CLD to FC On or closing the Ext FC Switch binary input, or receiving a

command from Tracer will initiate the sequence to enter FC.

If the chiller is in AUTO and not running UCP2 will start the condenser water pump just as it does for powered cooling (Since the unit is in AUTO the chilled water pump should already be running. Once condenser water flow is confirmed the FC valve relays #1, #2, and the FC Aux. relay are all energized. If the FC valve closed limit switches do not open within 3 minutes a MMR diagnostic is generated. Once the FC valve closed limit switches open the unit is considered in FC.

If the chiller is in AUTO and is running powered cooling, the chiller will do a normal friendly shutdown when FC is commanded from either source. The compressor will enter RUN: UNLOAD, POST LUBE, and overdrive the IGVs closed as usual. Once the IGV's have been overdriven closed and condenser water flow has been confirmed, the three FC relays will be energized.

In FC manual vane control shall not be active.

It is not necessary to check the status of the IGVs during FC. The IGVs must be closed during FC; it is sufficient to assume that they are closed since they are overdriven closed on all compressor shutdowns and hard (powerup) resets.

Once the FC valves have opened, a FC valve closure will generate an MMR diagnostic.

If there is a diagnostic in FC, Stop FC as normal and Stop the Condenser Water Pump.

5 FC can be terminated from either the Front Panel CLD, the Ext. FC Switch input at the Options module, or the Tracer (or a diagnostic). Once commanded to Off, the Two FC relays are de-energized. If the FC valve closed limit switches do not close within 3 minutes a MMR diagnostic is generated. Once the limit switches are closed the chiller status should revert back to AUTO and powered cooling may be entered if there is a call for cooling.

6 **On all FC chillers (FC is installed),** the FC valve limit switches must be closed to both start and run powered cooling, otherwise a MMR diagnostic will be generated. The IGVs must be held closed for 3 minutes on each startup following a free cooling mode.

7 On FC units the failure of communications between the Options module and the Chiller module will cause a MMR diagnostic at the Chiller module.

Hot Gas Bypass

Customer Benefit:

Hot Gas Bypass eliminates or reduces cycling on process or other installations having load variations that occasionally include brief periods of no or very light load. Eliminating cycling shortens the time required to respond to load increases, and prevents chiller starts during periods when chiller starts are prohibited.

HGBP is also used as a way to correct applications where the chiller has been oversized.

Explanatory Comments:

Hot Gas Bypass is a chiller option that is intended to reduce the capacity of the chiller at minimum load conditions by bypassing condenser gas to the evaporator. On standard chillers, minimum load is determined by the amount of gas that leaks through the inlet guide vanes when they are fully closed. By adding HGBP a portion of this gas comes directly from the condenser, thus reducing the amount of cooling done by the chiller.

For CVHE/F/G/B Chillers:

See also High Compressor Discharge Temperature Protection.

In the Machine Configuration menu, UCP2 has an entry to indicate that hot gas bypass is installed. The installation of HGBP will enable all of the HGBP valve diagnostics, HGBP screens in the CLD, and communications diagnostics with the I/O module. The HGBP valve can be independently controlled in the Service Tests menu. Tracer is also be able to Enable/ Disable HGBP.

When HGBP is Enabled, HGBP control will check to see if the IGV position is less than or equal to the larger of either Fully Closed or the "Guide Vane Closed Travel Stop". When this condition is satisfied and the ELWT is 0.5°F below the chilled water setpoint an integral is permitted to ramp up. When the integral reaches a predetermined value, the HGBP mode is Entered.

Once the HGBP mode is entered, the output of the evaporator leaving water temperature control algorithm will be scaled for tics (versus steps) and sent to the I/O module to modulate the HGBP valve. The inlet guide vanes are given a loading pulse until the "HGBP Mode, IGV Target" is attained.

Exiting Hot Gas Bypass:

While in the HGBP mode, the same integral that allowed HGBP to be entered is ramped if the ELWT is 0.5°F above the chilled water setpoint. This allows the HGBP mode to be terminated if the load increases. When this integral is greater than or equal to some preset value, HGBP control is terminated, and LWT control is directed to the inlet guide vanes.

If the user Enables the "Maximum HGBP Time" timer, the algorithm shuts the CenTraVac down after the timer has expired. The "Maximum HGBP Time" will be user adjustable. When the timer is Enabled, the mode display is modified to show the Hot Gas Bypass time remaining.

During HGBP, the normal differential to stop is obeyed. If the differential to stop or the "Maximum HGBP Time" timer requires the Centravac to shutdown, the HGBP valve will be held while the inlet guide vanes are driven closed. When the inlet guide vanes are fully closed, the Centravac will shutdown.

Hot Gas Bypass Valve Operation:

The HGBP valve is constantly driven closed when neither in the HGBP mode nor under manual HGBP valve control. During this time, the I/O module will be checking for a valve closed indication from the HGBP valve switch input and will issue a valve diagnostic if the valve is not found to be closed. Upon seeing a transition from either HGBP mode or manual HGBP valve control, the I/O module will allow 3 minutes to expire before calling out a Hot Gas Bypass Valve closure overdue diagnostic.

Manual Hot Gas Bypass Valve Control:

The HGBP valve is capable of manual control while the unit is running and during the stop mode. The manual HGBP control is based on a load, hold, or unload signal from a user specified duration setpoint every 5 seconds.

Design:

The HGBP feature is designed as specified above. The following is added for further clarity.

Hot gas bypass (HGBP) is a control option designed to avoid chiller cycling during low load conditions while still maintaining the chilled water temperature set point. This is accomplished by artificially increasing the load on the compressor. The compressor load is artificially increased using the hot gas bypass valve to divert refrigerant gas from the condenser back into the suction side of the compressor. The hot gas bypass valve is modulated by appropriately scaling the output of the ELWT control algorithm.

HGBP Control Actuator Characteristics: Single phase induction motor moving a butterfly valve

HGBP Control Algorithm Inputs: ELWT control error, IGV target position

HGBP Control Algorithm Output: number of tics to open/close the hot gas bypass valve

HGBP Control Algorithm Sample Rate: Sample Rate: = 5 sec

Install and Enable

To get the HGBP control option to function it must first be installed. To install the HGBP control option enter the **Machine Configuration Group**. In this group make sure to

1 Install Hot Gas Bypass Control.

Installing HGBP control sets up the display features associated with HGBP. However, for the control algorithm to be operational it must be enabled. To enable the HGBP control algorithm enter the **Field Start-up Group**.

2 Enable Hot Gas Bypass Control.

In addition, this group also has three user adjustable setpoints associated with the HGBP control option. The three setpoints are:

1) HGBP mode, IGV Target:%

In the HGBP mode, the HGBP valve modulates capacity while the inlet guide vanes move to a target position set by the user. The inlet guide vanes move to the target position by a maximum of 40 steps every sample period.

2) Guide Vane Closed Travel Stop:%

In order for the hot gas bypass staging integral to begin integrating, the inlet guide vane step position must be below a minimum step position known as the guide vane closed travel stop. In addition, the ELWT must be 0.5°F below the chilled water setpoint.

3) Maximum HGBP Time:

When the maximum HGBP time is enabled the maximum HGBP timer is used to determine how long the chiller is allowed to operate in the hot gas bypass mode.

Hot Gas Bypass Control Algorithm

The HGBP staging integral begins to execute once the ELWT falls below the CWS by 0.5°F, and the inlet guide vanes are below a user specified minimum position (usually zero). Once the HGBP staging integral has reached a preset number, capacity control transitions to the HGBP valve. The HGBP value is modulated by converting ELWT step commands into time based (tic) commands. Once transition occurs, the inlet guide vanes are loaded by 40 steps every sample period until they reach a user specified target value. To exit the HGBP modulating mode, the evaporator leaving water temperature must begin to rise above the CWS. If the ELWT exceeds the CWS by 0.5°F, the staging integral begins to integrate. Once the staging integral reaches a preset number, capacity control transitions back to the inlet guide vanes.

Ice Machine Control

UCP2 will accept a contact closure input to initiate Ice building. When in the ice making mode, the compressor will be fully loaded and will continue to operate until the ice contacts open or the return water temperature reaches an Adjustable Termination Setpoint. If terminated on return setpoint, UCP2 will not allow the chiller to restart until the ice making contact is opened.

UCP2 will provide an output contact closure that can be used as a signal to the system that ice making is in operation. This relay will be closed when ice making is in progress and open when ice making has been terminated by either UCP2 or the remote interlock. It is used to signal the system changes required to convert to and from ice making.

Ice mode operation will be indicated by an "Ice Building" operation mode that can be displayed at the unit or communicated over the communications link.

The UCM shall provide a Service level Enable/Disable menu entry for the Ice Building feature when the Ice Building Option is installed.

The UCM shall accept either an isolated contact closure (call it External Ice) or a Remote Communicated input (Tracer) to initiate an Ice building mode where the unit runs fully loaded at all times. Ice building shall be terminated either by opening the contact or based on entering evaporator water temperature. The UCM shall not permit the Ice Building mode to be entered again until the unit is switched to the Non-Ice Building mode and back into the Ice Building mode.

It is not acceptable to reset the CWS low to achieve a fully loaded compressor; the UCM shall force the compressor to full load.

When entering ICE-BUILDING the compressor is loaded at its maximum rate and when leaving ICE-BUILDING the compressor is unloaded at its maximum rate. For CTV only: while loading and unloading the compressor all surge detection is ignored.

> *Implementation Note: Surge detection is not explicitly prevented while loading and unloading the chiller. While the above requirement is valid it is not expected that a surge would be detectable during the relatively short load and unload intervals.*

In Ice building, softloading and current limit setpoints less than the maximum are all ignored. For example, if the Front Panel Current Limit setpoint is set to 80%, in Ice Building the Active Current Limit setpoint is automatically reset to its maximum value.

In the Ice Building mode if the unit gets down to the freezestat setting (water or refrigerant) the unit will shutdown on a diagnostic, just like in normal operation.

Condenser, current and evaporator limits are active during Ice Building.

If any other limits are placed on IGV or Slide Valve stroke during Normal Cooling, the UCM will ignore these limits during ICE-BUILDING; that is, the IGVs or Slide Valve will be fully loaded/ stroked/extended during ICE BUILDING.

ICE-BUILDING and ICE-BUILDING COMPLETE are modes displayed by the UCM at the front panel and communicated to the Tracer.

If the UCM has the capacity for some other feature to reset the cooling tower temperature, the cooling tower temperature is reset to its minimum value or the cooling tower commanded to run at full capacity.

ICE-BUILDING may be terminated by one of three means:

1 Opening the External Ice Contacts/Remote communicated input (Tracer), or satisfying an evaporator entering water temperature setpoint, or surging for 15 minutes at full open IGV

or

2 In general, if there is an MAR diagnostic during either ICE-BUILDING or ICE BUILDING COMPLETE and the diagnostic clears the chiller shall return to either ICE-BUILDING or ICE-BUILDING COMPLETE, respectively

or

3 If the ice building complete mode is reached and the ice building complete mode is exited due to a diagnostic or a system stop command, removing the diagnostic or returning the system to the auto mode will cause the system to return to the ice building complete mode. The system will leave ice building complete when the ice building command is released in any mode.

During ICE-BUILDING, any other action specified for Normal Cooling due to surge detection is overridden. If surge is detected continuously for 15 minutes while in ICE-BUILDING and while the IGVs are fully open, shutdown the chiller on a latching MAR diagnostic; the chiller is latched out of ICE-BUILDING until the Ice-Building command is cycled; Normal Cooling is permitted. (Notice in both ICE-BUILDING and NORMAL COOLING a surge diagnostic is a MMR diagnostic., however, if there was a surge diagnostic. when in ICE-BUILDING the diagnostic is automatically cleared when the ice-building command is withdrawn.)

The UCM shall accept a non-volatile "Front Panel Ice Termination Setpoint" adjustable from 20 to 31°F (-6.7 to -0.5°C) in at least 1°F (0.1°C) increments. When the evaporator entering water temperature drops below the ice termination setpoint the chiller will enter it's shutdown sequence.

If ICE-BUILDING is terminated by either the External Ice contacts opening or the Remote Communicated input (Tracer) while the compressor is running, as noted above, the compressor will be unloaded at its maximum rate, however, the chiller will continue to operate at minimum capacity for an adjustable 0 to 10 minutes; call this the "Ice-to-Normal Cooling Timer" (default value to be 5 minutes). If during the Ice-to-Normal Cooling Time the LWT becomes greater than the Normal Cooling Differential To Stop shutdown temperature, the chiller will be returned to Normal LWT control and shutdown on the Normal Differential to Stop criteria. If the Normal Cooling Differential to Stop shutdown temperature is not reached during the Ice-to-Normal Cooling Time, the chiller enters its shutdown sequence; chiller restart will then be based on the Normal Cooling Differential to Start criteria.

Ice Building will only be permitted when both the unit is in Auto and the last mode of operation has been normal (non-ice building) AUTO (either running or not running). See the following table:

Unit Status 0 = Stop 1 = Auto	Ext Ice Input	Entr Evap Temp Compared to Ice-ter Setpt	Chiller Mode
0	Ice (Short)	>	Stop

1	Normal (0pen)	>	Auto
1	Ice (Short)	>	Ice-building, Run Full Load.
1	Ice (Short)	<	Ice-completed, Ice-building Terminated Because the Ice Completion Setpt was Met.
1	Ice (Short)	>	Ice Completed, Cannot Restart Ice-building Because the Ext Ice Input was not Cycled Out and Back Into "Ice Building".
1	Normal (Open)	>	Auto, Normal Chiller Operation Based and Chilled Water Setpoint.
1	Ice (Short)	>	Ice-building.

Pumps:

Condenser pump control shall be as in Normal Cooling.

Chilled Water pump control shall be as in Normal Cooling.

Upon termination of Ice Building based on evaporator entering water temperature, either the UCM or Unit must provide a contact closure that can be used to turn off the pump system. This requirement shall be satisfied as follows:

During the ICE-BUILDING COMPLETE mode the CHWP relay shall be de-energized immediately upon entering "Ice Building Complete" (following the "post lubrication" mode) as if the chiller had been manually put to STOP. Assuming the chiller is still in the AUTO mode when the External Ice Contacts are opened, the CHWP relay shall be re-energized.

Ice Building Relay:

The ice building relay will be held on as long as there is a valid ice building command and the Ice building complete mode has never occurred. If ice building is interrupted by a diagnostic or some type of stop command, the relay will be held on. This is because clearing of the diagnostic or re-entering the auto condition will allow ice building to resume. Said another way, the ice building relay is on whenever there is a Ice Building command (External or Remote Communicated (Tracer)) but we are not in the Ice Building Complete mode.

Recommended Wire Lengths for PTs

The maximum recommended wire length for PTs in a single PT system:

Wire Gauge	Max lead length(ft)	Max lead length (m)
8	5339	1627
9	4234	1291
10	3357	1023
11	2663	811
12	2112	643
13	1674	510
14	1328	404
15	1053	321
16	835	254
17	662	201
18	525	160
19	416	126
20	330	100
21	262	79
22	207	63

The maximum recommended wire length for PT leads in a dual PT system are:

Wire Gauge	Max Wire Length Primary (ft)	Max Wire Length Primary (m)	Max Wire Length Secondary (ft)	Max Wire Length Secondary (m)
8	3061	933	711	217
9	2428	740	564	172
10	1924	586	447	136
11	1526	465	355	108
12	1211	369	281	85
13	960	292	223	68
14	761	232	177	53
15	603	184	140	42
16	478	145	111	33
17	379	115	88	26
18	301	91	70	21
19	238	72	55	16
20	189	57	44	13
21	150	45	34	10
22	119	36	27	8

Note: These wire lengths are for copper conductors only

Note: The above lengths are maximum round trip wire lengths. The maximum distance the PT can be located is 1/2 of the listed value.

Checking for an Open, Burnt, or Shorted CentraVac Motor Windings

1 Remove power from the machine and remove the three main fuses.

2 Disconnect the top three leads from the motor lugs.

3 Verify the terminal to terminal and terminal to ground resistances are correct by using the tables below.

For Low to Medium Voltage Machines (Less than 4160 V):

Meas. Point	Chassis GND	T1	T2	T3	T4	T5	T6
Chassis GND	N/A	V x 1,000*	V x 1,000*	V x 1,000*	V x 1,000*	V x 1,000*	V x 1,000*
T1	V x 1,000*	N/A	∞	∞	< 1 ohm	∞	∞
T2	V x 1,000*	∞	N/A	∞	∞	< 1 ohm	∞
T3	V x 1,000*	∞	∞	N/A	∞	∞	< 1 ohm
T4	V x 1,000*	< 1 ohm	∞	∞	N/A	∞	∞
T5	V x 1,000*	∞	< 1 ohm	∞	∞	N/A	∞
T6	V x 1,000*	∞	∞	< 1 ohm	∞	∞	N/A

where:

∞ = Infinity

V = The rated motor voltage.

* The rated motor voltage multiplied by 1,000 is the minimum resistance that you should measure here. The actual resistance that you measure will probably be higher.

For High Voltage Machines (4160 V and higher): Consult Trane Technical Service for this information.

Information on Tracer

Tracer is automatically installed when it does control. If it only does monitoring, it will not automatically install and, in fact, a loss of comm with Tracer will be called if a person manually installs the Tracer option. If the TCI and/or Tracer option are automatically installed by hooking them up, the CLD menus will be automatically changed to 'installed'. If loss of comm occurs with the Tracer or TCI, UCP2 will default to front panel setpoints, but the diagnostic 'Tracer Communications Lost' will be called at UCP2 and Tracer will not be de-installed. On a power up, if the Tracer option was previously installed, the TCI module will call out a 'Tracer failed to Establish Comm' if the Tracer does not take control within two minutes.

If Tracer communications are lost for 15 continuous minutes after communication have been established, then front panel setpoints are used by UCP2.

LEDS:

The diagnostic LED in the upper left hand side of the module is only active for the printer module, and should never come on for a TCI module.

The Green LED labeled RXA should be continuously flashing.

The Red LED labeled TXA should blink about once every two seconds.

The Green LED labeled RXB will blink constantly

The Red LED labeled TXB will blink once every minute for comm 3, and once every 20-60 seconds for comm 4.

Dip Switches:

For a TCI comm 3 module, the dip switches should be in the following positions:

1 - Off

2 - Off

3 - Off

For a TCI comm 4 module, the dip switches should be in the following positions:

1 - Off

2 - On

3 - Off

UCP2/Tracer Compatibility List:

Go into the Service Tests menu and display the software revision levels, or view the part numbers on the modules.

Confirm that all of UCP2 modules are equal to or greater than the revision levels listed below.

Module	Module Hardware	Software
CTV Chiller	X-13650450-02	02
Circuit	X-13650451-04	03
CTV Stepper	X-13650455-03	03
LCLD	X-13650448-02	06
TCI Com 4 Baud 9600	X-13650457-03	03
TCI Com 3 Baud 1200	X-13650460-02	02
Options	X-13650452-02	02

Purge	X-13650454-04	03
Starter	X-13650453-04	05

UCP2 Clock:

UCP2 clock will retain it's last time stored in it at power down, but will not increment while powered down. It is necessary to update the time and date if UCP2 is powered down for an extended period of time. If UCP2 has been powered down for an extended period, then a informational warning 'Check Clock' will be announced.

The Year 2000:

UCP2 is year 2000 compliant, because UCP2's valid range of dates is January 1st, 1980 to February 5th, 2116. No date problems will occur in this range, including the year 2000.

There will be no operating effect for UCP2 going to the year 2000. 90 percent of all Trane centrifugal chillers installed in 1938 were still running in 1994. However, it is unlikely that a chiller installed in 1996 will run twice that amount of time and make it until 2116. If a chiller does live until to the year 2116, the clock will roll over to January 1st, 1980. UCP2 does not use the date for any control functions. The date and time is displayed for the operators information, and as a time/ date stamp for diagnostics.

UCP2 has been tested, and transitions to the year 2000 without any problem.

Date information is not required to be entered in the initial configuration of UCP2. However, most people do like to set up the clock on initial startup.

The format of UCP2's date follows: Time, Month, Day, Year. Example: 11:59 pm Dec 31, 2116.

The years are input as 4 digits.

The valid range of dates is from January 1, 1980 to February 5, 2116.

When UCP2 reaches the end of the date range, the clock rolls over to January 1, 1980.

Date calculations are not used in the standard operation of the UCP2. UCP2 does not perform any date based feature activation/deactivation.

Diagnostics are time stamped and the time stamp is displayed in the following format: 6:31 pm Feb 12, 1997.

UCP2 does perform leap year calculations, but does not perform daylight savings time calculations.

Chilled Water Reset

The chilled water reset function can provide energy savings and/or better critical zone control and/or better indoor air quality when applied to the right system type.

The chilled water setpoint is reset based on a temperature (return chilled water, zone, outside air), or other input such as humidity or a customer supplied analog signal.

The most common use of chilled water reset is to provide constant return chilled water temperature. UCP2 makes this particular form of chilled water reset very easy to set up. One way to do this is to make it the default setting.

Constant Return Reset is a good starting point in a comfort cooling application. If you think about it, at full load you both cool (sensible) and dehumidify (latent) the air at the coil. The coil is designed to do so much sensible and latent cooling at a given entering water temperature. If you can get sufficient sensible and latent cooling at full load, it follows then that by maintaining a constant leaving water temperature off the coil (entering to the chiller) at part load you have a good chance of satisfying both your sensible and latent loads. Of course, if at part load the customer finds the air is either too wet or too dry, the Chilled Water Reset Ratio can be adjusted up or down to compensate.

Due to extremely low usage, CWR based on Zone Temperature has been eliminated from the basic UCP2.

UCP2 resets the chilled water temperature setpoint based on either return water temperature, or outdoor air temperature. Return Reset is standard, Outdoor Reset is optional.

The following are selectable:

1 One of three RESET TYPEs: no CWR, RETURN WATER TEMPERATURE RESET, OUTDOOR AIR TEMPERATURE RESET, or CONSTANT RETURN WATER TEMPERATURE RESET. The UCP2 will not permit more than one type of reset to be selected.

2 RESET RATIO Setpoints.

For outdoor air temp. reset there shall be both positive and negative reset ratios.

3 START RESET Setpoints.

4 MAXIMUM RESET Setpoints.

The maximum reset's are with respect to the chilled water setpoint.

The equations for each type of reset are:

Return

CWS' = CWS + RATIO (START RESET - (TWE - TWL))

and CWS' > or = CWS

and CWS' - CWS < or = Maximum Reset

Outdoor

CWS' = CWS + RATIO * (START RESET - TOD)

and CWS' > or = CWS

and CWS' - CWS < or = Maximum Reset

where

CWS' is the new chilled water setpoint,

CWS is the active chilled water setpoint before any reset has occurred

RESET RATIO is a user adjustable gain

START RESET is a user adjustable reference

TOD is the outdoor temperature

TWE is entering evap. water temperature

TWL is leaving evap. water temperature

MAXIMUM RESET is a user adjustable limit providing the maximum amount of reset. For all types of reset, CWS' - CWS < or = Maximum Reset.

The values for "RESET RATIO" for each of the reset types are:

Reset Type	Reset Ratio Range	Increment (English Units)	Increment (SI Units)	Factory Default Value
Return:	10 to 120%	1%	1%	50%
Outdoor	80 to -80%	1%	1%	10%

The values for "START RESET" for each of the reset types are:

Reset Type	Start Reset Range	Increment (English Units)	Increment (SI Units)	Factory Default Value
Return	4 to 30°F (2.2 to 16.7°C)	1°F	0.1°C	10°F (5.6°C)
Outdoor	50 to 130°F (10 to 54.4°C)	1°F	0.1°C	90°F (32.2°C)

The values for MAXIMUM RESET for each of the reset types are:

Reset Type	Maximum Reset Range	Increment (English Units)	Increment (SI Units)	Factory Default Value
Return	0 to 20°F (0.0 to 11.1°C)	1°F	0.1°C	5°F (2.8°C)
Outdoor	0 to 20°F (0.0 to 11.1°C)	1°F	0.1°C	5°F (2.8°C)

Both Return and Outdoor Reset do not apply to hot water control mode where UCP2 is controlling the Leaving Condenser Water Temperature.

In addition to Return and Outdoor Reset, UCP2 will provide a menu item at the Clear Language Display for the operator to select a Constant Return Reset. Constant Return Reset will reset the leaving water temperature setpoint so as to provide a constant entering water temperature. The Constant Return Reset equation is the same as the Return Reset equation except on selection of Constant Return Reset, UCP2 will automatically set RATIO, START RESET, and MAXIMUM RESET to the following.

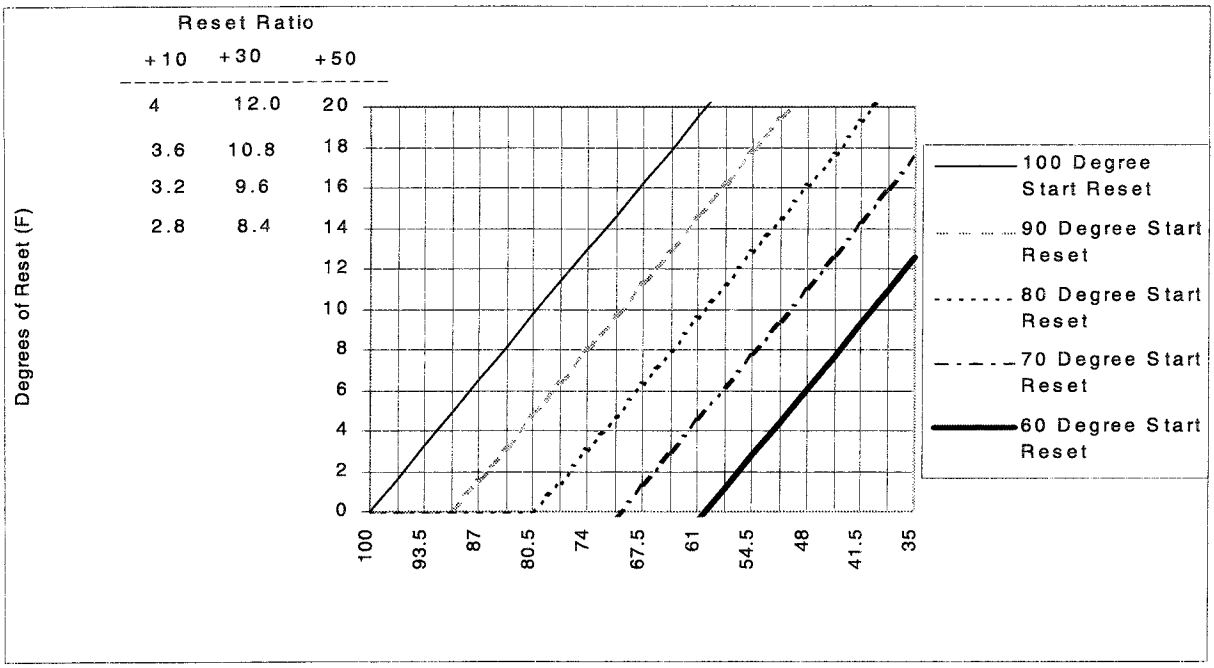
the RATIO = 100%

the START RESET = Design Delta Temp.

the MAXIMUM RESET = Design Delta Temp.

The equation for Constant Return is then as follows:

Constant Return



CWS' = CWS + 100% (Design Delta Temp. - (TWE - TWL))

and CWS' > or = CWS

and CWS' - CWS < or = Maximum Reset

Notice that Constant Return is nothing more than a specific case of Return Reset offered for operator convenience.

When any type of CWR is enabled, UCP2 will step the CWS toward the desired CWS' (based on the above equations and setup parameters) at a rate of 1°F every 5 minutes until the Active CWS equals the desired CWS'. This applies when the chiller is running. When the chiller is not running the CWS is reset immediately (within one minute) for Return Reset and at a rate of 1°F every 5 minutes for Outdoor Reset. The chiller will start at the Differential to Start value above a fully reset CWS or CWS' for both Return and Outdoor Reset.

The preceding graph shows the reset function for Outdoor Air Temp:

Note: This graph assumes that Maximum Reset is set to 20 degrees.

Using the Equation for calculating CWR for Outdoor Air Temp

Equation:

Degrees of Reset = Reset Ratio* (Start Reset - TOD)

Degrees of Reset:

Degrees of Reset = Active CWS - Front Panel CWS

or

Degrees of Reset = CWS' - CWS

To obtain Active CWS from Degrees of Reset:

Active CWS = Degrees of Reset + Front Panel CWS

Reset Ratio:

The Reset Ratio on the CLD is displayed as a percentage. To use it in the above equation it must be converted to it's decimal form.

Reset Ratio percent /100 = Reset Ratio decimal

Example of converting Reset Ratio:

If the Reset Ratio displayed on the CLD is 50% then use (50/100)=.5 in the equation

TOD = Outdoor Air Temp

Start Reset = Outdoor Air Start Reset

Example of Calculating Reset for Outdoor Air Temp:

If:

Reset Ratio = 35%

Start Reset = 80

TOD = 65

Maximum Reset = 10.5

How many Degrees of Reset will there be?

Degrees of Reset = Reset Ratio* (Start Reset - TOD)

Degrees of Reset = .35*(80-65)

Degrees of Reset = 5.25

If:

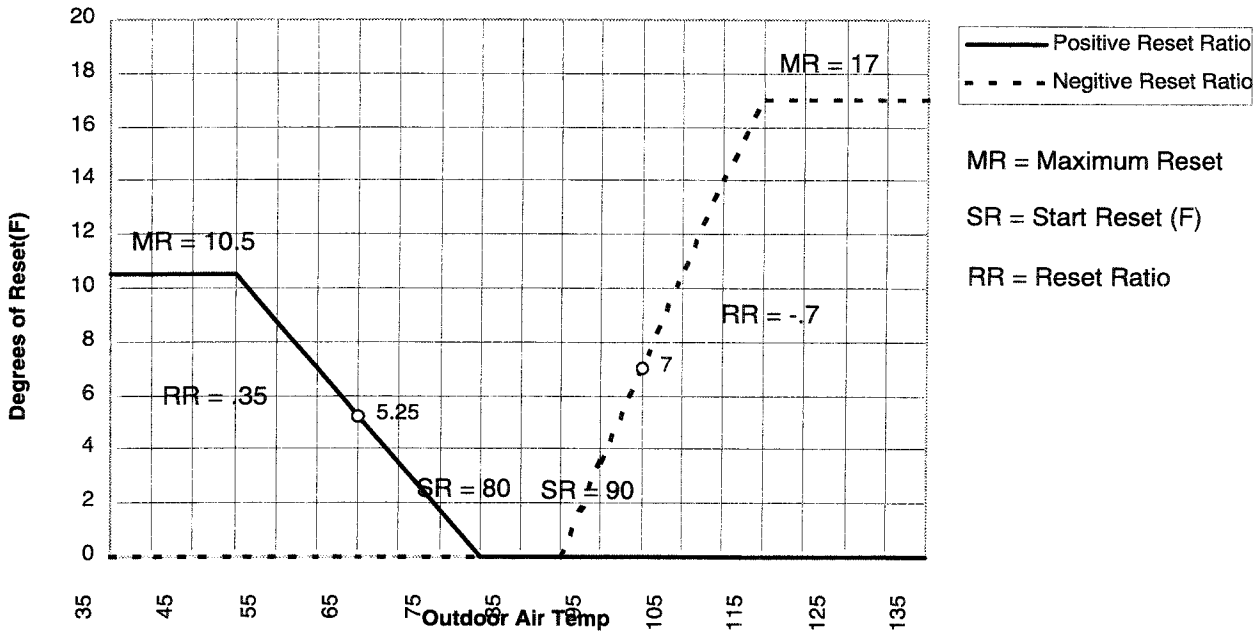
Reset Ratio = -70%

Start Reset = 90

TOD = 100

Maximum Reset = 17

How many Degrees of Reset will there be?

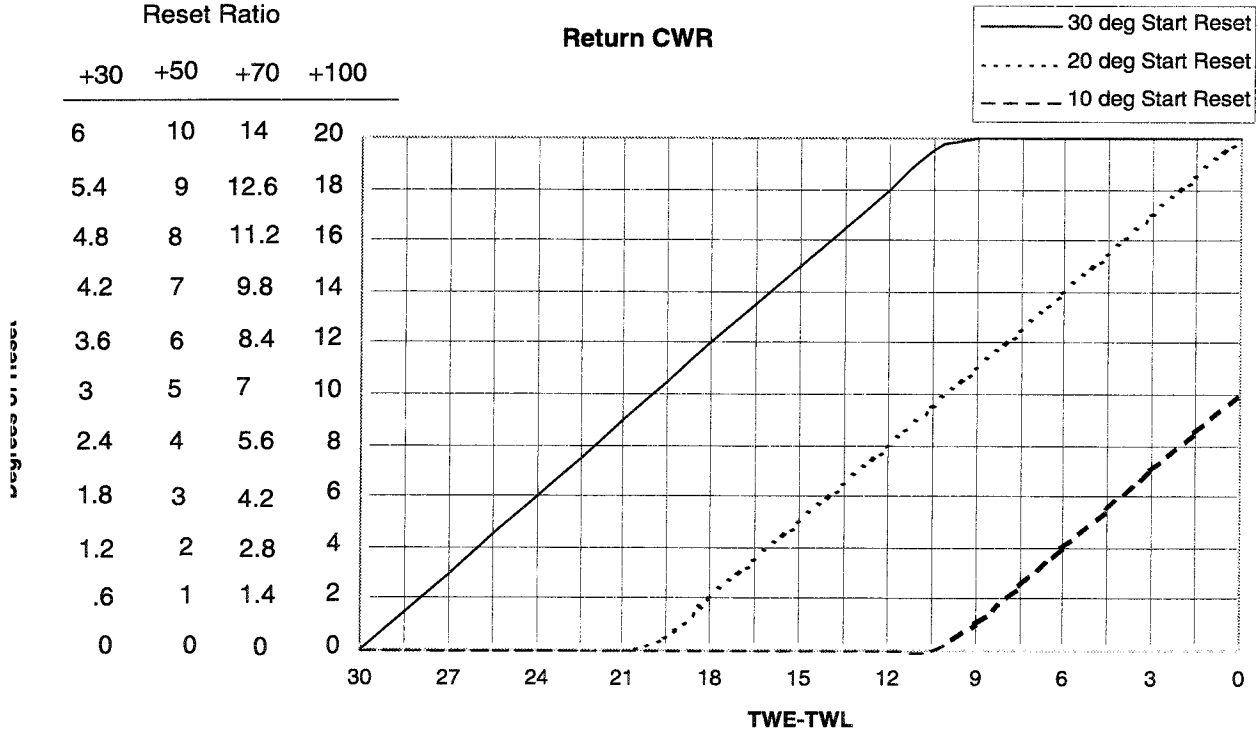


Degrees of Reset = Reset Ratio* (Start Reset - TOD)

Degrees of Reset = -.7*(90-100)

Degrees of Reset = 7

The following graph illustrates the reset functions of the above examples:



Degrees of Reset vs Outdoor Air Temp

The following graph shows the reset function for Return CWR:

Reset Ratio			
+30	+50	+70	+100
6	10	14	20
5.4	9	12.6	18
4.8	8	11.2	16
4.2	7	9.8	14
3.6	6	8.4	12
3	5	7	10
2.4	4	5.6	8
1.8	3	4.2	6
1.2	2	2.8	4
.6	1	1.4	2
0	0	0	0

Return CWR

Note: This graph assumes Maximum Reset is set to 20 degrees.

Example of Calculating Return Reset:

If:

Reset Ratio = 50%

Start Reset = 25

TWE = 65

TWL = 45

Maximum Reset = 8

How many Degrees of Reset will there be?

Degrees of Reset = Reset Ratio* (Start Reset - (TWE-TWL))

Degrees of Reset =.5*(25-(65-45))

Degrees of Reset = 2.5

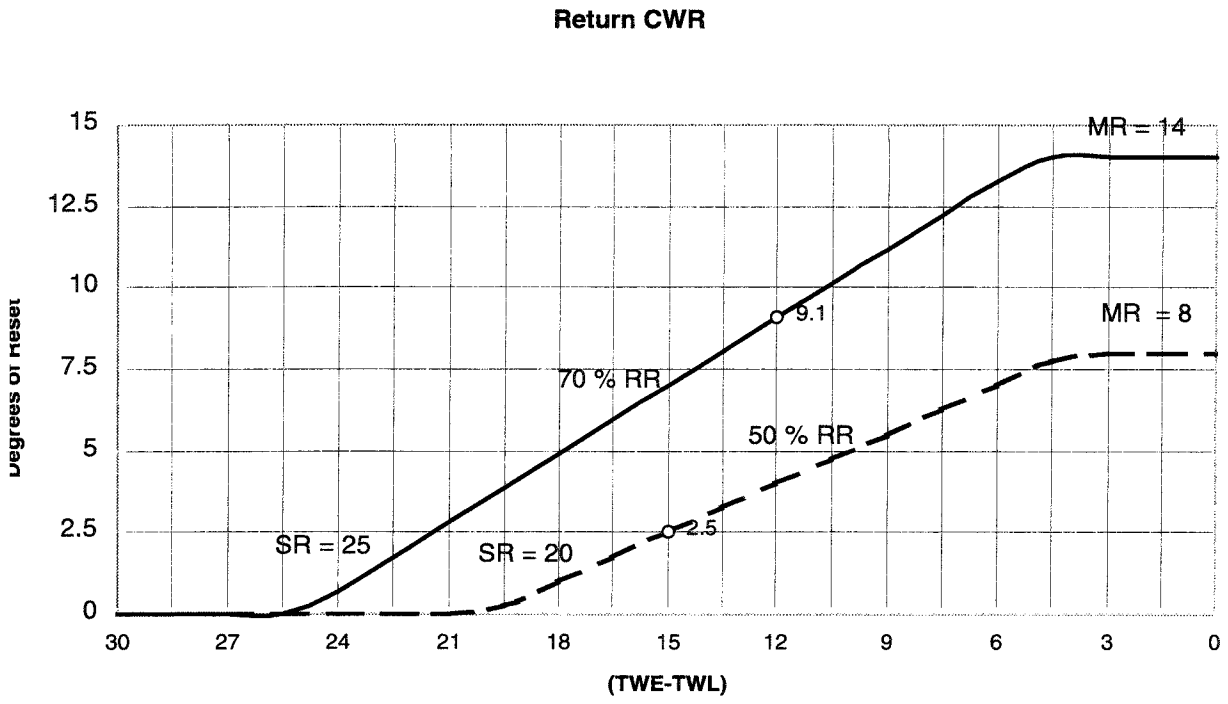
If:

Reset Ratio = 70%

Start Reset = 20

TWE = 60

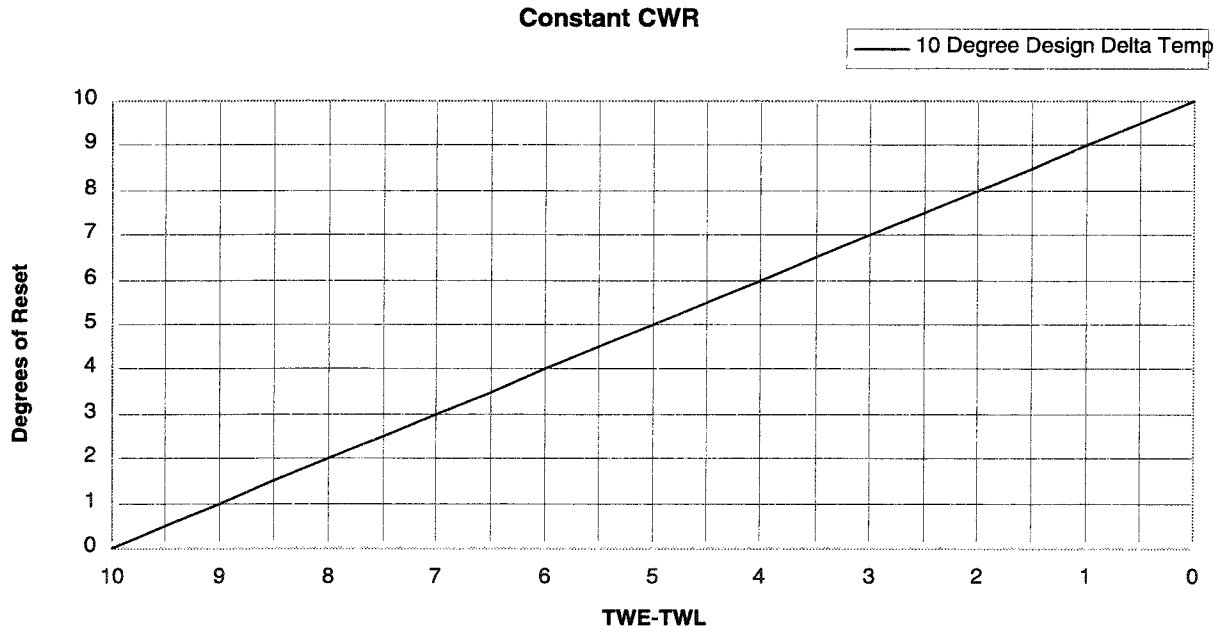
TWL = 53



Maximum Reset = 14

How many Degrees of Reset will there be?

Degrees of Reset = Reset Ratio* (Start Reset - (TWE-TWL))



Degrees of Reset =.7*(20-(60-53))

Degrees of Reset = 9.1

The following graph illustrates the Reset Actions of the above examples:

Note: This graph assumes a Design Delta Temp of 10 degrees.

Information on the Printer Option

Th Printer module is essentially a TCI comm 4 board with a daughter board installed to communicate RS232 to the Printer. The Printer module is a listen only device and its software revision level will not show up in service tests.

The diagnostic LED in the upper left hand side of the module is only active for the printer module, and when it is on, this indicates a loss of communications with the Chiller module.

The Green LED labeled RXA should be continuously flashing.

The Red LED labeled TXA should never come on.

The Green LED labeled RXB will blink once every few seconds while the Printer module is printing, only if X-ON X-OFF handshaking is enabled.

The Red LED labeled TXB will blink constantly while the printer is printing.

The DIP switch settings for the Printer module follow:

1-off

2-off

3-on

Dip switch settings for the Okidata Microline 184 turbo printer follow:

General Service Bulletin

CVHE-SB-33A

Library	**Service Literature**
Product Section	**Refrigeration**
Product	**Centrifugal Liquid Chillers**
Model	**CVHE, CVHF,CVHG,**
Literature Type	**Service Bulletin**
Sequence	**33A**
Date	**September 26, 1996**
File No.	**SV-RF-CTV-CVHE-SB-33A-**
Supersedes	**SV-RF-CTV-CVHE-SB-33 - 3/95**

Literature History: CVHE-SB-33 - Original issue of bulletin - March 1995 - CVHE/F/G Installation Procedure for the Thrust Bearing Assembly
CVHE-SB-33A - September 1996 - Redefined installation procedures, clarified units affected

Subject: CVHE/F/G Installation Procedure for the Thrust Bearing Assembly

Introduction:

A production design change has been made to the CVHE/CVHF/CVHG product line which affects the installation procedure for the thrust bearing assembly. This bulletin will outline these changes and explain how to identify which parts are required for field service replacement of the duplex ball bearing assembly. Also, the proper procedure and tools required for thrust bearing replacement are outlined in this bulletin.

Note: This procedure must be followed in lieu of the procedure described in CTV-SG-2.

Units Affected:

All CVHE ("C" design sequence and later), CVHF and CVHG CenTraVacs are affected by this bulletin. Beginning with design sequence "2B" for the CVHE, "J0" for the CVHF, or "C0" for the CVHG machines, the following changes were made in production:

1. The motor shaft diameter at the thrust bearing journal was increased to provide interference fit of 0.0002" to 0.0011".

2. The number of shaft threads at the motor end of the shaft were increased.

3. The diameter of the motor shaft shoulder adjacent to the inner race of the thrust bearing assembly was increased.

4. The thrust bearing end of the motor shaft is stamped "K4" to indicate the above changes are present.

©American Standard Inc. 1996

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Discussion:

It should be noted that the motor thrust bearing (at the OPPOSITE DRIVE END of the motor, i.e., electrical terminal end of the motor) can be replaced without disassembling the compressor.

DRIVE END refers to the shaft extension or compressor end of the motor. OPPOSITE DRIVE END refers to electrical terminal end of the motor.

Figures 1 and 2 show cutaway and exploded views of the motor. Refer to these and other illustrations shown during disassembly and reassembly.

⚠ WARNING:
Before working on this or any electrical equipment, always disconnect all electrical power. Failure to disconnect power may result in serious personal injury or death due to electric shock or entanglement in rotating parts.

Motor Thrust Bearing Replacement:

Disassembly

1. Go to the OPPOSITE DRIVE END of the motor. Remove the oil supply and drain lines at this end of the motor. Paint should be removed from the lines prior to cutting the lines (use a tubing cutter) if flanges are not present to allow removal. Use sandpaper to remove the paint. See Figure 3. The cut copper tubing will be reconnected by soft soldering. All openings must be sealed while work is in progress to prevent debris from contaminating the lubrication system.

2. Remove the OPPOSITE DRIVE END bearing inspection plate. Remove the old O-ring and clean the sealing surfaces of the plate. See Figure 4.

3. To insure proper component alignment when the motor and/or compressor is reassembled, drill two 1/4-inch holes in the motor end bell which will allow for installation of two roll pins during reassembly. These holes must be drilled before loosening the motor end bell retaining bolts. Figure 4 illustrates where these holes are to be drilled. Make certain there are roll pins installed before proceeding with Step 4.

4. Loosen the bearing bracket (motor end bell) retaining bolts. Remove two of the bolts and replace them with guide pins which are used to support the bracket and motor shaft weight. See Figure 5.

5. Remove the four 9/16-inch capscrews and bearing retaining ring. Refer to Figure 6.

6. Remove the eight 3/8-inch-16 Allen-head screws which secure the bearing seal. See Figure 7.

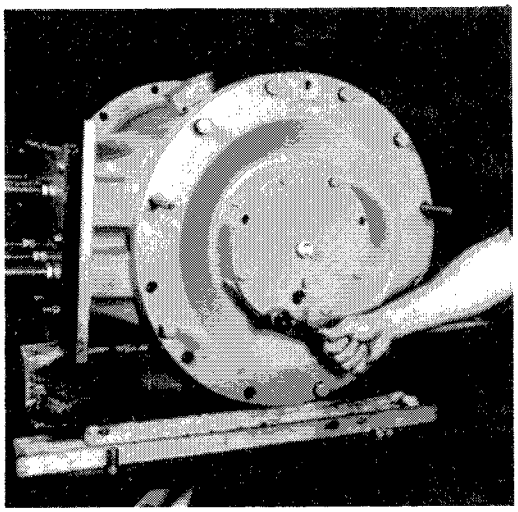

Figure 23
Installing Opposite Drive End Bearing Inspection Cover

7. Remove the bolts retaining the bearing bracket. There are two short bolts used in the electrical terminal box area as shown in Figure 8. These should be identified properly so that they are reinstalled correctly.

Using the jack-bolt holes, remove the bearing bracket. The bearing bracket must be separated from the outer ball bearing race. The bearing bracket weight must be supported from overhead (use a chain hoist or similar). Separate the bearing bracket from the bearing race using a gentle back and forth rocking action. As the bracket is removed it will drop slightly as the sealing surface is cleared (when the bracket has been moved out approximately 1/2-inch). Once the sealing surface is cleared the bearing bracket can be lowered until the rotor rests on the stator. See Figure 9. Extreme care must be exercised to prevent the bracket from jamming on the bearing and to prevent movement of the rotor assembly which could in turn damage the stator assembly. Remove the bearing bracket completely.

8. Remove the thrust bearing lockwasher and locknut. Refer to Figures 10 and 11. Bend back the lockwasher tab and then use an impact wrench and socket tool to drive off the locknut.

9. Remove the thrust bearing. Refer to Figure 12. Use a bearing puller tool. The puller must pull on the inner race of back bearing to prevent damage to the bearing and shaft. Important items to remember when pulling the bearing are:

a. The puller must be square with respect to the shaft.

b. The puller must pull on the inner race. It will be necessary to place 0.050-inch shims between the puller and bearing to accomplish this.

c. The bearing must not be allowed to drop on the shaft or puller. A cloth rag should be used to protect the bearing.

d. Never heat the bearing to remove it since this may damage the bearing or the motor.

e. The weight of the puller must be supported by a sling and chain fall.

10. Remove the inner bearing cap (seal). See Figure 13. Exercise care to prevent damaging the gasket. Notice that there is an oil drain hole at the bottom of the seal. This must be plainly marked to insure that the seal is reinstalled with the drain hole at the bottom. The notch in the bearing cap must be positioned at the top when facing the motor.

Reassembly

1. Go to the OPPOSITE DRIVE END of the compressor motor. Place the OPPOSITE DRIVE END inner bearing cap with a new gasket on the motor shaft. Make certain the oil drain hole in the cap is at the bottom and the notch is at the top (Figure 13).

2. When changing a CVHE/CVHF/CVHG thrust bearing assembly, it is critical to determine what shaft design is present. The only sure way to determine what shaft is present is to examine the thrust bearing end of the shaft and see if a "K4" is stamped there. The "K4" stamped in the end of the shaft may vary in size from 1/4" high to 1/16" high so it may be difficult to see it through the sight glass in the bearing inspection cover. If the motor shaft has not been changed the design sequence can be used to determine what shaft type is present. After determining the shaft design, use the appropriate procedure described as follows:

Great care must be taken to avoid damage to the shaft shoulder and journal during thrust bearing removal. After the thrust bearings are removed, examine the shaft for signs of excessive wear or fretting, especially at the shaft journal and shoulder. The shaft should be measured at the journal O.D. to insure that the shaft is in tolerance. This will require a calibrated micrometer which is capable of reading "0.0001". If the shaft condition is in question, call the CenTraVac Technical Service department in La Crosse for assistance.

Non-"K4" Marked Shaft
The following bearings will be required for a **non- "K4"** marked shaft:

Shaft Size	**Part No.**	**Non-"K-4" Shaft Journal Dimensions**
Small diameter (2.16" Bore)	BRG0913	2.1650" to 2.1655"
Large diameter (3.54" Bore)	BRG0914	3.5429" to 3.5434"

These bearings have a small inner race I.D. which gives a press fit of 0.0002" to 0.0011" with a non "K4" shaft.

⚠ **Caution: These bearings can only be used with a non- "K4" Marked Shafts!**

Note: These bearings come with a new lockwasher and locknut.

"K4" Marked Shaft
The following bearings will be required for a **"K4"** marked shaft:

Shaft Size	**Part No.**	**"K-4" Shaft Journal Dimensions**
Small diameter (2.16" Bore)	BRG0609	2.1656" to 2.1661"
Large diameter (3.54" Bore)	BRG0610	3.5435" to 3.5440"

Note: These bearings come with a new lockwasher and locknut.

Installing the Bearings:

Note: Use either Step 3 or Step 4 depending on bearing manufacturer, DO NOT USE BOTH STEPS WHEN INSTALLING THE BEARINGS!

Only matched bearing sets shall be installed on the motor shaft as shown in Figure 14. A matched bearing set will have the same numerical serial number but one of the bearings will have a letter following the serial number. The bearing set should not be washed unless absolutely necessary. If the bearings are washed, great care must be taken to insure cleanliness of the solvent and washing container.

The bearing set should be heated uniformly to a final temperature of 230°F to 250°F. If a induction heater is used, the bearings should be demagnetized before installation on the shaft. A maximum of 5 gauss magnetism is allowable. A hand held gauss meter can be used to measure residual magnetism.

3. Mounting NTN Bearings:

   a. Each bearing shall be marked for high spots. High spot marks are usually small circles stamped or etched into the face of both the inner and outer races of each bearing. Any bearing set without inner and outer races marked for high spots shall be rejected.

   b. The bearing set shall be mounted on the motor shaft in a back-to-back arrangement (sides of outer races with identification marks should face each other). Install the first half of the bearing set on the motor shaft with the thin side of the outer race facing the rotor until the bearing seats against the shaft shoulder. See Figure 15.

   c. Note the position of the high spot marks on both races of the installed inner half of the bearing set. Rotate the outer race of the installed bearing until the high spot marks line up with each other.

   d. Prior to installing the outer half of the bearing set on the motor shaft, line up the high spot marks on both races. Install the bearing on the motor shaft with the thin side of the outer race facing out of the motor and the high spot marks on both races 160° to 200° away from the high spot marks on the inner half of the bearing. See Figure 16.

4. Mounting SKF Bearings:

   a. Each bearing shall have alignment marks. One half of a "V" has been scribed or etched on the OD of the outer race of each bearing and a line has been scribed across the bore of the inner race of each bearing. When the bearing halves have been properly arranged on the shaft, the halves of the "V" on the OD of the outer races will line up to form a complete "V" and the lines in the bores of the inner races will also line up.

   b. The bearing set must be mounted on the shaft in a back-to-back arrangement.

   c. Remove the first half of the bearing set from the heater. Note the location of the scribed line in the bore of the inner race. Align the inner race scribed line with the keyway of the shaft. Install the first half of the bearing set on the motor shaft with the thin side of the outer race facing the rotor. Allow the bearing to seat against the shoulder on the shaft. See Figure 15.

   d. Rotate the outer race of the installed bearing half unit until its "V" lines up with the scribed line in the bore of the inner race.

   e. Prior to installing the outer half of the bearing set on the motor shaft, line up the scribed line in the bore of the inner race with the half "V" on its outer race. Install the bearing on the motor shaft with the thin side of the outer race facing out from the rotor and both alignment marks lined up with alignment marks on the first bearing. Refer to Figure 16.

5. Seating the Bearings:

Note: The duplex ball bearing alignment sleeve tool is not required for thrust bearing installation and total indicated runout readings for the thrust bearing assembly are not required.

Hold the inner race of the outer bearing against the inner bearing half until the bearing tightens on the shaft. Allow the assembled bearing set to cool to 100°F or less. Install a hydraulic assembly nut on the shaft and hand tighten the piston end of the nut against the outer bearing. Refer to Figure 17. Attach a hydraulic hose to nut, bleed air from system and using a hydraulic pump with a regulator, pressurize the hydraulic nut to 2200 psi to seat the bearings against the shaft shoulder. See Figure 18. Verify the bearing is seated against the shaft shoulder by trying to put a 0.001 inch feeler gauge between the bearing race and the shaft shoulder. A properly seated bearing will have a .000 clearance. Relieve the pressure from the hydraulic nut, remove the hose from the hydraulic nut, and remove nut from shaft. Install a new tab washer and locknut. Do not use a hammer and spanner wrench to tighten the locknut. Use the proper size socket tool listed in Table 1 and use the following procedures.

6. Torquing of the Locknut:

Ideally a torque wrench should be used to apply the required torque to the locknut. This may be possible for the small diameter shaft units. For the large diameter shaft, a pneumatic impact wrench will be required to provide the torque required without allowing the rotor to turn in the stator. The following torque value is required.

Small Diameter Shaft - 60 to 80 Ft. - Lb.
Large Diameter Shaft - 160 to 200 Ft. - Lb.

To obtain an accurate torque value, the following method can be used to torque the locknut when a torque wrench cannot be used.

a. Install a new tabwasher and locknut, using the following parts: These parts should be included with the new bearing set.

Small Diameter Shaft	**Large Diameter Shaft**
Tabwasher - WAS0594	Tabwasher - WAS0595
Locknut - NUT0434	Locknut - NUT0435

b. Torque the nut to 10% of final torque value using a torque wrench and socket tool. This will require a torque of 6 to 8 Ft. - Lb., for the small nut and 16 to 20 Ft. - Lb. For the large nut.

c. Mark the nut and inner race in a straight line to act as a reference point. Use a fine tipped marker pen or equivalent.

d. Mark the inner race in a clockwise direction the following distance from the first mark:

Small Nut: .3" to .5" range
Large Nut: .5" to .7" range

This will provide a degree of rotation method for torquing the locknut.

e. Use the appropriate socket tool for the size of nut and pneumatic impact wrench to rotate the locknut until the mark on the nut falls in the range from (d). If a air source is not available, a large cylinder of dry nitrogen with a regular adjusted to 120 psi can be used to power the pneumatic impact wrench. A 3/4" drive wrench will probably be required for the large locknut.

f. Align a lockwasher tab with a slot in the locknut. Continue tightening the nut to align a tab to a slot. Do not loosen the locknut to align a tab to a slot - always tighten.

g. Carefully bend the locking tab into the slot in the nut. Be very careful not to pry on the bearing races or cage and take great care to ensure bearing cleanliness. Use a soft material, such as brass or nylon to bend the tab. Be careful that no metal burrs or shavings enter the bearing assembly.

h. Rotate the outer race of the bearing set to check for free turning. A slight continuous drag is normal due to the built in bearing preload. If difficulty is encountered in rotating the outer races, tap the face of the outer race assembly around the circumference of the outer race using a rubber or rawhide mallet. This should allow free rotation of the bearing assembly.

7. Install 3/8" -16 threaded rod into the opposite drive end bearing seal. Align the seal so that the oil drain hole is on the bottom. Be sure the gasket is installed and located properly. Refer to Figure 19.

8. Install the opposite drive end bearing bracket O-ring using LocTite 515 "Gasket Eliminator". Lift the bearing bracket using a chain hoist. The bearing bracket should be positioned on the guide rods which were installed in Step 4 of the disassembly section (Page 2) to support the weight. When positioning the bracket, the threaded rod connecting to the inner seal must pass through the bolt holes in the bearing bracket such that the oil drain hole is on the bottom.

Work the bearing bracket into place and secure it with several bolts. The bracket should slide over the bearings with minimal force.

9. Install the two roll pins that were drilled for prior to disassembly (or which were factory installed). These pins are necessary for proper relocation of the bracket so that the original compressor seal clearances are re-established. Tighten all bearing bracket bolts to 150 Ft. - Lb. Torque.

10. Refer to Figure 20. Set the inner seal by installing the socket head capscrews. Properly installed the outer race of the bearings should extend approximately 1/16-inch beyond the bearing bracket. If not, the bearing seal is not properly seated and the bearing will be allowed to float. This will result in serious compressor damage. Reposition the seal if necessary. Tighten the retaining bolts to 24 Ft.- Lb.

11. Install the bearing retaining ring and bolts, then tighten to 24 Ft. - Lb. See Figures 21 and 22. This retaining ring provides a clamping force on the bearing outer race to prevent it from rotating.

12. Install the opposite drive end inspection cover. Be sure and use LockTite 515 on the O-ring and outboard flange. See Figure 23.

13. Reassemble the bearing oil supply and drain lines. **If the lines were cut, use a copper coupling and soft solder to reconnect these lines, such as StayBrite silver bearing solder (96% tin, 4% silver) or 95-5 solder (95% tin, 5% antimony). These solders melt and flow in the 430°F to 465°F range. Do not over flux these joints.**

Note: (Use paste flux and not liquid acid flux). If these joints are brazed rather than soldered, it is absolutely mandatory to purge the lines with an inert gas while brazing. The preferred method is soldering.

14. Pressurize and leak test the chiller.

15. Air run chiller and take vibration readings per CVHE-SB-18 to insure unit meets vibration specifications. If the vibration levels are out of specification, a trim balance will be required.

Parts Information:

The following parts shown in Table 1 are required to allow a duplex ball (thrust) bearing to be installed. See Figure 24 for example of hydraulic assembly nut, hose and hand pump assembly complete.

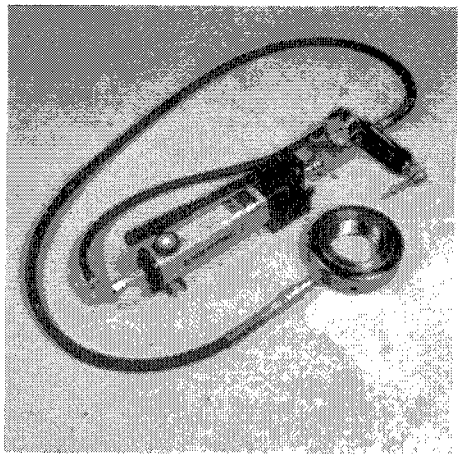
Table 1

Qty	Description	Manufacturer/Part No.	Trane Part No.
1	Hydraulic Hose 6' Long - 10,000 psi 3/8" NPT Male x 1/4" NPT Male	ENERPAC H870	HSE0363
2	Coupler - Female Hydraulic 1/4" NPT M	ENERPAC 3050-2	CPL0392
1	Coupler - Male Hydraulic 1/4" NPT F	ENERPAC 3010-1	CPL0393
2	Adaptor - 1/4" NPT Female x 0.25" BSAT Male	ENERPAC F3HG	ADP0371
1	Hydraulic Assembly Nut-Small Bearing	SKF HMVC-11	NUT0729
1	Hydraulic Assembly Nut-Large Bearing	SKF HMVC-18	NUT0730
1	Socket for Large Locknut (1/2" Drive	WHITTET-HIGGINS BAS-11	TOL194
1	Socket for Large Locknut (3/4" Drive	WHITTET-HIGGINS BAS-18	TOL193
1	Hydraulic Hand Pump Assembly	See Figure 25	

The hydraulic assembly nuts require the installation of adapter ADP0371 to provide a fitting for attaching a quick coupler. This will require removal of the coupler fitting provided on the assembly nuts from SKF. This is a British thread and requires the use of a copper gasket when installing the adapter into the assembly nut. Install a coupler fitting into the 1/4" pipe fitting of the adapter on the assembly nuts (CPL0392). This will allow quick change out of the hydraulic nuts when going from one size to the other.

Attach the coupler (0.25 NPTF) CPL0393 to the male NPT connection on the hydraulic hose (HSE0363) as shown on Figure 24. The 0.375 NPT end of the hose attaches to the relief valve fitting of the hand pump assembly (No. 13 on Figure 25). A 0.375 coupler can be used to allow easy hose removal for transport, if desired.

Figure 24
Example Showing Hydraulic Assembly Nut, Hose and Hand Pump Assembly



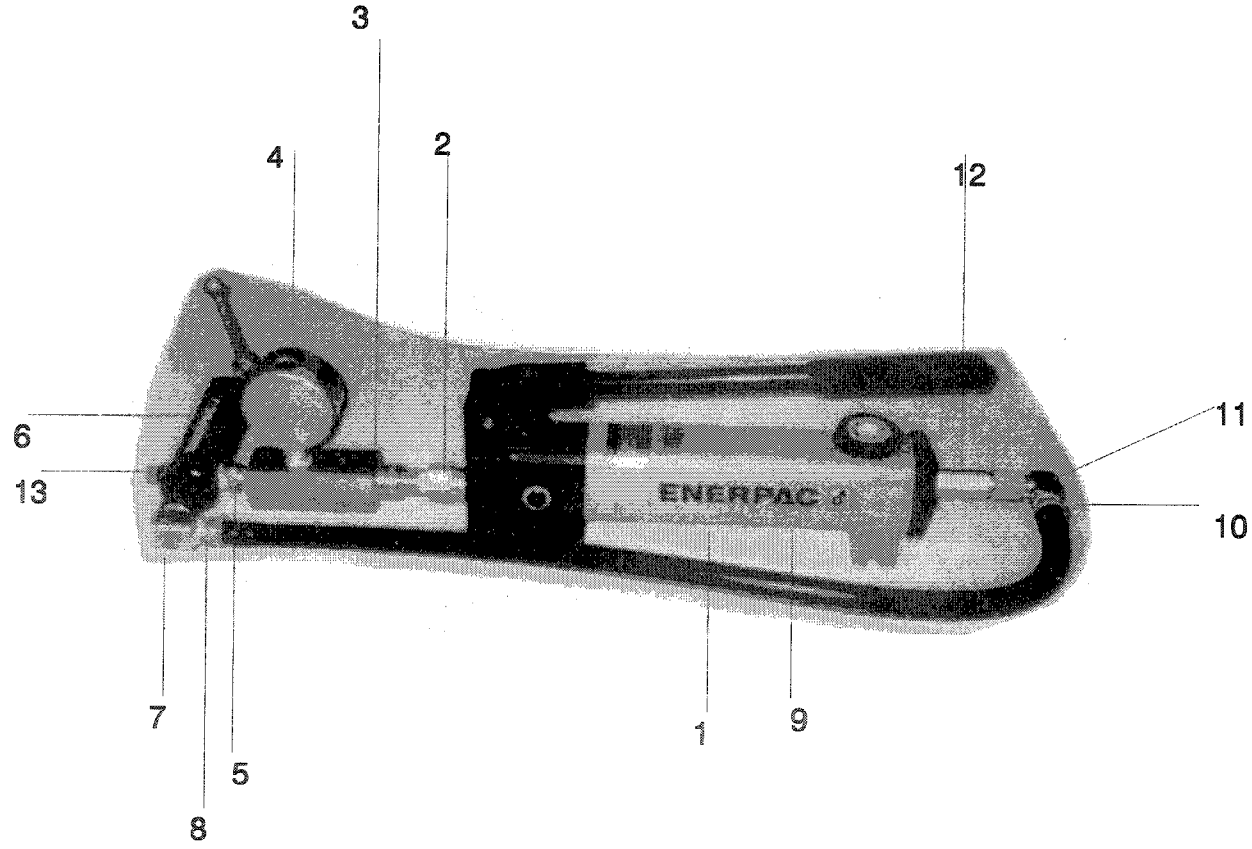


Figure 25
Showing Location of Parts on a Trane Hand Pump Assembly

Hydraulic Hand Pump Assembly:

The parts required for the hand pump assembly are given in Table 2. Before anything is connected to the Enerpac P-141 hand pump, the tank return kit tie rod must be installed in the P-141 pump. This will require removing the hydraulic oil from the pump, removing the acorn nut on the end cap and removing the tie rod by unscrewing from the pump housing. Install the tie rod from the tank return with the slotted end thread protruding through the end cap. This will allow the hydraulic oil to return to the tank. When installing the fitting on the rod end (Item 12 on Figure 25), torque to 15-19 Ft. - Lb. Be sure to install the copper washer on the tie rod end before installing the fitting. Use a good grade pipe sealant that is compatible with hydraulic oil for all pipe thread joints.

Note: An alternative to Item 12 can be fabricated by using the adapter provided in the tank return kit (7/16" N.C. female x 7/16" NF female) and 1/4" NPT high pressure coupling. Weld the pipe coupling on the fine thread end of the adapter provided in the return kit. This will provide a 7/16" N.C. female to 1/4" NPT female fitting.

Literature History:
CVHE-SB-36 (8/95)–Original Issue of Bulletin.

Subject: CVHE/CVHF/CVHG Across the Line Starters

Introduction:

The starter module, 2U1, recently has had software changes which will require changes to existing starters if the module is replaced. The updated module is identified by part number MOD-259 or X13650453-07.

Background:

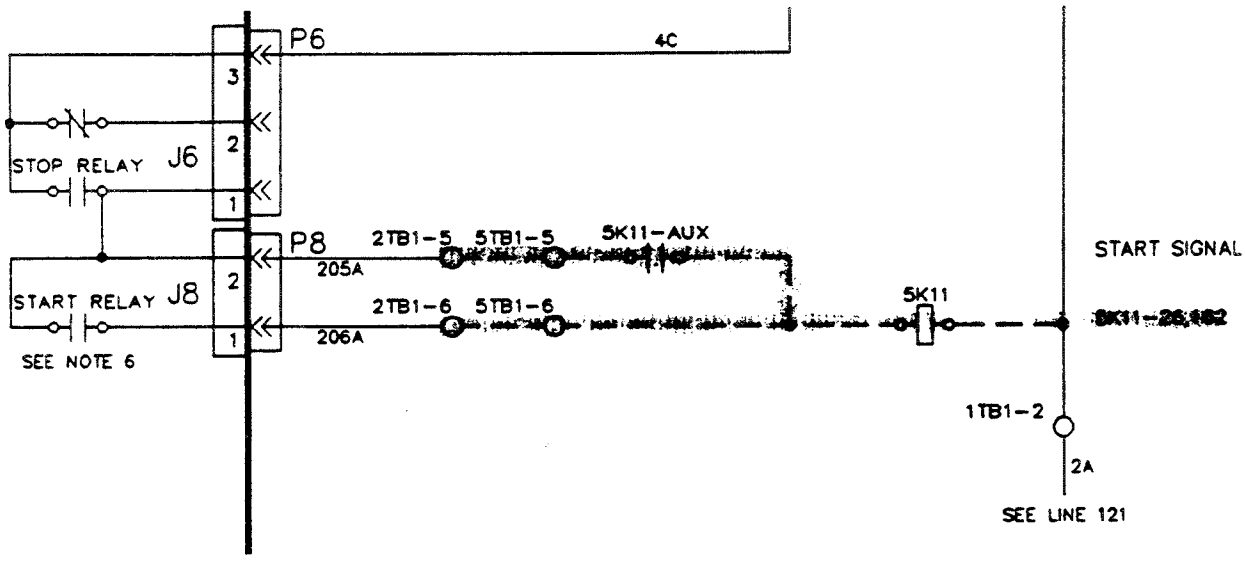
The starter module required software changes because the logic (software) could allow the transition resistors of Y-Delta starters to potentially overheat. The logic (software) was changed to better protect all types of starters. The only starter type that requires a wiring change is the Across-the-Line type with the above referenced module.

On previous versions of the starter module (ext -02 to -06), the logic of the module did not look for a contact closure at J4. This is reflected by the wiring shown in Figure 1.

The current module (ext-07) software requires a contact closure at J4 to signify transition. This required the additional pilot relay and contacts to be field wired to insure proper operation. Reference Figure 2 for the current recommendation for field supplied wiring of the starter module.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Figure 1
Previous Wiring for Across the Line Starters



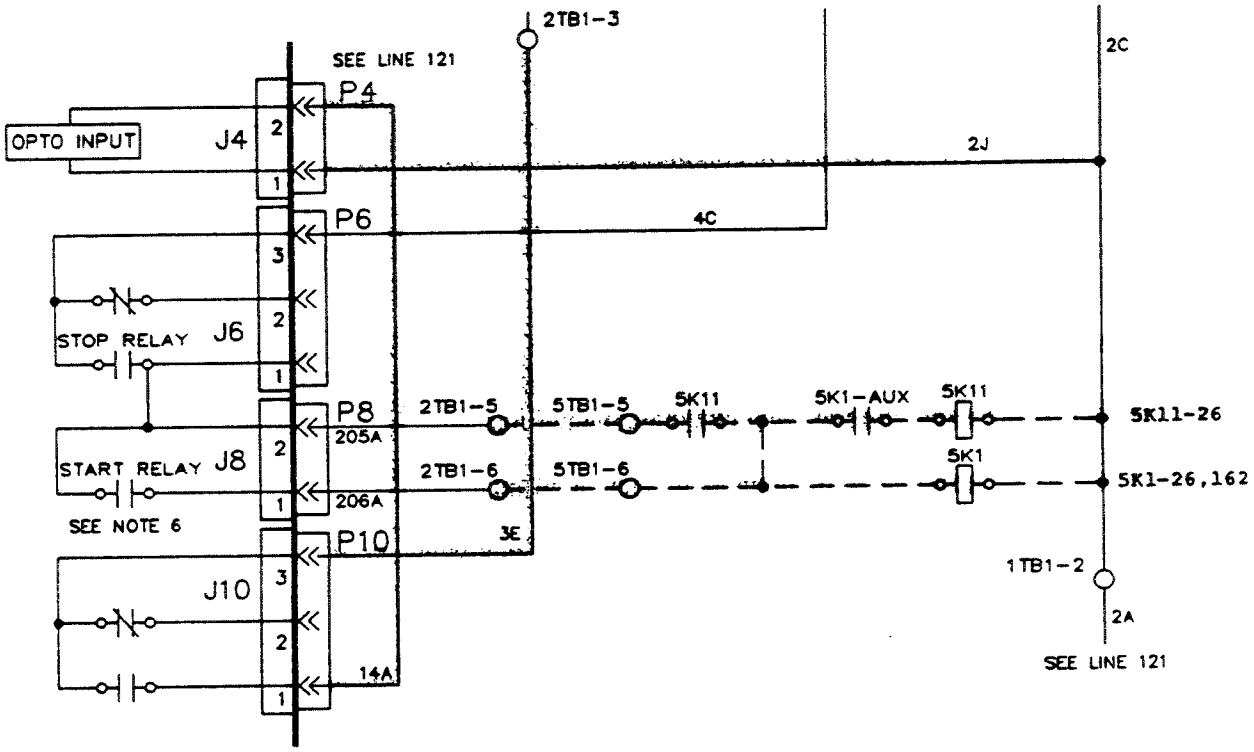


Figure 2
Shows Current Recommendations for Field Supplied Wiring of the Starter Module

Required Action

1. Identify the type of starter you are changing the starter module, 2U1, on. **The wiring changes only are needed on <u>across the line starters</u>.**

2. If the existing starter module in the unit has a part number of X13650453-01 through -06 and you replace it with a module of X13650453-01 through -06, no further action is required.

3. However, if the starter module in the unit is X13650453-01 through -06 and you replace it with a X13650453-07 or higher, you need to complete the remainder of the service bulletin.

4. Secure the supply power and chiller disconnect switches open. Follow all applicable warnings and cautions for the starter and wiring.

5. With the power off, label and disconnect the terminal plugs from the module. Remove the old module.

6. Install the new module. Reconnect all existing connections that were removed. Check the connections for tightness. All connections should be tight, plugs should be snug fitting, and wiring leading up to the terminals should not be under any kind of tension.

Note: All field wiring must conform to NEC guidelines, as well as to any applicable state and local codes.

7. Add the wiring as shown in Figure 2. A wire must be added to jump from terminal 2 of J4 to terminal 1 of J10. A wire must be added from terminal 1 of J4 to transformer terminal 2T4-H4. A wire must be added from terminal 3 of J10 to 2TB1-3.

8. Aside from the changes made in this bulletin, it is always a good practice to inspect both the power and control wiring/connections of your starter, chiller, and field connections before power is applied. This includes, but is not limited to flow switches, temperature sensors, customer connections, etc.

Water-Cooled, Hermetic CenTraVac® Models CVHE/CVHF/CVHG Units

Subject: In-Warranty UCP2 Return Module Checklist

Introduction:

This is an informational service bulletin only. No Labor or Material authorized. This bulletin provides instructions that must be followed when returning all UCP2 modules in the future.

Discusssion:

Effective **February 1, 1996**, all failed **"In-Warranty" UCP2 modules** must be returned with the appropriate paperwork (**"In-Warranty" UCP2 Module Return Checklist**). A blank copy of the form will be shipped to you in the box along with the replacement module.

Important:

This form must accompany the returned module and must be filled out properly or the claim will not be processed. Place in the box with the module that will be sent back to Trane. It is not necessary to stock this form in your office, however a copy is printed as part of this service bulletin for your information.

Subject: Lubrication of First Stage Inlet Guide Vane Tang Operator O-Rings on CVHE/CVHF/CVHG Units

Introduction:

This is an informational service bulletin only.

The purpose of this general service bulletin is to describe the proper procedure for lubrication of the first stage IGV tang operator o-rings for CVHE, CVHF and CVHG units.

Discussion:

The first stage IGV tang operator uses dual o-rings to seal to atmosphere. A small pipe plug is provided in the body of the operator to allow manual lubrication of these o-rings. On an annual basis, remove the pipe plug and fill the cavity with Trane OIL-22. This will provide adequate lubrication to the o-rings.

Note: Be sure and reinstall the pipe plug when the lubrication has been completed.

Subject: CVHE/F/G Rupture Disc Installation Procedure

Introduction:

This service bulletin describes the proper procedure to follow when changing or installing a rupture disc on a CVHE/F/G CenTraVac®.

Discussion:

In order to prevent premature failure of the carbon rupture disc used on low pressure centrifugal chillers, it is imperative to follow the proper rupture disc installation procedure. The disc must be oriented in the proper direction, centered in the clamping flanges with gaskets located on both sides of the disc, and the bolts tightened gradually to specified torque value. (See Figures 1 and Figure 2). No spacers should be used between the flanges. Two methods of bolt retention are used. The first method (Figure 1) utilizes a nut and shows a non-threaded flange (used prior to 1997). The second method (Figure 2) uses a tapped threaded flange (starting about 1997).

Recommended Action:

When installing a new rupture disc, make sure the discs' smooth flat face is positioned toward the "outside" pipe assembly, as shown in Figure 1 or Figure 2. While the bolts are loose, position the disc and rubber gaskets so that their outside diameter is approximately the same distance from each of the four retaining bolts. This will give a good concentric orientation. While in this position, tighten the bolts by hand to prevent the disc and gaskets from moving. Using a torque wrench set to **20 ft-lbs.** Gradually tighten each bolt, using an alternating sequence of opposite bolts until the final torque is reached. Be sure to tighten gradually in a series of steps and not all at once. This will allow the disc to be clamped uniformly.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Subject: Software Change to Upgrade the Lubrication Protection System

Introduction:

The purpose of this bulletin is to advise Trane Service Companies of a MANDATORY RETROFIT to existing field CVHE/CVHF UCP2 chillers with software which upgrades the lubrication protection system with the latest features of the Circuit module. Each Service Manager will receive a letter and a list of units in their territory along with a copy of the confidential service bulletin.

Units Affected:

All domestic CVHE/CVHF units with UCP2 Control Panel manufactured between August 1993 and December 1996 or any centrifugal unit retrofitted with a UCP2 Control Panel before 1997.

Discussion:

Circuit module software which enhances the oil protection system for UCP2 chillers is now being used in production. This enhanced protection includes the following features:

1) Positive oil pressure trip point at 2/3 of minimum oil pressure set point. (Minimum oil pressure set point is 9 PSID)

2) Increase pre-lube time to 60 seconds from 30 seconds.

3) Increase post lube time to 3 minutes from 2 minutes.

4) Faster software filter on the oil pressure linearized values to improve response to sudden changes in oil pressure.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

SUBJECT: MOTOR TERMINAL BOX SWEATING

INTRODUCTION:

The purpose of this bulletin is to provide information on CVHE/CVHF/CVHG motor terminal boxes that may experience condensation of moisture inside the motor terminal box. THIS IS A FIX ON FAIL RETROFIT.

BACKGROUND:

Under certain unit operating and ambient conditions, units built after 1990 that have remote mounted starters may experience condensation of moisture inside the motor terminal box. Units with unit mounted starters are not affected. Moisture inside the motor terminal box may cause an electrical short to ground.

LABOR AND TRAVEL AUTHORIZATION:

This service bulletin authorizes 3.0 man-hours on affected units to make the necessary changes and 1.0 man-hours travel per unit. ALL CLAIMS MUST BE SUBMITTED ON THE "SERVICE WARRANTY SALES ALLOWANCE CLAIM" FORM 1-30.09-2 WITHIN 30 DAYS OF THE REPAIR.

MATERIAL AUTHORIZATION:

This service bulletin authorizes the following:

A. Order from Trane Parts;
1. Qty. 1 RES-00334, Heater with mounting hardware. 22.03
2. Qty. 1 LBL-00129, Label 1.73

B. Local Purchase; 14ga
1. Wire, electrical, ~~16ga.~~, insulated, copper stranded, 500-inches maximum.
2. Conduit, 240 inches maximum and fittings.
3. Insulation, 3/4-inch thick , closed cell neoprene, 4-feet X 5-feet (or 4-feet x 8-feet, see Item 14 of Required Action).
4. Tie wraps and electrical connections as required.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

©American Standard Inc. 1997

MATERIAL DISPOSITION:

There are no materials to dispose.

UNITS AFFECTED:

CVHE/CVHF/CVHG units with remote mounted starters (including Starters by Others) that shipped between January 1990 thru August 1997 that are operating in equipment rooms where the dewpoint in the equipment room exceeds 70 degree F (21.1 degrees C) and the motor cooling refrigerant is less than 60 degrees F (15.6 degrees C) can produce condensing moisture inside the motor terminal box. If condensing moisture is observed on the EXTERNAL SURFACE OF THE MOTOR TERMINAL HOUSING FLANGE, the INSIDE OF THE MOTOR TERMINAL BOX must be examined for the presence of condensing moisture.

⚠ WARNING
HAZARDOUS VOLTAGE! DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING OR BEFORE OPENING MOTOR TERMINAL BOX.

REQUIRED ACTION:

Note: If the motor terminal box has been inverted with the motor leads entering through the bottom, proceed with the Required Action but mount the heater in the top of the box.

1. Determine and verify that moisture is condensing inside the motor terminal box prior to proceeding with the FIX ON FAIL modifications listed below.
2. Obtain all materials listed in MATERIALS AUTHORIZATION above.
3. Secure the supply power and open the disconnect switch prior to opening the motor terminal box.
4. Drill hole in left side of box for punch and use punch to make hole for connector. (See Figure 1.)
5. Drill two holes so that heater will be centered in box and 3-inches from front. (See Figure 1.)
6. Remove all metal shavings from inside box.
7. Mount 90 degree connector to box. (See Figure 1.)
8. Install conduit to motor junction box and control panel.
9. Insulate the outside of the motor housing flange with the 3/4 inch insulation.

10. Apply first piece of insulation to back of box. (See Figure 2.)

11. Apply second piece of insulation to back; try to center connectors in holes. (See Figure 2.)

12. Attach insulation to right side of box. (See Figure 2.)

13. Attach insulation to left side of box after cutting hole for connector. (See Figure 2.)

14. If unit was provided with "double thickness" insulation for high humidity or Ice Storage, the outside of the motor terminal box must also be insulated. Obtain extra insulation and insulate the outside of the motor terminal box. Do not insulate the cover.

15. Mount and bolt heater to box with terminals facing forward. (See Figure 3.)

16. Install last piece of insulation around heater. (See Figure 3.)

17. Run conduit wires (9D and 2Z) to terminals and attach connectors.

18. Wire inside of control panel as shown in Figure 4.

19. Set conduit up to conduit bundle and ty-wrap to oil discharge line. (See Figure 4.)

20. Verify wiring is correct. (Also refer to Junction Box Wiring drawing, 2307-5175.)

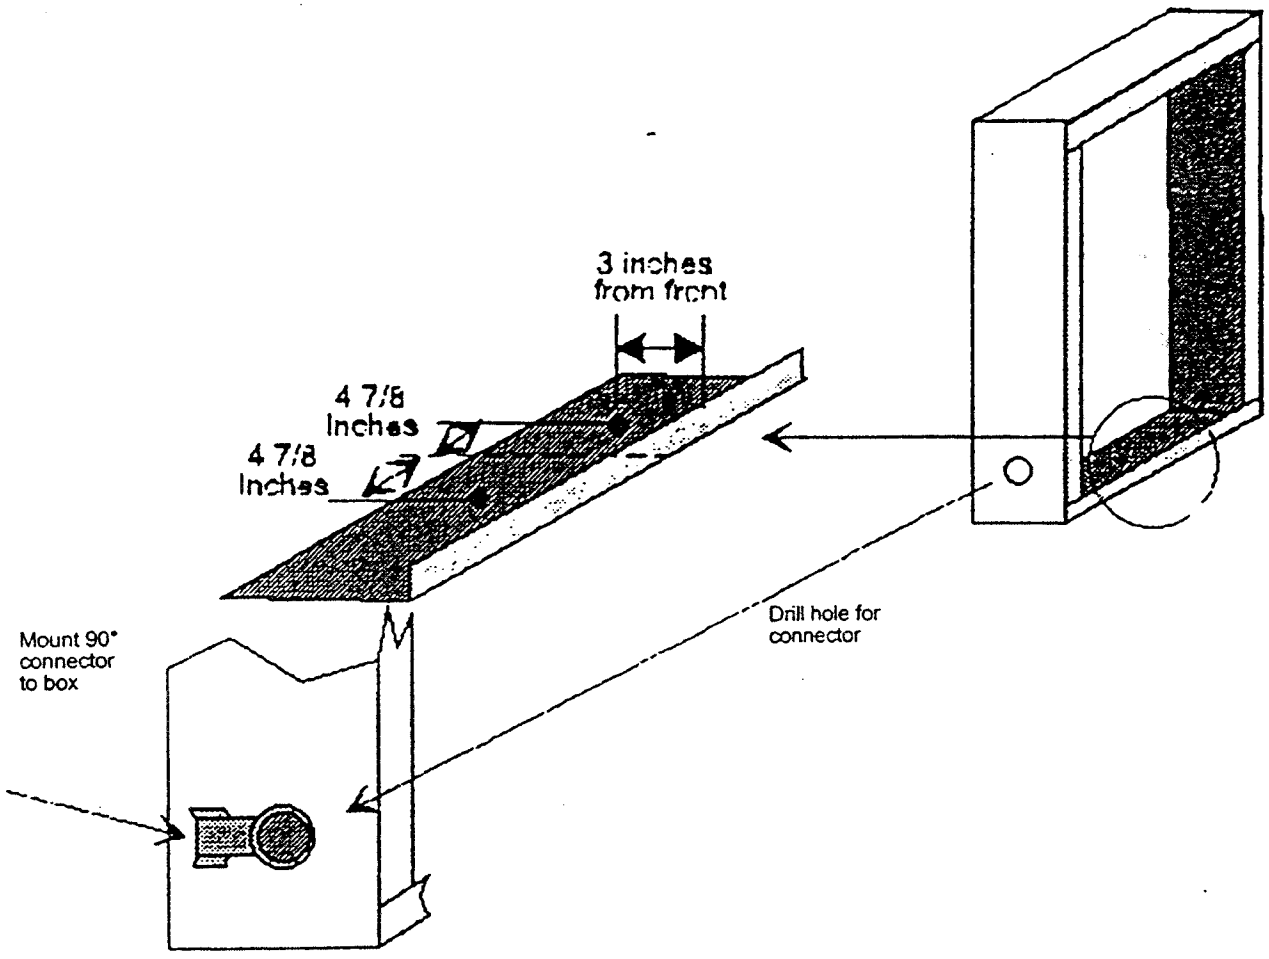
21. Do not insulate Motor Terminal Box Cover, replace cover and attach label LBL-00129 to outside of the cover.

Note: After insulation is applied, apply firm pressure (preferably with a rolling tool) to 100% of the surface to ensure all air pockets are removed.

EXPIRATION DATE:

The effective cut-off date is March 31, 1998.

Figure 1
Drilling Instructions per Items 4 - 8



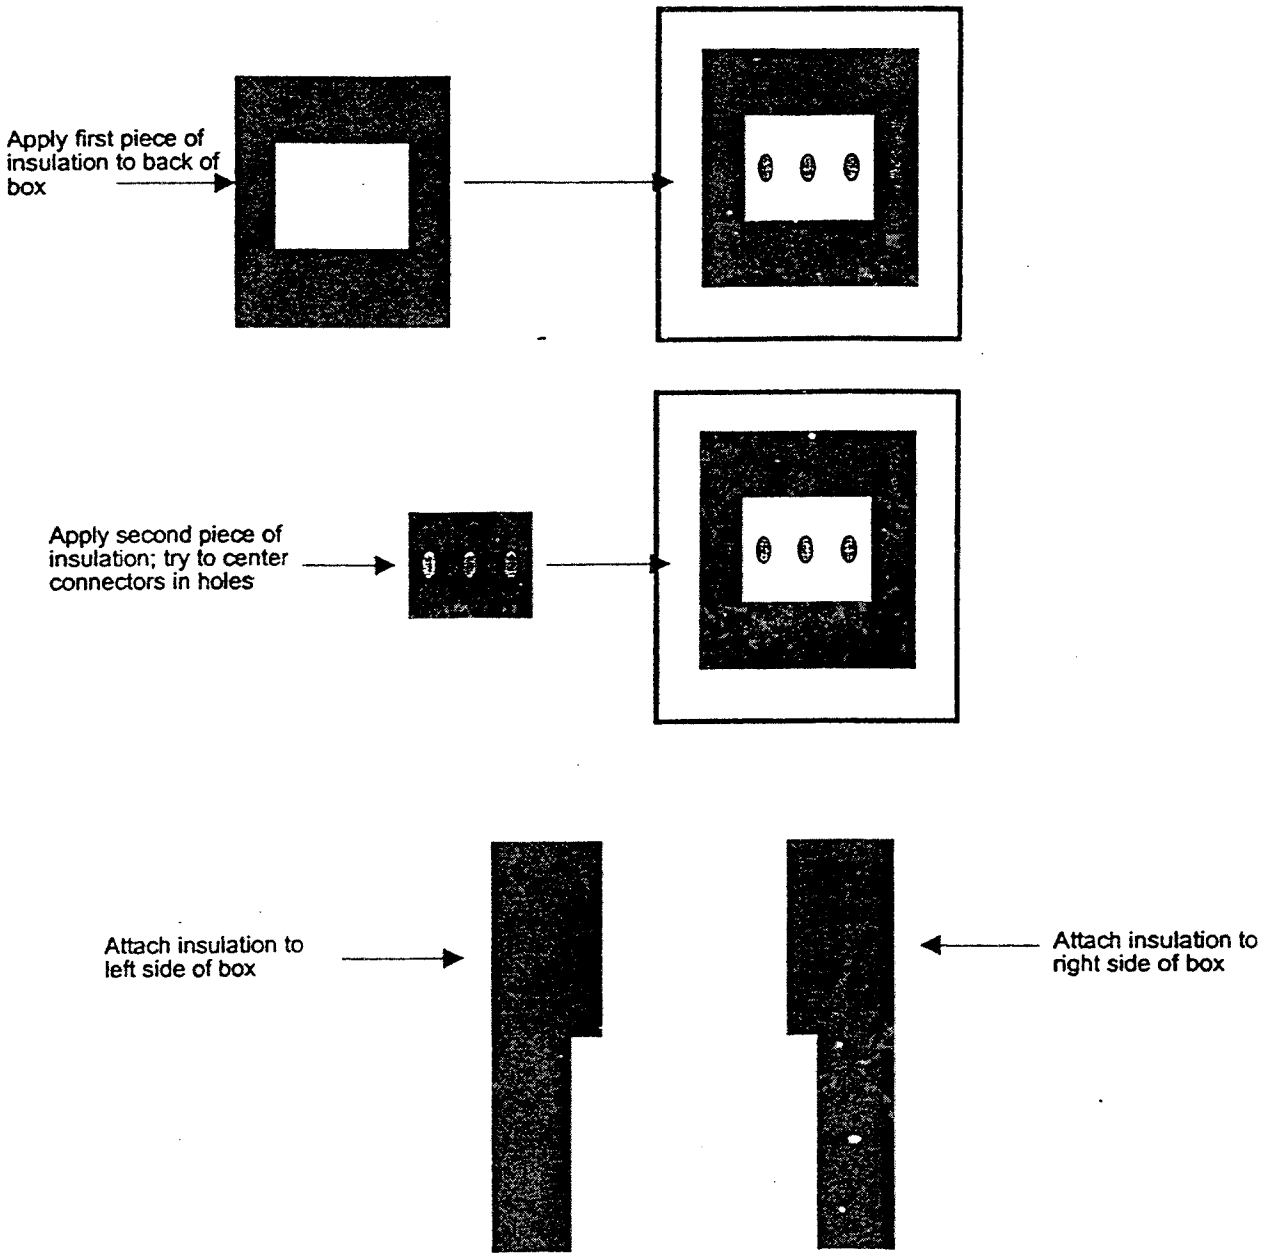


Figure 2
Insulation Instructions per Items 10 - 13

Note: Proper adhesion of insulation is important, clean all surfaces prior to installation of insulation, and roll or press all insulation surfaces to assure total surface and adhesion.

Subject: Solid State Starter Logic Module (2U2) Failures

Introduction:

The purpose of this bulletin is to provide troubleshooting and replacement information on the solid state starters used on the CVHE/CVHF/CVHG units.

IMPORTANT!
TO PREVENT INJURY OR DEATH DUE TO ELECTRICAL SHOCK, PLEASE FOLLOW THE WARNINGS PROVIDED THROUGHOUT THIS MANUAL REGARDING HAZARDOUS VOLTAGE WHEN SERVICING.

Discussion:

The Trane solid state starter is designed to start the chiller motor smoothly at a reduced torque and current. A complete starter consists of a 2U1 starter module, a 2U2 solid state controller, MOV (Metal Oxide Varistor) transient suppressers, and a 3-pole, 6 SCR, full wave power section all mounted in a common panel. All of the regulating, gating and logic functions are contained in the 2U2 logic module.

The original 2U2 logic module has an internal bridge rectifier that is undersized. This undersized component can fail and cause mis-firing of the gates leading to poor ramp-up of the motor. Follow the procedures below to troubleshoot the starter. The procedure will work on any version of logic module.

Corrective Action:

Several procedures are listed below to assist in determining which component in the starter has failed.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

©American Standard Inc. 1997

Logic Module (2U2) Control Settings and Adjustments

The 2U2 Logic module has three adjustable potentiometers.

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
Failure to disconnect power before servicing can cause severe personal injury or death.

Refer to Figure 1.

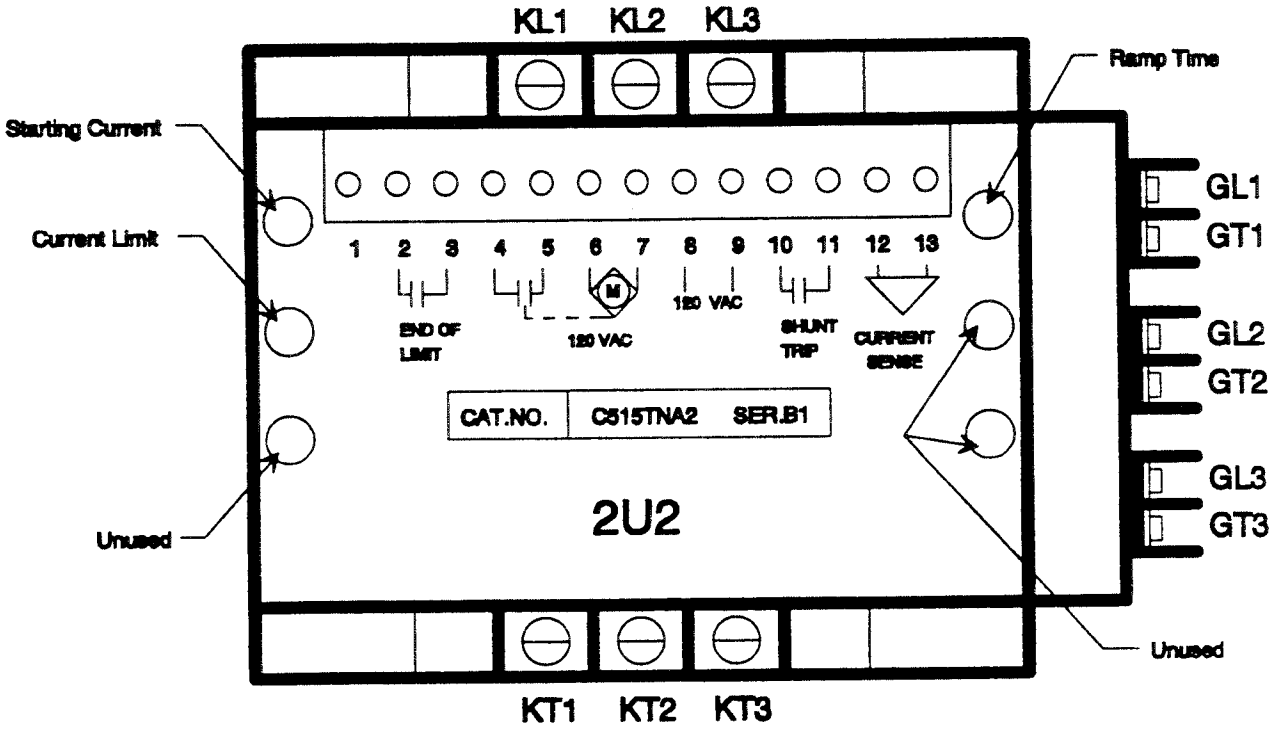
1. Starting Current - Factory Set @ 100% (full counter clockwise).
2. Current Limit - Factory Set @ 300%
3. Ramp Time - Factory Set @ 5 to 6 seconds.

The 2U2 Logic module also has three unused potentiometers.

The solid state starter is designed to provide adequate ramp-up current as necessary within five seconds to accelerate the motor. After the compressor is up to speed, the 2U2 logic module will close an internal set of contacts called "end of limit". When the "end of limit" contacts are closed, the compressor will be sent across the line by closing the by-pass contacts.

Initial Check-Out Procedures

[ ] Confirm all control voltage is separate from the power wiring.
[ ] Confirm all wiring is landed correctly.
[ ] Tighten all connections.
[ ] Inspect all components for damage by inspecting the starter for arcing, overheating, and other damage.



Fuse Check-Out

WARNING
TO PREVENT INJURY OR DEATH DUE TO ELECTRICAL SHOCK OR CONTACT WITH MOVING ⚠ PARTS,
use care when measurements, adjustments, or other service-related operations are performed with power on.

Four fuses can be replaced if necessary. The fuses that need to be checked are:

[ ] **2F1**: Each end to chassis ground should be ±10% of incoming voltage.
[ ] **2F2**: Each end to chassis ground should be ±10% of incoming voltage.
[ ] **2F3**: Each end to chassis ground should be ±10% of incoming voltage.
[ ] **2F4**: Each end to chassis ground should be 115 VAC ±10%.

Figure 1
Adjustable Potentiometers on 2U2 Module

Current Feedback Resistor (CFR) Check-Out

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
Failure to disconnect power before servicing can cause severe personal injury or death.

Refer to the four selection tables in the chiller drawing package that shipped with the unit (schematic 260352) to confirm that the correct current feedback resistor (CFR) is installed. If the correct resistor is installed, use the tables to determine the proper resistance setting for the CFR. Use the following steps to confirm that the CFR is set for the proper resistance value.

1. Disconnect the resistor from terminals 2TB5-32 and 33.
2. Place an ohmmeter across the resistor and record the value.
3. Refer to the applicable table in schematic 260352 to determined the correct resistance value.
4. If steps 2 and 3 do not correspond, use a small set screw on the resistor to adjust the resistance value.
5. With the correct resistance value set, re-install the resistor.

For example (using schematic 260352):

Starter model number (off starter nameplate):
CVSF238********
FLA for tables (use unit RLA found on nameplate) = 238

1. Go to tables on schematic to determine proper resistor.
2. Second table (labeled VC36ELJ) #2 shows proper resistor for the 238 RLA is C515P48.
3. If proper resistor is used, use same table to read resistance value of resistor. This CFR would be set at 850 ohms.

Power Pole Check-Out

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
Failure to disconnect power before servicing can cause severe personal injury or death.

The entire power pole must be replaced if one or more of the internal components fails the check-out procedures.

See Figure 3 for a typical Power Pole schematic for the following measurements.

1. Measure the resistance values across the terminals listed in Table 1.

   Note: It is not abnormal for two of the measurements in Table 1 to be closer together in values than the third measurement.

2. If any of the values fall outside of the range replace the power pole.

3. If the resistances are acceptable, measure the resistance values listed in Table 2 and record.

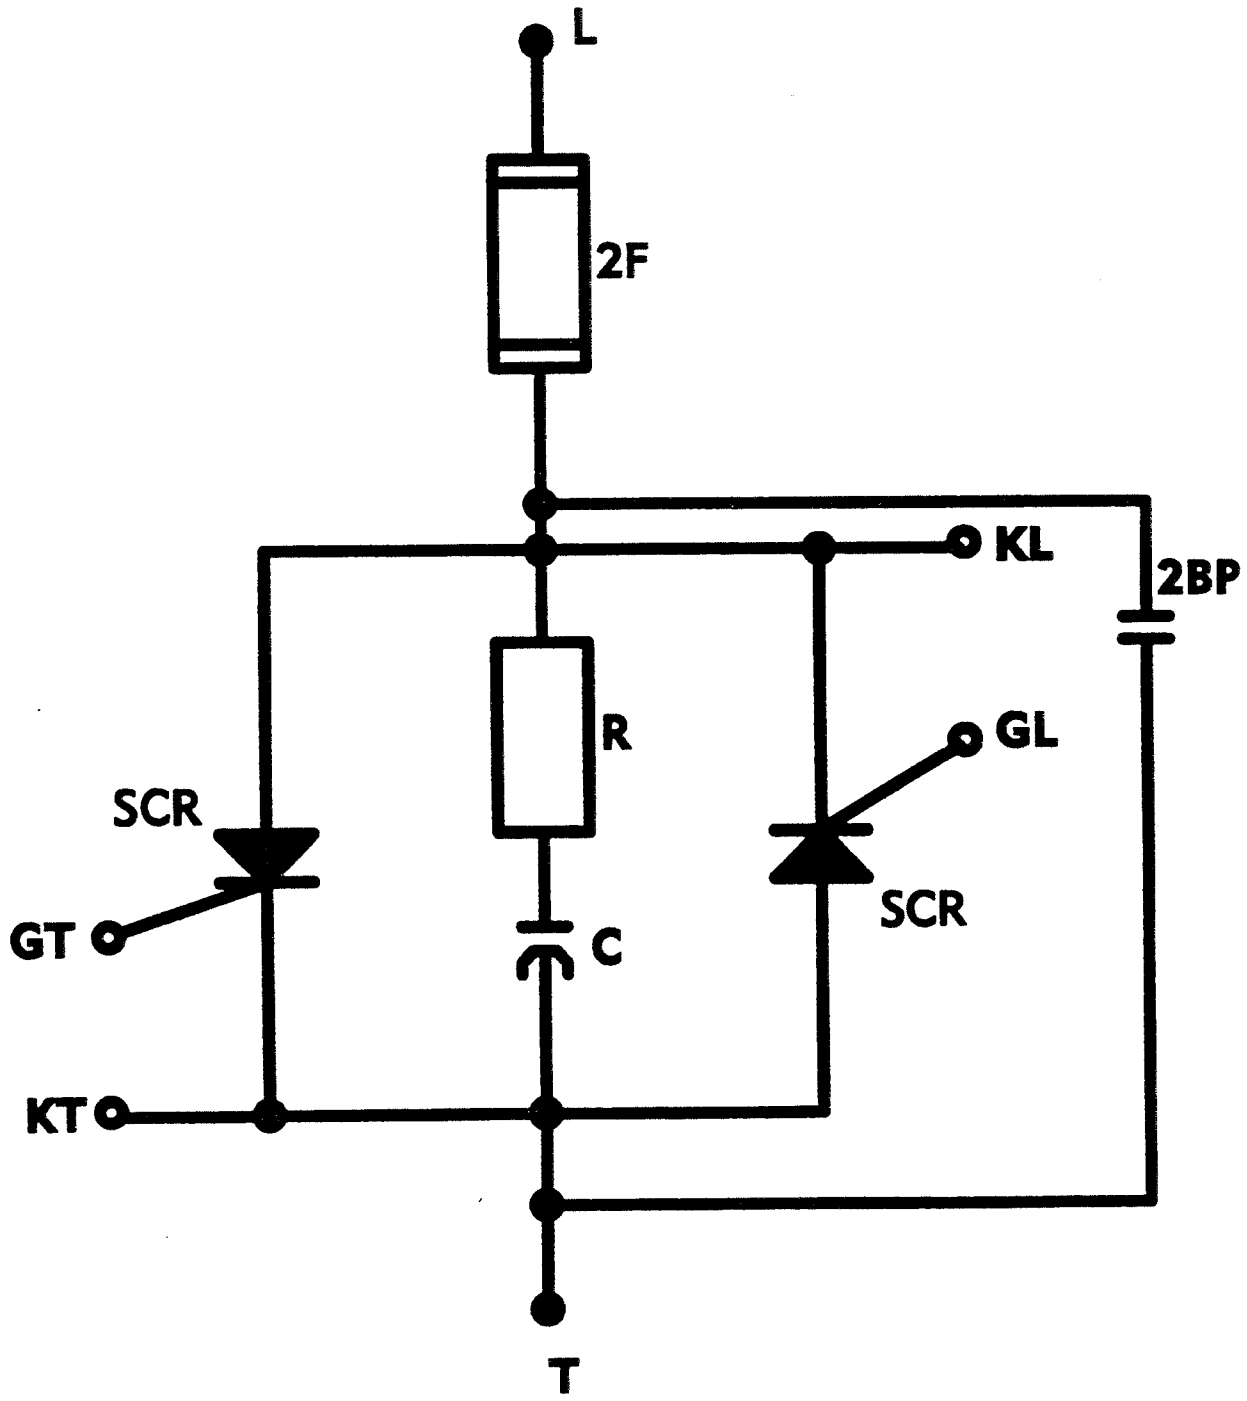


Table 1
Power Pole Resistance with Wire Leads Connected

Terminal Points on Power Poles	Resistance Value (Ohms)
KL1 to KT1	>10 K ohms
KL2 to KT2	>10 K ohms
KL3 to KT3	>10 K ohms

Table 2
Power Pole Resistance with Wire Leads Connected

Terminal Points on Power Poles		Resistance Value (Ohms)
KT1 to GT1	KL1 to GL1	5-100 ohms
KT2 to GT2	KL2 to GL2	5-100 ohms
KT3 to GT3	KL3 to GL3	5-100 ohms

Figure 3
Typical Power Pole Schematic

4. If any of the values fall out side of the range, replace the power pole.

5. If the resistances fall within the range, ensure that the starter is connected to the motor and proceed with Step 6.

⚠ WARNING
TO PREVENT INJURY OR DEATH DUE TO ELECTRICAL SHOCK OR CONTACT WITH MOVING PARTS, use care when measurements, adjustments, or other service-related operations are performed with power on.

6. Apply power to the unit but do NOT let the compressor start. Make sure the CLD shows an operating mode of "STOP".

7. Measure and record the following voltages:

   [ ] KL1 to KT1
   [ ] KL2 to KT2
   [ ] KL3 to KT3

The measured voltage must be 0.58 times the incoming line voltage.

For example: Units with 480 VAC line to line voltage will have 278 VAC ± 5% measured between the points listed in Step 7.

8. If the voltage readings in Step 7 are out of range, replace the power pole and retest.

9. If the power poles pass the above check-out proceed with the next section.

Power Pole Fan Check-Out

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
Failure to disconnect power before servicing can cause severe personal injury or death.

Fans are used on the power poles to keep the components from overheating. Confirm that the fans are operating and that the rotation of the fans is correct.

1. The 2TR1 time delay relay will close at start-up and should pull air up from the bottom of the cabinet through the power poles.

2. The 2TR1 time delay relay will allow the fans to operate 15 minutes after shutdown.

Control Power Check-Out

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
Failure to disconnect power before servicing can cause severe personal injury or death.

The logic module (2U2) uses 120 VAC supplied by the 2T4 transformer. Check the control power by performing the following steps:

1. Measure the voltage across 2TB1-1 and 2TB1-3. The voltage must be 120 VAC ± 10%.
2. If the voltage falls out of range, check the 2F4 fuse and the 2T5 transformer.
3. If the voltage falls within range, measure the voltage between 2TB1-5 and 2TB1-3. The voltage must be 120 VAC ± 10%.
4. If the voltage falls out of range, check the connection and operation of the high pressure cutout switch.
5. If the voltage falls within range, check the 24 VAC control power by measuring the voltage between J2-1 and J2-2 on the 2U1.
6. If the voltage is out of range, check the 2T4 transformer.
7. If the voltages are within range, go to the next section.

Logic Module Shunt Trip Check-Out

1. The Power Pole Check-Out procedure on page 4 must be conducted prior to the following tests.

⚠ WARNING
TO PREVENT INJURY OR DEATH DUE TO ELECTRICAL SHOCK OR CONTACT WITH MOVING PARTS, use care when measurements, adjustments, or other service-related operations are performed with power on.

Apply power to the starter but do NOT allow the compressor to start. If the breaker opens immediately, the internal shunt trip of the logic module (2U2) has been activated. To check the shunt trip follow the procedures below:

2. With the Starter Line Circuit Breaker open, remove the 2U1-J16 plug and isolate it. This will disable the shunt trip coil.

3. Reset and close the breaker.

4. Test the output of the logic module (2U2) between pins 10 and 11. This internal shunt trip is a dry contact closure that closes on application of power and opens on a fault.

5. If the shunt trip does not initially close, reconfirm that the power poles are operating properly. If the power poles pass the check-out procedures, replace the logic module (2U2).

6. If the shunt trip is closed, but the UCP2 is displaying a "Solid State Starter - Fault Relay Open", check the 2U1 starter module and the interconnecting wiring.

Logic Module (2U2) Check-Out

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
Failure to disconnect power before servicing can cause severe personal injury or death.

Disconnect all power from the unit and perform the following steps.

1. Disconnect the leads from GL1, GL2, GL3, GT1, GT2, GT3, KL1, KL2, KL3, KT1, KT2, and KT3 at the 2U2 Logic module.

2. Measure the resistance between KL1 to GL1, KL2 to GL2, and KL3 to GL3 at the 2U2 Logic module. The resistance must be 1000 ohms æ 10 ohms.

3. Measure the resistance between KT1 to GT1, KT2 to GT2, and KT3 to GT3 at the 2U2 Logic module. The resistance must be 1000 ohms ± 10%.

4. If any of the resistances are out of range, replace the 2U2 logic module.

⚠ WARNING
A PORTION OF THE FOLLOWING PROCEDURE IS DONE WITH POWER APPLIED TO UNIT.
TO PREVENT INJURY OR DEATH DUE TO ELECTRICAL SHOCK OR CONTACT WITH MOVING PARTS , Use Care When Measurements, Adjustments, Or Other Service-related operations Are Performed With Power On.

5. If the resistances are correct, reconnect the leads that were removed in Step 1 and proceed with the Starting Sequence Check-out.

Starting Sequence Check-Out

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRIC POWER INCLUDING REMOTE DISCONNECTS BEFORE SERVICING.
Failure to disconnect power before servicing can cause severe personal injury or death.

If the compressor is not rotating after a start signal, follow the procedures below to confirm that the 2U2 and 2U1 modules are functioning properly.

1. Check phase rotation, it must be A-B-C. Improper wiring sequence to L1, L2 and L3 will cause the shunt trip to fault. Improper wiring to the 2U2 can also cause the shunt trip to fault.

2. Meg the compressor motor and confirm that the problem is not in the motor.

⚠ WARNING
A PORTION OF THE FOLLOWING PROCEDURE IS DONE WITH POWER APPLIED TO UNIT. TO PREVENT INJURY OR DEATH DUE TO ELECTRICAL SHOCK OR CONTACT WITH MOVING PARTS , Use Care When Measurements, Adjustments, Or Other Service-related operations Are Performed With Power On

3. Close the disconnect and initiate the chiller through a starting sequence.

4. Measure the voltage across the 2T5 transformer and the 2F4 fuse. Place the voltmeter across 2TB1-1 and 2TB1-3, the power supply is 120 VAC ± 10%.

5. If no voltage is measured, check the fuse and the 2T5 transformer. If power is present, measure the voltage across 2TB1-3 and 2U2 pin 8. The voltage is 120 VAC ± 10%.

6. If no voltage is present, check the operation and connections of the HPC switch and the interconnecting wiring.

7. Also check the voltage across 2TB1-3 and 2U2 pin 2 for 120 VAC ± 10%. If it is not present check wiring and connections between the transformer and the module.

8. Measure the voltage from 2U2 pin 7 to ground for 120 VAC ± 10%. If voltage is present, the heatsink motor temperature sensors may have opened.

9. Try to restart and measure the voltage from 2U2 pin 6 to 2TB1-3 for 120 VAC ± 10% at initiation of compressor start. If no voltage is present, check the 2U1 "Start" and "Stop" relays.

10. To check the 2U1 stop relay, measure the voltage between J6-3 to ground, 120 VAC ± 10% should be present any time control voltage is applied.

11. To check the 2U1 start relay, disconnect the 2P8 plug from J8-1. Measure the voltage from J8-1 to ground, 120 VAC ± 10% should be present after the start command is given.

12. If the start or stop relays are not functioning properly, replace the 2U1 starter module.

13. If the compressor starts but does not ramp properly, proceed with the ramp-up check-out of the starter.

Starter Ramp-up Check-Out Procedure

If the compressor starts but does not have a smooth ramp-up, use the procedure below to check settings and component operation. Before using this procedure, change the following settings in UCP2 to ensure that the compressor motor does not go across the line during the test.

Located in **Service Settings, Machine Configuration Group (+ - + - + -)**

[ ] Maximum Acceleration Timer #1 = 4
[ ] Maximum Acceleration Timer #2 = 251
[ ] Acceleration Time Out Action = Shutdown

1. Adjust Current Limit potentiometer on 2U2 to 100%.

2. Adjust Starting Current potentiometers to 100%.

3. Scroll to % RLA under the Compressor Report menu or place a clamp-on ammeter on each incoming leg. Monitor and record readings during start.

4. Initiate a unit start.

5. % RLA should reach 100% or ammeter should reach unit RLA listed on unit nameplate within 2 seconds, and hold the reading for 2 seconds, and the unit should then shut down on failure to accelerate.

6. If the reading is something other than the RLA listed on the nameplate (± 10%), the starter is controlling to an incorrect value. Check the operation of the 2T10 transformer and the setting of the CFR.

7. If the transformer and CFR are operating properly replace the 2U2 logic module.

Note: Other problems can cause the compressor to have a poor ramp. For example, a compressor starting located will pull higher amps than normal and could cause the unit to go across the line.

Units Affected:

Any unit manufactured with a shipping date of July 13, 1995 through June 30, 1997 with a solid state starter must have the 2U2 logic module replaced if this module has not been replaced after July 15, 1997.

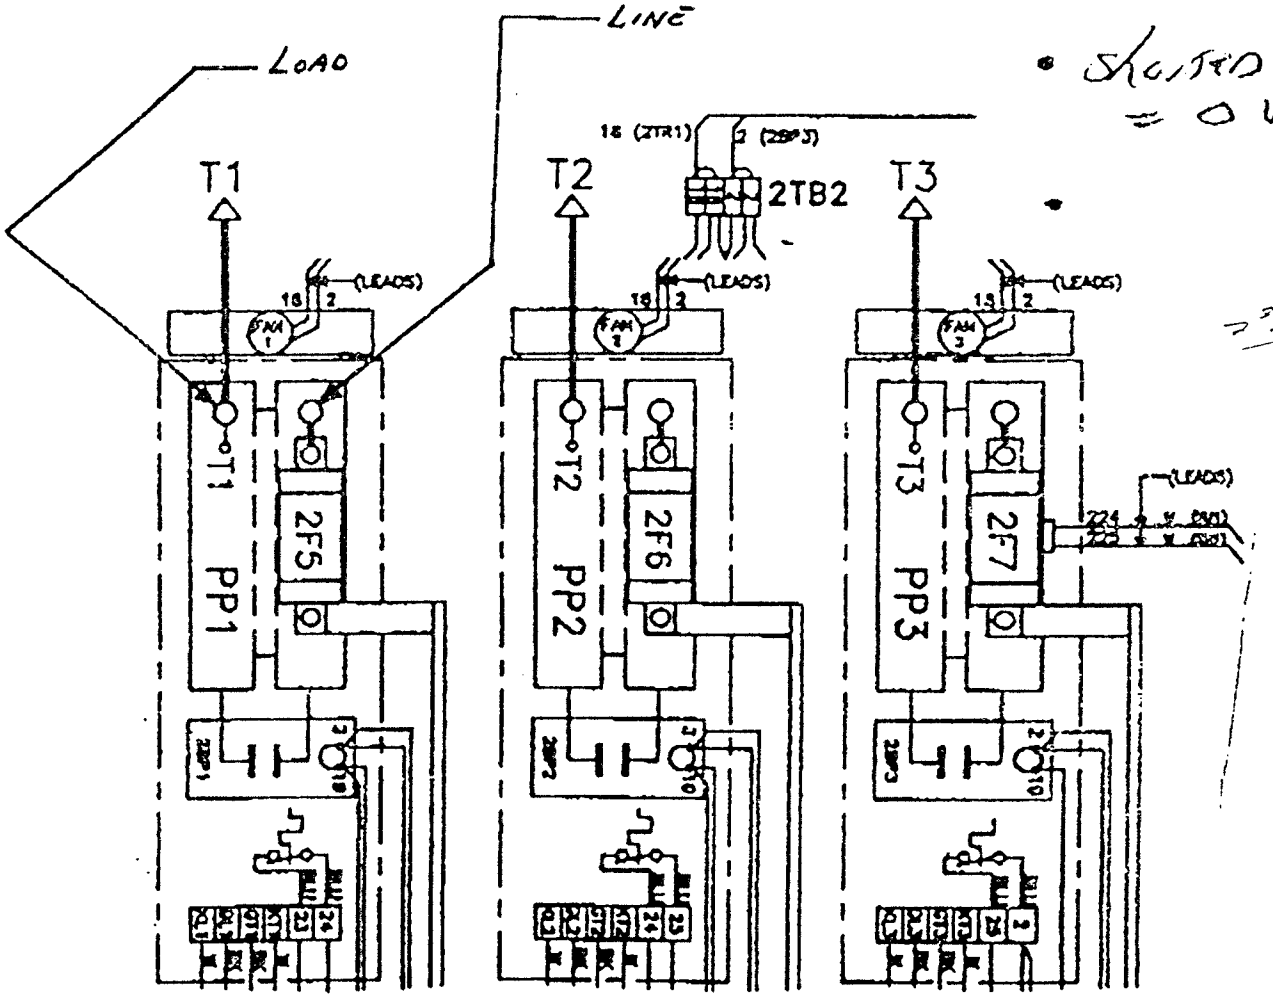
Parts Ordering:

One 2U2 logic module (MOD-00444) is required for each unit with a solid state starter. Contact your local Trane Parts Center to obtain parts.

BLOCKING VOLTAGE TEST

Add CMHE-SB-44

L1 265 VAC
L2 265 VAC
L3 265 VAC



to

With the starter disconnect closed and the unit at STOP, check the voltage between the line and load side of each power pole. A good power pole will show 58% of line voltage.
Lower voltage will indicate a defective power pole.

DISCONNECT MOBIL

Higher settings indicate

From Power Pole

Confidential Service Bulletin

CVHE-CSB-45C

Library	**Service Literature**
Product Section	**Refrigeration**
Product	**Centrifugal Liquid Chillers**
Model	**CVHE/F/G**
Literature Type	**Confidential Service Bulletin**
Sequence	**45C**
Date	**October 19, 1998**
File No.	**SV-RF-CTV-CVHE-CSB-45C-10/19/98**
Supersedes	**SV-RF-CTV-CVHE-CSB-45B-6/19/98**

Literature History: CVHE-CSB-45A, released March 24, 1998.
Revised bulletin, CVHE-CSB-45B, June 19, 1998, "Note" added on Page 2.
Revised bulletin, CVHE-CSB-45C, October 19, 1998, Extended cutoff to June 1, 1999.

Subject: GPM/TONNAGE OPTION USED ON CVHE/F/G UNITS - REVISION

Introduction:

The purpose of this bulletin is to provide information concerning the GPM/Tonnage option used on the CVHE/F/G water chillers using the UCP2 controls. This is a "Fix on Fail" service bulletin and NOT a Mandatory retrofit.

Units Affected:

All CVHE/F/G units using UCP2 controls that have the < = 150 PSIG GPM/Tonnage option installed on the unit.

Background:

A problem has been found with some of the CVHE/F/G machines using the UCP2 controls, where the GPM/Tonnage option is installed, in which you get inaccurate or no GPM/Tonnage readings. The problem is typically in the Alco reversing valve and/or transducers. This option is used for information only and creates no unit operational problems.

This bulletin discusses a change to the GPM/tonnage option that enhances its reliability and improves readout accuracy.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

©American Standard Inc. 1998

NOTE: BE SURE AND RECORD ALL SETTINGS FROM THE OPERATOR SETTINGS AND SERVICE SETTINGS MENU INCLUDING THE FIELD STARTUP AND MACHINE CONFIGURATION GROUP SETTINGS BEFORE REMOVING THE CHILLER MODULE. THIS DATA WILL NEED TO BE REPROGRAMMED INTO THE UCP2 AFTER THE NEW CHILLER MODULE IS INSTALLED.

Discussion:

The current/(old) GPM/Tonnage option has a Alco reversing solenoid valve that reverses every 30 seconds, transducers mounted on the solenoid valve and tubing that runs from the transducers to the Evaporator and Condenser water boxes. One Transducer for the Condenser and one for the Evaporator.

Note: You will remove and discard the solenoid valve, piping and transducer as part of this retrofit.

The kit has four (4) transducers. Two each for the Condenser and two for the Evaporator. The new transducers will mount/attach to the Y-strainers at the water boxes. Provided cables will then be run back to new switching relays mounted in the control panel. The chiller module provides new software required for the enhancement.

For further accuracy/improvement of the GPM/Tonnage, the customer may move the transducers from the water box to the piping several feet from the chiller.

To complete the unit modifications, follow the instructions provided in the retrofit kit and also attached to this service bulletin. The two new switching relays, 1K1 and 1K2, are wired in as shown on the attached detail from wiring diagram 2307-5214 on terminals 1U1-6-1, 1U1-J6-2. Also the (4) new transducers for the condenser and evaporator water boxes are connected in as shown on terminals 1U1-J9-1 thru 10.

UCP2 Settings:

The following UCP2 control panel settings apply to this option.

1. (All Units) Machine Configuration menu: Differential Water Pressure Sensing option. You need to install either: <=150 PSIG or> = 150 PSIG.

2. There are (3) "new" screens you need to be aware of located in the field startup service settings group. These screens are listed below. These screens are NOT used on all units. They are used only on "open systems" (often times associated with air wash application) where the system on shutdown may go negative due to siphon action of the water. On these systems only, you must set the following three (3) screens.

a. Set this screen to Manual

CTV Only	Water Pressure Calibration: [Setting]
	Press (+) (-) to Change Setting

Possible values of [Setting] are:

Auto (Rom Default)
Manual

b. Measure and install the actual evaporator water pressure drop.
If the above menu is set to "Manual", the following two menus shall be displayed.

CTV Only	Measured Evap Diff Wtr Press: X.X PSID/kPa Press (+) (-) to Change Setting

Possible values are 0 to 25 PSID (0 to 172.4 kPa) in 0.1 PSID (kPa) increments. Rom default is 0.0 0.0 PSID (kPa).

C. Measure and install the actual condenser water pressure drop.

CTV Only	Measure Cond Diff Wtr Press: X.X PSID/kPa Press (+) (-) to Change Setting

Possible values are 0 to 25 PSID (0 to 172.4 kPa) in 0.1 PSID (kPa) increments. Rom default is 0.0 PSID (kPa).

As a point of clarification, when the 1st screen is in the Auto mode for the typical application, we do a calibration when the unit is off and the pumps are off. In the Manual mode, we do not use this calibration time, we use the Manual calibration numbers you install and calibrate on startup.

Material Authorization:

This service bulletin authorized one KIT05532 for each unit identified with a GPM/Tonnage option that is having problems. The kit contains (4) transducers, cables, (2) switching relays and sockets, chiller module and fittings to adapt the transducers to the water boxes. Instructions and parts lists are included with each kit.

Material Disposition:

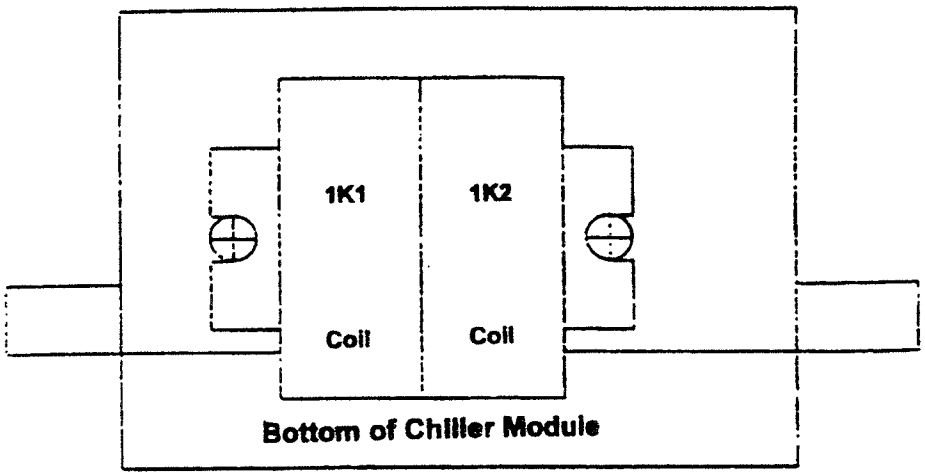
The old material can be disposed in the field.

Labor Authorization:

Eight hours labor including travel. ALL CLAIMS MUST BE SUBMITTED ON THE "SERVICE WARRANTY SALES ALLOWANCE CLAIM" FORM 1-30.09-2 WITHIN 30 DAYS OF THE REPAIR.

Expiration Date:

The effective cutoff date of this bulletin is June 1, 1999.



GPM/Flow Sensing
Electrical Instructions For Retrofit Kit:

1. Connect 4 transducers to mechanical set ups, used to detect water flow, which are on the entering and leaving evaporator and entering and leaving condenser water boxes.

2. Install chiller module or EPROM.
   - Install a new chiller module if the present module is part number X13650450 extension-09 or earlier.
   - Install an EPROM kit if the present module is part number X13650450 extension -10 or later.

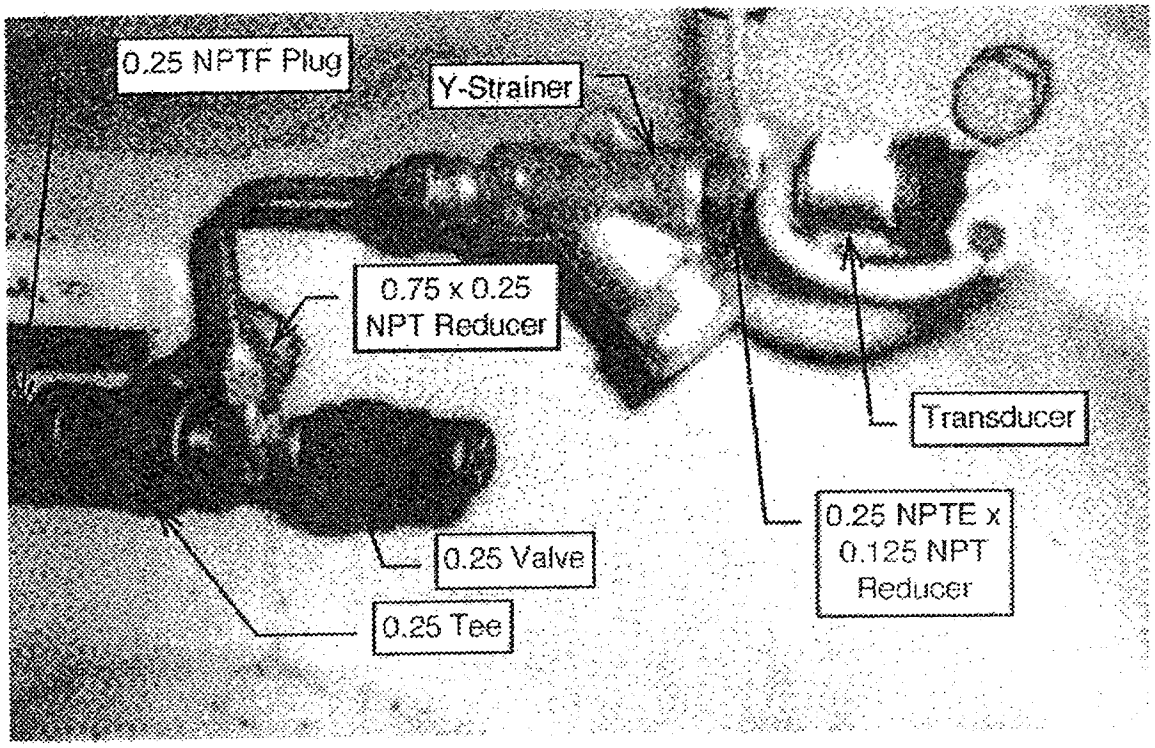
Important: If the chiller module is being installed, before removal record the 5 coefficients below, located in the Service Settings menu and re-enter after retrofit is complete. Evaporator Flow Equation Exponent, Evaporator Fluid Coefficients, Condenser Flow Coefficient and Condenser Flow Equation Exponent.

3. Mount 3.5 inch din rail on the bottom of the Chiller Module using the screw already on the module enclosure. Mount sockets on din rail, plug relays into sockets and attach relay clips to sockets. As shown in the picture below the coil will be at the bottom of the module.

4. Wire the transducers, using the transducer cables, to the UCP2 chiller module.
   Refer to 1U1-J6-1, 1U1-J6-2 and 1U1-J9, 1 through 10, drawing 2307-5214 rev C.

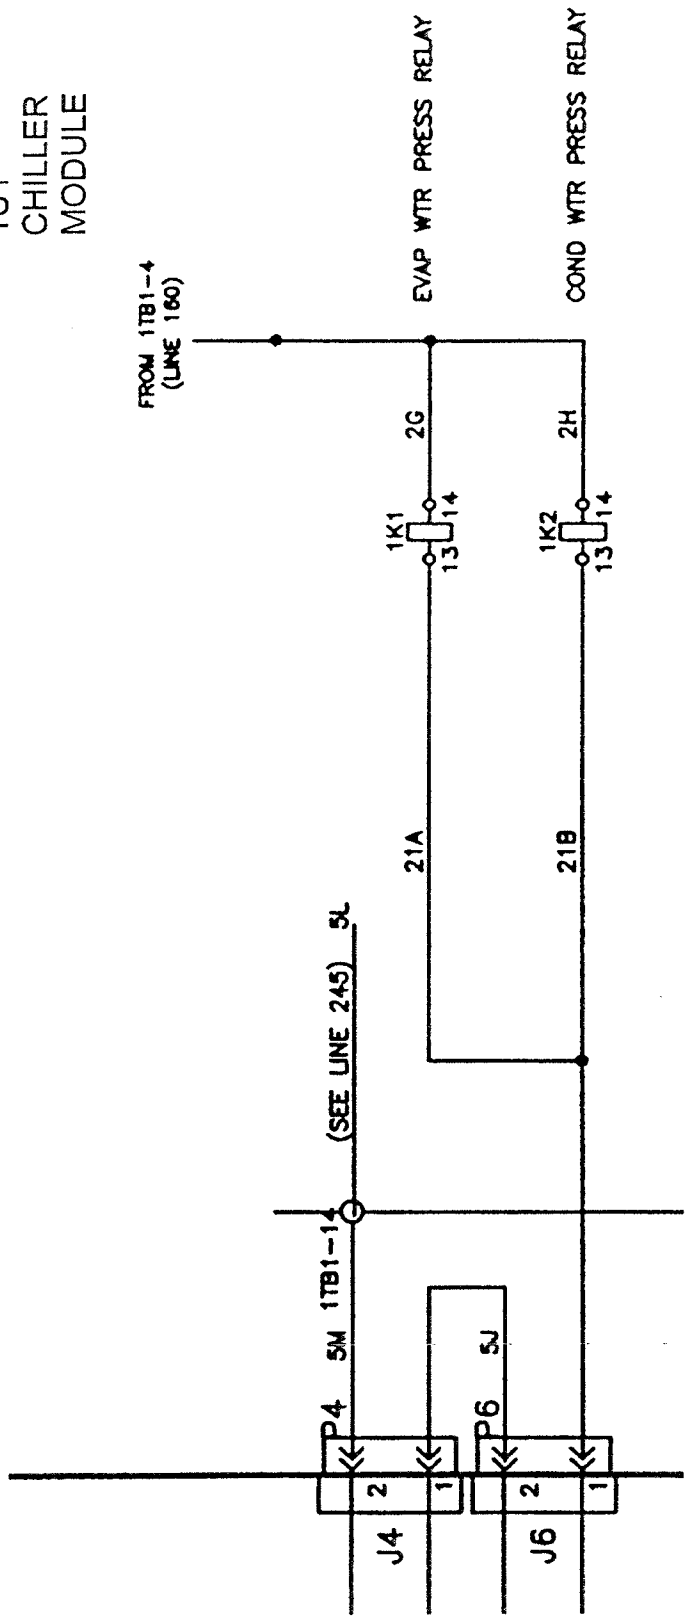
Water Pressure Differential Option Assembly:

Water Pressure Differential Option Retrofit Kit #1:
- Evaporator and condenser non-marine water boxes.



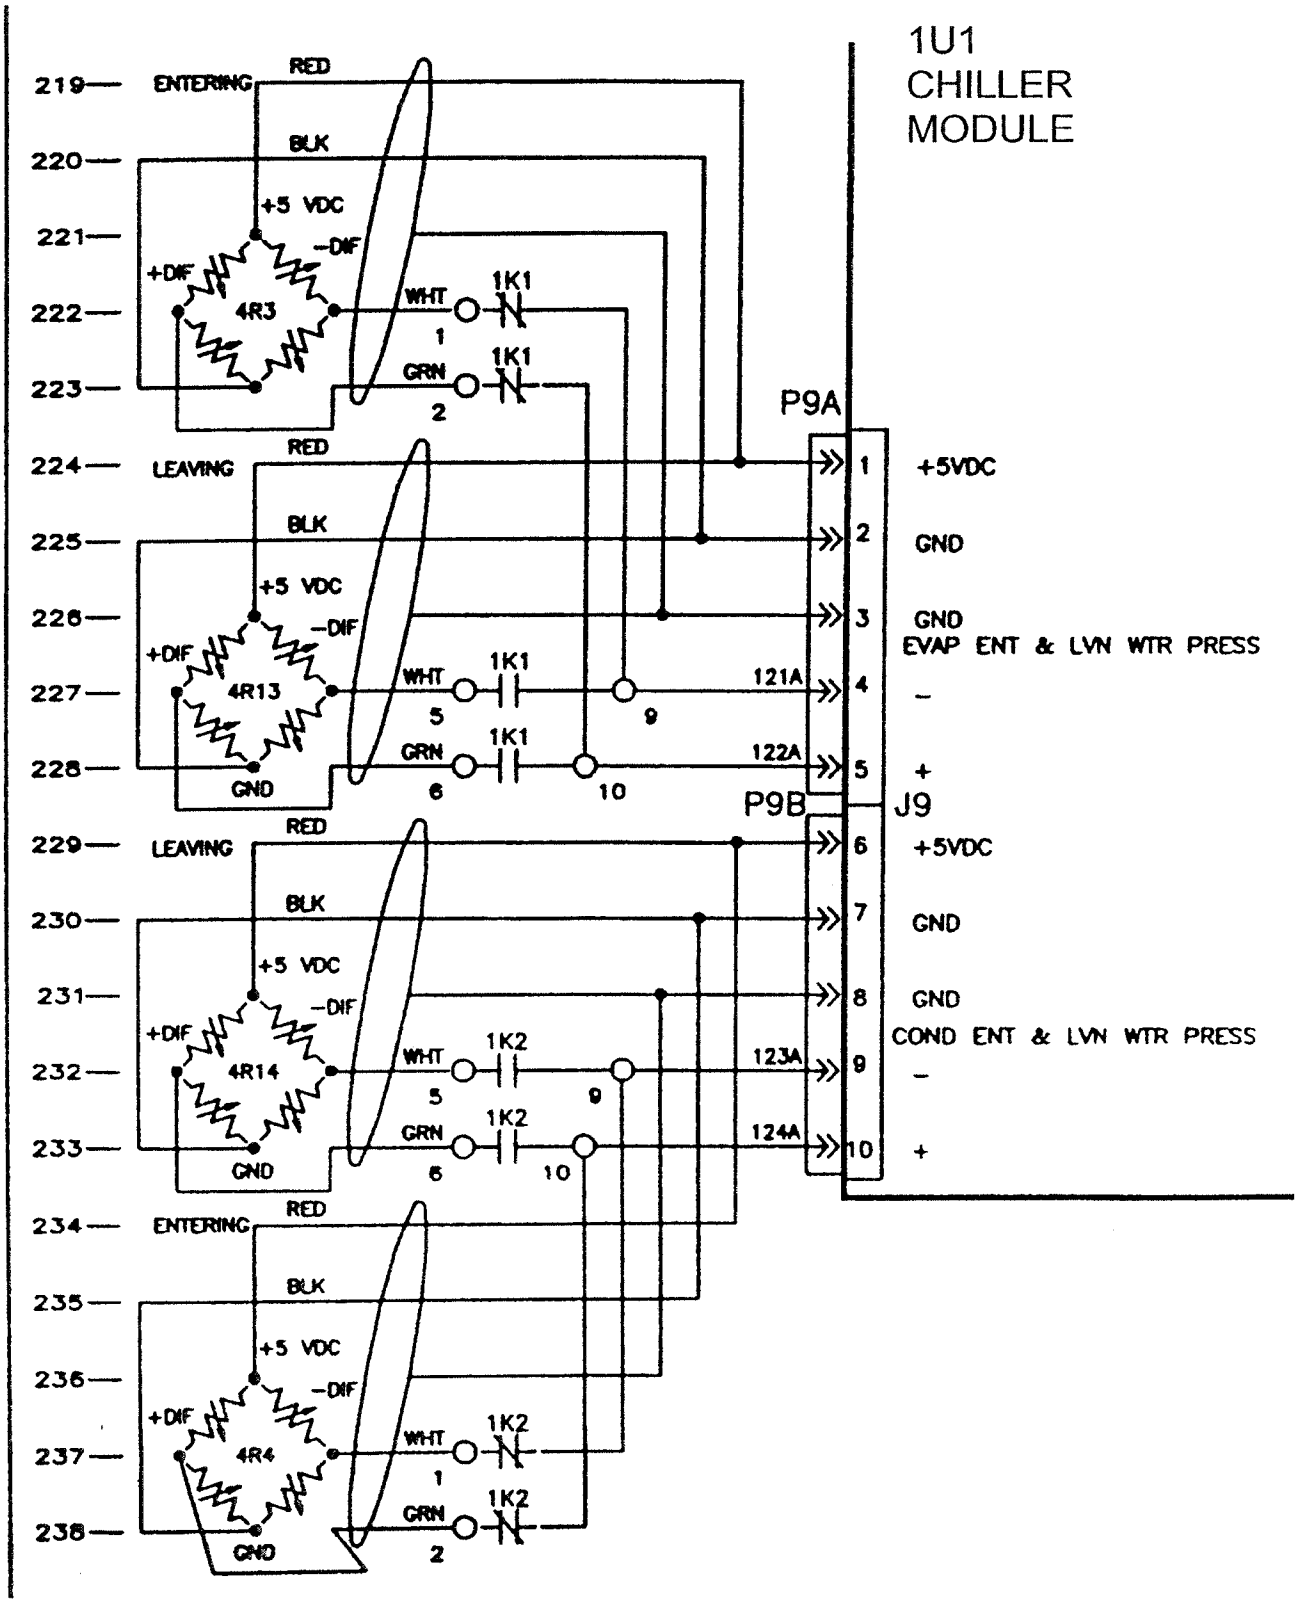
Water Pressure Differential Option Retrofit Kit #2:
- Evaporator and condenser marine water boxes.
- Evaporator and condenser 032 and 050 cast condenser non-marine water boxes.

The example below shows how the retrofit should look after completion on a evaporator or condenser non-marine water box (KIT #1). The following are basic field retrofit instructions:



1. Shut off water valves located on the water boxes.
2. Do NOT remove the Y-strainer from the valve if you have the following:
   - Y-strainer is attached to the valve with copper tubing like above (go to step 5).
   - Y-strainer is attached directly to the valve as on a marine water box (go to step 5).
3. Otherwise, remove all piping and/or components from the water box valve to the transducer location.
4. Attach Y-strainer to valve assembly, making sure the flow is in the correct direction and up right.
   - As above (KIT #1) using flare fittings and 0.25 copper tubing OR
   - Directly to the valve (KIT #2) using a flare union and 0.25 NPT adapter.
5. Attach 0.25 NPTE x 0.125 NPT adapter to the Y-strainer.
6. Attach the transducer to the reducer.
7. Attach transducer connector and cable.
8. Run the transducer cable back to the UCP2 by following the temperature probe cable.
9. After installation is complete, turn valve on and check for leaks.

Note: Use the proper thread sealer on all joints, such as Loctite.



Example of KIT #1

1U1 Chiller Module - J6-1 AND J6-2 - Detail From Drawing 2307-5214C

1U1 Chiller Module - J9-1 Through 10 - Detail From Drawing 2307-5214C

Literature History: Original bulletin, CVHE-CSB-46, dated February 26, 1998
Revised bulletin, CVHE-CSB-46A, dated June 18, 1998, added "Note" on page 2.

Subject: Fast Restart Situation for UCP2 Equipped Centrifugal Chillers

Introduction:

The purpose of this bulletin is to advise Trane Service Companies of a FIX ON FAIL RETROFIT to existing field CVHE/CVHF/CVHG chillers equipped with the UCP2 Control panel. A situation can occur where the chiller shuts down for no apparent reason and tries to restart, usually after approximately 35 seconds. The inlet guide vanes are not stroked closed before the restart takes place. Depending on compressor load, the unit may lock out on a "Compressor did not Accelerate" or a "Current Overload" diagnostic and will require a manual reset to restart or the compressor will start and run with no diagnostics generated. This situation has been termed "Fast Restart".

Units Affected:

All centrifugal chillers utilizing the UCP2 control panel manufactured from August 1993 to March 1998.

Discussion:

Under certain circumstances, when a slight power interruption to the UCP2 occurs (750 msec or so), the Starter module (and sometimes the CLD) experiences a power reset. However, the chiller and stepper modules do not reset. As a result, the chiller and stepper modules operate under the belief that the compressor is still running. If the inlet guide vanes are in the "auto" mode, the vanes will open farther in response to losing capacity. When the Starter module resets, the restart inhibit timer is set to 30 seconds if the winding temperatures are below 165° F. When this timer expires, the compressor motor is restarted. The Chiller module responds to the high starting current by closing the inlet guide vanes as a result of entering a current limit mode. The compressor may not accelerate fast enough to prevent a "compressor did not accelerate" latching diagnostic, or may go out on a "Current Overload" diagnostic, depending on load.
To correct this problem, a new Chiller module (MOD00706, X13650450-15-0) and a new Starter module (MOD00740, X13650453-16-0) are required.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Sequence	47
Date	March 12, 1998

Subject: UCP2 CVHE/F/G Extended Storage Requirements (Unit Is Installed With All Electrical)

Introduction:

The purpose of this bulletin is to provide information on extended storage requirements for UCP2 centrifugal chillers to be removed from service for an undetermined length of time.

Important!
To prevent injury or death, please follow the warnings provided throughout this manual regarding hazardous voltage and refrigerant removal.

Discussion:

⚠ WARNING
USE CARE WHEN SERVICING SYSTEM WITH POWER ON. Failure to do so could result in injury or death due to electrical shock or contact with moving parts.

The following steps are necessary in order to properly prepare a unit for storage.

1. Remove all liquid refrigerant if the unit is charged.

⚠ WARNING
TO AVOID INJURY OR DEATH DUE TO INHALATION OF, OR SKIN EXPOSURE TO REFRIGERANT, CLOSELY FOLLOW ALL SAFETY PROCEDURES DESCRIBED IN THE MATERIAL SAFETY DATA SHEET. Failure to do so may expose operating and/or servicing personnel to liquid and/or vaporous refrigerant.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

©American Standard Inc. 1998

2. After the liquid refrigerant is removed, using a recovery/recycle unit or vacuum pump, pull a vacuum to remove remaining refrigerant vapor from the unit.

3. After all traces of refrigerant are out of the unit, a positive nitrogen charge should be put into the unit (6 to 8 PSIG). This positive pressure must be checked monthly to insure no noncondensibles get into the unit. Use a pressure gage on the evaporator shell to verify that the 6 to 8 PSIG dry nitrogen holding charge is still in the chiller. If this charge has escaped, contact a qualified service organization and the Trane sales engineer that handled the order.

4. The refrigerant charge should be stored in proper refrigerant containers. Due to possible leakage, do not store in used drums.

⚠ WARNING
USE CARE WHEN MEASUREMENTS, ADJUSTMENTS OR OTHER SERVICE-RELATED OPERATIONS ARE PERFORMED WITH POWER ON. Failure to do so could result in death due to electrical shock or contact with moving parts.

5. Maintain control power to the control panel. This will maintain oil temperature in the oil sump and the capability of the control panel to present report information. The Chiller, Refrigerant and Compressor Reports should be viewed once a week for normal readings. Any abnormal observation must be reported to the Trane Sales Engineer that handled the order.

6. Remove the factory installed jumper or the field installed wiring on terminals J5-1 and J5-2 on the 1U1 Chiller Module in the unit control panel. This will prevent unwanted chiller operation.

7. Set the purge operating mode to OFF on UCP2 chillers.

8. The oil can be left in the unit.

9. The water side should not cause a problem if shut down and drained. There may be slight scaling inside the tubes, but not enough to cause a problem. Customer should inspect and clean tubes before the unit is returned to service.

Important
Do not use untreated or improperly treated water, or equipment damage may occur.

Important
Scale deposits are best removed by chemical means. Be sure to consult any qualified chemical house in the area (i.e., one familiar with the local water supply's chemical mineral content) for a recommended cleaning solution suitable for the job.

10. Motor bearings: If the motor sits for a long time the bearings could take a set and cause bearing problems/replacement later. Once every six months the chiller oil pump must be started and the compressor motor bump started to rotate the shaft. Contact a qualified service organization to perform this task. If the compressor motor cannot be bump started, then the shaft must be rotated manually by a qualified service organization.

11. Obtain an oil analysis initially after 6 months of storage, and once each succeeding year. If no oil breakdown is evident do not change the oil. If breakdown is evident, the oil must be replaced.

12. If the unit is stored for more than five years, and the storage is expected to be indefinite, the unit should be examined for leaks every five years from the initial storage date.

13. When the unit is to be returned to service, the services of a qualified service organization should be obtained to conduct all activities associated with the startup of a new chiller.

Units Affected:

All electrical installed UCP2 CVHE/F/G centrifugal units.

Material Authorization:

No material authorized.

Labor and Travel Authorization

No labor or travel authorized.

Expiration Date:

No expiration date for this service bulletin.

Overview

This document describes the proper procedures for returning Suva® 123 empty cylinders, defective containers, and product to DuPont. As a shipper of record, you are responsible for maintaining container integrity at all times, preparing and properly labeling each vessel, preparing a proper bill-of-lading (BOL), and ensuring that the shipment complies with all DOT regulations.

To assist you, DuPont will provide Material Safety Data Sheets (MSDS), Return Authorization (RA) tags, plus an easy-to-use bill-of-lading and Return Authorization form. Please contact your DuPont Customer Service Representative to obtain these items.

DuPont will pay the return freight if you call DuPont Transportation (TONA) at (800) 554-8662 to arrange shipment, use an approved carrier, and prepare and ship the containers in accordance with this guideline.

Emergency Response

Companies shipping used refrigerant to DuPont may use the CHEMTREC 24-hour emergency telephone number (800) 424-9300. However, if your company is not a member of the Chemical Manufacturing Association (CMA) in Washington, D.C., this telephone number may not be used as the required Department of Transportation (DOT) emergency response telephone contact when shipping other hazardous materials.

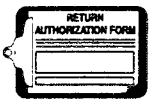
Returning Empty Containers (Not Recovered Refrigerant)

1. Complete Return Authorization (RA) form (see Example A).

   Note: RA form is attached behind bill-of-lading (BOL) form.

2. Contact DuPont TONA at (800) 554-8662 to arrange shipment and obtain RA number. Remember to add RA number to the Return Authorization form and BOL. DuPont TONA will inform you of the RA number, carrier, and DuPont return location. Normally this is the site that originally shipped product to you.

   Note: Empty containers should be returned on the same pallet(s) as received and properly secured to the pallet to provide a safe return to DuPont. Use banding to secure cylinders to pallet(s).



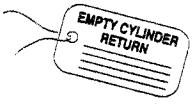
3. Complete BOL form (Example B), indicating correct quantities, weight, DOT description, and RA number.

   Note: For return shipments to Kingston, Ontario, the carrier will complete the necessary customs paperwork (Canadian Customs Invoice).

4. Identify each pallet with an "Empty Cylinder Return" tag, which must cross-reference the RA number and customer purchase order number (see Example C).

5. Ship to DuPont. Provide the carrier with BOL and attach RA form (packing list) to the shipment.

6. Fax a copy of the RA form to the designated DuPont return facility within 24 hours of shipment.



❶ 

Complete RA form.

❷ 
Call (800) 554-8662 to arrange shipment and get RA number.

❸ 

Complete BOL form.

❹ 

Tag each pallet.

❺ 
Ship to DuPont. Provide the carrier with BOL and attach RA form (packing list) to the shipment.

❻ 
Fax RA form to DuPont return facility.

Will Accept

- Any DuPont Suva® 123 returnable container.

  Note: The DOT requires valves to be protected for shipping on all cylinders, including returned empties. Contact your customer service representative for details.

  Note: If a container shows visible damage, the full cost of the container will be charged. Examples of visible damage include:

  – Use of flame on cylinders, as evidenced by burn marks through the paint.
  – Dents 4″ in length or greater.
  – Gouges in the metal to a depth of 3/8″ or greater.
  – Severe rusting (more than 50% of the cylinder).

Returning Defective Containers

1. Complete Return Authorization (RA) form (see Example D).

   Note: RA form is attached behind bill-of-lading (BOL) form.

2. Contact DuPont TONA (800) 554-8662 to arrange shipment and obtain RA number. Remember to add RA number to the Return Authorization form and BOL. DuPont TONA will inform you of the RA number, carrier, and DuPont return location. Normally, this is the site that originally shipped product to you.

   Note: Defective containers should be consolidated and shipped with return cylinders.

3. Complete BOL form, indicating correct quantities, weight, DOT description, and RA number.

   Note: For return shipments to Kingston, Ontario, the carrier will complete the necessary customs paperwork (Canadian Customs Invoice).

4. Identify each container with a "Returned for Inspection" tag. This tag must be filled out completely and must cross-reference the RA number and customer purchase order number (see Example E).

5. Ship to DuPont. Provide the carrier with BOL and attach RA form (packing list) to the shipment.

6. Fax a copy of the RA form to the designated DuPont return facility within 24 hours of shipment.

❶ 

Complete RA form.

❷ 
Call (800) 554-8662 to arrange shipment and get RA number.

❸ 

Complete BOL form.

❹ 

Tag each container.

❺ 
Ship to DuPont. Provide the carrier with BOL and attach RA form (packing list) to the shipment.

❻ 
Fax RA form to DuPont return facility.

Will Accept for Credit If the Following Criteria Are Met:

- The date code sticker on the container is less than two years old.
  - For cylinders, information on small (1/2″ × 3/4″) sticker:
    120L8A, or 120/8A, or 120/8A, where
    120 = 120th day of the year
    8 = Year, 1998
    L or A = Filler's I.D.
- The container does not show visible damage.
- The container is lightweight or empty, and the protective shrink-wrap is intact on the valve.
- If the shrink-wrap is removed, the customer determines the container is defective during use and the defect is verified by a DuPont site inspection.

Credits/Refunds

- Credit amount will be based on the current list price of product.
- If container is full and no defect is found, a 30% handling fee will be assessed based on the current list price of product.
- All defective containers reported and returned by customer will be inspected to determine appropriate disposition as shown in the table below.
- For situations where defect cannot be readily identified upon receipt, credit will be issued up front; if defect is later found, offsetting debit will be applied.

Container Contents?		Shrink-wrap Intact?		Defect Confirmed?[1]		Credit and Charges[2]
Partially Empty	Full	Yes	No	Yes	No	
X		X		X		Full
X			X	X		Full
X			X		X	No credit
	X		X	X		Full
	X		X		X	Full less 30% handling fee

(1) Common defects include broken valves, leaks at valve stems, rupture disc failure, and empty or lightweight containers with shrink-wrap intact.

(2) **Please Note:** Individual cases will be reviewed with Sales/Marketing for final disposition.

Returning Product (e.g., Overstock/Excess Inventory)

1. Contact your DuPont Sales or Customer Service Representative for approval and disposition. All product returns are subject to DuPont approval and will be based on DuPont's ability to resell the product.
2. Complete Return Authorization (RA) form (see Example F).

   Note: RA form is attached behind bill-of-lading (BOL) form.
3. Contact DuPont TONA (800) 554-8662 to arrange shipment and obtain RA number. DuPont TONA will inform you of the RA number, carrier, and DuPont return location. Normally, this is the site that originally shipped product to you.

   Note: Product returns should be consolidated and shipped with return cylinders.
4. Complete BOL form, indicating correct quantities, weight, DOT description, and RA number.

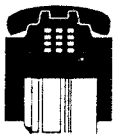
   Note: For return shipments to Kingston, Ontario, the carrier will complete the necessary customs paperwork (Canadian Customs Invoice).
5. Identify each container with a "Returned for Inspection" tag. This tag must be filled out completely and must cross-reference the RA number and customer purchase order number (see Example G).
6. Ship to DuPont. Provide the carrier with BOL and attach RA form (packing list) to the shipment.
7. Fax a copy of the RA form to the designated DuPont return facility within 24 hours of shipment.

❶  Call DuPont Sales or Customer Service Representative for approval.

❷ 

Complete RA form.

❸  Call (800) 554-8662 to arrange shipment and get RA number.



❹ 

Complete BOL form.

❺ 

Tag each container.

❻  Ship to DuPont. Provide the carrier with BOL and attach RA form (packing list) to the shipment.

❼  Fax RA form to DuPont return facility.

Will Accept for Credit If the Following Criteria Are Met:

- The container is full and the protective shrink-wrap is intact on the valve.
- The container does not show visible damage.
- If the shrink-wrap is removed, product can be returned through recovered refrigerant program. Contact your DuPont sales or customer service representative for details.

Credits/Refunds

- Credit amount will be based on the customer's last purchase price of product.
- A 30% restocking fee will be assessed based on the current list price of product.

Shipping Procedures

1. Verify that the cylinders (valves, plugs, reliefs, etc.) are secure and not leaking.
2. Make sure that all containers show the proper UN number and shipping name and reflect the appropriate hazard class.
3. Identify all containers and pallets with RA tags that include RA number and customer purchase order number.
4. Return freight collect. DuPont TONA will tell you which DuPont location to ship to. Normally, this is the site that originally shipped the cylinders to you.
5. All shipments must be properly blocked and braced.

Proper Palletizing

Empty Cylinder Returns

- Empty cylinders should be palletized vertically on a standard 4-way pallet (same pallet(s) as received) and secured for shipment using adequate banding materials. Bands should be at two or three locations vertically (6–12" below the top shoulder, 6–12" above the base, and the center) to ensure the load does not separate during transport.

Options for banding material include:

1) **Steel banding that uses the 3/4" wide by 0.023" thick banding with 3/4" clips. Kits that have the bander, crimper, seals, and banding are about $275.00 each.**
2) **Poly strapping. A kit costs about $90.00 including the tensioner, cutter, buckles, and 1,000' plastic banding.**

Steel banding and poly strapping kits can be ordered through any local supply house for shipping materials. They can also be ordered through the following:

Shipper's Supply Co. (contact is Charlie West)

Preparing Bill-of-Lading

DuPont will provide a bill-of-lading (BOL) form for return shipments. All items on this form should be filled out by the shipper except those specifically indicated to be filled out by the carrier. The BOL form must contain the following information:

- Proper shipping name, hazard class, UN number
- Name of carrier
- Date
- Company name and address of shipper
- Signature of shipping company's representative
- Shipping destination
- Number and types of containers
- Freight prepaid or collect
- Gross product weight, in pounds (includes the weight of the containers, except for tank trucks)
- DOT "Nonflammable Gas" placards are not required for shipments of Suva® 123 in any container size since this material is not regulated by the DOT.
- Driver's signature

Supersedes	

Revision History: CVHE-SB-48 - Original issue March 25, 1998
CVHE-SB-48A - January 15, 1999

This is an informational bulletin only.

Subject: New Shipping Containers for Refrigerant R-123

Introduction:

Beginning May 1, 1998, all domestic centrifugal refrigerant releases will ship R-123 in new returnable cylinders. These cylinders will be available in two sizes, 200 lb. and 50 lbs. rather that the former drums which held 200 lb. and 100 lbs. of refrigerant. This bulletin describes the cylinders and explains the return procedure to be followed by the Service Company.

Units Affected:

All domestic low pressure centrifugal units using refrigerant R-123 that have refrigerant released after August 10, 1998.

Background

Trane has been working with its refrigerant supplier, DuPont, for several years to develop a returnable R-123 cylinder to replace refrigerant drums. Numerous field complaints associated with drums was the reason for this project, primarily leakage and disposal issues. Also, drums could not be subjected to a deep vacuum without collapsing. These issues are resolved with the new refrigerant cylinders.

Discussion:

A drawing of the new refrigerant cylinders is shown in Figure 1. The 50-lb. cylinder is actually a 100-lb. cylinder charged with 50-lbs. of R-123. Both cylinders are the same outside diameter but different height (See Table 1).

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

©American Standard Inc. 1999

FIGURE 1
New DuPont Refrigerant Cylinder

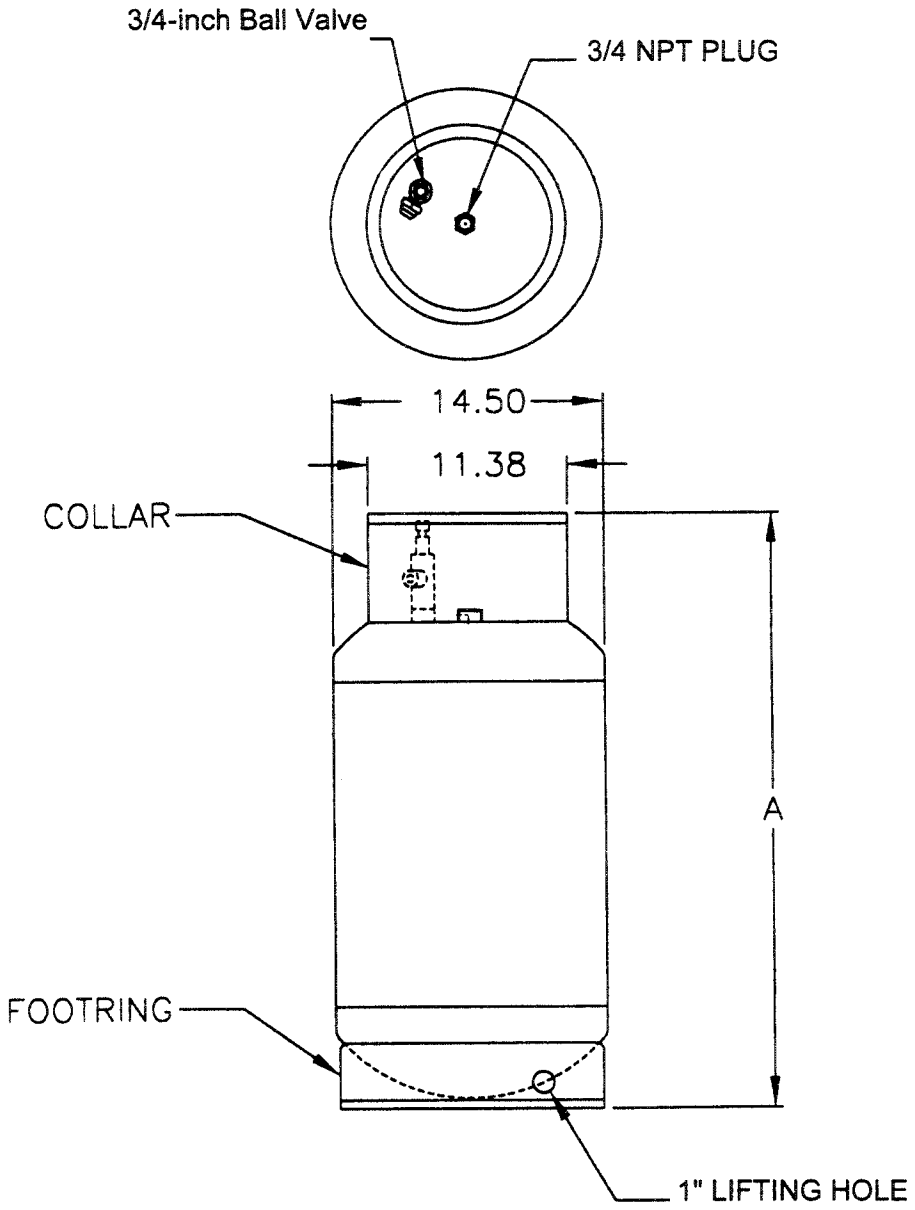

TABLE 1			
EXT	CHARGE	A	TARE WT
01	50#	22.5	40#
02	200#	37.8	60#

A 3/4-inch ball valve with 5/8 refrigerant flare fitting is attached to the top of the cylinders to allow product unloading. The flare fitting can be removed which allows any 3/4-inch male pipe fitting to be used if a flare is not suitable for a particular application. A one-inch hole is provided in the foot ring to allow a lifting hook to be used for hoisting the cylinder for unloading. These cylinders were designed to allow refrigerant transfer at a rate as good or better than the former drums when using the gravity feed method of charging. If heat is to be applied to the cylinder, use a warm water bath or heat blankets. Do not allow the temperature to exceed 150 deg. F. Never use a direct flame on any portion of the cylinder. A 3/4-inch pipe fitting located in the center of the cylinder top is plugged. This plug is not designed to be removed and should be considered permanent. The new cylinders are marked "For R-123 Use Only".

These cylinders do not require a deposit but must be returned to DuPont within 180 days of shipment. If the service company decides they want to keep the cylinders, or if the cylinders are not returned within 6 months of shipment, a one time charge of $150.00 per cylinder will be assessed to the service company by Trane headquarters. To minimize rental charges by DuPont, refrigerant should not be ordered to the jobsite unitl shortly before needed. Return the cylinders promptly after unloading the refrigerant. Be sure to replace all caps on the valve assembly before returning the cylinders. DuPont will provide each domestic sales office with the required forms and paperwork required to return the cylinders. If additional forms are required or questions on the procedure arise, call **DuPont Customer Service Representative, Maureen Ranegan at (800) 441-9286.** All of the details associated with the return of the cylinders are covered in the DuPont instructions, which follow.

Revision History: CVHE-SB-48 - Original issue March 25, 1998
CVHE-SB-48A - January 15, 1999 changed "Units Affected" and page 3, 2nd Paragraph
CVHE-SB-48B - February 1, 2000 - Revised Return procedures.
CVHE-SB-48C - May 8, 2001 - Returnable Containers Redesign

Subject: Returnable Containers for Refrigerant R123 This is an informational bulletin only

Introduction:

Beginning August 10, 1998, all domestic centrifugal refrigerant releases began shipping R123 in new returnable cylinders **except** for Alaska, Canada and Hawaii who still receive R123 in drums. These cylinders are available in two sizes, 50-pounds. and 200-pounds, rather than the former drums which held 100-p ounds. and 200-pounds of refrigerant. (See Figure 1.) This bulletin describes the cylinders and explains th e return procedure to be followed by the Service Company.

Requirements:

Service offices will not be liable for cylinder deposits after a set time period. Instead, service o ffices will be expected to return cylinders after the chiller has been charged. **Non-compliance by individual offices will result in cylinder deposit invoicing by LBU.** The use of Empty Cylinder tags is no longer required. Field service offices now must call **LBU Technical Services**, not Du Pont, for required forms. In addition, return paperwork must be faxed to **LBU Order Services** for accurate crediting of returned cylinders. These numbers are referenced below for your convenience.

LBU Technical Services Telephone number : 608-787-5305
LBU Order Services Fax number: 608-787-3265

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Units Affected:

All domestic low pressure centrifugal units using refrigerant R123 that have refrigerant released af ter August 10, 1998. (Exceptions are Hawaii, Alaska and Canada.)

Background:

Trane has worked with its refrigerant supplier, DuPont, to develop a returnable R123 cylinder to re place refrigerant drums. Numerous field complaints associated with drums was the reason for this project, (primarily leakage and disposal issues). Also, drums could not be subjected to a deep vacuum without collapsing . These issues are resolved with the new refrigerant cylinders. Dip tubes have been added to the cylinder fl eet and will be available to the field in May 2001.

Discussion:

A drawing of the new refrigerant cylinders is shown in Figure 1. The 50-pound cylinder is actually a 100-pound cylinder charged with 50-pounds of R123. Both cylinders are the same outside diameter but different height (See Table 1).

Two ball valves are attached to the top of the cylinders to allow product unloading. The flare fitti ng on the vapor valve can be removed which allows any 3/4-inch male pipe fitting to be used if the provided 5/ 8-inch flare fitting is not suitable. A one-inch hole is provided in the foot ring to allow a lifting hook to be used for hoisting the cylinder for gravity method unloading. If heat is to be applied to the cylinder, use a warm water bath or heat blankets. Do not allow the temperature to exceed 150 ° F. Never use a direct flame on any portion of the cylinder. Do not remove the valves for any reason. To avoid potential back strains from inver ting cylinders, the push-pull method is recommended through use of the dip tube.

Note: A "T" handled service tool (TOLO1251) has been developed to permit operating the ball valve stems through the collar openings. The cost is around $25.

A charging procedure which is known to give fast unloading times (4 to 6 minutes per 200-pound cyli nder) is outlined below.

Recommended Charging Procedure

1. Drain water from evaporator or circulate water while breaking vacuum. This is the most important step of all. Try to have the installer do this after he has leak tested the water side of s ystem or put a drain hose on when checking vacuum rise test. Breaking vacuum is not necessary if the evapor ator is properly drained.

2. Using a set up for push-pull unloading, run a hose from the liquid valve to the unit evaporator charging valve. Run a hose from the vapor valve to the exhaust connection of a vacuum pump. Run a hose from the intake side of the vacuum pump to the 3/4-inch ball valve located under the chiller suction elbow.

©American Standard Inc. 2001

3. For the first cylinder only, open the evaporator ball valve and then the cylinder liquid valve lo cated in the center on the top. After a few minutes, open the suction elbow valve and start the pump. Open the vapor valve. As there is initially no refrigerant vapor in the chiller, you can't pull vapor pressure from the unit.

4. When empty, stop the pump, close both cylinder valves, and close off the valve on the line to the evaporator. Disconnect hoses from cylinder, replace all valve caps and hook up the nex t cylinder.

5. Unloading of each cylinder using push-pull method will get progressively faster, whereas with the gravity method, it gets slower.

6. When finished with unloading, be sure to replace the 5/8-inch fitting on the vapor valves (if the y were removed) as well as any caps.

These cylinders do not require an initial deposit but must be returned to DuPont after unloading. If LBU decides that an office is not making an effort to return cylinders, a one-time charge of $150.00 per cylinder will be assessed to the service company by Trane headquarters. Some loss of cylinders due to theft or con tractor negligence is expected. Service companies will not be held liable for occasional losses of cylinders , provided the number is small. Return the cylinders promptly after unloading the refrigerant. LBU will provide each domestic sales office with the required forms and paperwork required to return the cylinders. If que stions on the procedure arise, call **Jeanette Dickerson of Trane LBU Order Services, 608-787-2635.**

Supersedes	New

Subject: CVHE/F/G and CDHF General Guidelines for Oil Analyses and Recommended Oil Changes

Introduction:

This is an informational Service Bulletin concerning the recommended timing intervals for doing oil analysis and oil changes on new chillers.

Discussion:

The following recommendations will be incorporated in the next Operation and Maintenance Manual (CVHE-OM-8). Following these recommendations should reduce the chillers overall lifetime oil consumption and minimize refrigerant emissions. The oil analysis should be performed by a qualified laboratory experienced in refrigerant and oil chemistry and the servicing of Trane Centrifugal Chillers. In conjunction with other diagnostics performed by a qualified service technician, oil analysis can provide valuable information on the performance of the chiller to help minimize operating and maintenance costs.

Recommended Action:

- After the first six months of operation it is recommended to have an oil analysis done.
- After one year of operation it is recommended to change the oil and filter and have the removed waste oil analyzed.
- Beyond the first year, recommendations are to subscribe to an annual oil analysis program rather than automatically changing the oil each year.

Labor, Material and Travel Authorization:

This is an informational bulletin only and there is no labor, material or travel authorized.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Literature Type	General Service Bulletin
Sequence	50
Date	March 16, 1999
File No.	SV-RF-CVHE-SB-50
Supersedes	New

Literature History: Original issue of CVHE-SB-50, March 16, 1999

Subject: New Oil Regulator Block Assembly

Introduction:

This is to advise Trane Service Companies of possible defects in the new oil regulator block assembly. A number of chillers have shipped with a possible weak oil regulator spring and defective oil regulator block assembly. Two situations can occur while operating the chiller. First, with a weak spring the operator may not be able to adjust the oil pressure properly. Secondly, the regulator block may have a sharp-machined surface located in the oil regulator block bore, causing damage to the regulator diaphragm and a reduction in oil pressure.

Units Affected:

CVHE/F/G units manufactured the first quarter of 1999. A separate "E" mail was sent to each office listing the affected units in their service area. Service companies who did not receive a "E" Mail notice do not have units affected in their area.

Production Changes:

No production changes are required.

©American Standard Inc. 1999

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. Qualified, experienced technicians should do the installation and servicing of the equipment referred to in this booklet.

Corrective Action:

A number of chillers have shipped with the defective oil regulator blocks (a machined surface with a sharp edge located in the oil regulator block bore and with a weak regulator spring). The oil regulator block assembly and oil filter should be changed out before commissioning the chiller for service. It is recommended that the oil regulator block assembly and filter change out be performed during normal start up or even earlier.

Parts Order Information:

Order one each of the following parts to retrofit each affected Chiller. These can be ordered through the PRIDE system, La Crosse Service Parts.

KIT06443, New Oil Regulator Block Assembly
FLR01592, Oil Filter

Material Disposition:

The cast iron regulator block itself can be scrapped in the field. The oil regulator, diaphragm assembly and 2-bolt flange must be returned to the attention of Jerry Tripp. Use the following address:

The Trane Company, Manufacturing Plant 2,
Attention: Jerry Tripp, 12W
East Door - 2312 East Avenue South

Subject: Solid State Starter (Inside the Delta) Service Manual

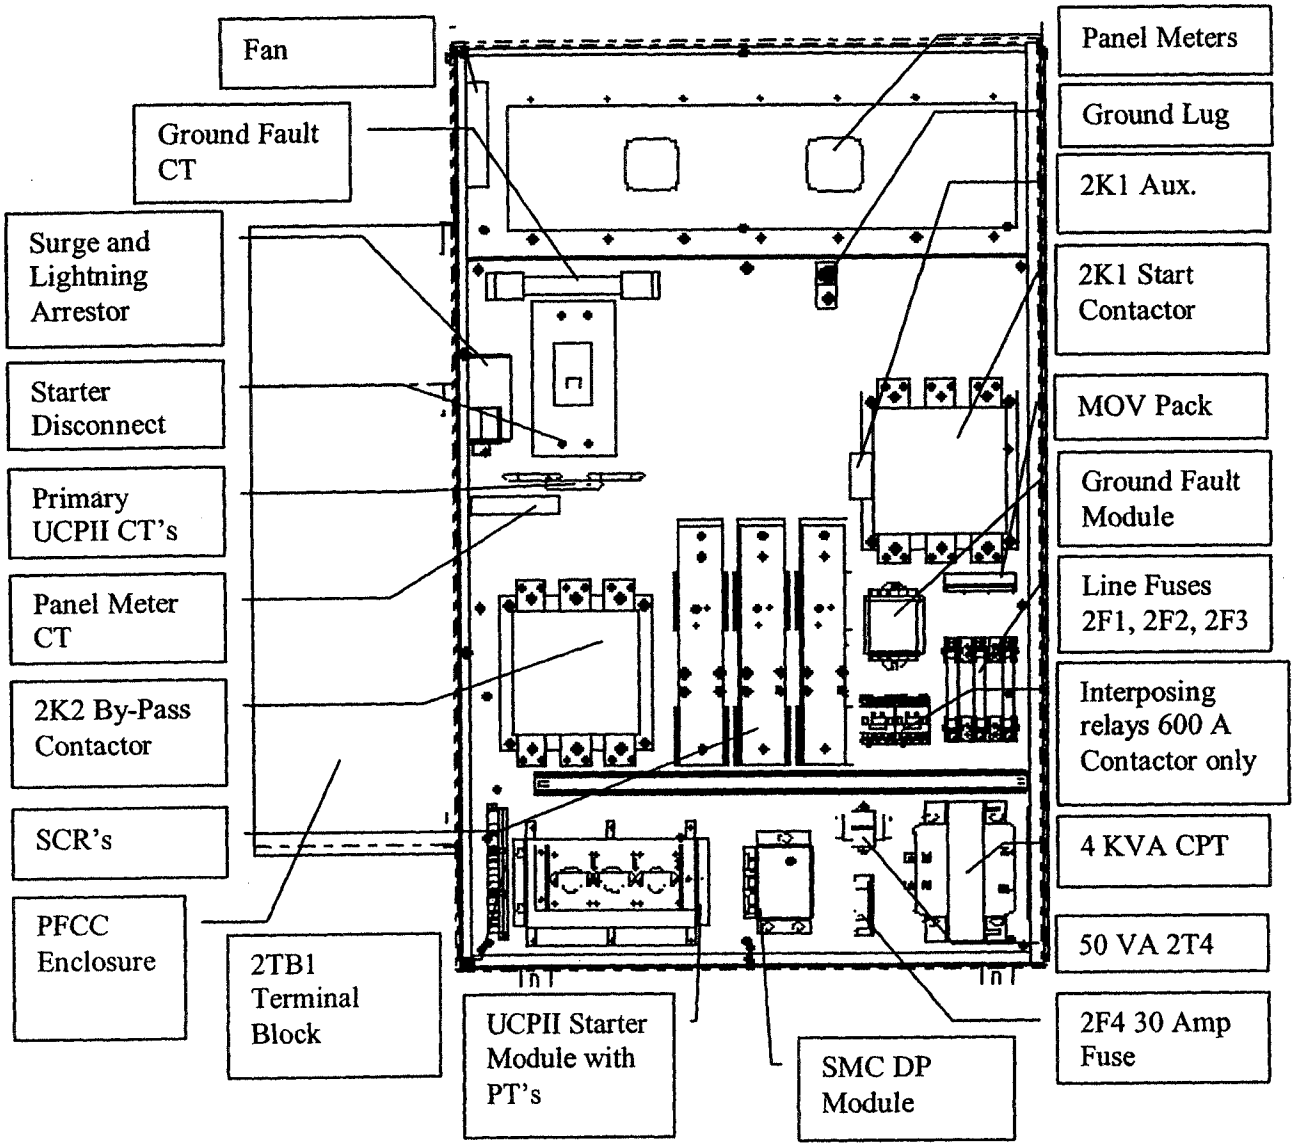
Introduction:

The purpose of this bulletin is to provide troubleshooting and replacement information for the SMC-DP (Smart Motor Control Definite Purpose) solid state starter used on CVHE/F/G, CDHF/G, CVGF units.

IMPORTANT!
TO PREVENT INJURY OR DEATH DUE TO ELECTRICAL SHOCK, FOLLOW THE WARNINGS PROVIDED THROUGHOUT THIS MANUAL REGARDING HAZARDOUS VOLTAGE WHEN SERVICING.

Related Documents:

CTV-TS-22	Solid State Starter, Inside the Delta
CON-AM-23 (888)	Application Engineering Manual, CENTRAVAC® Motor Starters
EB XXX	CenTraVac® Motor Starter Power Quality Requirements



Discussion:

The SMC-DP is designed to start the chiller slowly at a reduced torque and current. A starter consists of an SMC-DP control module, a MOV (Metal Oxide Varistor) transient voltage protection package, 3 power poles or SCR's (Silicone Controlled Rectifier), a bypass contactor (2K2) and a starting contactor (2K1). This is a reduced voltage starter that controls starting characteristics of the CenTraVac motor by controlling the voltage applied to the motor. The SMC-DP operates inside the delta of the motor windings and utilizes a microprocessor to analyze the feedback voltage from the motor to determine CenTraVac motor up to speed.

Corrective Action:

Several procedures are listed to assist in determining which component of the starter has failed.

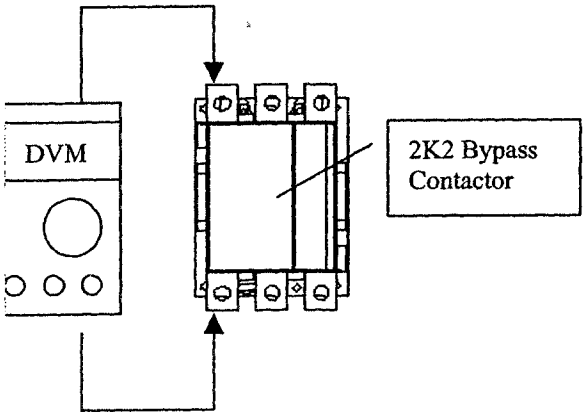
Component layout:

SMC-DP Module adjustments:

The SMC-DP comes pre-set from the factory to an approximate start time of Y-Delta start; no field adjustment is necessary. See appendix "A" for additional adjustment information for slower or faster starting requirements. A faster start draws more inrush current and produces more torque, allowing for a faster starting time.

Initial Check out Procedures:

[ ] Confirm all control voltage is separated from power wiring.
[ ] Confirm all wiring is landed correctly
[ ] Confirm all critical connection are tightened to proper torque



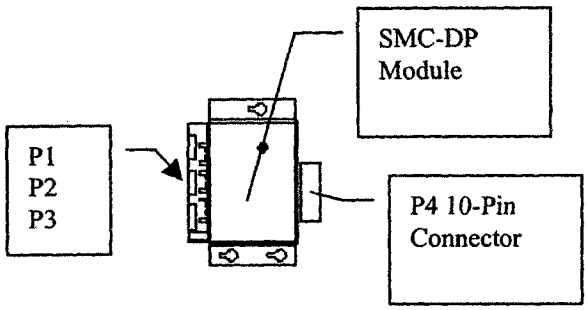
Inspect all starter components for damage, which could be caused by arcing, overheating, and other damage.

Power Pole Check-Out:

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRICAL POWER BEFORE SERVICING. FAILURE TO DISCONNECT POWER BEFORE SERVICING CAN CAUSE SEVERE PERSONAL INJURY OR DEATH.

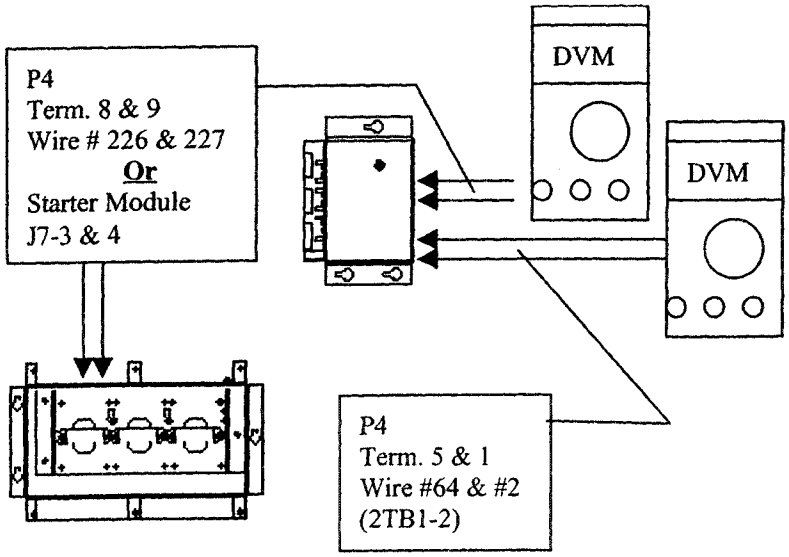
The entire power pole must be replaced if one or more of the internal components fail the checkout procedure.

1. Disconnect P1, P2 and P3 from the SMC module.
2. Measure resistance across each power pole by measuring across the open 2K2-contactor line load terminals (see below). Resistance must be greater than 10,000 Ohms.
3. Replace any power pole that measures below 10,000 ohms. It is not unusual for the measurements to vary greatly pole to pole.



⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRICAL POWER BEFORE SERVICING. FAILURE TO DISCONNECT POWER BEFORE SERVICING CAN CAUSE SEVERE PERSONAL INJURY OR DEATH.

Starting Sequence Check-Out:



If the compressor is not rotating after a start signal is given and the UCP2 has detected an SMC-DP fault "**Solid State Starter Fault Relay Open**", follow the procedures below to confirm that the SMC-DP is functioning properly. Two DVM's will be needed for this procedure.

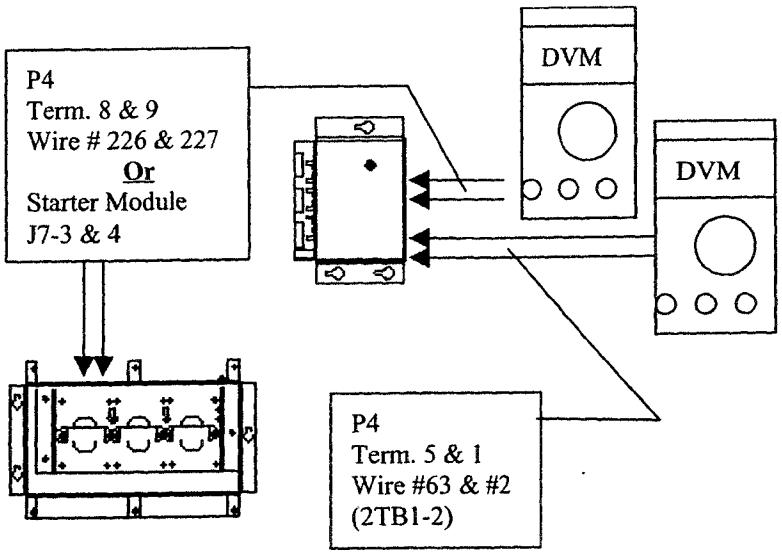
1) Check all 3-phase power connections. Confirm phase rotation is ABC.
2) Disconnect all electrical power before servicing. Failure to disconnect power before servicing can cause severe personal injury or death.
3) Disconnect the (6) motor power leads at the motor.
4) Confirm that the problem is not in the motor (Meg the compressor motor).
5) Reconnect motor power leads, close the disconnect and confirm three-phase voltage is present at the starter disconnect and input terminals to starting contactor (2K1). Voltage should be rated voltage +/- 10%.
6) Confirm that P1, P2 and P3 are connected in proper order to SMC-DP module. Incorrect sequence will prevent start.

7) Confirm operation of start relay and fault relay state on SMC-DP board.

   a) Measure voltage at terminals P4 7 and 1 (2K1 coil relay 115 volts) of the SMC board during start.

b) Measure fault relay state on starter module J7-3, 4 (contact closure) during start. Relay will open if a fault condition exists.
c) Assure continuity between SMC board (P4 1 & 7) and contactor coil (A1 & A2).
d) Initiate start command from UCP2. Compressor motor should start.
e) Note: for a 600-amp contactor an interposing relay is installed to drive the 600-amp contactor coil. Verify 2K2-coil control voltage is present at contactor coil terminals A1 & A2.

8) If 115 volts is present and contactor fails to operate replace contactor/ coil.
9) If 115 volts is present and contactor operates, inspect condition of contacts. If contacts are damaged, replace contacts.
10) If 115 volts is not present prior to a fault relay open, replace SMC-DP module.



By-Pass Sequence Check-Out:

If the compressor rotates after start signal is given but fails to reach full speed, by-pass contactor (2K2) failed to pull-in, and the UCP2 has detected an SMC-DP fault **"Solid State Starter Fault Relay Open"**, follow the procedures below to confirm that the SMC-DP is functioning properly.

1) Confirm line current drawn during start is 58%+5/ -10% of motor locked rotor current. Current greater than this value may indicate motor problem, current less than this may indicate motor problem or low voltage (less than 90%) condition. Refer to Appendix B for time start adjustment.

2) Confirm operation of by-pass relay and fault relay state on SMC-DP board.

a) Measure voltage at terminals P4 5 and 1 (2K2-coil relay 115 volts) of the SMC board during start.

b) Measure fault relay state on starter module J7-3, 4 (contact closure) during start. Relay will open if a fault condition exists.
c) Assure continuity between SMC board (P4 1 & 5) and contactor coil (A1 & A2).

d) Note: for a 600-amp contactor an interposing relay is installed to drive the 600-amp contactor coil. Verify 2K2-coil control voltage is present at contactor coil terminals A1 & A2.
e) Initiate start command from UCP2. Compressor motor should start.

3) If 115 volts is present and contactor fails to operate replace contactor/ coil.
4) If 115 volts is present and contactor operates, inspect condition of contacts. If contacts are damaged, replace contacts.
5) If 115 volts is not present prior to fault relay open, replace SMC-DP module.
6) If contactor is confirmed to be good, check that P1, P2 and P3 are connected firmly in the SMC-DP module. Loose connections may cause faulty firing forcing the unit to shut down.
7) Refer to power pole section and check SCR's. If SCR are shorted, replace power pole.

MOV Pack Check-Out:

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRICAL POWER BEFORE SERVICING. FAILURE TO DISCONNECT POWER BEFORE SERVICING CAN CAUSE SEVERE PERSONAL INJURY OR DEATH.

The part new has a clear potting material. This part has a limited life and should be checked every year during general starter inspection. If this potting material is cloudy or turning brown, this part should be replaced. A slight discoloration is an indicator that the MOV pack is starting to fail. A dark brown or black color is an indication that the part failed.

SMC-DP Low Line Detection Fault:

Symptom (failure)
If the compressor rotates after start signal is given but fails to reach full speed, by-pass contactor (2K2) failed to pull-in, and the UCP2 has detected an SMC-DP fault "Solid State Starter Fault Relay Open" or UCP2 has issued an MMR "Phase Loss" or "Phase Reversal". All of the previous starter checks along with the phasing of the CT's must be verified before proceeding.

Background
Motors started with solid state starters will inherently draw a larger % of LRAD during start compared to wye-delta. This is due to the physics of the solid state starter applied to a delta configured motor. The SCR's start and ramp the motor to rated speed. For comparison a motor started with a wye-delta starter will pull 100% of LRAY or about 33% of LRAD to achieve at speed in a certain amount of time then transition to delta. This same motor started with a solid state starter will pull between 58-62% of LRAD (with default setting) to achieve at speed in the same time as the wye-delta motor starter. These are equivalent torque starts.

Problem
This elevated current may cause a significant line to line RMS voltage sag. This is realized most often by an engine/ steam driven alternator (generator) power circuit that has a high source impedance. The solid state starter may interpret this voltage waveform as a "power supply failure" and initiate a safe shutdown. This "power supply failure" protection was installed for early detection that a power supply would be lost. The maximum sag usually occurs in the first 2 to 23 line cycles of current when the solid state starter is ramping voltage. The motor will draw peak current during this voltage ramp.

Solution

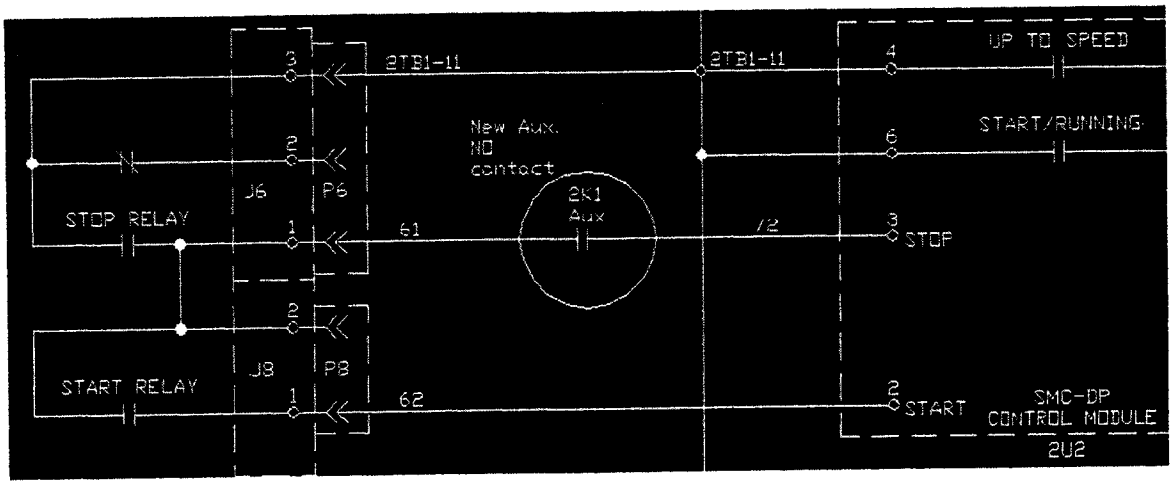
This sensing circuit ("power supply failure") can be disabled and safely start the motor and operate the starter. By disabling this circuit the starter is allowed to operate safely with a greater line to line RMS voltage sag (Maximum sag of 25% of the line to line RMS rated voltage). The motor can safely operate here, however motor acceleration is not guaranteed. See Appendix A for starter modifications. These modifications should only be done if the failure is described in the symptom section above.

Solid state starters also have the ability to change the current inrush profile. The starting profile is set default to a 58-degree notch and is adjustable between 35 and 76 degrees. The larger the notch the lower the peak inrush and the longer the start time. By reducing the peak inrush the voltage sag can also be reduced. See Appendix B for notch adjustment.

Trane recommends that the notch adjustment be raised first to remedy the "Power supply failure" fault see Appendix B for notch adjustment. If raising the notch does not remedy the "Power supply failure" fault or the chiller compressor motor fails to accelerate fully then disable the "Power supply failure" detection circuit. See Appendix B to disable sensing circuit. It is recommended, after the sensing circuit is disabled, that the notch be returned to a setting that will guarantee that the chiller compressor motor will accelerate fully.

Appendix A

Solid State Starter Modifications:



If installed SMC-DP board is **FRN T5.1**:

1) An upgrade kit must be ordered kit # 150DP-FRN52KIT which contains:
   - SMC-DP module; FRN T5.2
   - Auxiliary relay PN 195-GA20
   - #14 AWG wire

2) Replace SMC-DP FRN T5.1 module with **FRN T5.2**

3) Move Switch #8 on SMC-DP board to **"ON"** position (pull SW#8, far left, toward you when mounted inside of starter)

4) Replace installed 2K1 auxiliary relay (1) NO contact with provided relay PN 195-GA20; (2) NO contacts. Re-install wire #8 & #9. Wire second 2K1 Aux NO contact between 2U2 pin #3 (wire #72) and 2U1 J6-1 (wire #61) with

provided #14 AWG wire. Label wiring per schematic. Ty wrap control circuit to existing control wire bundle. The purpose of this relay is to prevent contactor chatter.

5) Mark-up starter schematics fastened to the starter door with the above control changes

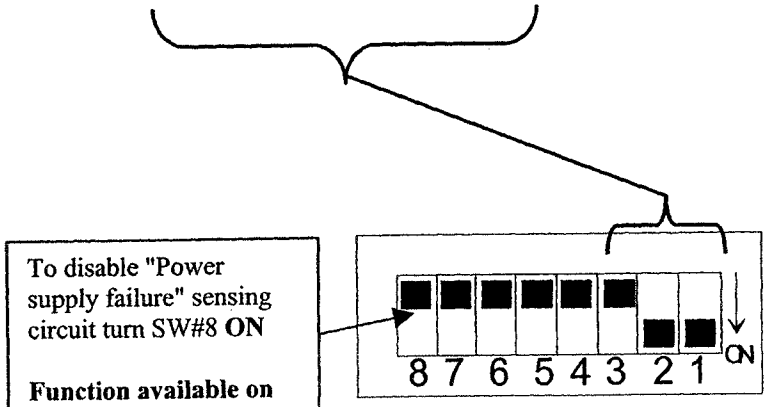
6) **RETURN THE FRN T5.1 SMC-DP MODULE TO:**

Rockwell Automation
1201 South Second Street
Milwaukee, WI 53204
Attn: Victoria Alia, Bay 3-V21

**Package the SMC-DP module in the same container that the new module was shipped in.

Mark package with the following

- Office
- Job Name
- Unit serial number
- Chiller sales order #



If the SMC-DP board is marked as FRN T5.2 this board and starter already have the capability of disabling the sensing circuit. SW#8 will only need to be turned to the "ON" position in order to disable circuit.

Appendix B

Variable Torque Setting:

The following table lists the adjustments available on the SMC-DP module. Remove the black cover label located on the side of the SMC-DP module to gain access to eight-position dip switch. These switches are factory set to allow approximately equivalent Wye-Delta starting torque (inrush current of 58-62% of LRA). There are eight switches available, Switch 1, 2, & 3 are used for this adjustment. Switches 4,5,6, & 7 are rendered useless. Possible adjustments listed below:

SW 3	SW 2	SW 1	"Notch"	Approx. % peak LRAD
Off	Off	Off	35	70
Off	Off	On	45	67
Off	On	Off	50	65
Off	On	On	58 – Default	63
On	Off	Off	63	58
On	Off	On	66	56
On	On	Off	70	52
On	On	On	76	45

To disable "Power supply failure" sensing circuit turn SW#8 **ON**

Function available on SMC-DP FRN T5.2 boards only

Note: Starting torque will increase as "Notch" is decreased. Inrush current increases as "Notch" is decreased (start time is shortened).

Appendix C

Supplementary Troubleshooting Table

⚠ WARNING
HAZARDOUS VOLTAGE
DISCONNECT ALL ELECTRICAL POWER BEFORE SERVICING. FAILURE TO DISCONNECT POWER BEFORE SERVICING CAN CAUSE SEVERE PERSONAL INJURY OR DEATH.

SMC-DP issues a **"Solid State Starter Fault Relay Open"** fault to UCP2.

Symptom	Possible Problem	Solution
Motor fails to start	Phase loss	Check connections to SMC, confirm that three phase power is present in panel
	Lost Motor Connection	Check motor and contactor connections for looseness
	Miswired SCR control connections	Check P1,P2 and P3 that they are in proper order on the SMC-DP control module
	Voltage sag	Turn on SW#8 to disable "power supply failure". Must have FRN T5.2 SMC-DP module
Starting contactor fails to close	Failed Starting Contactor (2K1)	Confirm operation of start relay on SMC-DP board. Initiate start command from UCP2. If start contactor (2K1) fails to close, prior to fault relay open, confirm 115 volt source by measuring voltage at terminals 7 and 1 (2K1 coil relay) of the SMC board and the fault relay contact on starter module J7-3, 4. If 115 volts is present and contactor fails to operate replace contactor.
	Failed contacts	If 115 volts is present and contactor operates, inspect condition of contacts. If contacts are damaged, replace contacts.
	Failed SMC-DP module	If 115 volts is not present prior to a fault relay open, replace SMC-DP module.

Continued

Motor Attempts to Start, But aborts before bypass attempts to close	Shorted SCR	Perform continuity check across the power poles with P1, P2, and P3 connection removed. Measurements should exceed 10K for good power pole
	Failed Bypass contactor (2K2)	Confirm operation of bypass relay on SMC-DP board, prior to fault relay open, during a start-up. Confirm 115-volt source by measuring voltage at terminals 5 and 1 (2K2-coil relay) of the SMC board and the fault relay contact on starter module J7-3, 4. If 115 volts is present and contactor fails to operate replace contactor.
	Failed contacts	If 115 volts is present and contactor operates, inspect condition of contacts. If contacts are damaged, replace contacts.
	Failed SMC-DP module	If 115 volts is not present prior to fault relay open, replace SMC-DP module.
	Erratic firing of SCR's	Check P1, P2, P3 connection on SMC-DP control board for looseness.
	If none of the above	Replace SMC-DP control module
Motor starts, accelerates to full speed, bypass closes then opens	Bad bypass control relay on SMC-DP board	Replace SMC-DP control board.

Subject: CenTraVac® AFDB Water Cooled Inverter R035 and R036 Drive Settings

Introduction:

Initial production AFDB (water cooled inverters) have two of the drive setup parameters (R035 and R036) programmed incorrectly. R035 and R036 are actually reversed.

The purpose of this bulletin is to inform Trane Service Companies of the problem. Please note that this applies to a small number of 1st production units, some of which have been corrected at startup by your service technicians or prior to shipment.

Discussion:

Relay 1, (drive in run), and Relay 2, (at speed), on the drive mounted RMI board are programmed incorrectly. Relay 1, designated as "drive in run" on terminals 55 and 56, is incorrectly programmed to close when the drive is "at speed". Likewise Relay 2, designated as "at speed" on terminals 52 and 53, is incorrectly programmed to close when the drive is running (drive in run). Relay 1 is the backup system to engage the interposing relay, "2K1, K1", to run the oil pump in the event the UCP2 control system malfunctions.

©American Standard Inc. 1999

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. Qualified, experienced technicians should do the installation and servicing of the equipment referred to in this booklet.

Units Affected:

This bulletin applies to all initial production units with ship dates between July 1998 through June 1999.

Production Changes:

No production changes. As of July 1, 1999 the units have been programmed correctly.

Corrective Action:

1. Stop the drive.

2. Press the PROGRAM key, then press the UP or DOWN arrow until (R___) is displayed.

3. Press enter until (R000) is displayed.

4. Press the UP arrow key until (R035) is displayed and press ENTER. A "1" should be displayed, if the **incorrect** number is programmed. (We actually want "9" to be displayed, so if a "9" does come up the drive is programmed properly.)

5. Press the UP arrow key until "9" is displayed. This re-configures Relay 1 to close when the drive is "at speed".

6. Press the PROGRAM key once until (R035) is displayed again.

7. Press the PROGRAM key until (R036) is displayed and press ENTER. A "9" should be displayed if the **incorrect** number is installed. We want a "1" displayed when correctly programmed.

8. Press the DOWN arrow until "1" is displayed for the "drive run" setting, and press ENTER. This re-configures Relay 2 to close when the drive is running "drive run".

9. After the above steps have been completed, press the Program key until "0" is displayed. The drive is ready to start.

Subject: 3KVA Transformers in Low Voltage Starters Unit Mounted and Remote Mounted on CenTraVac® Chillers

Introduction:

The Cutler-Hammer unit and remote mounted low voltage starters with 3KVA transformers, produced from March 1999 through June 1999, have a potential for the weld to break loose from the bracket and the transformer falls.

The intent of this service bulletin is to inform you of the problem and request that you send a service technician to the job site to disconnect the transformer wires, install a bolt if it does not already have one on the bracket, and reconnect the 3KVA transformer wiring.

IMPORTANT!
TO PREVENT INJURY OR DEATH DUE TO ELECTRICAL SHOCK, FOLLOW THE WARNINGS PROVIDED IN THIS MANUAL REGARDING HAZARDOUS VOLTAGE WHEN SERVICING.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

©American Standard Inc. 1999

WARNING

HARZARDOUS VOLTAGE! DISCONNECT ALL ELECTRICAL POWER BEFORE SERVICING. Failure to disconnect power before servicing can cause severe personal injury or death.

CAUTION

TO AVOID DAMAGE TO STARTER COMPONENTS, REMOVE DEBRIS FROM INSIDE THE STARTER PANEL. Failure to do so may cause an electrical short that seriously damages the starter components.

Discussion:

A problem has been discovered on the 3KVA Transformers, manufactured during a limited time period noted above, where the weld breaks loose from the bracket and the 3KVA transformer fails. The problem is a defective weld between the transformer and transformer-mounting bracket. Some of the transformers have been repaired at the starter manufacturing plant prior to shipment, but some have shipped to the field without being repaired.

The new design is a bolt-on design. The purpose of this bulletin is to outline a repair procedure and replace all welded 3KVA transformer brackets on starters. To help identify the defective transformers is a field inspection drawing (Figure 1) showing Bolted Base Design verses Welded Base Design and instructions (Figure 2) for installing the Bolted Bracket assembly.

Recommended Action:

- It should be determined if the transformer is of the Welded Base Design or Bolted Base Design. See Cutler Hammer Sketch SK_060199 shown in Figure 1 to determine which base design was shipped.
- If the starter has a Welded Base Design Transformer, it should be repaired with the Bolted Base Design Bracket Kit. See Figure 2.

Figure 1
Field Inspection for Bolted and Welded Base Design (SK 060199)

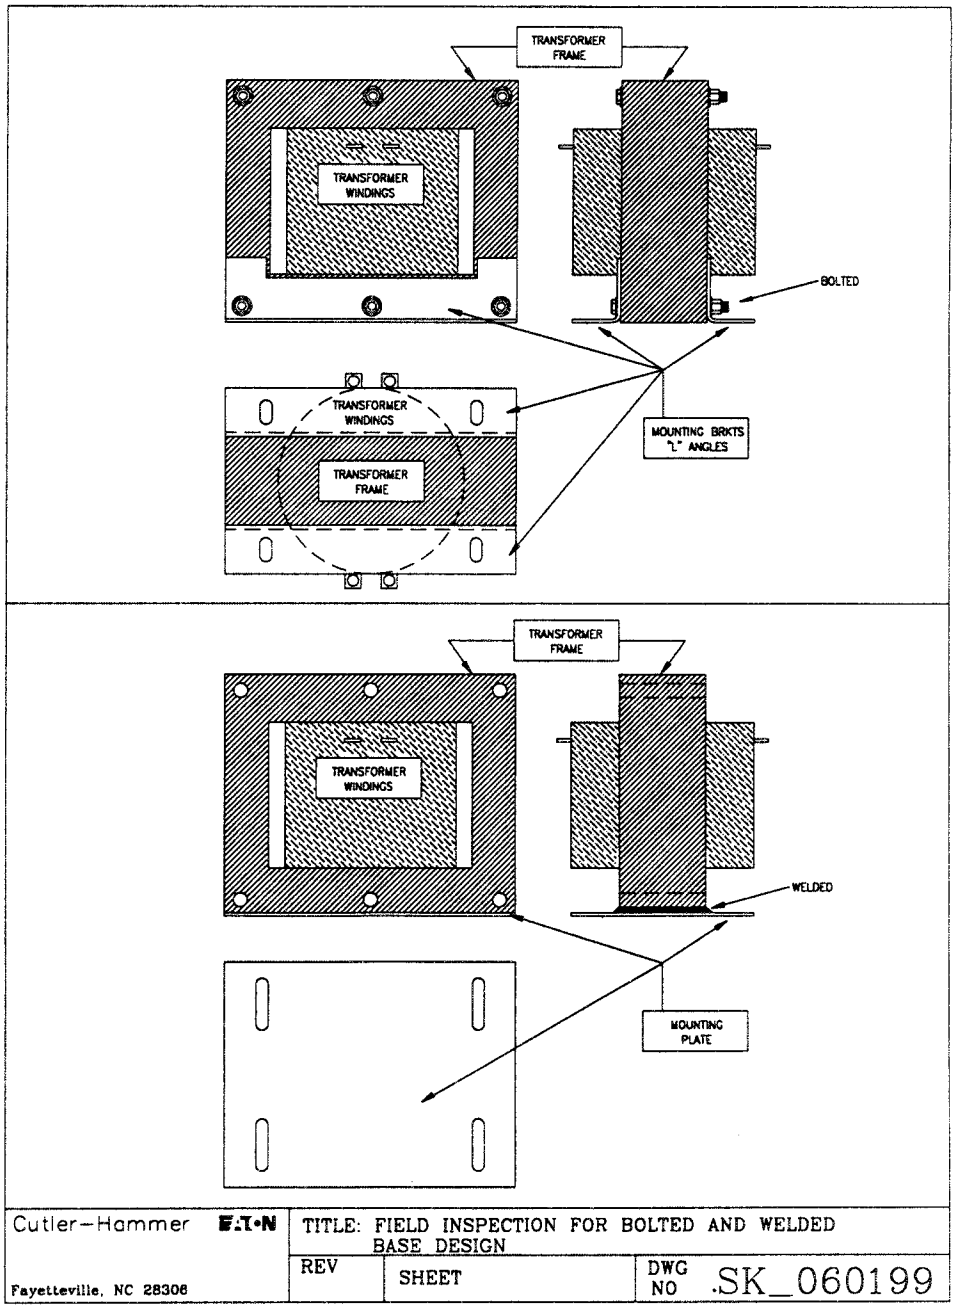

Figure 2
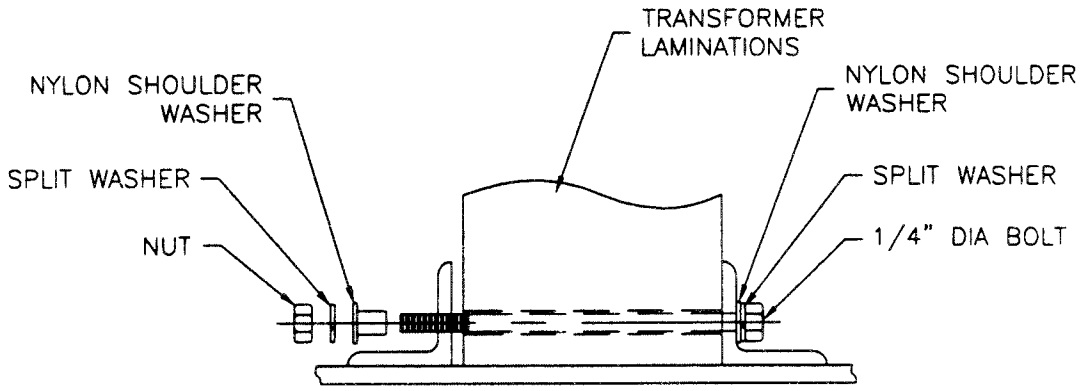
Instructions For Cutler-Hammer Mounting Bracket Assembly

BOLTED BRACKET ASSEMBLY INSTRUCTIONS



NOTE: USE PARTS CONTAINED IN KIT 333-0100.

1) Position 1 bracket on each side of lamination at base of transformer. The long holes in the angle bracket face the back panel of the starter. The 5/8" X 6-1/4" cut out in the angle bracket mounts toward the laminations. Line up holes in bracket with holes in lamination.

2) Assemble a steel split washer and then a nylon shoulder washer to a bolt. (See diagram.) Insert the bolt through the brackets and lamination stack making sure the shoulder washer is seated in the lamination stack. Assemble a second shoulder washer and steel split washer to the threaded side of the bolt making sure the shoulder washer is seated in the lamination stack. Hand-tighten the nut on the bolt.

3) Repeat step 2 for the other side of the transformer.

4) Tighten 2 nuts and bolts to a torque of 12 foot-pounds (2) 7/16" open-ended wrenches.

Subject: Liquid Cooled Adaptive Frequency™ Drive Start-Up Procedures Form

Introduction:

This service bulletin is for **information only.**

Discussion:

Provided for your use and information, is a copy of the "Pre-Start-Up Checklist and Service Request" form by Rockwell Automation to be used for scheduling factory start-up service when that option is requested.

This form is also located in the most recent Adaptive Frequency Drive manual, **AFDB-OM-1**, published in 1998.

Recommended Action:

Important: To schedule start-up services. Follow the directions on the form carefully and fax the completed form to:

Rockwell Automation – La Crosse, WI FAX: 1-608-781-7182

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

TRANE®

General Service Bulletin

CVHE

Cutler-Hammer Starters with Freedom Series Sizes 4 and 5 Contactors

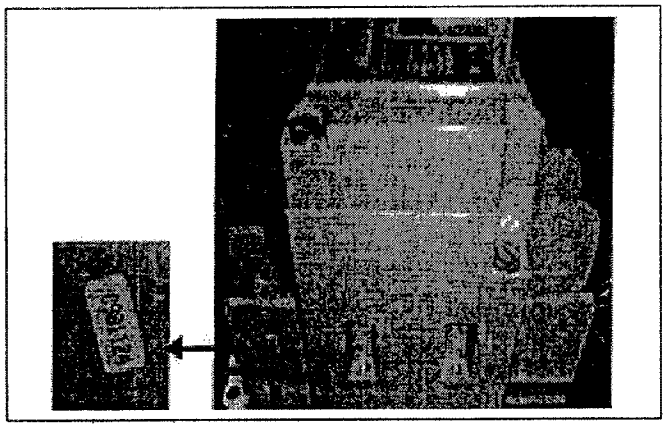
ORDER No: CVHE-SVB001-EN DATE: February 21, 2001

Introduction

The purpose of this service bulletin is to advise the Trane Service Companies and Trane Parts Outlets of a problem associated to Cutler-Hammer Y-Delta and Across-the-Line Starters used with the CVHE, CVHF and CVHG chillers. (When retrofitting starters on the Series R chillers refer to RTHC-SVB003-EN, RTHB-SVB003-EN, RTAA-SVB003-EN.)

This is a potential SAFETY HAZARD and corrective action must be taken as soon as possible.

Potential for a safety hazard in some Cutler-Hammer 180mm Wide Contactors and Starters has been discovered. Contactors and Starters possibly involved include: Freedom Series NEMA sizes 4 and 5; Freedom Series IEC size P-S; Definite Purpose 200A-360A; and Electrically Held Lighting contactors rated 200A-300A.



The potential for this hazard is greater in those applications where the contactors or starters are continuously energized for long periods of time (minimum 2 days energized) without being de-energized. The hazard exists when heat on the 2K1 and 2K2 contactor and starter magnet causes material on the magnet surface to polymerize (melt, coating the power head with a fatty acid). This may prevent the contactors and starters from opening when de-energized, thus keeping the motor energized. The problem may occur in the power head of the 2K1-start contactor and the 2K2 run contactor that are size 4 or 5 Freedom contactors.

© 2001 American Standard Inc. All rights reserved.

Discussion:

CVHE, CVHF and CVHG units built between July 1, 2000 and February 12, 2001 may have the contactors in question. The date codes of the affected contactors and starters are from July 1, 2000 (Date Code = C000701) to January 14, 2001 (Date Code - C010114). When facing the front of the contactor, the Date Code appears on a label on the right side of the contactor and is *7* characters in length. The "C" indicates the manufacturing plant, the next two numbers represent the year, the next two numbers are for the month and the final two numbers are the day. See Figure 1.

Figure 1
Identifying Date Code

C = Manufacturing plant for all 180mm devices

00 = Year (2000)
08 = Month (August)
03 = Day (Third day of the Month)

Date Code Example: C000803
C 00 08 03

WARNING
IN THE EVENT A CONTACTOR OR STARTER REMAINS ENERGIZED FOR LONG PERIODS, HEAT ON THE 2K1 AND 2K2 CONTACTOR AND STARTER MAGNET CAUSES MATERIAL ON THE MAGNET SURFACE TO MELT AND COAT THE POWER HEAD POSSIBLY PREVENTING THE CONTACTORS AND STARTERS FROM OPENING WHEN DE-ENERGIZED. This occurrence could result in personal injury and property damage if a contactor and starter magnet are not de-energized in less than 48 hours

TRANE

Corrective Action:

Follow the repair procedure listed below.

WARNING:
LOCK UNIT DISCONNECT SWITCH IN OPEN POSITION, failure to do so could cause injury or death due to electrical shock or contact with moving parts.

Repair Procedure:

- Disconnect and lockout power to the starter.
- Identify the 2k1 and 2k2 contactors that need retrofitting.
- Remove contactor cover (2 screws)
- Remove the power head (2 screws)
- Install new power head (2 screws)
- Install cover (2 screws)

Close starter panel-door and restore power to starter.
Average time for changeout per contactor is 5 to 10 minutes.

Units Affected

The 2K1 and 2K2 contactors have a date code on the side of each contactor. Contactors that apply and need the retrofit have a date code from July 1, 2000 to January 14, 2001. Contactors that have a date code starting with F01 and later do not require the retrofit. ***(F = new manufacturing plant, see Date Code Example.)***

Parts Information

Refer to the Table 1 for necessary parts.

Note: One Power Head is required per contactor, two (per) starter.

Table 1: Parts Required

Description	***Quantity***	***Part Number***
Power Head Size 4	2	HED00624
Power Head Size 5	2	HED00625

Material Disposition

Scrap in the field. Do not reuse power head.

Since The Trane Company has a policy of continuous product and product data improvement, it reserves the right to change design and specifications without notice. Only qualified technicians should perform the installation and servicing of equipment referred to in this publication.

TRANE®

General Service Bulletin

Sticking 1K5 Oil/Refrigerant Pump Motor Relays

CVHE, CVHF, CVHG, CDHF and CDHG

Order No: CVHE-SVB02A-EN July 12, 2001

Introduction

We have had reports of sticking 1K5 oil/refrigerant pump relays on all direct drive centrifugal chillers. Models affected are CVHE, CVHF, CVHG, CDHF and CDHG. This bulletin describes the action to take if a sticking relay is found.

Discussion

The original 1K5 relay for the oil/refrigerant pump motor was an Allen Bradley 1 hp, 120 volt relay, part number 700HHF62A1. This relay has had a history of sticking in the closed position, which causes the oil/refrigerant pump motor to stay energized even when the chiller shuts down. This in turn will cause the chiller to lock out on an MMR diagnostic of "Oil Pressure Sensor Calibration" due to the fact that the oil pump is running when the chiller thinks it is off. Thus, the 3 psid pressure differential between oil supply and oil sump pressures is exceeded after 5 minutes of shutdown and the machine will lock out on the calibration diagnostic.

© 2001 American Standard Inc. All rights reserved.

Corrective Action

To correct the problem of a sticking 1K5 relay, a new Cutler-Hammer 1.5 hp, 120 volt relay, Trane part number RLY02529 should be ordered and installed.

Units Affected

All direct drive centrifugal chillers, which incorporate the oil/refrigerant, pump and have the original 1K5 Allen Bradley 1 hp, 120-volt relay.

Parts Information

Order one relay per each unit affected through the PRIDE system, La Crosse Service Parts.

RLY02529, 1K5 oil/refrigerant pump relay

Production Changes

There are no production changes per this service bulletin.

General Service Bulletin

Sticking 1K5 Oil/Refrigerant Pump Motor Relays

CVHE, CVHF, CVHG, CDHF and CDHG

Order No: CVHE-SVB02A-EN July 12, 2001

Introduction

We have had reports of sticking 1K5 oil/refrigerant pump relays on all direct drive centrifugal chillers. Models affected are CVHE, CVHF, CVHG, CDHF and CDHG. This bulletin describes the action to take if a sticking relay is found.

Discussion

The original 1K5 relay for the oil/refrigerant pump motor was an Allen Bradley 1 hp, 120 volt relay, part number 700HHF62A1. This relay has had a history of sticking in the closed position, which causes the oil/refrigerant pump motor to stay energized even when the chiller shuts down. This in turn will cause the chiller to lock out on an MMR diagnostic of "Oil Pressure Sensor Calibration" due to the fact that the oil pump is running when the chiller thinks it is off. Thus, the 3 psid pressure differential between oil supply and oil sump pressures is exceeded after 5 minutes of shutdown and the machine will lock out on the calibration diagnostic.

© 2001 American Standard Inc. All rights reserved.

Corrective Action

To correct the problem of a sticking 1K5 relay, a new Cutler-Hammer 1.5 hp, 120 volt relay, Trane part number RLY02529 should be ordered and installed.

Units Affected

All direct drive centrifugal chillers, which incorporate the oil/refrigerant, pump and have the original 1K5 Allen Bradley 1 hp, 120-volt relay.

Parts Information

Order one relay per each unit affected through the PRIDE system, La Crosse Service Parts.

RLY02529, 1K5 oil/refrigerant pump relay

Production Changes

There are no production changes per this service bulletin.

Service Bulletin

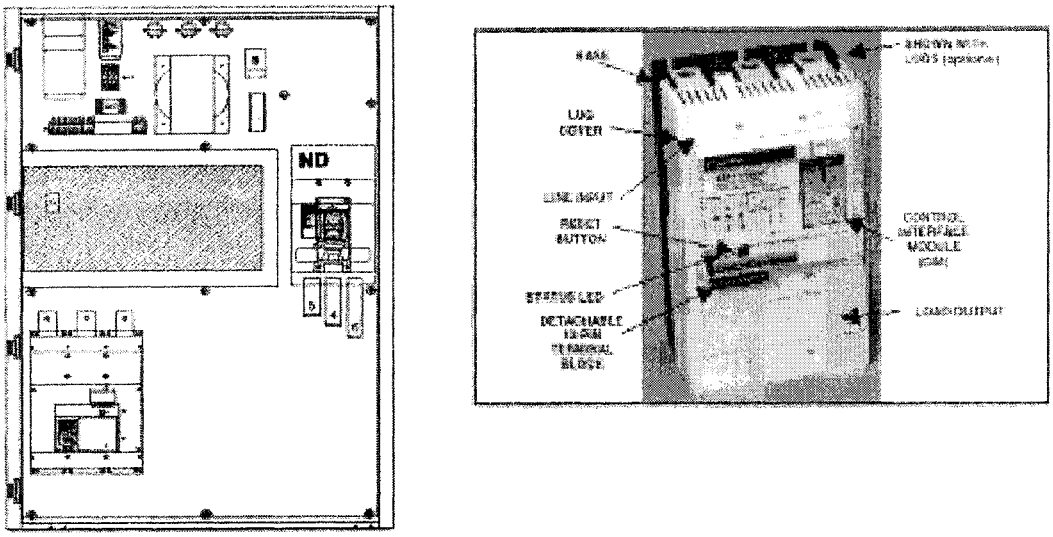
Intelligent Technology for Solid State Starter

CVHE, CVHF, CVHG, CDHF, CDHG and CVGF

ORDER No.: CVHE-SVB04C-EN DATE: January 2003

Introduction

The purpose of this bulletin is to provide set-up, operation, troubleshooting and replacement information for the "IT" (Intelligent Technology) solid state starter used on CH530 equipped Trane CVHE, CVHF, CVHG, CDHF, CDHG and CVGF units. See Figure 1.



NOTICE: Warnings and Cautions appear at appropriate locations throughout this manual. Read these carefully.

⚠ **WARNING:** Indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

⚠ **CAUTION:** Indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury.

CAUTION: May also be used to alert reader to a situation that could result in equipment or property only damage.

Figure 1. Unit mounted "IT" solid state starter

⚠ WARNING

Hazardous Voltage!

Starter and motor components may be energized even if the motor is not running. Disconnect all electric power, including remote disconnects before servicing. Follow proper lockout/tagout procedures to ensure the power cannot be inadvertently energized. Failure to disconnect power before servicing could result in death or serious injury.

CAUTION!

Equipment Damage!

Motor components may be energized even if the motor is not running. Do NOT apply a deep vacuum to the unit if the unit is energized. Disconnect all electric power before evacuating the chiller. Failure to do so may cause damage to the equipment.

Applying a deep vacuum to an IT Solid State Starter equipped unit, while power is applied to the unit, can cause an electrical arc-over inside the motor housing. This can cause motor winding or motor terminal damage or failure.

CAUTION!

Proper phasing of the line power supplied to the IT Solid State Starter is very important. Line power to the IT Starter MUST be phased A-B-C (per the schematic). Use a phase meter to confirm proper phase rotation before the first operation of the chiller. Failure to confirm proper power phasing before unit operation can result in equipment damage.

Note: Chillers with IT Starters that are shipped after November of 2002 will have phase rotation protection built into the IT Starter in order to better prevent equipment damage.

© 2003 American Standard Inc. All rights reserved.

The Intelligent Technology Solid State Starter is applied "inside the delta". As such, motor leads, terminals, and windings are energized continuously whenever the unit disconnect is closed, even if the unit is not running.

The Intelligent Technologies (IT) Inside the Delta Soft Starter is an electronic, self-contained, panel- or enclosure-mounted motor soft-starting device. It is intended to provide 3-phase delta-connected induction motors with a smooth start both mechanically and electrically. The IT line of soft starters utilizes six SCRs in 3 anti-parallel; one pair in series with each phase winding of the Delta-connected motor. Controlling the SCRs' conduction period controls the voltage applied to the motor. This in turn controls the torque developed by the motor. After the motor reaches speed, contacts inside the starter are closed to bypass the SCRs.

The Intelligent Technologies (IT) Soft Starter is designed to fulfill the industrial service requirements for applications such as Chillers and Compressors where Wye-Delta starters are historically applied.

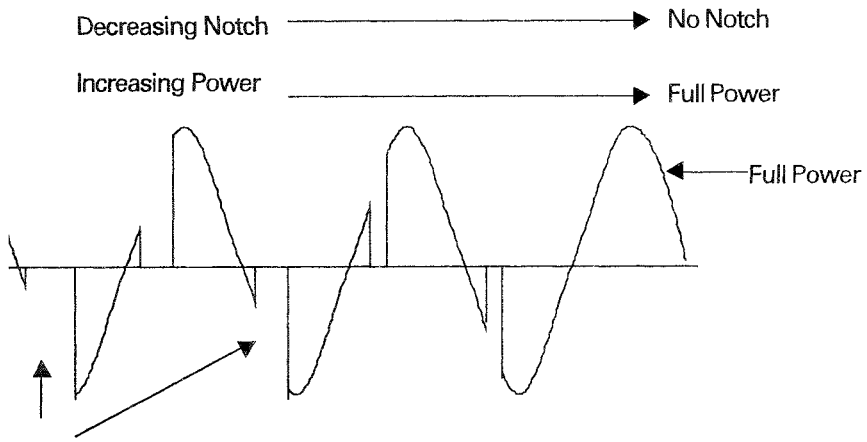
The Intelligent Technologies (IT) Soft Starter meets all relevant specifications set forth by NEMA ICS 1, ICS 2 and ICS 5, UL 508, IEC 60947-4-2, CE, and CSA. This user manual covers useful information that is necessary to know in order to set-up, operate, troubleshoot and maintain the IT Soft Starter.

Environmental Requirements

- Operating ambient temperature range -40°C to 50°C (-40°F to 122°F).
- Storage temperatures range -50°C to 70°C (-58°F to 158°F).
- Elevation up to 2000 meters (6600 feet). Above 2000 meters derate 0.5% per 100 meters (330 feet) up to a maximum of 5000 meters (16000 feet).
- Maximum humidity 95% non-condensing.
- Clean, dry, non-corrosive.

Available Sizes

- 110 mm (110-233 amp)
- 200 mm (234-526 amp)
- 290 mm (527-1472 amp)



Available Voltage Range

- 200-600 Vac 50 and 60 Hertz

Operating Theory

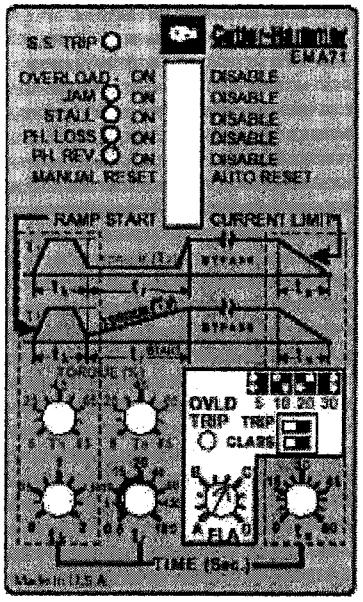
The IT starter uses micro-processor controlled Silicon Controlled Rectifiers (SCRs) to "notch" or temporarily modify the voltage sine wave of each power leg passing through the starter. The larger the "notch" is, the less power and torque will be available to provide work in the motor. During starting process, the notch is large and is progressively reduced in size in order to provide more power and motor torque. The size of the notch can be expressed in the terms of the degrees of the sine wave that it consumes. Refer to Figure 2.

Figure 2. Shows example of size of notch in terms of the degrees of the sine wave that it consumes.

Settings and Interface

To program and operate the IT starter, a "Control Interface Module" (CIM) is used. The CIM is mounted on the front face of the IT starter. The CIM contains the dip switches and rotary controls used to select the settings of the IT starter. Also on the CIM are LEDs that provide status concerning unit operation and faults.

Note that any change to a dip switch will cause all LEDs to flash momentarily. Any adjustment to a rotary control will cause the LEDs to light, and they will stay lit until the adjustment has been completed.



The IT starter does not have to be powered in order to make adjustments on the CIM. Once the unit is energized, the CIM will load its parameters into the IT starter. To verify the CIM is operational press the "fault reset" button that is just below the CIM. All LEDs will momentarily flash if the CIM is powered and communicating.

Dip and Rotary Switch Settings

Refer to the following table for the recommended settings on the CIM. If a switch is labeled "non-settable", this means that the feature is internally set at a fixed value for the Trane application, and it cannot be changed using the switches. Moving the switch will have no effect.

CIM Dip or Rotary Switch	Settable/ Non-Settable	Default/Masked Setting
Overload	Non-settable	On
Jam	Non-settable	Disable
Stall	Non-settable	Disable
Phase loss	Non-settable	Disable
Phase reversal	Non-settable	Disable
Manual reset	Non-settable	Automatic reset
S.F. (special function)	Non-settable	Disable
Ramp start and Current limit	Settable	Ramp
T_1 (kick start)	Non-settable	0% torque
t_k (kick start time)	Non-settable	0 seconds
T_2 (advance or limit)	Settable	25%
t_s (soft-stop time)	Non-settable	0 seconds
t_r (ramp)	Settable	25 seconds
FLA	Non-settable	"D"
Overload Trip Class	Non-settable	Class 30

Figure 3. Control interface module (CIM)

The LEDs that are present next to the dip switches are not used to show the status of the dip switches because the features represented are not used in the Trane application. However, the LEDs are used when reading fault codes that may be present in the starter. Refer to the troubleshooting section of this Bulletin.

Rotary Switch Settings

The lower portion of the CIM module contains several rotary switches that must be set to provide proper operation of the IT starter.

The **"T_1"** rotary switch is the kick start torque setting. Because kick start is not used in the Trane application it can remain set to 0% torque. Non-settable.

The "t_k" rotary switch is the kick start time setting. Because kick start is not used in the Trane application it can remain set to 0 seconds. Non-settable.

The "T_2" rotary switch is the initial torque setting for ramp starting, or it is the torque and current limit setting if the Current Limit method of starting is selected. Refer to the "Starting Options" section of this bulletin for the recommended settings. (Default is 25%.)

The "t_r" rotary switch is the time setting for the ramp and current limit starting methods. Refer to the "Starting Options" section of this bulletin for the recommended settings. (Default is 25 seconds.)

The "t_s" rotary switch is the time setting for the "soft-stop" feature of the IT starter. Because soft stop is not used in the Trane application it can remain set at 0 seconds. Non-settable.

Overload Trip Settings

Overload protection for the Trane chiller motor is provided by the Trane unit control system. Because overload protection is not required from the IT starter, the overload trip settings are internally set to the highest settings of "D" and trip class 30. The overload trip settings on the CIM will have no effect, but can be set to "D" and trip class 30 in order to prevent confusion. Non-settable.

Solid State LED

An LED on the upper left corner of the CIM will be lit when the IT starter has tripped on a starter fault. Refer to the troubleshooting section of this bulletin.

Status LED

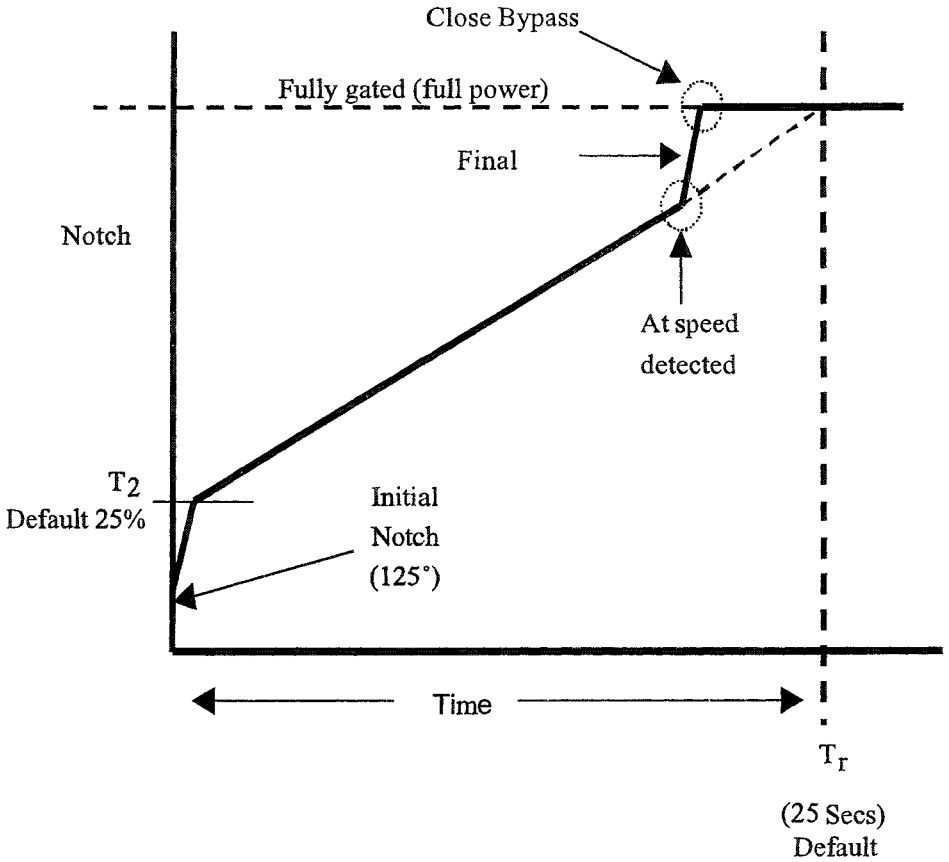
An LED labeled "Status" is provided on the front face of the IT starter. This LED will be green when power is on or during normal operation and will be red or off when a problem is present. Refer to the troubleshooting section of this bulletin.

Starter Fault Relay

The IT solid state starter normally open control contacts found between terminals 95 and 98 are connected to a Trane CH530 dual low voltage binary input board (PN X13650728 J2-1, 2). The contact logic is:

No fault detected by starter = closed
Fault detected by starter = open
Power off to starter = open

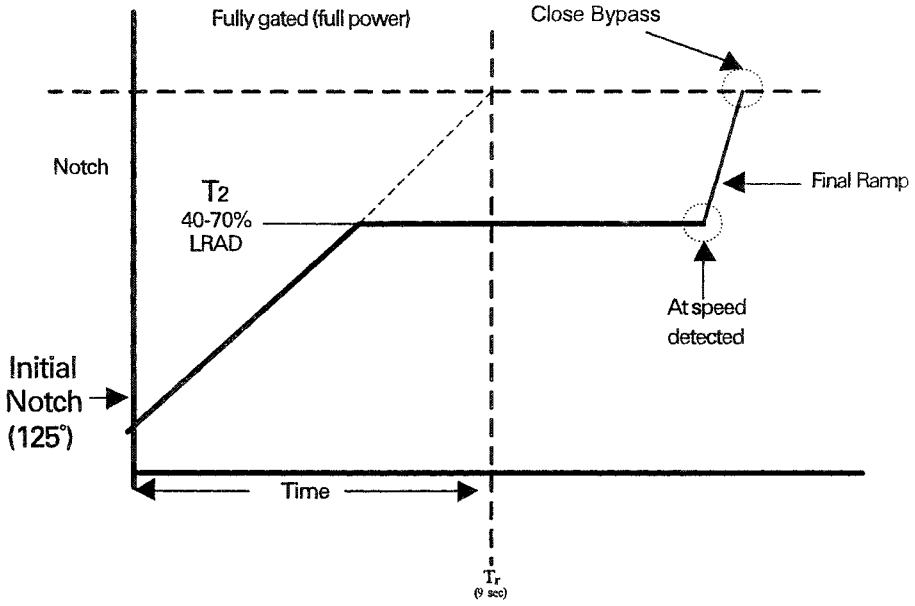
If there is a fault condition a Trane CH530 diagnostic "Solid State Starter Relay Open" will occur. The CH530 "Solid State Starter Relay Open" diagnostic is an MMR diagnostic and must be reset manually in the CH530.



The fault signal in the IT starter itself will be automatically cleared by the IT starter when a fault no longer exists.

Service Test: Dry run is not possible with IT Starter because starter must be powered to be functional and provide no fault signal.

Starting Options



The Trane applied IT starter does not use Cutler-Hammer's Kick Start feature. Of the two types of starting that are available, the most commonly used (and Trane's default method) is the "Ramp" start. The Ramp starting method is selected using the Ramp Start or Current Limit dipswitch on the CIM. In the Ramp starting sequence, the motor is first energized at the largest possible notch size (125°) and then is ramped very quickly to a slightly smaller notch size that provides an initial torque value. The initial torque value can be set using the rotary switch labeled "T_2" on the CIM; the Trane recommended setting for T_2 is 25%. After reaching the initial torque setting, the notch size is then decreased (and the torque is increased) over the range of the acceleration ramp start time. The acceleration ramp start time can be set using the rotary switch labeled "t_r" on the CIM; the Trane recommended setting for t_r is 25 seconds. This will result in a smooth increase in the power that is applied to the motor. When the starter microprocessor controls sense the motor is up to speed, the starter will quickly ramp to full power (no notch) within 2 seconds and the starter's internal bypass contacts will then close. Refer to Figure 4.

Figure 4. Ramp start

A second method of starting using Current Limit is available for use when it is desired to limit the maximum amount of current drawn during the chiller starting. The Current Limit starting method may be selected using the Ramp Start and Current Limit dipswitch on the CIM. In the Current Limit starting method the power is smoothly ramped from the initial notch up to the 2 setting, which is typically 15 to 50% of torque (40 to 70% of LRAD). The current limit torque value can be set using the rotary switch labeled "T_2" on the CIM; the Trane recommended setting for T_2 is 25%. After reaching the current limit torque value, the notch size and power is then held at that value while the motor accelerates. How quickly the starter ramps up towards the T_2 setting is determined by the setting of t_r. The t_r is set using its rotary switch on the CIM; it is typically set at 9 seconds for this type of starting. Refer to Figure 5.

Figure 5. Current limit start

The Trane recommended setting for T_2 when using current limit starting is 25%, which will limit current to approximately 50% of LRAD. If job site conditions require other torque or current values, the table below can be used as a guideline for setting T_2. T_2 must always be set large enough to ensure that the motor will successfully start and accelerate under all conditions.

Torque Setting (T_2)	Approximate % of Locked Rotor (LRAD)
56%	75%
45%	67%
36%	60%
27%	52%
19%	44%
14%	37%
9%	30%

Sequences

Starting – The CH530 chiller control will issue a start command from terminal J8-1 on the starter module to the start and permissive terminals on the IT starter. Holding relay 2K11 will also be energized and will hold it in to make the temporary start signal into a continuous run signal.

When the start and run signal is received on the start and permissive terminals of the IT, the IT will immediately begin to fire the SCRs at the widest possible notch (125°). The rate at which the notch is then reduced and the power to the motor increased, is then determined by the method of starting that is selected (I.E., Ramp or Current Limit).

Motor Acceleration - Regardless of the starting method used the Trane chiller unit controls will allow a maximum of 27 seconds from commanding a start signal and applying power to the solid state starter, to receiving the up-to-speed signal. If the motor acceleration is not confirmed within 27 seconds the unit controls will issue a stop command to the starter and a diagnostic will occur. The failure to accelerate diagnostic requires a manual reset of the unit controls. (The bypass cannot be forced to close at the expiration of this timer.)

Bypass – A bypass contactor exists inside the IT starter, in parallel with the SCRs. The contactor will carry 100% of chiller RLA . It will not, under normal starting or running circumstances, make or break current that is greater than the frame amps of the starter. The bypass contactor is energized when the motor is "at speed" and the SCRs are fully phased on (zero notches). During stopping the bypass contactor will be de-energized only after the SCRs are fully phased on. The bypass contactor will not break full load current during a loss of voltage; the SCRs will be gated on to take the load.

Stopping Profile – When the chiller controls remove the 24-vdc signal from the start and permissive terminals and asks the IT starter to stop, the SCRs will be fully phased on. The bypass contactor will be de-energized, and the SCRs will then be turned off at the earliest available zero current cross (when the current sine wave passes through zero). The stopping profile time from removal of the 24-vdc signal shall be less than 50ms. The SCRs will not, under normal circumstances, make or break current greater than the chiller's RLA. Trane does not use the soft stopping profile.

Power Wiring

Line power provided to the IT starter must be phased A-B-C. Failure to properly phase the incoming line power for IT equipped chillers shipped previous to November of 2002 may result in incorrect firing of the SCRs and possible tripping of the unit circuit breaker and/or equipment damage. IT equipped CVHE/F/G and CVGF chilllers built after November 2002 have additional phase reversal protection added to the IT starter. Failure to connect with a proper phasing of A-B-C will result in a starter fault and the chiller will not start. A flash code will be provided on the IT that indicates a "Phase Connection Sequence Fault."

Starter Device Input and Output

A 12-pin detachable terminal block is provided on the front of the IT starter to connect the starter to the control circuit of the chiller.
The terminals are labeled:

"-" = 24-vdc common.

"+" = 24-vdc supply.

"P" = Permissive input. If power is not present on this terminal the unit will not start or run. For Trane applications this terminal should be connected with a jumper to terminal 1.

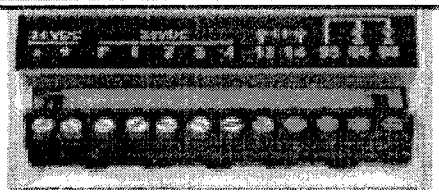
"1" = Start input. This terminal receives the start/run signal from the chiller control system.

"2" = Jog forward input. This terminal is not used on the Trane application.

"3" = Overload disable input. This terminal is not used on the Trane application.

"4" = Fault reset input. This terminal is not used on the Trane application. The fault flash codes will appear if 24-vdc is applied continuously to this terminal.

"13" and "14" = Terminals 13 and 14 provide a "up–to-speed" signal back to the chiller control system. It is a normally open relay that closes its contacts when the IT starter determines the motor has successfully accelerated.



"95" = Common for the starter fault relay of the IT starter.

"96" = Normally closed contact for the starter fault relay of the IT starter. This contact provides a fault signal to the chiller control system.
OK = closed
Fault = open
No Power = open

"98" = Normally open contact for the starter fault relay of the IT

Each connection in the terminal block is capable of holding one or two 0.33-2.5mm^2 (#22 - #14 AWG) wires, or one 4mm^2 (#12 AWG) wire. Each terminal should be tightened to 0.4 N-m (3.5 In-Lb.).

⚠ Caution	⚠ Attention
Only apply 24V DC to the control terminal block unless specified otherwise in this manual. All control wiring is #22 - #12 AWG. Failure to follow this caution could result in severe damage to the controller.	Appliquer seulement une tension de 24 V c.c. aux bornier sauf avis contraire dans ce manuel. Toute la filerie de commande est de calibre 22 à 12 AWG. L'inobservation de cette mesure pourrait causer des dommages importants au contrôleur.

Accessories

MOVs – Most utility power systems experience periodic transient voltages. Line or power factor correction capacitor switching, nearby lightening strikes, utility supply faults, or a user starting or shutting down a large load such as a motor can cause these voltages. The IT starter has been designed to handle transient voltages of up to 4kV lasting up to 20 seconds. If transient voltages of greater magnitude or of a longer duration than the standard withstands rating capability are expected, then a protective module must be installed. The protective module contains Metal Oxide Varistors (MOVs). MOVs are devices that remain in a passive state until a transient voltage occurs. Under the transient condition the MOV turns on and holds the peak line voltage down to a level that is less than the IT transient voltage rating. When the transient clears, the MOV returns to a passive state. MOVs are factory installed on a new starter, or they may be purchased for installation in the field. Contact Trane AfterMarket for information concerning the purchase and installation of MOVs.

PFCCs – If Power Factor Correction Capacitors (PFCCs) are installed on the system they must NOT be connected to the load side of the IT starter. Do NOT connect PFCCs between the IT starter and the motor. PFCCs must be installed on the line side of the IT starter. A separate isolation contactor is required to energize the capacitors. The capacitors are only energized after the motor is up to speed.

Troubleshooting

The following section presents information useful for diagnosing a problem with the Trane applied IT starter. While many potential situations are outlined, it is possible you may run into a problem that is not covered here. If you have worked through the following troubleshooting procedure and find that you require further assistance, please contact the appropriate business unit technical service group. Please always have the following information ready when you call or use web resources:

Trane Sales Order Number	
Trane Unit Serial Number	
Unit Design RLA	
Starter Catalog Number	
Style Number	
Starter Serial Number	
CIM Dip Switch Settings	
CIM Rotary Switch Settings	

Before You begin To Troubleshoot:

⚠ WARNING

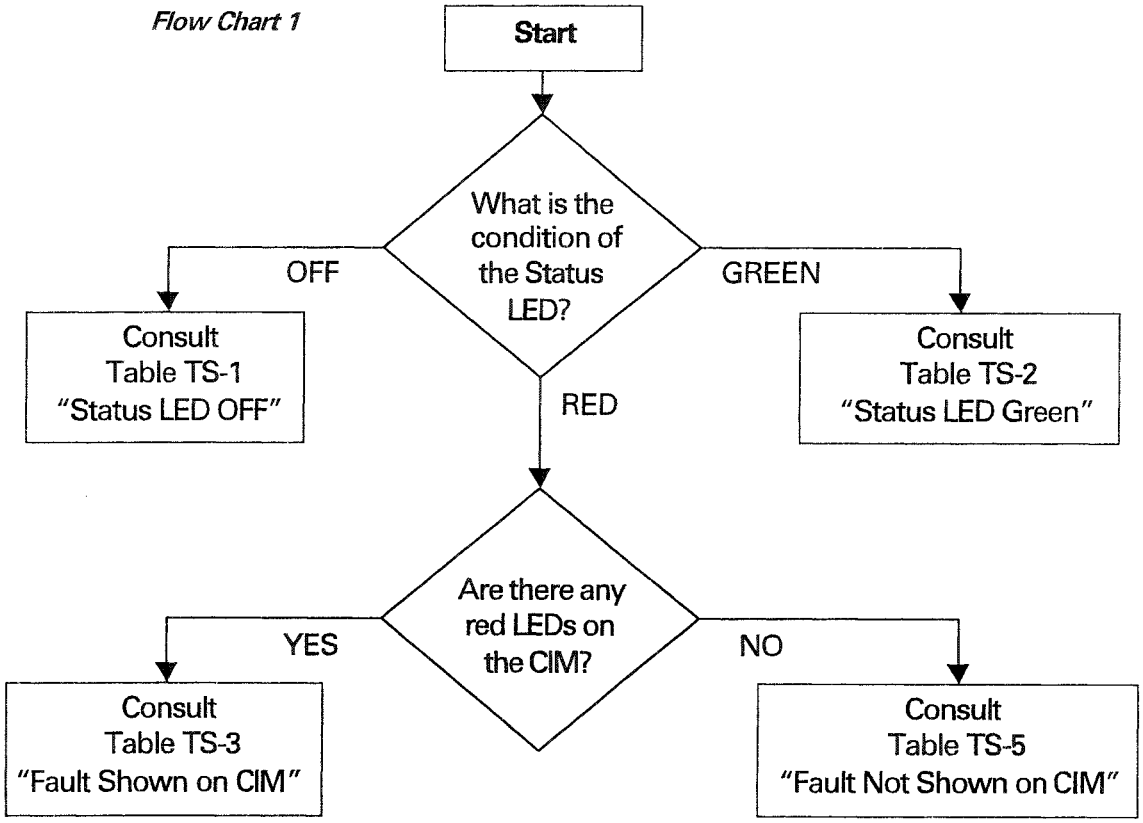
Hazardous Voltage!

Use extreme caution when service related work, adjustments, measurements or other service work is performed with power on.

If troubleshooting procedure requires equipment to be energized, all work must be performed by properly qualified personnel, following appropriate safety practices and precautionary measures.

Failure to do so could cause death or serious injury.

We highly recommend you read this entire section of the manual before troubleshooting the IT starter.



You may want to obtain the following equipment to aid you in troubleshooting:

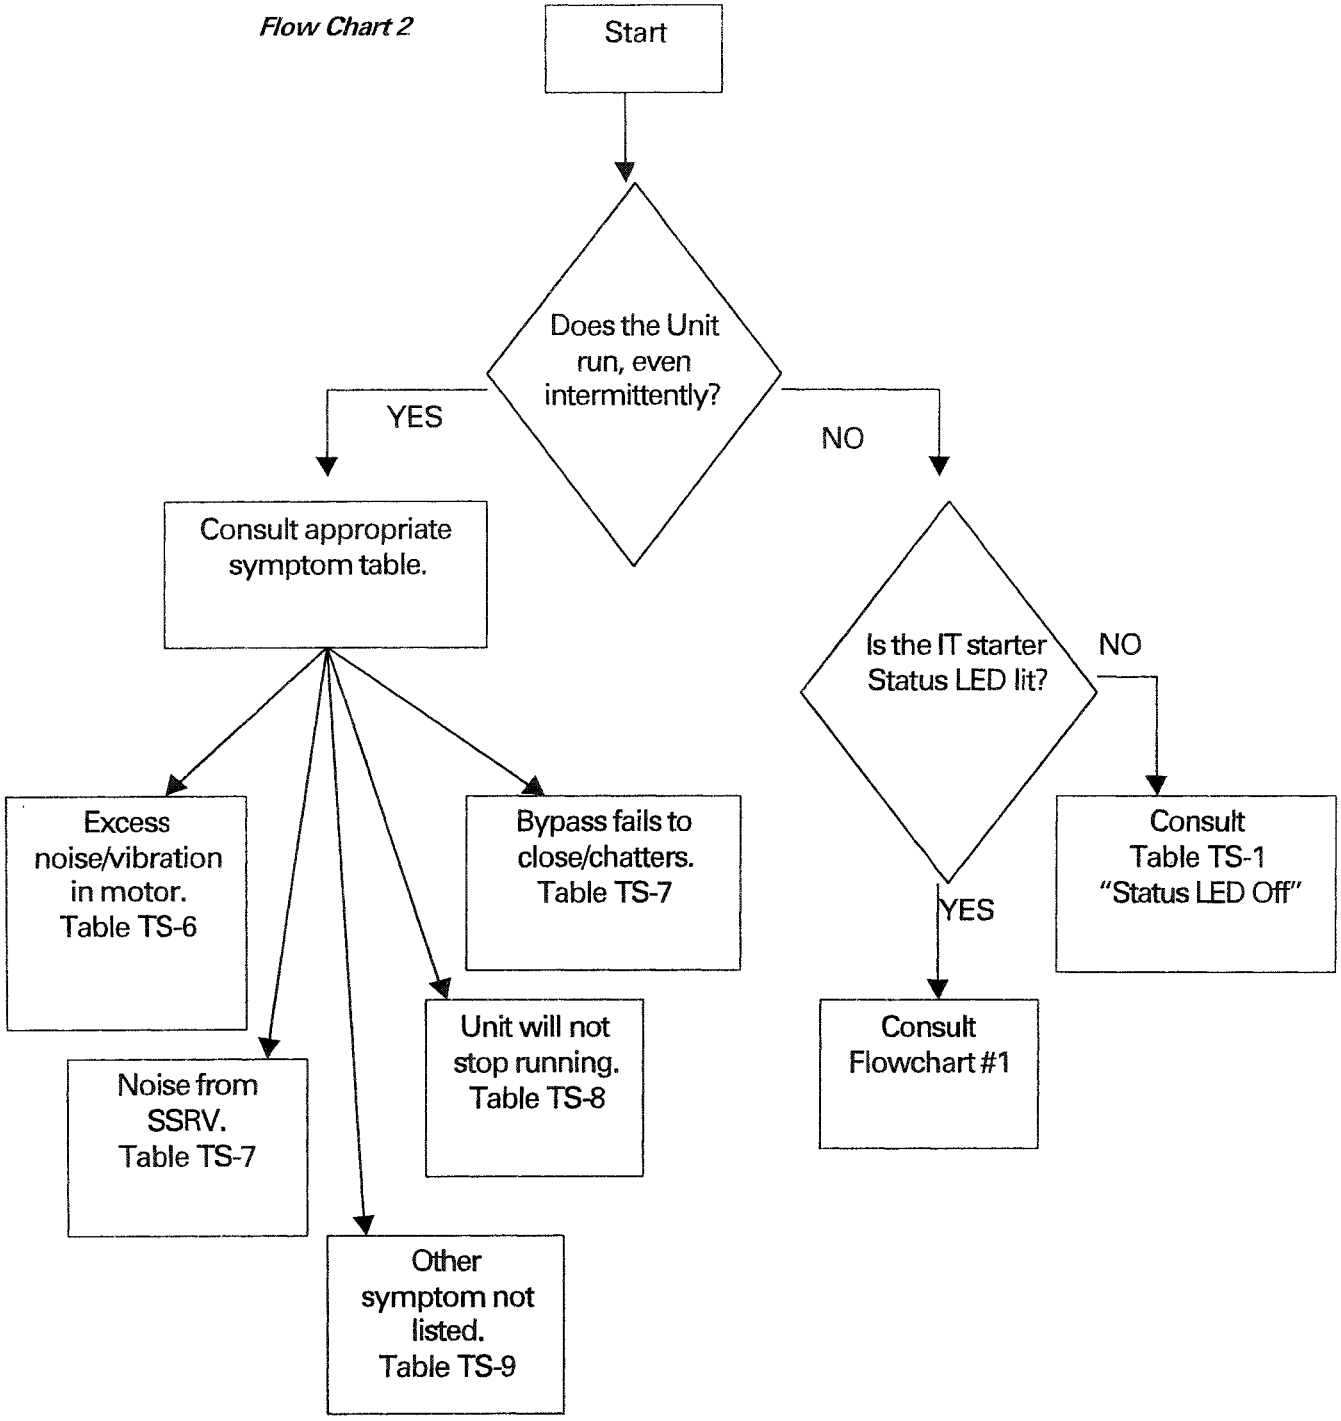
Multimeter
Clamp-on ammeter

Define the Problem

The IT starter fails to start. No power is applied to the motor.	Use Flowchart #1
The IT starter trips during startup, or fails to reach rated speed before going into bypass.	Use Flowchart #1
The IT starter trips or stops running during normal conditions.	Use Flowchart #1
None of the above descriptions match the problem.	Use Flowchart #2

Flow Chart 1

Flow Chart 2



Start
Does the Unit run, even intermittently?
YES
NO
Consult appropriate symptom table.
Excess noise/vibration in motor. Table TS-6
Noise from SSRV. Table TS-7
Other symptom not listed. Table TS-9
Unit will not stop running. Table TS-8
Bypass fails to close/chatters. Table TS-7
Is the IT starter Status LED lit?
NO
YES
Consult Table TS-1 "Status LED Off"
Consult Flowchart #1

Table TS-1. Status LED off

Symptom and Indication	Possible Problem	Possible Solution
No indication on the unit or on the CIM.	Loss of 24-vdc control power	Check control wiring
		Verify 24-vdc power from power supply
		Check power supply fuse/breaker
	Failed CIM	Disconnect the CIM. If the Status LED lights, replace the CIM. If not, the control board may be defective.
	Failed control board	Contact service or parts
No status light, but CIM is powered.	Failed LED indication	Reset the unit, verify operation
		Cycle the 24-vdc power to the unit.

Table TS-2. Status LED green

Symptom and Indication	Possible Problem	Possible Solution
Status LED is green, but no indication on the CIM.	Line power fault	Check wiring connection on load and line side.
		Check line power breakers/fuses
		Verify 24-vdc power is available for terminals P and 1 on the starter.

Table TS-3. Fault shown on CIM

Symptom and Indication	Possible Problem	Possible Solution
SS or over temp LED is lit on CIM.	High temperature – see flash codes	Allow unit to cool down with 24-vdc applied to + and -.
		Verify operation of unit cooling fans.
		Clear any restrictions to airflow.
	Possible hardware failure – see flash codes	If code 32 is indicated, check actual motor start time vs. the "Tr" setting. Tr should not be set more than 2 or 3 seconds longer than the actual motor start time.
		Contact technical assistance
PH LOSS LED is lit on the CIM.	One or more line voltages missing or is low.	Verify that proper line voltage is present and that no other equipment was affected.
		Confirm the line power connections are correct and tight.
		Check line power fuses, circuit breakers, and disconnects.
		Press the reset button below the CIM to clear the fault.
	Phase voltages or currents unbalanced	Check same solutions for phase loss.
		Confirm the motor current is acceptably balanced when the line voltage is balanced. If not, investigate system/motor.
		If line voltage is balanced but load voltage is not, check bypass. Contact technical assistance.
		Check load connections at starter and at motor terminal box.
OVLD TRIP LED is lit on the CIM. (Thermal overload trip, the Trane unit controls should trigger before the IT starter).	Motor is overloaded.	Check motor for load problems.
	FLA not set to motor ratings.	The IT starter uses the highest RLA value of "D" for Trane applications.
	Trip class not set properly.	The IT starter uses the highest trip class of "30" for Trane applications.
	Fault exists in memory.	Press the reset button below the CIM to clear the fault. If the fault remains, allow the system to cool and try again.
	Failed current sensor	Contact technical assistance.

Starter Fault Flash Codes sent to the CIM

To obtain the fault flash codes from the CIM, press and hold the reset button (located below the CIM) down or apply 24-vdc to terminal 4. All LEDs on the CIM will flash in a sequence that will define the faults that are present. Count the number of times all the LEDs on the CIM flash.

For example, if you see three flashes, and then two more flashes after a short pause, the flash code is 32.

The CIM can provide multiple flash codes if more than one error condition has caused a stop. Once you see the same flash codes repeated you will have seen all of the flash codes for the error conditions that caused the stop.

For example, if you see three flashes, a pause, then two flashes, a pause, then four flashes, a pause, then one flash, the flash codes are 32 and 41. If you then see three flashes, a pause, then two flashes, you are seeing the first code again. This means you have seen all of the flash codes for this stop. You may release the reset button or remove the 24-vdc from terminal 4.

TableTS-4. Flash codes

Code	Fault	Possible Cause
11	Thermal Overload	See Table TS-3
12	Motor Stall	NA (not used by Trane)
13	Motor Jam	NA (not used by Trane)
14	Phase Sequence ACB	NA (not used by Trane)
15	Pole Over-temperature	See Table TS-3
16	SCR Failed to Fire	Loose connection or defective unit
21	115v Power Supply Low	Weak control power or defective unit
22	Phase Loss	See Table TS-3
23	By-pass Dropout	Weak control power or defective unit
24	SCR Contactor Overcurrent	Load amps excessive
25	Phase Imbalance	See Table TS-3
26	Non-volatile Memory Error	Internal control board fault
31	Zero Voltage Cross Failure	Control power applied out of sequence or PFCCs on motor
32	Shorted SCR, Phase Loss, Load Disconnect	See Table TS-3
33	Serial Communications Lost	Internal control board fault
34	SCR Instantaneous Over-current	Current exceeded start ratings during the starting or stopping mode
41	24-vdc Power Supply Low	Improper 24-vdc supply or weak control power
42	Timer System Fault	Internal control board fault
43	Watchdog Reset Occurred	External electrical noise or internal control board fault
44	PLL (DSP)	Internal control board fault
45	Illegal Address	Internal control board fault
46	Phase Connection Sequence Fault	Line power not phased ABC

Table TS-5. Fault not shown on CIM

Symptom Indication	Possible Problem	Possible Solution
Status LED is lit, but no indication on the CIM.	No communication with the CIM. on the CIM should light.	Verify connection between starter and CIM. Press the reset button on the starter, all LEDs
	Sensor Failure.	Cycle the 24-vdc power to the unit. Allow unit to reset.
	Bypass opened during run.	Press the reset button to reset the fault.
		Weak 24-vdc power supply. Verify that the 24-vdc power supply output rating is large enough to close the bypass contacts with a minimum output rating of 250 watts for 0.15 seconds.

Table TS-6. Excessive noise and vibration in motor

Symptom Indication	Possible Problem	Possible Solution
Motor vibration during start-up.	Load fluctuations.	Check load conditions.
	Misapplication.	Ramp time set too low for application.
		Torque set too low for application.
	Load voltage or current is unbalanced, but line voltage is balanced.	Check line and load connections at the starter, and at the motor terminal box.
	Hardware failure.	Contact technical assistance.
Motor vibration during normal run.	Load fluctuations.	Check load conditions.
		Check motor connections.

Table TS-7. Noise from starter - bypass fails to close/chatters

Symptom Indication	Possible Problem	Possible Solution
Audible noise from IT starter.	Bypass contact chatter.	Check 24-vdc control power to IT starter.
		Verify 24-vdc power supply meets power inrush requirements of 250 watts for 0.15 seconds.
	Loose connections.	Remove power from unit, check all connections.
	Loose mountings.	Remove power from unit, check all mounting hardware.

Table TS-8. Unit will not stop

Symptom Indication	Possible Problem	Possible Solution
Motor will not shut off.	Control wiring is incorrect.	Verify 24-vdc is removed from the P terminal when stop is desired.
		Verify no stray strands of 24-vdc power are connected to the P terminal.
	Bypass fails to open.	Open disconnect. Remove all power from unit and check continuity of poles.
	Shorted SCR.	Open disconnect. Remove all power from unit and check continuity of poles.

Table TS-9. Other symptoms

Symptom Indication	Possible Problem	Possible Solution
Motor short circuited.	Winding fault.	Identify and correct motor fault.
		Verify all power connections are secure.
		Verify no shorts exist in cabling or motor terminal box.
Motor starts too slowly.	Incorrect setting.	Increase torque or current limit setting.
		Decrease ramp time.
Motor starts too quickly.	Incorrect setting.	Increase ramp time.
		Decrease torque or current limit setting.
Unit CH530 controls provide a phase reversal or mpl diagnostic during starting attempt.	Incorrect phasing of power.	Correct the line phasing.
	IT starter response.	Increase aggressiveness of IT settings.
		Increase the phase reversal grace period setting in CH530
	Poor incoming power quality.	Correct power quality.
Starter circuit breaker Trips.	Incorrect phasing of power.	Correct the line phasing.
	Motor short circuited.	See this table.
	Motor starts too quickly.	See this table.
	Incorrectly set or faulty breaker	Check breaker.

Removing the Controller Interface Module (CIM):

Note that the IT starter, with the CIM attached, is installed up side down in the Trane starter panel.

1. To remove the CIM, release the catch lever located in the cover just below the center of the CIM. Move the latch away from the CIM.
2. Disconnect the communication cable from the bottom of the CIM assembly by pressing the lever to unlatch the communication plug.
3. Re-install the CIM in the reverse sequence.
   Note: The edge of the CIM opposite of the latch must be inserted into the cover first, prior to snapping the CIM into the latch.

General Service Bulletin

UnitMount™

Medium Voltage Starters on Trane CenTraVac Chillers

ORDER No.: CVHE-SVB06A-EN DATE: April 2002

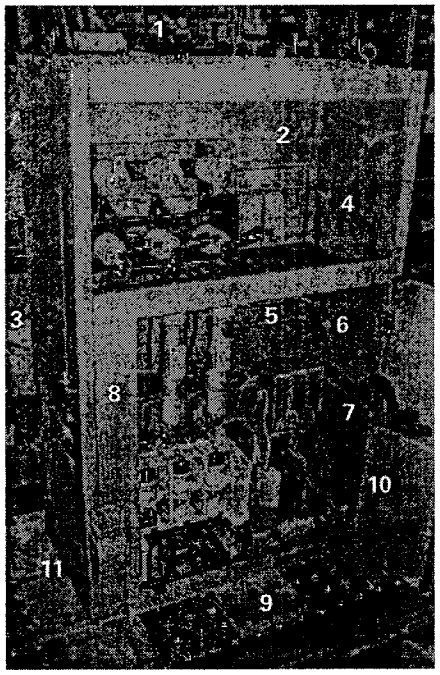
Introduction

This bulletin discusses the set-up, inspection, operation, and maintenance of the Trane supplied UnitMount™ medium voltage starter, used on Trane CVHE, CVHF, CVHG, CDHF, and CDHG chillers.

General Information

UnitMount™ medium voltage starters consist of an isolation switch, current-limiting power fuses, vacuum contactor, and associated components for the control and protection of the medium voltage motor on a Trane CenTraVac™ Chiller. (See Figure 2.)

The isolation switch has a limited make and break rating, suitable only for the closing and opening the load of the 4kva control power transformer supplied inside the starter. The switch is mechanically interlocked with the main vacuum contactor to insure that the motor is disconnected from the line before the switch can be operated.



The vacuum contactor is either a 200 amp or 400 amp design, dependant on the actual motor load. Refer to Cutler-Hammer Instruction Book IB-48018N for more specific instructions on the contactor.

Line voltage from a medium voltage source enters the cabinet from cables located through the lead-plate in the roof of the enclosure. The line voltage is isolated in the upper portion of the starter enclosure by the isolation switch, when the switch is in the open position. A horizontal barrier is located at the bottom of the switch compartment to prevent accidental contact with the incoming power circuit while preventing inadvertent contact with the incoming power while servicing the starter. The barrier and all bolted covers must remain in place as long as the incoming cables are energized.

A viewing window is located in the bolt-on cover in front of the isolation switch to allow visual confirmation of the switch blade position. (See Figure 1.)

The starter control components are located in the low voltage control compartment that is accessible behind the low voltage door located on the lower right front of the starter. The low voltage door may be opened with the starter isolation switch in the closed position. Care should be taken if the low voltage door is opened with the isolation switch closed since there will be control voltage (120 vac) present in the control compartment.

Located inside the low voltage control compartment are the components that interface the starter with the Trane CH530 unit control. The CH530 Starter module controls the contactor sequence during motor starting.

Component List

1. Line Cable Lead Plate
2. Isolation Switch
3. Side Access Panel
4. Horizontal Safety Barrier
5. Bolted Main Fuses
6. Control Power Primary Fuses
7. 4 kVA Control Power Transformer
8. Potential Transformers
9. Vacuum Contactor
10. Starter Control Compartment (Rear View)
11. Isolation Switch Operating Handle

Starter Identification

A rating nameplate is located on the lower left corner of the medium voltage door. The nameplate includes the following information:

- Line voltage, frequency, phase
- Load current range
- Cutler-Hammer General Order Number
- Trane Service Model Number
- Short Circuit Rating

Contactor Information

Table 1

	Type SL-200	Type SL-400
Maximum Interrupting Current (3 operations)	4500 amps	8500 amps
Rated Current (continuous)	200 amps	400 amps
IEC Make-Break Capability – AC4	Make 4000 A Break 3200 A	
Short Time Current	30 sec - 2400 A 1 sec - 6000 A 8.7 MS (0.5 cycle) - 63kA peak	
Standard Service Altitude	-1000 to +2000 meters	
Optional Service Altitudes	-3500 to –1001 meters +2001 to +5000 meters	
Mechanical Life	2.5 million operations	
Electrical Life	300,000 operations	
BIL	60kV (1.2 x 50 microseconds)	
Dielectric Strength (60Hz)	20kV (1 minute)	
Closing Time	80 milliseconds	
Opening Time	30 to 250 milliseconds (selectable) Trane UnitMount setting is 50 milliseconds	
Arcing Time	12 milliseconds (3/4 cycle) or less	
Pick-up Voltage	80% rated coil voltage	
Drop-out Voltage	60% rated coil voltage	
Control Voltage (Trane UnitMount)	110/120 volts AC, 50/60Hz	
Control Circuit Burden	Closing 600 VA Holding 30 VA	
Auxilliary Contact Rating	Voltage (max) 600V Continuous Current 10 A	
Maximum Insulation Voltage	7200V	
Weight	47 lbs (21.3 kg)	49 lbs (22.2 kg)
For further contactor information refer to the appropriate Cutler-Hammer literature		

Fuse Information

The control power transformer fuses (2F1, 2F2, 2F3) are rated at 5 amps. For voltages less than 5000 volts 5kV fuses are used. For voltages above 5000 volts 8.3kV fuses are applied.

The standard main line fuses used in the Trane UnitMount™ application are:

Table 2

Voltage	Running Amps	Fuse Rating	C-H Part Number
5 kV	8 to 75	6R	5982C31G06
	76 to 150	12R	5982C31G08
	151 to 288	24R	5982C32G02
7.2 kV	8 to 75	6R	5982C36G05
	75 to 150	12R	5982C36G07
	151 to 288	24R	5982C36G09

Operation

Mechanical Interlocks - Door, Switch, Contactor Interlock

This mechanical interlock prevents inadvertent closure of the isolation switch if the enclosure door is open. When the door is closed, a bracket fastened to the inside of the enclosure door causes the interlock to move out of the blocking position.

The medium voltage door must be closed with the door latches fully tightened to insure that the interlock is properly engaged. Failure to fully tighten the latches will block the movement of the isolation switch handle and also prevent the main contactor from closing when a start signal is received from the chiller control panel.

The same interlock assembly prevents the isolation switch from being operated if the main contactor is energized. The interlock also prevents the contactor from being closed if the isolation switch handle is in an intermediate position.

Mechanical Interlocks - Door and Switch Shaft Interlock

When the isolation switch is closed, an interlock piece welded to the operating handle of the switch captures a door mounted bracket, preventing the door from being opened. When the switch is opened, the handle is rotated down to release the door-mounted bracket. The door is then free and may be opened.

Isolation Switch Operation

The opening and closing of the isolation switch is through an off-center stored energy mechanism that provides for quick-make and quick-break. The switch main shaft is driven by a chain and sprocket from the front operating handle. As the handle is rotated, it is chain connected to a sprocket which in turn drives the operating spring to a charged position. As the operator continues to rotate the handle, the charged operating spring is driven off-center by the chain and releases its energy into rotating the operating shaft. The switch blades will not move in either a closing or opening direction until the operating spring causes rotation in the main shaft. It should be noted that once the springs are moved off-center, the operator has no further control of the opening or closing operation. Therefore, the switch has CPT load make and break ratings independent of operating personnel performance.

To operate the chiller, the starter isolation switch must be in the closed position. In the closed position, the primary of the 4kva control power transformer (CPT) is energized to provide voltage to the starter and chiller control circuits. Power is also then available to the line side of the main contactor, allowing the motor to be energized when the contactor receives a start command from the chiller control panel.

The isolation switch is closed by pulling out on the handle latch button and rotating the handle upward. The isolation switch is opened by pulling out on the interlock button on the handle housing and then rotating the handle downward.

A clear viewing window is located in the bolt-on cover in front of the isolation switch. The window allows visual confirmation of the isolation switch blade position.

⚠ CAUTION

Failure to clear the latch button lever from the housing mechanism can cause extreme damage and jam the operating handle.

To service the chiller or starter, the starter isolation switch must be in the open position. The isolation switch is opened by pulling out on the interlock button on the handle housing and then rotating the handle downwards.

Always follow all local procedures related to lock-out and tag-out when servicing the chiller or starter.The isolation switch handle will accept a padlocking mechanism to insure that the isolation switch cannot be closed with the padlocking mechanism attached.

⚠ WARNING

Forcing handle operation against safety interlocks may result in property damage, bodily injury or death.

Do not force the isolation switch handle. If the handle cannot be easily operated, make sure that the main contactor is open. The handle and switch are interlocked with the contactor and cannot be operated with the contactor closed.

Contactor Operation

When motor starting is called for by the unit controls, the 2K1 contactor is closed by energizing the contactor control board terminals 1 and 2 with a 115v signal from the CH530 starter module. The contactor control board then rectifies the input voltage and applies a pulse width modulated DC output voltage to the contactor coils. The output voltage is approximately full voltage for the first 200 milliseconds after energization, during which time the contactor closes and seals. The output voltage is then automatically reduced by the contactor control board to approximately 15 VDC to maintain the contactor in the closed position.

When the unit controls decide to open the contactor, the CH530 starter module will open it's contact and interrupt the 115v control signal. When the signal is removed from the control board the contactor is held closed for a pre-set time and then is allowed to open. The range of time between the removal of the control power signal and the contact opening is adjustable from 30 to 250 milliseconds, and forTrane chiller applications it is normally set to the default setting of 50 milliseconds.

For more detailed information on the contactor's construction, operation, and maintenance refer to Cutler-Hammer instruction booklet IB-48018N.

Installation of UnitMount™ Starters

The UnitMount starter, whether actually on or off of a chiller, must be kept in a clean and dry location with ample air circulation and heat to prevent condensation. Like all electrical apparatus, the UnitMount starter contains insulation that must be protected against dirt and moisture.

For most applications the UnitMount starter will remain mounted on the chiller and only basic electrical connections will need to be made in order to place it into service.

For limited access applications which require the UnitMount starter to be removed and then re-installed after the chiller is in place, refer to the appropriate section of this manual.

Installation

UnitMount starters are designed to be installed, operated, and maintained by adequately trained and qualified workmen. These instructions do not cover all details, variations, or combinations of the equipment, its storage, delivery, installation, check-out, safe operation, or maintenance. Always comply with local, state, and national regulations, as well as safety practices, for this class of equipment.

Before making any connections, make sure all leads to be handled are dead.

⚠ WARNING

Hazardous Voltage!

There is a hazard of electric shock whenever working on or near electrical equipment. Electric shock may cause injury or death. Turn off all power supplying the equipment before starting the work. Lock-out the disconnecting means using a proper "lock-out or tag-out" system.

When it is not feasible to de-energize the system, then precautions must be taken.

- **Require persons working on exposed parts that are or may be energized to be qualified persons who have been trained to work on energized circuits. A qualified person is one who is familiar with the construction and operation of the equipment and the hazards involved. In addition, this person should have the following qualifications:**
- Be trained and authorized to energize, de-energize, clear, ground, lock-out, and tag circuits and equipment in accordance with established safety practices.
- Be trained in the proper care and use of protective equipment such as rubber gloves, hard hat, safety glasses or face shields, flash clothing, etc. in accordance with established practices.
- Be trained in rendering first aid.
- Be knowledgeable with respect to electrical installation codes and standards, for example, the National Electric Code (NEC).

Make connections in accordance with the submittal drawings furnished with the order. Select 75°C wire in accordance with the National Electric Code (NEC) guidelines where the conductor size is not specified in the submittals or unit instructions. A disconnecting means and short-circuit protection must be installed ahead of the starter, unless they are included as part of the starter.

Line Entry – Power Supply Wiring

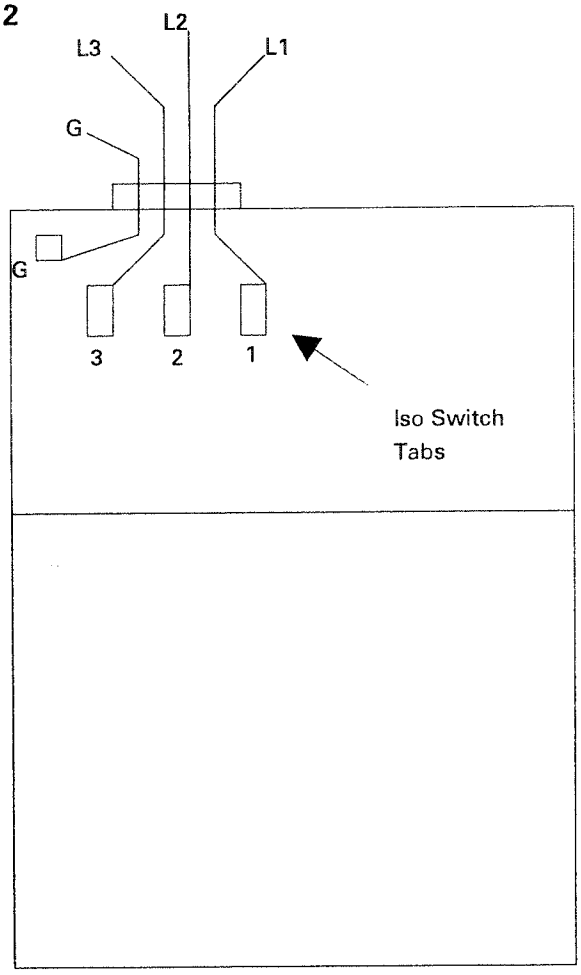
Line power entry into the UnitMount™ starter is thru a removable panel located on the top of the starter enclosure. In order to prevent debris from falling inside the enclosure the panel should be removed prior to drilling or cutting the panel to allow the installation of the wire or conduit.

⚠ CAUTION

To avoid damage to starter components, always remove any debris from inside the starter panel. Debris may cause an electrical short which can seriously damage the starter components.

The wire or conduit must be properly supported and protected as it enters the starter enclosure. Do not allow the abrasion of wire insulation on sharp panel edges etc.

After the power wiring to the starter is installed, the wire entry into the starter enclosure should be sealed as well as possible to prevent the entry of dirt, debris, or moisture into the starter enclosure.



Trane recommends the use of copper conductors to connect the 3-phase power supply to the UnitMount™ starter.

⚠ CAUTION

To avoid corrosion or overheating, use only copper conductors for terminal connections.

Make sure the incoming power wiring is properly phased, and if multiple conductors per phase are used, that each power supply conduit run to the starter carries the correct number of conductors to ensure equal phase representation, see Figure 2.

Figure 2

As you install the power supply conduit, make sure that its position does not interfere with the serviceability of any of the unit components, nor with plant room structural members and equipment.

The incoming power lines must not apply excessive stress or force to the tabs of the isolating switch. Ensure the lines or conduit are properly supported in the panel at the entrance to the enclosure.

Also, assure that the conduit is long enough to simplify any servicing that may be necessary in the future (e.g. starter removal).

The use of flexible conduit may be desired to enhance serviceability and minimize vibration transmission.

Line Connection

Connection of the incoming line to the starter is by the use of terminal lugs bolted to the line tabs on the top of the isolation switch. Again, ensure the power is properly phased. Use field provided crimp-type terminal lugs that are properly sized for the application. Grade 5, 3/8-16 steel hardware should be used to connect the lugs to the isolation switch tabs. Carefully tighten each connecting bolt to 25 ft-lbs.

The incoming power lines must not apply excessive stress or force to the tabs of the isolating switch.

Ground Connection

A copper bus for the incoming ground connection is provided in the left side of the enclosure.

Inspection Before Start-up

Each UnitMount™ Starter is properly adjusted at the factory before shipment. However, vibration and mechanical stresses imposed by transit and installation can adversely affect starter adjustment; therefore, a final inspection is essential before energizing. Refer to the inspection procedures defined in the Inspection and Maintenance section of this manual. If this inspection reveals the starter has come out of adjustment, the starter should be re-adjusted according to the procedures in Cutler-Hammer bulletins I.B.48034 and I.B.48018N.

Inspection procedures require closing and opening the isolation switch with the main door open. This requires override of the door safety interlock as described in the maintenance section of this manual. Always ensure the main line power to the starter is locked OFF prior to overriding the door safety interlock.

⚠ WARNING

Hazardous Voltage!

Defeating or disengaging safety interlocks on a UnitMount starter that is connected to a power source may result in property damage, bodily injury or death.

Do not defeat or disengage any safety interlocks when the starter is connected to any power source.

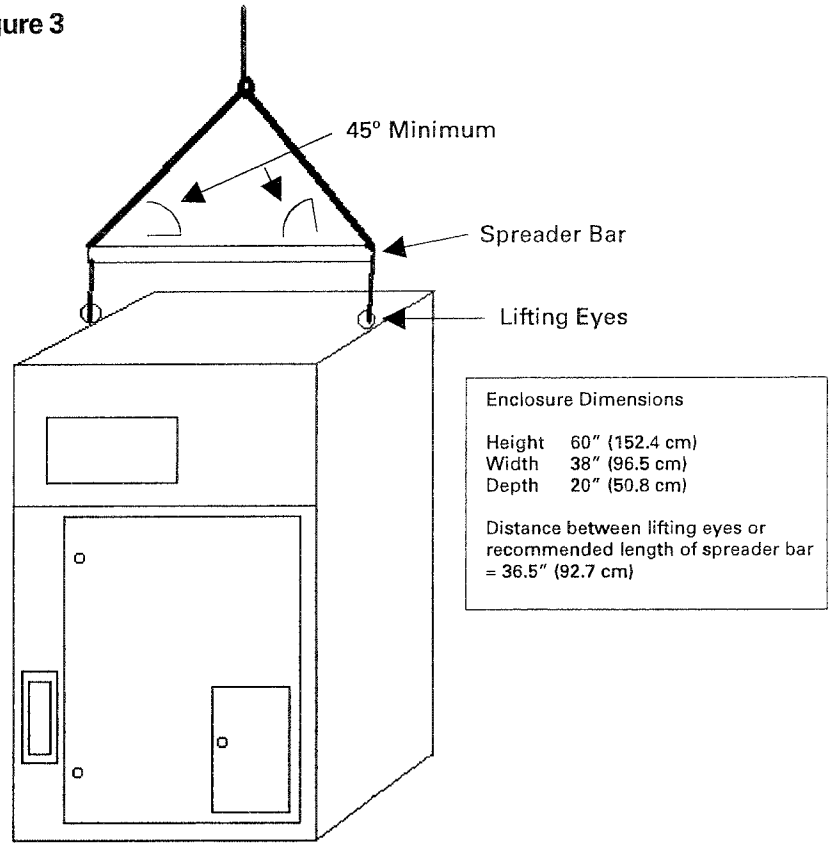
Instructions For Limited Access Installations

If required, additional clearance for unit rigging and installation procedures can be obtained by removing the unit mounted starter on chillers so equipped. The following procedure assumes the chiller is new and has never been installed and therefore there is no electrical power connected to the chiller.

1. Mark or label and disconnect, at the compressor motor terminal lugs inside the starter panel, the power wiring between the starter and the motor terminals.

2. Mark or label and disconnect the control wiring entering the starter panel. Remove the control wiring conduit and/or IPC bus from the starter panel.

3. Remove the bolts securing the bottom of the starter to the brackets on the evaporator.



4. For moving the starter panel away from the chiller it is recommended that a fork truck be used. Position the truck so that it is ready to take up the weight of the starter panel. The panel without PFCCs will weigh approximately 600 lbs. (272 Kg). With PFCCs the panel will weigh approximately 750 lbs (340 Kg). The panel is heavy and must be adequately secured before moving.

   Use care to prevent the forks from damaging the enclosure and/or the enclosure finish.

   If the use of a fork truck is not possible, the starter may be supported and lifted away from the chiller using the two lifting eyes that are located on the top of the starter. See the figure below.The proper use of a spreader bar is required. The lifting force applied to the eyes must be vertical. See Figure 3.

   If the starter enclosure is lifted using the eyes then the use of a spreader bar is required. Always use properly rated slings or chains with safety hooks or shackles. Do not allow the angle between the lifting cables/chains and the spreader bar to be less than 45 degrees.

Figure 3

5. Loosen the bolts which secure the starter enclosure to the flange on the motor. Steady the starter as the retaining bolts are removed because the panel may tip forward.

⚠ WARNING

Heavy Objects!

USE EXTREME CARE WHEN MOVING HEAVY COMPONENTS. THE STARTER MAY TIP IF MISHANDLED.
Failure to use caution could result in personal injury or death.

6. Support the weight of the starter panel with the fork truck or hoist/ lifting eyes and carefully remove the starter panel from the chiller.

7. Store the starter panel in a clean and dry location with ample air circulation and heat to prevent condensation from occurring. Always protect the starter from dirt and moisture.

8. When ready, reassemble the panel onto the chiller in the reverse order.

Inspection and Maintenance

Note!

Each UnitMount™ starter is properly adjusted at the factory before shipment. However, vibration and mechanical stresses caused by shipping and installation can affect the starter adjustment. Always inspect the starter before first energizing the starter.

⚠ WARNING

Hazardous Voltage!

There is a hazard of electric shock whenever working on or near electrical equipment. Electric shock may cause injury or death. Turn off all power supplying the equipment before starting the work. Lock-out the disconnecting means using a proper "lock-out or tag-out" system.

PRE-START INSPECTION

With the power to the starter locked OFF, panels on the sides of the starter enclosure may be removed in order to provide improved access to interior components and connections. Each access panel contains several screws that must be removed by working from the inside of the enclosure. Again, always ensure the power to the starter is locked OFF before removing any panels, and always correctly reinstall any removed panels before reenergizing the starter.

Prior to the initial energizing of a UnitMount Starter it is required that the commissioning technician perform an inspection.

Inspect the starter closely for any damage that may have occurred during shipping or installation. Check all hardware for tightness.

Remove any loose dust, dirt, or debris (scraps of wire, tools, etc.) that may have entered into the starter. Use of a vacuum cleaner is recommended.

Ensure no moisture or condensation is present in the starter enclosure.

Perform a vacuum integrity test as described in the maintenance section.

Check the ratings shown on the contactor label. Confirm the indicated control voltage is correct for the application (i.e. 110v/50Hz or 120v/60Hz).

Connect auxiliary control power and sequence the control power signal(s) to "dry-run" the circuit, including closing the contactor with the main power circuits de-energized and locked out. Refer to the maintenance section for instructions to connect auxiliary control power.

Check the insulation level of the starter and record the value for future reference. See the maintenance section.

With the main power to the chiller locked off, check the integrity of the door and isolation switch interlock mechanism. With the starter door open you should not be able to close the isolation switch. With the starter door closed and with the door latch screws fully tightened the isolation switch should operate normally.

With the main power to the chiller locked off, close and open the isolating switch at least three times to check the performance of the operating mechanism. Observe the operation of the switch thru the viewing window.

With the main power to the chiller locked off, check the integrity of the isolation switch and contactor interlock mechanism. Close the contactor using test power (refer to the maintenance section of this manual) and verify that the isolation switch cannot be operated while the contactor is closed. Do not apply excessive force to the isolation switch during this testing or severe damage to the mechanism may occur. If it is desired to test the operation of this interlock with the starter door open it will first be necessary to temporarily defeat the door interlock. To defeat the operation of the door interlock: pull the door interlock lever to the right, an assistant should then pull the latch lever on the handle and operate the switch.

MAINTENANCE AND TESTING

A starter maintenance program should be established as soon as the chiller has been installed and put into operation. After the starter has been inspected several times and the conditions noted, the frequency of inspections can increased or decreased to suit the conditions found. As an absolute minimum, it is recommended that the starter receive a general inspection two or more times a year, and a more detailed inspection at least once a year.

General

The starter must be kept clean and free of dust, dirt, debris, and insects. Use a vacuum to clean the enclosure as thoroughly as possible. Dust in the actual contactor itself can be removed by gently blowing the contactor with dry compressed air that is free from lubricants. Do not use compressed air to clean the remainder of the enclosure because of the risk of pushing debris into critical components.

Verify wiring integrity by grasping each wire and pulling to check tightness.

Visually check for hairline cracks in high stress areas such as the mechanical interlock brackets, contactor baseplate, auxiliary contact mounting bracket, etc.

Inspect for loose joints that produce excess heat and discolor conductors. Verify the insulation has not been damaged by high temperatures. Use care to not over-torque bolts while verifying tightness.

Torque Values

Table 3

Recommended Torque Values for class 8.8 Metric Hardware (unless otherwise specified in the instructions)

Diameter (mm)	Torque (N-m)	Torque (lb-in)	Torque (lb-ft)
4	2.8-3.1	24-27	
5	5.6-6.2	49-55	
6	9.4-10.4	83-92	
8	22.9-25.4	203-225	17-19
10	45.5-50.6	402-447	34-37
12	79.2-88.0	701-779	58-65

Ensure all panels, covers, arc shields, etc. are correctly in place.

Ensure no water is present in the starter enclosure. If water is present, determine it's source and correct it.

Insulation Level Test

Check the resistance between poles and from each pole to ground with a megger meter. The use of a 1000 to 5000 Vdc megger is acceptable. Record all readings. It is not practical to specify an absolute value for this reading since it is dependant on other connected apparatus and conditions of service. However, any unusually low meg readings (below 1 meg per 1000 volts) or an abrupt reduction in a reading when it is compared to previous readings, could be an indication of an issue that requires investigation and correction.

Interrupter Wear Check

The vacuum interrupters used in the UnitMount™ medium voltage starters are designed for a long electrical life. In normal usage up to 300,000 operations may be accomplished before replacement is recommended. If it is desired to check the actual amount of wear in the interrupters it may be accomplished using the procedure given in Cutler-Hammer Instructional Booklet I.B. 48018N.

Vacuum Integrity Test

Because of the extremely high voltages and specialized tools involved in performing a proper vacuum integrity test of the contactor, it is not recommended that the Trane chiller technician perform this test as part of a normal commissioning. If, however, a problem later develops or if it is desired to do this test as a part of a scheduled maintenance program, the Trane technician should only perform this test if he is properly trained and equipped for the task. If this test is desired it is commonly recommended that a Cutler-Hammer technician provide this service. Refer to Cutler-Hammer bulletin I.B. 48018N.

Contact Resistance Test

Because of the high voltages and specialized tools involved in performing a proper contact resistance test of the contactor, it is not recommended that the Trane chiller technician perform this test as part of a normal commissioning. However, if a problem later develops or if it is desired to do this test as a part of a scheduled maintenance program, the Trane technician should only perform this test if he is properly trained and equipped for the task. If this test is desired it is commonly recommended that a Cutler-Hammer technician provide this service. Refer to Cutler-Hammer bulletin I.B. 48018N.

Isolation Switch Maintenance

The isolation switch of the UnitMount™ starter should be inspected and have minor maintenance performed on it at least once a year. During the maintenance Cutler-Hammer conductive grease (C-H part # 7274A48H02) should be applied lightly to the contact surfaces of each break jaw. Avoid placing any lubrication on the insulation. Failure to regularly lubricate the break jaws may result in a failure of the switch to properly open or close. For cleanliness checks, alignment checks, adjustments, and lubrication refer to Cutler-Hammer Instructional Booklet I.B. 48034.

Test Power Connection

The low voltage control circuits of the UnitMount starter are located in the compartment immediately behind the small door on the lower right front of the starter. Inside the compartment are located the CH530 Starter LLID, terminal strips, test power connection, and other low voltage control components.

The control circuits of the UnitMount starter can be checked with the starter isolation switch 'open' (the main power is OFF), and temporary 110/120vac test power connected. Apply the test power using the test plug that is mounted in the low voltage compartment.

Open breaker 2Q1 and remove the test plug from the unwired receptacle that is mounted in the top of the low voltage compartment. Connect 110/120vac test power to the starter's test plug using a good quality heavy-duty polarized extension cord (polarized plugs and cords have one blade slightly wider than the other and can only be inserted one way into the outlet). The other end of the test power extension cord should be connected to a dependable 110/120vac source (i.e. wall outlet) that is capable of providing 15 to 20 amps of service.

With the test power applied the CH530 controls of the chiller will be active. The different starter components can then be exercised and tested using the CH530 (via the proper laptop service tool) to command them. The other chiller components including the oil sump heater and the EarthWise™ purge will also be operational with the test power connected.

When testing is complete and the use of temporary test power is no longer desired, the extension cord should be removed and the test plug re-inserted into the unwired receptacle before closing the isolation switch.

SL Contactor DIP Switch Settings

If issues or problems occur in the operation of the UnitMount™ starter SL medium voltage contactor, it would be recommended to check the DIP switch setting on the contactor's control board and to also check the actual output signal of the control board. The correct DIP switch settings forTrane UnitMount applications are shown below. Refer to Cutler-Hammer Instructional Bulletin I.B. 48018N for more detailed instructions.

Applied Control Voltage

	Switch				
Voltage	1	2	3	4	9
110/50	On	On	Off	Off	Off
120/60	Off	On	On	Off	Off

Ensure the R3 jumper is installed.

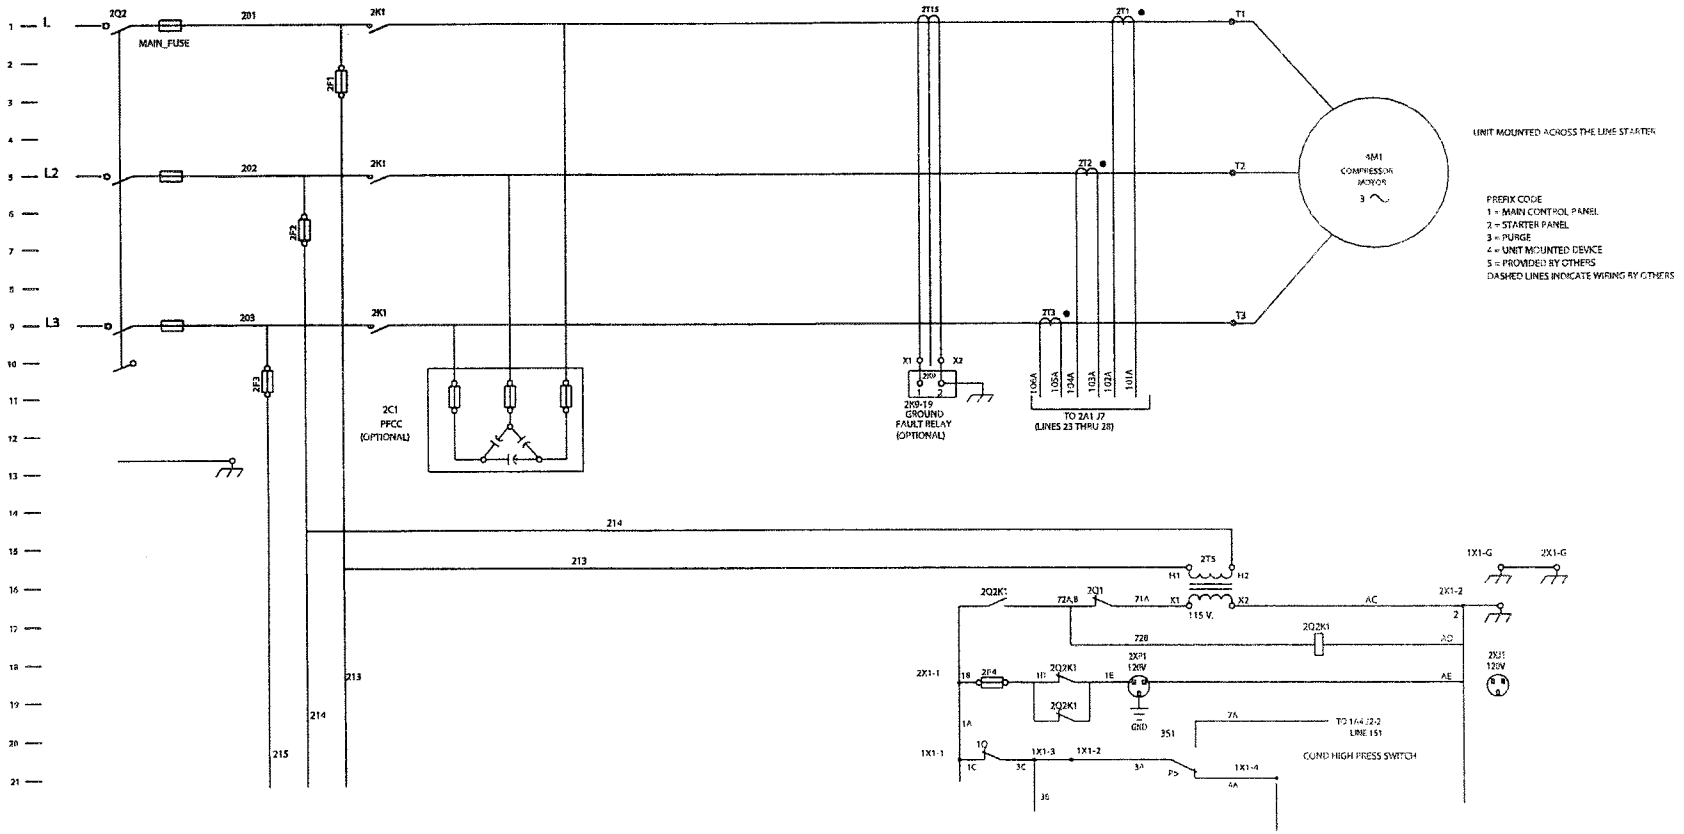
Dropout Time
(the recommended default setting is 50 ms)

Dropout	Switch			
Time	5	6	7	8
30 ms	On	Off	Off	Off
50 ms	Off	On	Off	Off
130 ms	Off	Off	On	Off
250 ms	Off	Off	Off	On

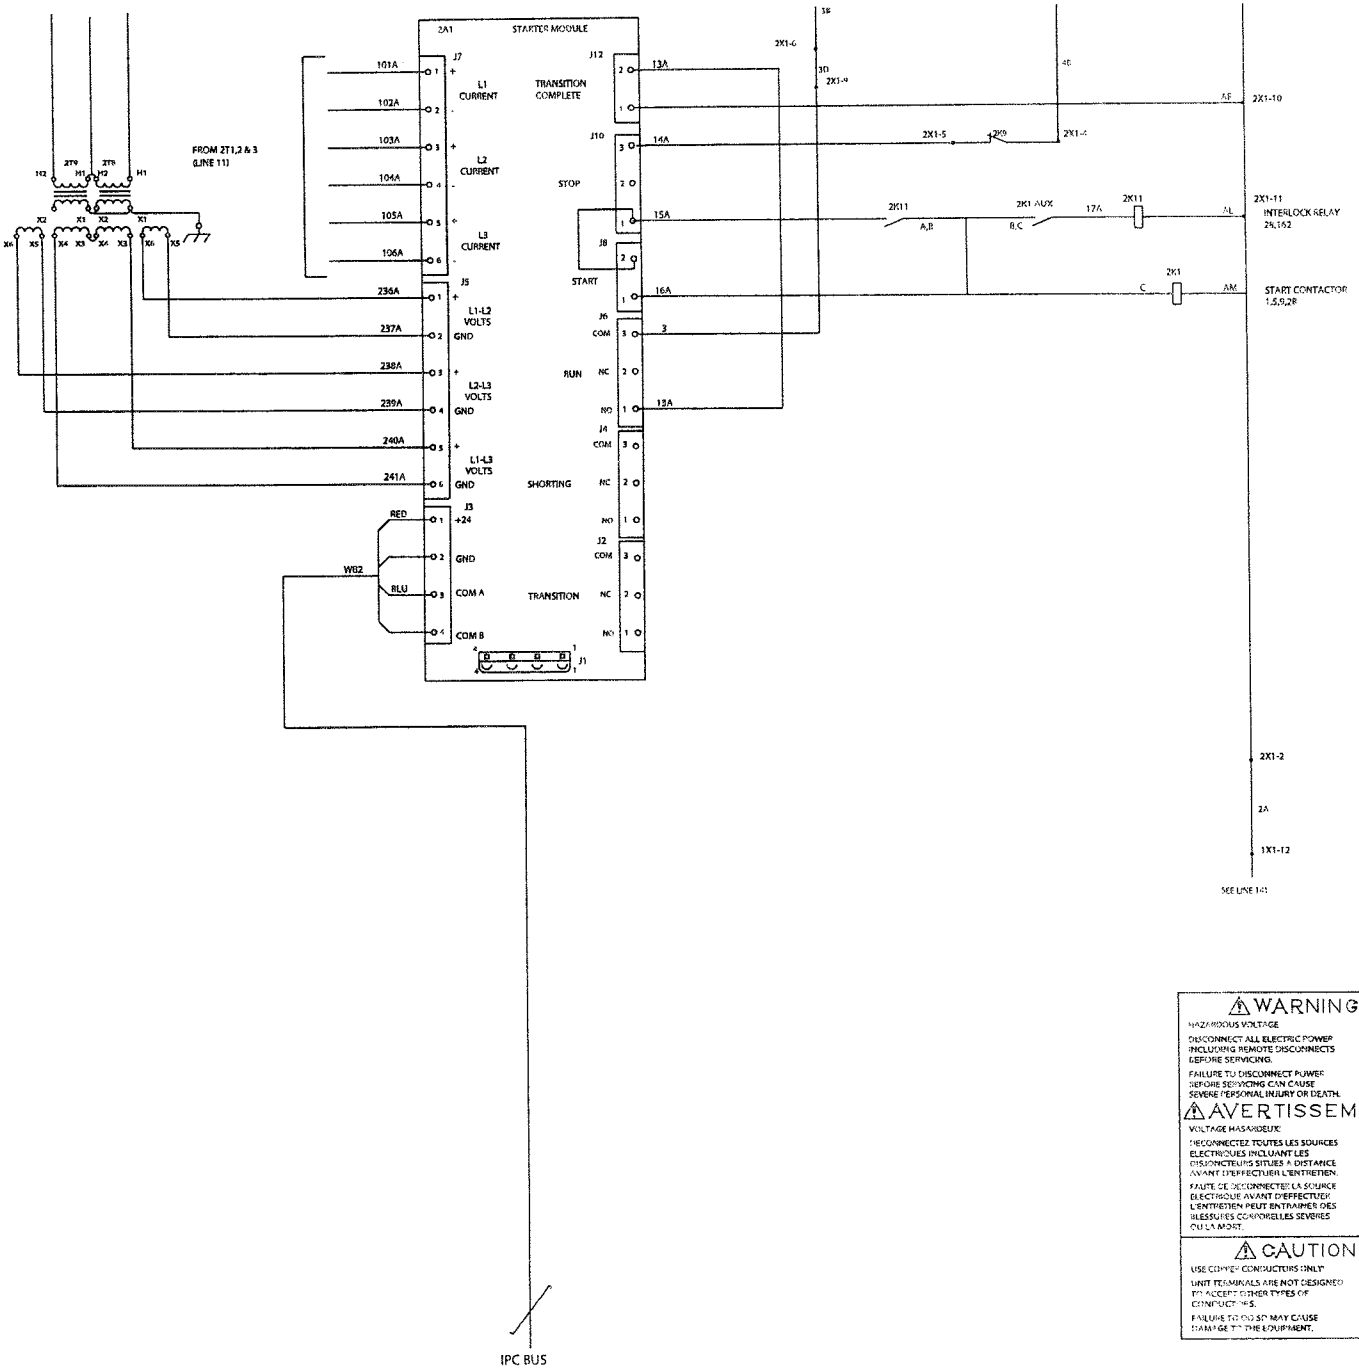
To test the output signal of the SL contactor control board it is first necessary to apply the rated control voltage (110v/50hz or 120v/60hz) across terminals 1 and 2 of the contactor control board (this provides a "start" signal).Terminals 3 and 4 on the contactor control board must remain connected with the factory installed jumper. Measure the DC output voltage across terminals 5 and 6 of the contactor control board. The voltage measured should be 9 to 16 vdc. If voltage is not found the board must be replaced.

Across the Line Starting Sequence – Trane CH530 Control

On a call for cooling, the CH530 chiller control will begin its starting sequence. For the starter, the CH530 first confirms that its transition complete input signal is not present. Note: even though an across the line starter does not have a true transition, the CH530 still requires the use of a transition complete input signal as part of it's method of confirming the motor has accelerated. If the transition complete input signal is found, the diagnostic "Transition Complete Input Shorted" will occur and the start sequence will be aborted.



If the transition complete input signal is not found, the CH530 will continue with the starting sequence by closing it's "Stop" and "Start" relays on the Starter module 2A1. Control power will flow through the Starter module contacts to the 2K1 contactor, which will energize and close it's contacts. An auxillary switch on 2K1 will be closed by the action of 2K1, and allows power to flow to holding relay 2K11, 2K11 closes its contacts and locks itself and 2K1 into an energized state. The "Start" relay on the Starter module will open it's contacts 2 seconds after being closed, but the contactor 2K1 will remain energized because of the action of holding relay 2K11. The "Stop" relay on the Starter module remains closed whenever the compressor is running.



After closing contactor 2K1 the CH530 monitors the motor amp draw. The CH530 determines that the motor has successfully accelerated when the amp draw drops to less than 85% of unit RLA for 1.5 continous seconds. For most across the line starter applications the total time to accelerate the motor is typically less than 6 seconds. A maximum allowable acceleration time limit can be set in the CH530 control and is usually set at 6 seconds. If the acceleration of the motor is not confirmed within this time after closing contactor 2K1, the diagnostic "Compressor did not Accelerate – Shutdown" will occur and the start sequence will be aborted.

If acceleration is confirmed within the allowed time, the CH530 will then close its "Run" relay contacts on Starter module 2A1. Closing the Run relay contacts will apply control power to the Transition Complete input of the Starter module and the starting sequence is complete. If the Run relay or the Transition Complete inputs fail to achieve the correct state a "Starter did not Transition" diagnostic will be called out and the chiller will be stopped.

Summary of Proposals
Sheraton Grand Hotel

1. RTHA-350 – reconditioned chiller installed $58,453.00 + tax

2. Option on Proposal One – Replace bypass valve on cooling tower #3. Parts provided by customer. Replace 8" valve in bypass line. Use existing actuator. Install four (4) 8" isolation valves in condenser water piping. This will isolate the two condenser water loopss. Work to be done after hours. Install frequency drive with bypass on #3 condenser water pump. This will allow chiller to start with cold tower water. Price includes temperature controls to control drive.
$10,509.00 + tax

3. Automation tie-ins to RTHA-350 $ 1,800.00 + tax

4. Refrigerant Monitor installed and tied in to CSI part of ASHRAE 15-1992 $ 7,220.30 + tax

5. Chiller room exhaust system final part of ASHRAE 15-1992 $ 5,261.00 + tax

6. Replacement of AHU 8 & 9 and duct changes including CSI tie-ins $38,990.00 + tax

7. Building B exhaust fans per STR-3569 - Changes to motor starters per Sam Toub $21,731.00 + tax

Payment Terms: 30% upon acceptance, 40% upon equipment delivery, 30% upon completion.

General Service Bulletin

CH530 Software Mandatory Retrofit for All Field Units

CVHE, CVHF, CVHG

ORDER No: **CVHE-SVB09A-EN** DATE: July 31, 2002

Introduction

The purpose of this bulletin is to advise customers of a problem associated with Tracer CH530 Controller used on CenTraVac™ units. This bulletin is to inform the field of the failures and to describe the corrective action. Typical product applications include the CVHE, CVHF and CVHG family of chillers. The action described in this bulletin is being taken to address a equipment hazard concern.

NOTICE: Warnings and Cautions appear at appropriate sections throughout this literature. Read these carefully.

⚠ **WARNING** *indicates* a potentially hazardous situation which, if not avoided, could result in death or serious injury.

⚠ **CAUTION** *indicates* a potentially hazardous situation which, if not avoided, may result in minor or moderate injury. It may also be used to alert against unsafe practices.

CAUTION *indicates* a situation that may result in equipment or property-damage only accidents.

© 2002 American Standard Inc. All Rights Reserved

Discussion

CAUTION

Equipment Damage!

Due to software failure DynaView™ controllers are locking up. While in this locked up state the compressor is off which creates operation problems such as all the oil being pumped out of the sump. Failure to download new software could result in equipment damage.

The potential for this hazard is severe oil pump and compressor damage.

Operational Problems are:

- DynaView Main Processor Lockups; Oil Pump remains ON after post lube, and Display does not report valid information.

  The Main Processor problem occurs randomly during chiller post lube shutdowns. The oil pump will be found running after the post lube time expires. This problem only occurs when the Earthwise™ Purge is in Auto or Stop. **To temporarily avoid the potential problem select ADAPTIVE Purge mode (Default) until new software can be downloaded.**

- Purge Liquid Level nuisance alarms; chillers are encountering many "High Liquid level warnings and alarms". The purge software has been modified to prevent these nuisance indications.
- AFDD Inlet Guide Vanes and Drive Speed Stability (Hunting). The rate of motor speed change has been modified to better match the rate of IGV changes.
- Additional enhancements with the new software:
  Gauge Refrigerant Pressure choice on DynaView
  Improved Restart Inhibit Feature

CTV Main Processor 4.0 Software (6200-344-04-00) Details

1) Chiller :

a) Corrected the Main Processor lockups as seen in the field. (Root cause was discovered to be caused by a purge control function. See Purge item a)
b) Add new restart inhibit function.
c) Added new setpoints for Restart Inhibit Free Starts, Restart Inhibit Start to Start and, Restart Inhibit Diagnostic enable/disable.
d) Added gauge/absolute switch to pressure display for DynaView
e) Added Amps and Volts to the ASHRAE Chiller Log menu.
f) Added a new sub-mode for min capacity time remaining.
g) Change HGBP Valve Travel Time setpoint max to 180 seconds.

2) **Purge:**
   a) Set the processing of the Purge Liquid Level Switch transitions. This corrects the MP lockups seen in the field.
   b) Corrected the nuisance Purge Liquid Level Too High diagnostics being seen in the field by changing;
      - Purge Liquid Level Too High Warning diagnostic being called out from 30 seconds to 20 minutes
      - Purge Liquid Level Too High Continuously diagnostic being called out from 15 minutes to 20 minutes.
      - Purge Liquid Level Too High Continuously diagnostic being called out with four warnings in 2 hours to four warnings in 4 hours.
   c) Auto carbon regeneration is no longer allowed in Purge stop mode. Previously it was allowed in all modes. Manual carbon regeneration while in the Purge stop mode can be initiated from TechView™.
   d) The Purge Carbon Regeneration Temperature Not Satisfied diagnostic is now called out at the Carbon Regeneration Temperature setpoint - 30 F and lower after 4 hours. It used to be called out at the Carbon Regeneration Temp setpoint and lower. If the Purge Carbon Regeneration Temperature Not Satisfied diagnostic occurs, regeneration cycle will now continue as if it met the setpoint. Regeneration cycle used to stop upon occurrence of the diagnostic.

3) **AFD/IGV Control:**
   a) AFDD Chillers- AFD/IGV Control: These items will correct the "hunting" issue being seen in the field on AFD chillers.
- Implemented scaling factor between IGV/AFD Control.
- Filtered the IGV/AFD speed change in response to field data.
- Added filter to slow down AFD speed changes. This allows time for the IGV to position before the speed suddenly changes.
- Surge recovery algorithm now increases speed 1 Hz every 5 seconds.
- Added minimum pressure coefficient setpoint to TechView. Compressor is not allowed to drop below minimum pressure coefficient at startup.

Repair Procedure

Install CTV Main Processor Software, version 4.0 and associated TechView™ Software version 4.03 posted to TRANE.COM July 17, 2002.

Please note that this retrofit applies to already STARTED chillers, chillers not already started can be software upgraded as part of the normal startup.

If the unit has started prior to the software release arrangements should be made to immediately complete the retrofit.

Parts Ordering Information

No parts need to be ordered.

Material Disposition

No disposition necessary in the field.

Product Changes

All CVHE, CVHF, CVHG units shipped after July 17, 2002 will have new CTV Main Processor Software, version 4.0 installed.

General Service Bulletin

Rockwell water cooled AFDD liquiflow 1.5 PIC board field repair on 350, 450, 600, 750 & 1000 HP drives (CVHE, CVHF, CVHG Units)

ORDER No.: **CVHE-SVB10A-EN** DATE: October 2002

Introduction

The purpose of this service bulletin is to advise you of modification that needs to be made to the power interface control board (Pic).
This repair should be made at unit startup. If already started and running the unit is fine and the retrofit is not mandatory.

Discussion

CAUTION

Equipment Damage!

Components on a Power Interface Control Board could be damaged by isolated voltage spikes. Damaged components may cause failure of the Pic Board.

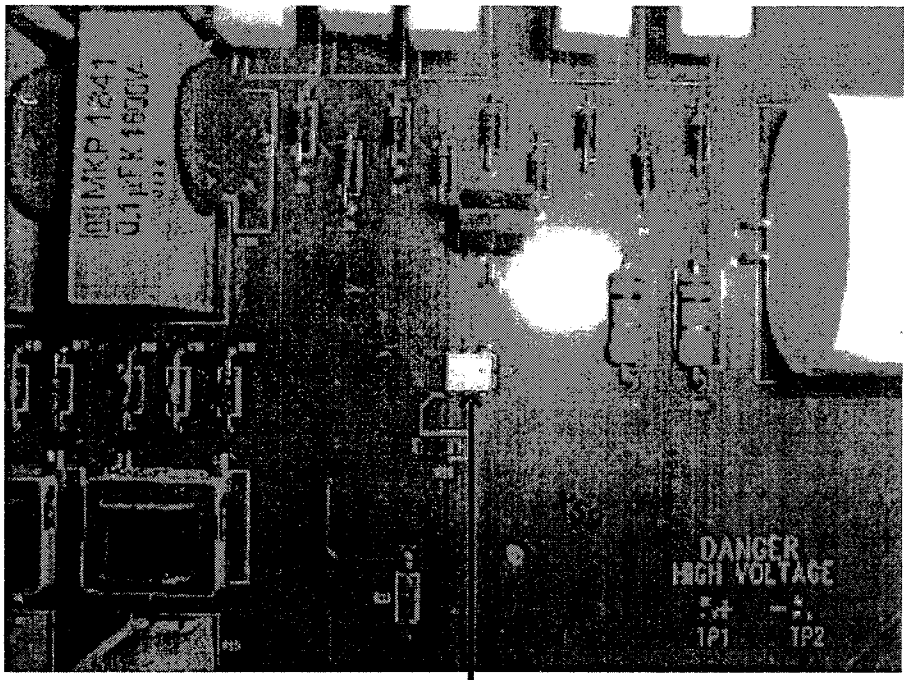
This is potential equipment damage and corrective action must be taken as soon as possible.

The liquid water-cooled adaptive frequency drive, Liquiflow 1.5 AFDD, has an electronic board in the drive called the Pic board that needs field modification. This is the Power Interface Control Board (Pic).

It has been determined that in a few isolated instances, that when high input line voltage conditions exist along with variations with board components on the Pic board component failures on the board may occur due to voltage spikes. The spike has in some cases damaged components causing failure of the Pic board.

If the board fails you typically get a diagnostics of Low DC buss.

When you look at the board, (Figure 1 and Figure 2), there is a component called a opto-coupler. It is a small square white part approximately ¼" square.



LiquiFlo1.5 Power Interface Controller (PIC) PCB Assembly Optocoupler Removal

Removal of the optocoupler referenced as U2 on the following PIC PCB assemblies is required for proper operation:

Rockwell Part #	Description
179561	600Hp LiquiFlo 1.5 Drive
179843	450Hp LiquiFlo 1.5 Drive
179844	350Hp LiquiFlo 1.5 Drive
179845	1000Hp LiquiFlo 1.5 Drive

The optocoupler is located in the center of the board, as shown in the following pictures:

Figure 1: Close-up View of U2 Location

Procedure

WARNING

⚠ Hazardous Voltage!

1. Remove all power from the drive and allow the DC bus to discharge.

© 2002 American Standard Inc. All rights reserved.

CAUTION
Static Electricity

Use a grounding wrist strap which is fabricated with a current limiting resistance for static control. Do not contact grounded objects other than through the wrist straps.

Failure to use it properly can result in static electricity damage.

2. In this retrofit, the PCB can remain mounted while performing the necessary procedures. However, utilize proper grounding procedures when working with the Printed Circuit Board.
3. Locate PIC board on respective drive (please reference manual for board location).
4. Remove the component U2, by clipping each of the six (6) pins on the topside at the board level.
5. Verify that none of the remaining pins are able to short together.
6. Confirm all ribbon cables are connected properly and reapply power.

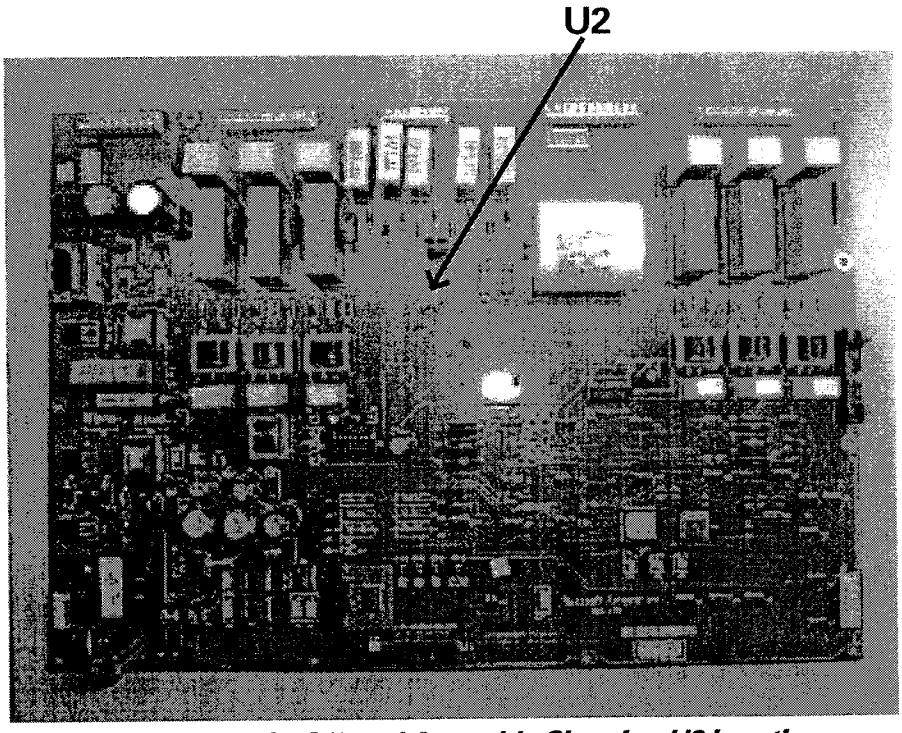


Figure 2: Full view of PIC Board Assembly Showing U2 Location

If the unit has not been started, this opto-coupler needs to be removed. If the unit has already been started it does not have to be removed. The opto-coupler switches a bleeder resistor in and out of the circuit. When we remove it we disable the function so the bleeder resistor is always in the circuit to dampen short voltage spikes at startup.

No functionality is sacrificed by removal of the U2 coupler. All future production Pic boards will have the U2 coupler removed. Pic boards that have been revised will have a revision of Rev 05 shown on the board. Boards that need to have the U2 opto-coupler removed will show a Rev 04 on the board.

Repair Procedure

WARNING

⚠ Hazardous Voltage!

Disconnect all electric power, including remote disconnects before servicing. Follow proper lockout and tagout procedures to ensure the power can not be inadvertently energized. Failure to disconnect power before servicing could result in death or serious injury.

Procedure:

- Remove all power from the drive and allow the DC bus to discharge.
- Utilize proper grounding procedures when handling printed circuit boards
- Locate PIC board on the respective drive (please reference your manual for board location)
- Remove the component U2, by clipping each of the (6) pins on the topside at board level.
- Verify that none of the remaining pins are able to short together.
- Confirm all ribbon cables are connected properly and reapply power.

Parts Ordering Information

No parts to be ordered.

Units Affected

Rockwell water cooled AFDD liquiflow 1.5 PIC board field repair on 350, 450, 600, 750 & 1000 HP drives.

Supersedes	New

Subject: CVHF Economizer Mandatory Retrofit

Introduction:

The purpose of this bulletin is to address a potential problem with economizer vibration on Model CVHF centrifugal chillers.

Discussion:

The CVHF economizer under some load conditions may exhibit excessive vibration. This vibration may result in the economizers developing cracks in the economizer shell. The cracks are found in the heat stressed area of the shell, around the vent pipe going to the compressor. **A list of units that need to be retrofitted will be sent to the office service manager under separate cover.**

Units Affected:

All CVHF units manufactured before August 5, 1993 or units that do not have bracing on both ends of the economizer and a reinforcement collar around the vent pipe going to the compressor may exhibit this vibration. Not all units are affected, but all units will have the extra bracing installed for added protection. Any CVHF unit meeting the above criteria must be retrofitted.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Mandatory Retrofit Procedure:

To reduce the potential for vibration of the economizer, engineering has developed bracing to be installed on each end of the economizer. The bracing is welded to the condenser and the economizer and bolted in the middle for removal. To reinforce the shell area around the vent pipe going to the compressor, a collar is to be welded around the pipe and welded to the pipe and the shell.

- If the unit contains refrigerant; remove it using proper recovery procedures.
- Bolt condenser bracket to economizer bracket using 7/16" bolts.
- Weld bracket (Figure 1) to condenser shell on each end of economizer. Refer to Figure 3
- Weld bracket (Figure 2) to both end plates of the economizer. Refer to Figure 3
- Weld reinforcement collar (Figure 4) around the vent pipe running from the economizer to the compressor. Refer to Figure 5

Note: After welding on the economizer pipe it is recommended that the bolts in the economizer to compressor flange be re-torqued. Welding on the pipe may cause the bolts to loosen.

- Leak test at repair areas and at motor/vent line flange.
- Evacuate and recharge unit using proper charging procedures.

Note: Refer to CTV-SB-60E to check proper charge of unit. Do not rely on the units name plate charge information. Several CVHF machines in the field were discovered to have the wrong charge information on the nameplate. An overcharge may intensify economizer vibration levels.

Parts Ordering Information and Authorization:

The appropriate items listed below are authorized to complete the retrofit on each affected CVHF in the service agencies area of responsibility. The required parts may be ordered through Trane Service Parts using the following Mnemonic numbers. Refer to Tables 1 - 3.

Subject: CVHF/CVHG Circuit Module Chip Retrofit on CVHF/CVHG Units

Introduction:

The purpose of the Circuit Module chip retrofit is to keep the oil heater energized during the compressor run cycle for early production refrigerant and oil pump centrifugal chillers.

Discussion:

The initial production run of CVHF and CVHG centrifugal water chillers that used the refrigerant/oil pump incorporated a 17-coil 5/8-inch outside diameter copper oil cooler coil located in the economizer. This oil cooler arrangement provided more than required oil cooling which can result in low oil tank temperatures during the compressor shut down sequence. Since the oil tank heater is de-energized during the compressor run cycle, as the unit goes through post lube additional oil cooling takes place before the oil tank heater has a chance to bring the oil temperature up while the compressor is idle. This can result in oil tank temperatures which fall below the 100 degree F threshold and will prevent the chiller from starting in a timely fashion. This problem has been addressed in production with the installation of a 9-coil 5/8-inch copper oil cooler coil instead of the original 17-coil oil cooler. For the refrigerant/oil pump units built with a 17-coil oil cooler, a circuit module retrofit chip is required to help keep the oil temperature from dropping below 100 degree F on unit shutdown. This chip keeps the oil tank heater energized whenever control power is provided to the chiller, both during compressor run and while the compressor is off.

Recommended Action:

Order one KIT07287 for each affected unit. This kit contains a circuit module chip, a ground strap and installation instructions. Install the chip per the instructions supplied in the kit.

Material Authorization:
One KIT07287 for each affected unit.

Material Disposition:
The old chip can be scrapped in the field.

Units Affected:
All CVHF and CVHG centrifugal units with the refrigerant/oil pump that incorporate a 17-coil oil cooler located in the economizer. For the CVHF, this includes units with the refrigerant/oil pump up to but not including design sequence "1P" and for the CVHG units with refrigerant/oil pump up to but not including design sequence "1G". The approximate date of manufacture for these units was January, 2000 to July, 2000.

Parts Ordering Information:
Order one chip per each unit through the PRIDE system, La Crosse Service Parts.

KIT07287, Circuit Module Chip

Production Changes:
No production changes are required at this time.

Labor Authorization:
This bulletin authorizes one hour of labor at standard labor rates to accomplish the chip changeout. No travel time authorized.

Expiration Date:
The expiration date of this mandatory retrofit is **May 31, 2001**.

General Service Bulletin

CTV-SB-19D

Library	Service Literature
Product Section	Refrigeration
Product	Centrifugal Liquid Chillers
Model	CTV
Literature Type	General Service Bulletin
Sequence	19D
Date	May 6, 1993
File No.	SV-RF-CTV-CTV-SB-19D-593
Supersedes	CTV-SB-19C-(589)

Literature Changes:

CTV-SB-19A (10/81) - Original issue of bulletin.

CTV-SB-19B (2/87) - Changed recommendation for all oil to be used in all CenTraVac© compressors (excluding CVHCs and LOCVs).

CTV-SB-19C (5/89) - Bulletin revised to include oil additive information and incorporate oil recommendations for Model RTHA Series R CenTraVac© (Table 1).

CTV-SB-19D (5/93) - Bulletin revised to remove RTHA and air cooled CenTraVac© information, recommend oil filter piping modifications.

Subject: Recommendations for: Oil Analysis, Oil Types, Oil Changes and Horizontal Oil Filter Modification On Centrifugal Compressors

Introduction:

This service bulletin provides specific recommendations for oil analysis programs, recommended oils and oil charges for Trane centrifugal compressors. It also gives recommendations for oil filter modifications, to the horizontal position.

Discussion:

The Trane Company recommends use of an oil analysis program with all Trane CenTraVac©s to determine the condition of the oil and the compressor motor bearings. When properly applied, an oil analysis program--such as the one provided by Trane/Service First---can be an important preventative maintenance tool for diagnosing the condition of the unit bearings.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Regardless of what oil analysis program is selected, it must be individually tailored to suit the specific requirements of the job in terms of sampling frequency and the types of analysis performed. When requested, Trane/Service First will suggest appropriate oil sampling intervals for a particular unit installation based on job site conditions.

Since oil analysis programs monitor changes in levels of wear metals and other contaminants in the oil over a long period of time, it is important that the oil samples taken are representative; that is, the samples must indicate actual increases in quantities of contaminants like wear metals. Let's look at an example. Ideally, when the oil charge is removed from a unit, the inside of the sump should be cleaned. If the oil charge is simply replaced without cleaning the sump, a certain percentage of the residue including wear metals remains in the unit. Therefore, the next oil sample taken for analysis will not only include contaminants produced since the last oil sample, but also an unknown amount of residue from unit operation prior to that time. This makes it very difficult to establish exact increases in wear metals, and lessens the ability of oil analysis to predict actual wear rates.

Keep in mind that The Trane Company does not recommend annual replacement of CenTraVac compressor oil when: (1) an oil analysis program is in use, and (2) the oil's acid and moisture content is maintained within acceptable levels. Oil analysis results will indicate whether or not the unit's oil charge should be replaced. However, it is important to change the unit oil filter on a yearly basis.

Oil Filter Modification:

To minimize oil loss and refrigerant vapor release it is recommended that the oil filter system be modified to utilize a screw on filter in the horizontal position. In addition to the horizontal oil filter, a refrigeration valve is installed on the top of the assembly. This refrigeration valve will be used for oil sampling.

Refer to figures 1 and 2 for illustration of the following parts:

A) 1 - 3/8 inch ball valve, Apollo number 70-802-3/8 or VAL 4260
B) 1 - 1/2 inch 3 way valve, Apollo number 70-903-1/2 or VAL 4261
C) 1 - 3/8 inch NPT refrigeration angle valve or VAL 0031
D) 1 - Tee
E) Modified oil filter top assembly. The existing oil filter top assembly can be field modified, refer to figure 2 or order new oil filter top (COV 2131).
F) Oil Filter
Oil Filter Bracket (BRK 1804)

Note: If valves with handles are used, remove handles to prevent tampering after installation is complete.

See figures 3 through 7 for key points of modification.

 © American Standard Inc.

Figure 1 - Recommended Modifications.

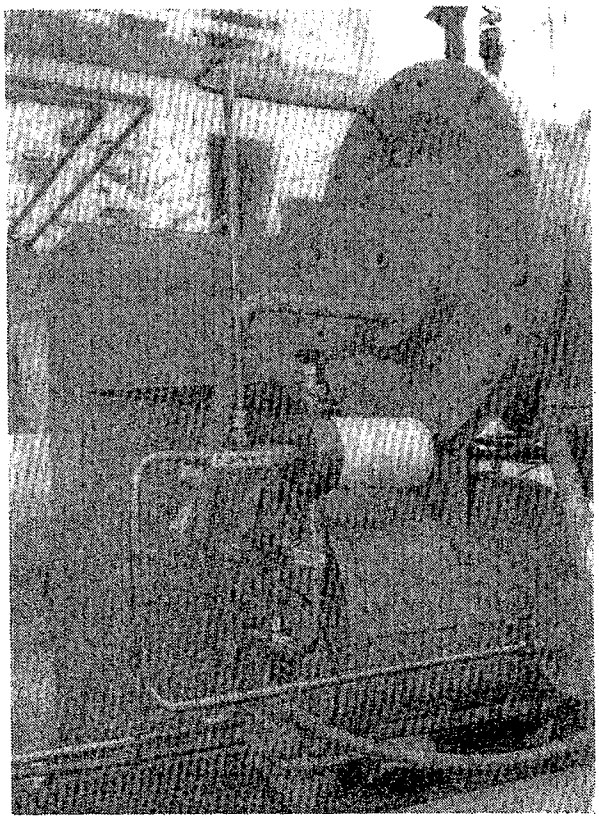

Figure 4 - Modified Oil Filter Top Assembly. Refrigeration Valve on Top.

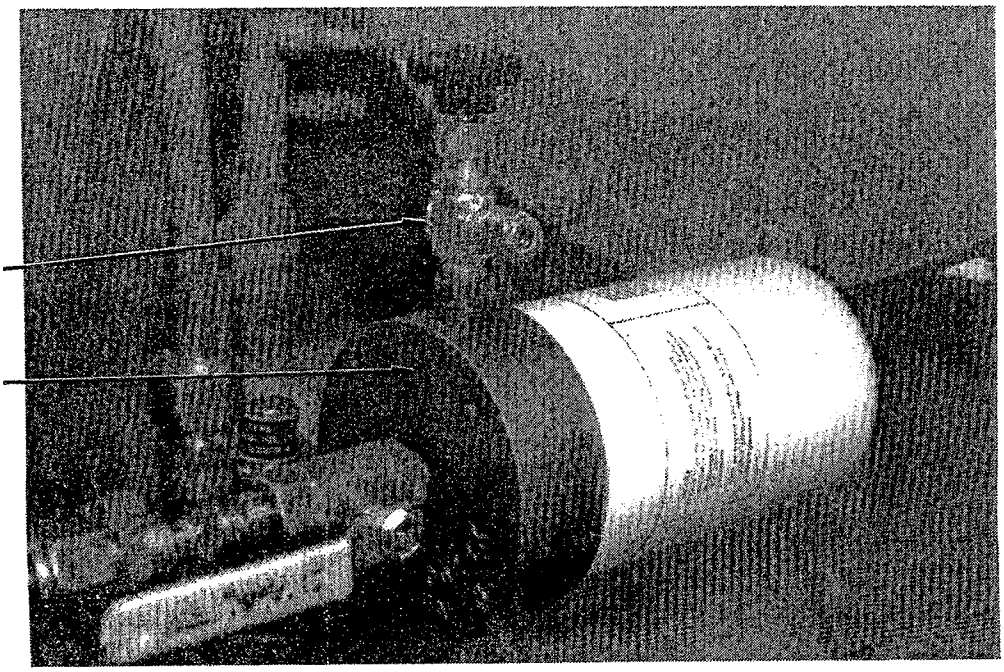

Figure 5 - Three-Way Valve Installed Between Oil Regulator and Oil Filter. Tee Installed Between Oil Regulator Relief Line and Three-Way Valve.

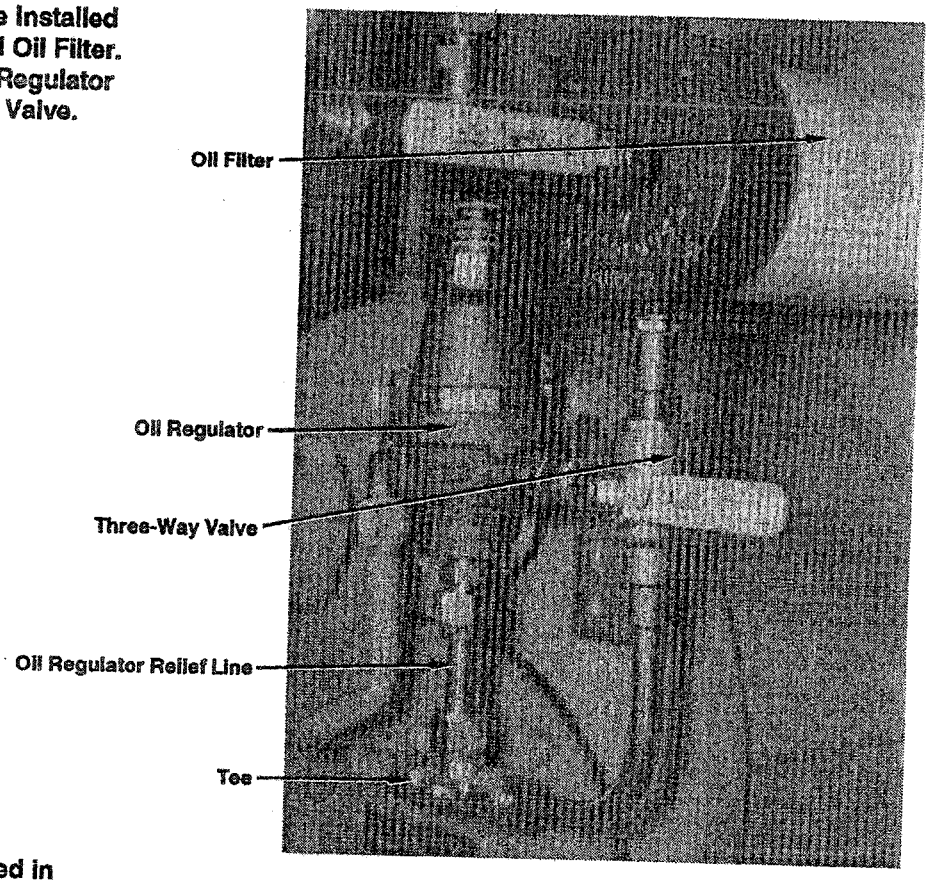

Figure 6 - Hand Valve Installed in Supply Oil Line.

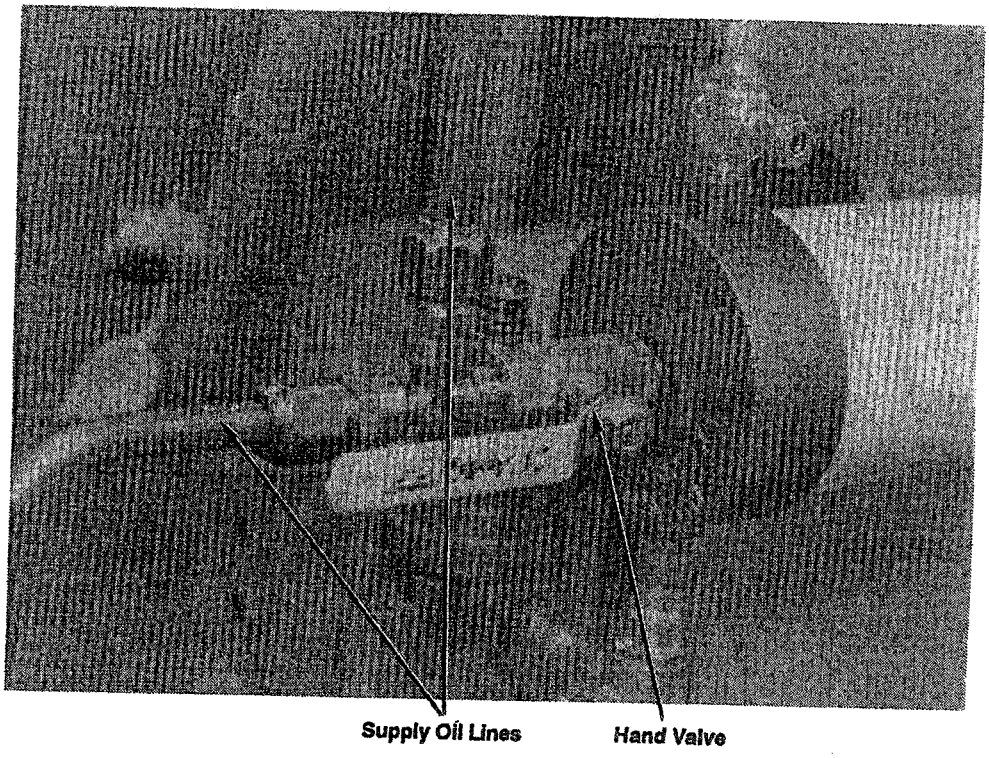

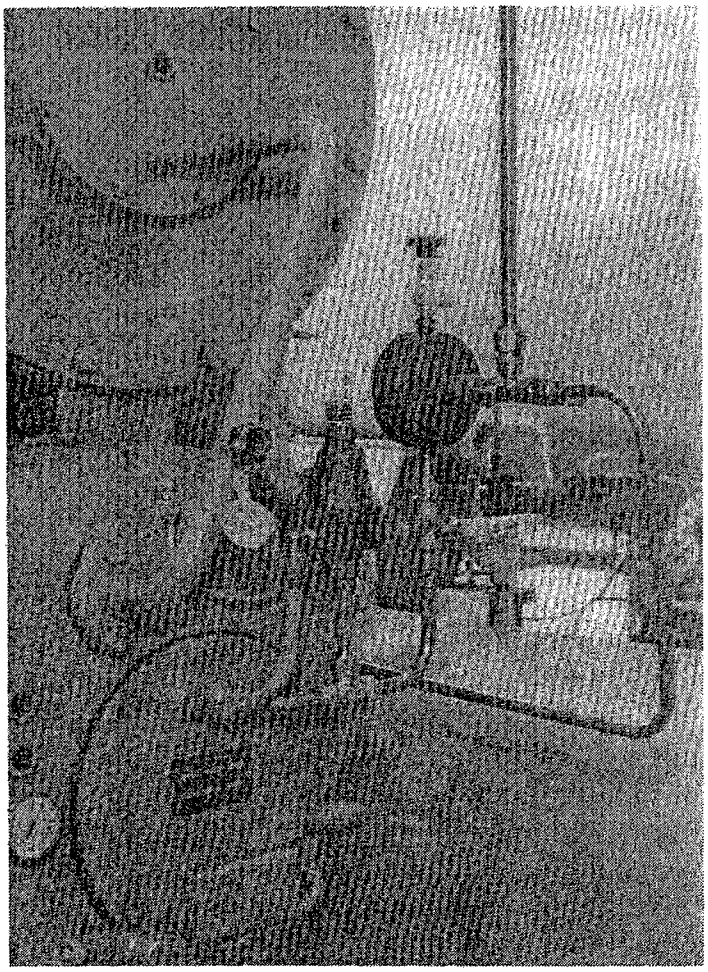

Figure 7 - Overall View of Modification

Oil Sampling Technique:

To ensure an accurate and useful oil analysis, follow these guidelines.

It is strongly recommended that only approved sample bottles be used for oil analysis. Special pre-labeled sample bottles are available from Trane/Service First upon request. The oil sample bottle used must be clean, dry, and free of any contamination.

A minimum of 4 fluid ounces of oil is required for analysis.

Make sure the centrifugal unit has been operating for 30 minutes or more. This will ensure the oil is well circulated.

With centrifugal unit operating, collect oil circulated to the bearing through the lubrication system. The recommended sample location is the 3/8" refrigeration angle valve (Valve C) on the oil filter top assembly. See Figure 1.

Do not collect oil samples from the charging valve on the oil tank.

Send oil samples in for analysis as soon as possible. Do not store oil samples; since moisture may infiltrate the sample container and distort analysis results.

Oil Filter Change:

These instructions are for changing a screw-on type oil filter in the horizontal configuration. Other filter arrangements will require different methods for change out. Whatever method is used, it is very important to minimize the loss of oil and the release of refrigerant vapor.

1. Turn compressor and oil pump motor off.

2. Turn three-way valve handle (Valve B) to a 45 degree position from the normal operating position.

Note: During normal operation the handle of 3-way valve should be in the horizontal position,or in a position to allow oil flow from the oil regulator into the oil filter.

3. Close 3/8" ball valve (Valve A).

Note: With the three-way valve handle set to a 45 degree position and the 3/8" ball valve closed, the oil filter will drain into the sump. Allow the oil filter to drain for a minimum of 30 minutes.

4. Open the 3/8" refrigeration angle valve (Valve C). Quickly rotate the three-way valve handle (Valve B) to a 90 degree position from the normal operating position. This isolates the oil filter and diverts oil flow from the oil regulator back to the oil sump.

5. Close 3/8" refrigeration angle valve (Valve C).

6. Remove and replace oil filter.

Note: Dispose of used oil filter per applicable federal, state and local regulations. Refer to CFC-Guide-2.

7. Open 3/8" ball valve (Valve A) and return three-way valve handle (Valve B) to 0 degrees (handle in the horizontal position or in a position to allow oil flow from oil regulator into oil filter.).

8. Restart centrifugal unit.

Chiller Service History

Background information about the chiller also impacts the oil analysis program. The attached "Refrigeration Oil Sample Identification" form (which must accompany any oil sample sent to Trane/Service First for analysis) is essentially a questionnaire that requests specific, pertinent facts about the chiller's operating characteristics, maintenance history and past repairs. It also asks specific questions about the accompanying oil sample: why it was taken, where it was drawn from the chiller, the brand of oil used, how much oil was added since the last oil change; etc. Especially critical for an accurate oil analysis are: (1) the date of the last oil change, (2) chiller operating time (hours and months) since the last oil change, and (3) the number of starts since the last oil change. (These questions are printed in red on the actual form, and are shaded on the example attached.)

To obtain copies of the "Refrigeration Oil Sample Identification" form, contact Trane/Service First; at 4500 Morris Field Drive, Charlotte, North Carolina 28208.

Recommended Oils

The physical and chemical properties of lubricating oils are important to the life and reliability of mechanical equipment. In refrigeration systems, these properties are uniquely important because the lubricating oil is exposed to the refrigerant used in the system.

Specific properties that determine an oil's suitability for use in a refrigeration system are its lubricity, chemical stability, solubility, aniline point, and absence of contaminants -- particularly moisture. Chemical stability affects the rate at which an oil discolors and forms acids in the presence of refrigerant, air, moisture and heat. Solubility affects the amount of refrigerant that can be absorbed into the oil; an elevated concentration of refrigerant in the oil can cause excessive foaming during equipment start-up. Aniline point is another important chemical characteristic because it indicates the effect of the oil on o-rings.

Tests of commercially available refrigeration oils have revealed unacceptably wide variations in product properties--primarily stability, solubility and contamination. In at least one case, it appears that an oil sold under a particular brand name and number was actually refined by several different vendors, each providing a product with substantially different characteristics. Contamination--especially by moisture--was prevalent in these tests, particularly in instances where the oil was repackaged (evidently using improper procedures), or allowed to stand in 55-gallon drums.

Also, because manufacturer specifications for commercial oils are often so generalized or incomplete, an oil's suitability for use in refrigeration systems cannot be verified.

For these reasons, Trane has discontinued its earlier brand name approvals for oils to be used in its CenTraVac compressors, and recommends that Trane-name oils be obtained from its parts distributors. Trane brand oils are purchased and tested to assure compliance with Trane's specifications, and are carefully repackaged in convenient containers using proper procedures.

Table 1
Recommended Oil Charge Quantities and Oil Codes

CenTraVac Chiller Model	Unit Oil Charge	Oil Code
CTV (old style)	11.0 gallons	OIL-22
CV6A thru 8C	7.0 gallons	OIL-22
CV9A thru 12F	10.0 gallons	OIL-22
CVHA	7.0 gallons	OIL-22
CVHB 060 thru 080	7.0 gallons	OIL-22
CVHB 095 thru 155	10.0 gallons	OIL-22
CVHD	13.0 gallons	OIL-22
CVHC	55.0 gallons	Mobil DTE Light (1)
LOCV	55.0 gallons	Mobil DTE Light (1)
OCV	10.0 gallons	OIL-22
PCV	7.0 gallons	OIL-22
CVHE	7.0 gallons	OIL-22
CVHF	7.0 gallons	OIL-22

Note:
(1) Mobil DTE light is the only oil acceptable for use in the large, Trane LOCV and CVHC CenTraVacs.
(2) Trane Oil-22 is also acceptable for use in the crankcase of Trane belt-driven purge compressors.

Additives

The Trane Company does not recommend the use of commercially available oil additives which are advertised to increase oil lubricity and /or improve heat transfer efficiency when added to the system. The possible effects that such oil additives may have on oil breakdown, acid formation and their long-term impact on elastomers and motor insulation materials has not been substantiated by laboratory tests or field-usage history. Normal product design life and efficiency can be assured only by using Trane-recommended products and by following all recommended maintenance procedures. Liability for any detrimental effects that the use of non-approved products may have on equipment performance or longevity must be assumed by the equipment owner, equipment servicer or the oil additive manufacturer.

With Trane oil, the user is assured of an uncontaminated oil that possesses the characteristics necessary for the intended application.

Note: The only oil recommended for use in all Trane CenTraVac chillers (excluding Models CVHC and LOCV) is Trane OIL-22; see Table 1

Summary

To assure accurate, useful oil analysis results:

1. Always obtain the sample from the oil supply line while the machine is running and take it from this same location every time the oil is sampled!

2. Fill out the "Refrigeration Oil Sample Identification" form completely! Do not omit any of the requested information on the assumption that Trane/Service First already has the necessary data. Insufficient data can lead to the misinterpretation of analysis results!

3. Use clean sample bottles. (Trane/Service First will supply these on request.)

4. Send in the sample immediately after taking it from the machine.

Note: A form (order no 1-27.85) explaining the importance of an oil analysis program is available from The Trane Company, and can be attached to the chiller for operator reference.

TRANE™

REFRIGERATION OIL SAMPLE IDENTIFICATION

(Attach to each sample for shipment)

Ship samples in any clean, dry, well sealed unbreakable plastic bottles (supplied upon request). A minimum of four fluid ounces of oil is required for analysis. Obtain samples while the machine is running. Flush all pipes, tubes, valves, etc., **before collecting** a sample. **Collect only the oil which is being circulated in the lubrication system. Avoid oil from dead spots and non-flowing areas.** We suggest installation of a permanent sampling valve.

Identification

The following information is requested for purposes of proper sample identification and analysis, and to allow meaningful interpretation of analytical results:

Job Name _____ Purchase Order No. _____

Location _____

Unit Model No. _____ Unit Serial No. _____

Compressor Model No. _____ Size _____ (tons) Compressor Serial No. _____

Type of Compressor: centrifugal _____ reciprocating _____ screw _____ hermetic _____ open _____

gear drive _____ direct drive _____ electric motor _____ steam turbine _____ other power _____

Compressor Manufacturer _____

What is the cooling application: air conditioning _____ process cooling _____ low temp _____

Sample

Indicate the lubrication system where oil sample was taken:

Compressor _____ gear box _____ other _____

Brand of oil _____ Date of last oil change: month _____ year _____

Operating time since last oil change _____ (hrs) (months) No. of starts _____

Oil added since last change _____ (qts.) Brand added _____ Oil sump capacity _____ (gals.)

Indicate refrigerant type: R-11 _____ R-113 _____ R-12 _____ R-22 _____ other _____

Condenser: air cooled _____ water cooled _____ other _____

Reasons

Indicate reason for obtaining chemical analysis: routine maintenance _____ other reason (give details) _____

_____

_____

_____

Has this unit been analyzed previously? _____ If yes, by whom? _____ Date _____ Lab No. _____

Service History

Please provide information and dates on the service history of the machine.

Motor burnout and replacement: _____ approx. date _____

Replacement of worn or failed bearing: _____ approx. date _____

Tubing failure – water entering machine: _____ approx. date _____

Excessive purging problems: _____

Other _____

_____

_____

How long has this machine been in service? _____ (years.) Start up date: _____

Sample was taken by: Name _____ Date _____

Outside Contractor _____

Service Company _____ Phone _____

Address _____ City _____ State _____ Zip _____

Ship samples to (UPS preferred)

SUBJECT: CENTRAVAC SOLID STATE MOTOR PROTECTION MODULE - OPERATION, CALIBRATION AND TROUBLESHOOTING

INTRODUCTION:

The purpose of this Service Bulletin is to discuss the operating characteristics of the Trane Motor Protection Module (MPM) and to outline the correct procedures for calibration and troubleshooting. The module is presently supplied on all Air Cooled CenTraVacs and Water Cooled CenTraVacs equipped with the new Trane Unit-Mounted Starter. In addition, it is also part of the new Motor Starter Protection System (MSPS) Retrofit Kit marketed by Service Products. This Bulletin also discusses the operation, calibration and troubleshooting procedure for the Motor Starter Protection System Retrofit Kit.

DISCUSSION:

Motor Protection Module (MPM) Features:

Listed below are the operational functions and features of the Motor Protection Module:

1. To provide precise compressor motor overload protection.
2. To protect against excessive locked rotor (in-rush) current draw.
3. To limit the length of time that in-rush current may be drawn.
4. To protect the unit from damage which can be caused by an electrical distribution fault.
   NOTE: A distribution fault is defined as a complete loss of line voltage for a period of less than 60 cycles.
5. The module initiates starter transition when the compressor reaches full speed.
6. To provide a DC voltage signal which is proportional to load.
7. It can be adjusted to compensate for high line voltage.
8. It is adjustable for 50 or 60 Hertz operation.

Motor - Starter Protection System (MSPS) Features:

The Motor Starter Protection System Retrofit Kit consists of three modules. One is the Motor Protection Module previously discussed, another houses the fault indicator circuit breakers and the third contains the Starter Protection System. The features and functions of the starter protection system are listed below:

1. To protect against the effects of pilot relay contact welding.
2. To protect against the effects of the loose control wiring.
3. To protect against the effects of intermittent control voltage (ie., fluttering flow switches, etc.)
4. It incorporates an adjustable undervoltage lock out for the control circuit.
5. The circuits are wired to protect the transition Resistor against excessive operating time.

CALIBRATION PROCEDURES (MOTOR PROTECTION MODULE)

CAUTION: WHENEVER WORKING ON THE MPM, AS WITH ANY ELECTRICAL EQUIPMENT, STOP THE MOTOR AND DISCONNECT ALL POWER TO THE UNIT. FAILURE TO DO SO MAY RESULT IN ACCIDENTAL SHOCK OR DEATH BY ELECTROCUTION. PREVENT PERSONAL INJURY BY ALWAYS DISCONNECTING ELECTRICAL POWER BEFORE WORKING ON ELECTRICAL EQUIPMENT.

NOTE: On units equipped with the Distribution Fault function, a small circuit board mounted in the center of the MPM must be tilted outward to perform MPM calibration. This is done by gently pulling on the two black tabs, located on the top of the circuit board, and tilting it down on its hinges.

I. Line Frequency Adjustment:

The MPM can operate on either 50 or 60 Hertz electrical systems. The line frequency is set as follows:

A. The installation line frequency must first be determined. (60 Hertz for all U.S. installations.)
B. The frequency switch (see Figure 1) should then be set to the position which corresponds to the installation frequency (see Figure 2).
C. Write in the setting made on the MPM nameplate (see Figure 3).

II. Compressor Motor Overload Setup:

The overload is set by adjusting the resistance of the current calibrator. The MPM is designed so that with the current calibrator correctly set, the overload will trip at 107% of the motor rated load current. The use of a 107% trip point prevents nuisance full load trip outs while still protecting the compressor motor from potentially damaging overloads.

The correct procedure for setting the current calibrator is as follows:

A. Determine the Rated Load Current (RLA) and the current transformer ratio for the unit. Where the actual jobsite voltage is equal to or lower than the specified voltage rating shown on the unit nameplate, the current calibrator setting can be established based on the nameplate RLA.

When the actual voltage is higher than the specified voltage, see Section V (High Voltage Compensation).

FIGURE 3 - MOTOR PROTECTION MODULE NAMEPLATE

If the unit is equipped with power factor correction capacitors which are connected on the load side of the overload current transformers, the RLA shown on the unit nameplate will have to be recalculated for the purpose of setting the overloads. On CenTraVacs shipped with factory installed power factor capacitors, the adjusted RLA should be shown on the electronic overload cover and the overload set accordingly. To determine the adjusted RLA on other units, the machine should be run to full load and amperage readings taken on the load and line sides of the capacitor terminal points. The nameplate RLA should be multiplied by the ratio of the current on the line side of the capacitors to current on the load side of the capacitors. This gives the adjusted RLA to be used to set the current calibrator. (See equation and example below.)

$$\text{Adjusted RLA} = \text{Nameplate RLA} \times \frac{\text{line side current}}{\text{load side current}}$$

Example: Motor Rating (RLA) = 100 amps
Current on line side of capacitors = 84 amps
Current on load side of capacitors = 92 amps

$$\text{Adjusted RLA} = 100 \text{ amps} \times \frac{84 \text{ amps}}{92 \text{ amps}} = 91 \text{ amps}$$

If the power factor capacitors are connected on the line side of the MPM current transformers or if the capacitor leads are run through the current transformers with the motor leads (Figure 4) the RLA must not be adjusted.

The motor nameplate RLA should be used to set the current calibrator in this case.

Refer to Engineering Bulletin EB-CTV-44 for additional information and recommendations concerning field addition of power factor correction capacitors.

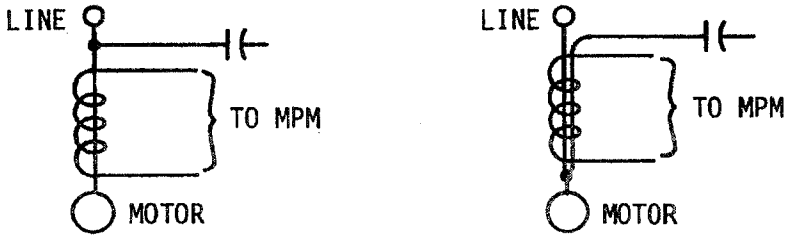

FIGURE 4 - Current Transformers

B. Once the correct RLA has been determined, the rated load secondary current (I_{sec}) from the current transformer can be determined. The value of I_{sec} at full load is dependent upon the location of the current transformers. The correct methods to determine I_{sec} are discussed below:

1. Current Transformer Monitoring Line Current
   If the current transformers are located to monitor line current, the value of the I_{sec} is determined by dividing the current transformer ratio into the RLA. (See the equation and example below.)

$$I_{sec} = RLA \div (CT\ ratio)$$

Example RLA = 91 amps

$$CT\ ratio = \frac{100}{5}$$

$$I_{sec} = \left(91 \div \frac{100}{5}\right)$$

$$I_{sec} = 4.55$$

2. Current Transformers Monitoring Phase Current
   If the current transformers are located in a star-delta starter in such a way that they monitor phase current, the value of I_{sec} is determined by dividing the current transformer ratio into the RLA and multipling this quantity by 0.58. (See the equation and example below.)

$$I_{sec} = RLA \div CT\ Ratio) \times 0.58$$

Example: RLA = 91 amps

$$CT\ Ratio = \frac{100}{5}$$

$$I_{sec} = (91 \div \frac{100}{5} \times 0.58$$

$$I_{sec} = 2.64$$

NOTE: When donut-type current transformers are used, the wires passed through them are sometimes wrapped around and passed through more than once. When this is done, the CT ratio is effectively divided by the number of times the wire passes through the CT. This means a 200/5 CT with the wire passed through it twice should be treated as a 100/5 CT.

C. With the I_{sec} value found above, use Table 1 to determine the correct current calibrator and its setting. For the above example in which the line current is being monitored (I_{sec} = 4.55), the correct current calibrator would be H818. The correct calibrator setting would be 82.6 ohms. With the calibrator setting adjusted in this manner, the overload trip point would be 107% of the nameplate RLA.

D. To set the current calibrator, it must be removed from the module. Using a digital ohmmeter (3-1/2 digit accuracy minimum) set the resistance of the calibrator to the value taken from Table 1.

E. Replace the current calibrator in the module. Write the calibrator number and setting on the MPM nameplate.

NOTE: With the current calibrator set correctly and the unit operating at full load, a DC voltage of approximately 8.25 VDC should exist across terminals V1-V2 in the MPM.

III. Locked Rotor Current Lockout Adjustment

The MPM protects the compressor motor from excessive LRA current draw during start-up. It does this by tripping the motor overload circuit breaker any time the set LRA is exceeded. The correct procedure for setting the LRA trip point is as follows:

A. The LRA current trip point setting is dependent upon the type of starter being used with the CenTraVac compressor motor.

B. The LRA current trip point is set using the LRA set potentiometer (Figure 1).

C. The correct setting position for the LRA set potentiometer as applied to different types of starters are shown in Figure 5.

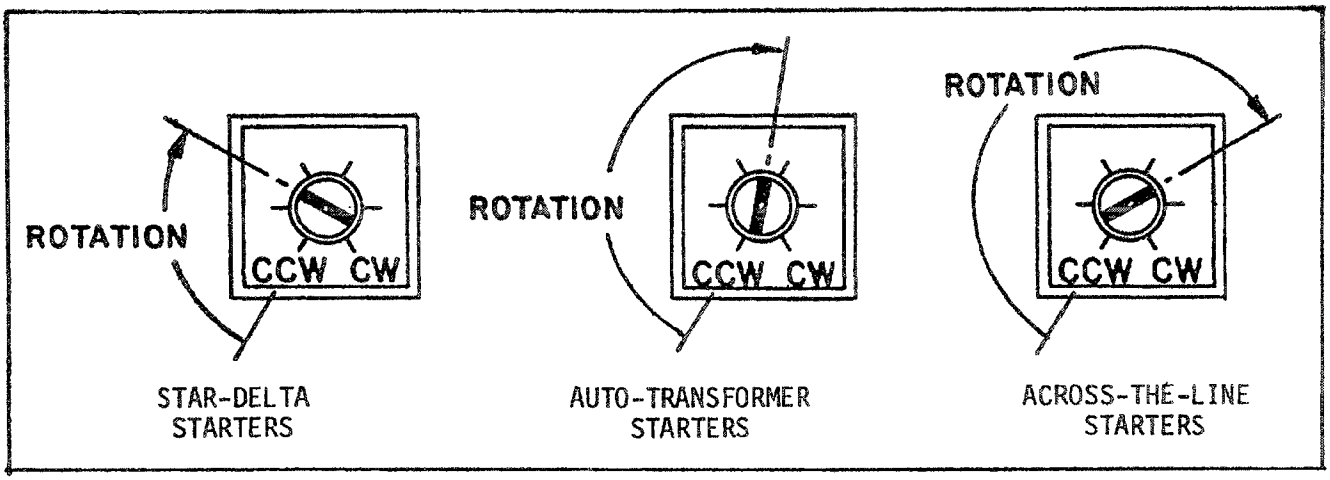

FIGURE 5 - LRA SET POTENTIOMETER POSITIONS FOR DIFFERENT TYPE STARTERS

D. To set the LRA set potentiometer, insert a screw driver in the adjusting slot and turn potentiometer to the fully counter-clockwise (CCW) stop. This establishes a reference position. From this point, the potentiometer should be rotated clockwise to the position, shown in Figure 5, which corresponds to the compressor motor starter being used.

E. As can be seen by the calibration markings on the LRA set potentiometer, this is a rough setting only. If it is found that the "motor overload" circuit breaker trips immediately (1 sec) upon energization of the starter, the LRA current trip point may have to be set higher. Doing this will not harm the operation of the MPM or the compressor motor.

F. Write the nameplate LRA and the nameplate RLA on the MPM nameplate. See Figure 3.

G. Calculate the "RATIO ___%" using the formula below. Write this on the nameplate. See Figure 3.

$$\text{Ratio \%} = \frac{\text{Motor LRA*}}{\text{Motor RLA}} \times 100\%$$

Example: Motor RLA - 100 AMPS

Motor LRA = 200 AMPS

$$\frac{200 \text{ AMPS}}{100 \text{ AMPS}} \times 100\% = \text{Ratio } 200\%$$

* Locked rotor amperes (LRA) is the reduced value obtained depending on the method of starting. See Table 2.

TABLE 2 STARTING CHARACTERISTICS FOR VARIOUS TYPES OF MOTOR STARTERS

Star-Delta	n/a	100	33	33
Open or Closed Transition	n/a	100	33	33

IV. Maximum Acceleration Time Set

The MPM limits the maximum acceleration time the motor can undergo by tripping the "Motor Overload" circuit breaker, locking the machine off whenever the machine does not transition in the time period set on the acceleration time adjustment (Figure 1). This prevents the motor from drawing LRA for an excessive period of time and overheating the motor. The maximum acceleration time is set as follows:

A. Determine the desired maximum acceleration time (between 1 and 63 seconds) for the unit. Table 3 gives recommended settings for typical units. This setting may vary, depending on the type of unit, type of starter and jobsite conditions. It should be set, based on the typical acceleration time for the particular unit and jobsite conditions.

TABLE 3 - TYPICAL MAXIMUM ACCELERATION TIME SETTINGS

STARTER TYPE	RECOMMENDED MAXIMUM ACCELERATION TIME SETTINGS
Star-Delta	12 Seconds
Auto-Transformer	8 Seconds
Across-The-Line	4 Seconds

B. Once the desired value is known, the combination of switches on the LRA time adjustment which adds to this value should be switched to the "ON" position (see Figure 6).

NOTE: If none of the switches are in the "ON" position, the unit will not start. The MPM allows no acceleration time in this situation and the "Motor Overload" circuit breaker will trip immediately upon attempted start-up.

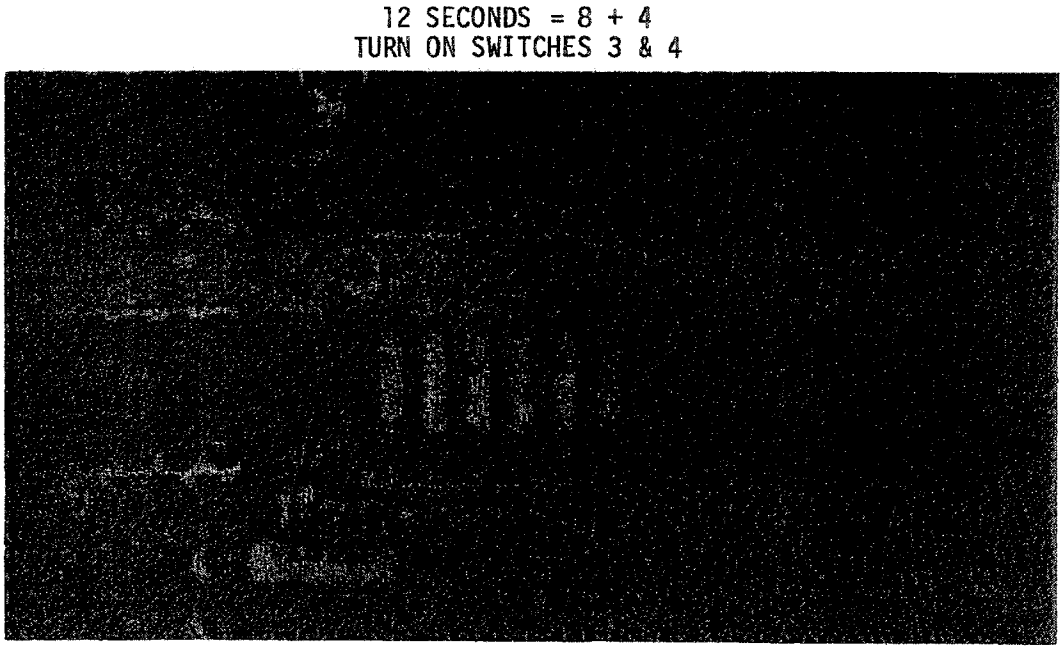

FIGURE 6 - MAXIMUM ACCELERATION TIME SWITCH

C. Write the LRA time adjustment setting on the MPM nameplate. See Figure 3.

V. High Voltage Compensation:

The RLA shown on the unit nameplate is based on original design conditions and the nominal voltage ordered. The actual jobsite voltage quite often varies from the nominal. Higher than nominal line voltage permits the motor to produce higher than rated horsepower without motor current draw in excess of nameplate. To prevent overloading of the motor due to higher than rated voltage, the MPM should be recalibrated. This can be done in either of two ways:

A. By removal of 10% current reset jumper from terminals J1 - J2 in the MPM (see Figure 1), the module is automatically recalibrated so that approximately 90% of the motor nameplate current rating is the new "rated" current for the application. The MPM should be setup normally, as removal of the jumper recalibrates all functions of the MPM.

B. The MPM can also be recalibrated to compensate for high voltage by resetting the current calibrator. The proper value is determined by multiplying the I_{sec} value, determined in the Compressor Motor Overload Setup section of this Service Bulletin, by the ratio of the rated voltage to the actual line voltage. (see the equation and example below.)

$$\text{New } I_{sec} = I_{sec} \times \frac{\text{rated voltage}}{\text{actual line voltage}}$$

Example: Original I_{sec} = 4.55
Rated Voltage = 460 volts
Actual line voltage = 485 volts

$$\text{New } I_{sec} = 4.55 \times \frac{460 \text{ volts}}{485 \text{ volts}} = 4.32$$

The new I_{sec} value is then used to enter Table 1 and determine a new current calibrator setting. The calibrator should be reset to this value. This will recalibrate all other MPM functions, compensating for the high voltage condition.

C. Whenever the MPM is recalibrated for high voltage, the LRA Potentiometer should be turned up one space higher than indicated on Figure 4 to prevent nuisance tripouts at start-up. The reason for this is that higher than nameplate LRA current draw would occur. This must be compensated for by turning up the LRA Potentiometer.

Any calibration of the module, such as removal of the J1 - J2 jumper or recalibration of the current calibrator should be noted on the MPM module cover along with the reason for recalibration.

NOTE: When any recalibration of the motor overload is performed on a water-cooled CenTraVac equipped with a pneumatic LLR, the LLR must be recalibrated just as the overload. If this is not done, nuisance overload tripouts will occur.

VI. CVAC Load Limiting Control Calibration

On CVAC's, the MPM controls the load limiting of the motor through a load proportional DC voltage which it sends to the vane control module. If the MPM has been calibrated correctly, the vane control module should start load limiting at 98% of RLA. The load proportional DC voltage can be measured across terminals V1 - V2 of the MPM. At rated load, this voltage will be -8.25 VDC. This voltage varies linearly with the machine running amperage.

Example: 100% RLA = (-)8.25 VDC
98% RLA = (-)8.25 x .98 = (-)8.09 VDC

VII. Vane Control Module Load Limit Calibration

A. The current calibrator must be correctly set before the control module load limiting can be calibrated.

B. The unit should then be started.

C. The voltage across terminals V1 - V2, in the control module, should be measured while the machine is being loaded. The control module current limiting calibrator should be set so the machine begins load limiting when the V1-V2 voltage reaches (-)8.09 volts DC. This corresponds to a machine load of 98% of FLA.

D. Manually unload and load the machine, rechecking to make sure load limiting begins at a V1-V2 signal voltage of (-)8.09 volts DC. The unload - load lights can be used to verify proper limiting as well as visually observing the damper motor.

E. The load limiting of the control module is now set correctly.

VIII. Dry Running Starters Equipped with the Motor Protection Module

Starters equipped with the Motor Protection Module can be dry run at startup in the same manner as starters not so equipped. There are two differences which should be noted.

A. Before the starter can be dry run, the Distribution Fault circuit Breaker must be disconnected. This can be done by simply removing a wire from the Distribution Fault Circuit Breaker. If this is not done, the starter will not sequence, but will lockout on distribution fault instantly upon initiation of the start.

This occurs because the distribution fault trip is initiated when the motor current drops below 20% of RLA with the M1 contactor energized. See the "Distribution Fault Trip Operation" section of this Bulletin for the reasoning behind this. The only time the above circumstances can occur, is during an actual distribution fault or a starter dry run.

B. The other difference which will be noticed, is that immediately upon energization of the dry run, the starter will go through transition.

This happens because the MPM initiates transition on the basis of motor current draw. During a normal startup, the vanes are closed which allows the motor current to drop from LRA to a value below RLA. When the motor current drops from LRA to 80% of RLA during start, the MPM initiates transition. During a dry run, there is no current draw, so the MPM, immediately (1 sec) initiates transition.

IX. Distribution Fault Circuit Breaker Operation

A distribution fault is defined as a loss of line voltage for less than 60 electrical cycles. This type of short duration power interruption can be damaging to many types of induction motor driven equipment.

The damage occurs because an induction motor acts as a generator for several seconds after power is disconnected. The voltage generated by the motor can hold in control relays and starter contactors when a voltage loss occurs. The period of time the contactors are held in, is approximately 60 electrical cycles or 1 second for a Water Cooled CenTraVac, and 20 cycles or 1/3 second, for an Air Cooled CenTraVac.

If line voltage is re-established during the period of time the contactors are being held in by the motor generated voltage, and the two voltages are out of phase, motor torques may occur which are 6 to 10 times normal running torques. These torques occur as the motor is pulled into phase and may be in either the forward or reverse direction. These high torques cause severe overloading of the impeller hub area, with resultant upsetting of the impeller keyway and in severe cases cracking or destruction of the impellers.

The Motor Protection Module detects a distribution fault by monitoring current draw and the M1 contactor. The tripping of the Distribution Fault Circuit Breaker is initiated based on the fact that, in normal operation, only during the occurrances of an actual distribution fault is it found that the motor current draw is less than 20% of RLA and the M1 contactor is energized at the same time. An induction motor will normally always draw over 20% of RLA, even when completely unloaded; and whenever the M1 contactor is energized, the motor is running. The only exceptions occur during a distribution fault or during a starter dry run.

The distribution fault lockout is initiated when the motor current drops below 20% of RLA with the M1 contactor energized. The motor Protection Module senses this set of conditions to be a voltage loss for the reasons explained in the previous two paragraphs. Tripping of the Distribution Fault Circuit Breaker is completed within 6 electrical cycles (1/10 of a second) of the time when the voltage loss occurs.

It should be noted that this provides a way to check for the proper operation of the distribution fault function of the Motor Protection Module. The Distribution Fault Circuit Breaker should trip instantly if it is left connected during a starter dry run.

CALIBRATION PROCEDURE (MOTOR STARTER PROTECTION RETROFIT KIT ONLY)

I. Low Voltage Lockout Calibration

The Motor-Starter Protection System Retrofit Kit incorporates an adjustment which allows the minimum operating control voltage to be set. If the unit experiences a control voltage below the setting of the low voltage lockout, the Starter Protection Module (SPM) locks the machine out with the "Starter Fault" circuit breaker. The low voltage lockout adjustment is on the outside of the Starter Protection Module. It is a slotted potentiometer type adjustment located on the side of the SPM module. (See Figure 7.) It can be set using the following guides:

A. Turning the low voltage set potentiometer fully counter-clockwise gives a trip point of 80 volts ± 10%.
B. Turning the low voltage set potentiometer fully clockwise gives a trip point of 108 volts ± 10%.
C. The nominal trip voltage can be adjusted to any value between these extremes by adjusting the low voltage set potentiometer. See the following equation:

Amount of potentiometer rotation required
(Desired Voltage - 80) ÷ 28 x 100% = Percent rotation

Example: Desired lockout voltage = 94 volts
(94 - 80) ÷ 28 x 100% = 50%

Turn the potentiometer 50% of the way from fully CCW to fully CW.

NOTE: A good nominal setting is 94 volts, or 50% rotation.

II. Start Circuit Protection

A "Starter Circuit" tripout will occur whenever the control circuit power to the starter is momentarily interrupted. Such interruptions could include a fluttering flow switch, loose wiring or a defective control. There is no calibration which can be performed on this circuit.

III. Transition Circuit Protection

A "Transition Circuit" tripout will occur if the transition resistors remain in the circuit for over one and a half seconds. This protects the resistors from conditions which will cause rapid burnout. There is no calibration which can be performed on this circuit.

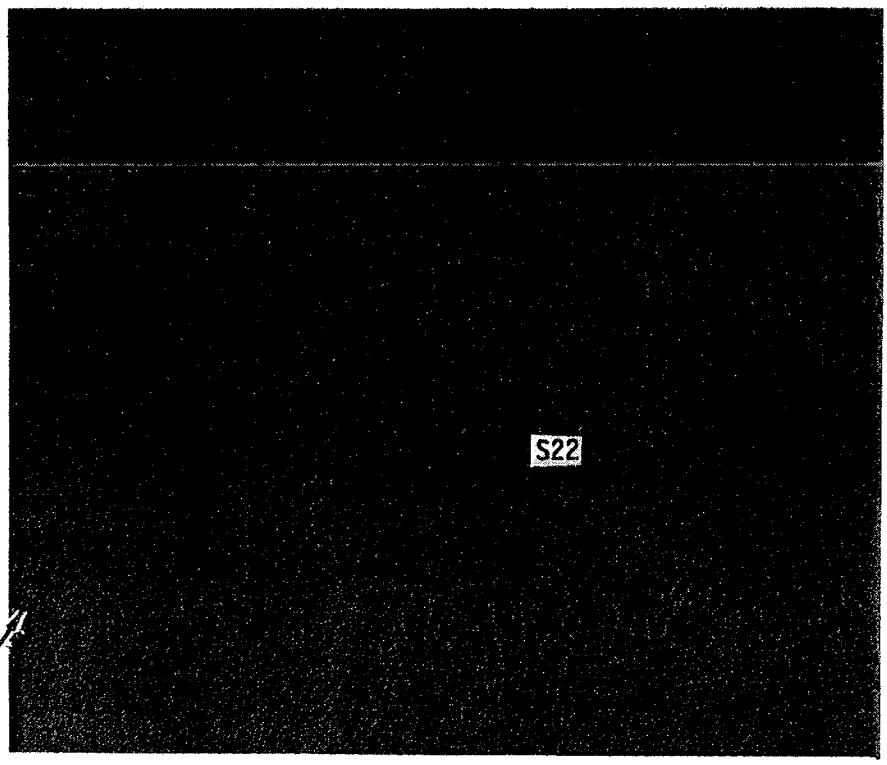

FIGURE 7 - STARTER PROTECTION MODULE

TROUBLESHOOTING MPM/MPS

The wiring diagrams on the following pages give typical wiring schemes for the Motor Protection Module and Motor Starter Protection System Retrofit Kit. Figure 8 shows the wiring of the MPM by description of the terminal board stud's interconnections. Figure 9 is a typical wiring diagram of a Unit Mounted Starter equipped with a MPM. Figure 10 is a typical wiring diagram of the Motor Starter Protection Retrofit Kit.

The charts on the following pages give troubleshooting sequences for the Motor Protection Modules. Problem symptoms are listed across the top of the chart, possible causes in the left hand columns and recommended solutions in the right hand column. The numbers in the columns under the problem symptoms indicate possible causes and solutions for those symptoms. The numbering indicates the probability of the corresponding cause/solution being the one which is causing the problem; 1 being the most likely, 2 the second most likely, and so on.

TROUBLESHOOTING NUISANCE TRIPPING

SYMPTOM/ POSSIBLE CAUSE	MOTOR OVERLOAD TRIPS	DISTRIBUTION FAULT TRIPS	STARTER FAULT TRIPS	TRANSITION FAULT TRIPS	RECOMMENDED ACTION
Incorrect Current Calibrator Adjustment or Installation	3				Determine proper setting, re-calibrate and install.
Incorrect LRA Trip Point Setting	4				Determine proper setting and re-calibrate LRA trip setting.
High Voltage Re-calibration Jumper Removed	7				Determine if jumper should be removed to compensate for high voltage.
Excessive Running Motor Current Draw	1				Check for faulty compressor motor.
Excessive LRA Motor Motor Current Draw	2				Check for faulty compressor motor.
Frequency Selector Switch Incorrectly Set	5				Check selector setting.
Motor Acceleration Time to Long	8				Contact La Crosse Service
Low Voltage To Unit			3**		Contact Power Company
Motor Current Drops Below 20% RLA		5			Contact La Crosse Service

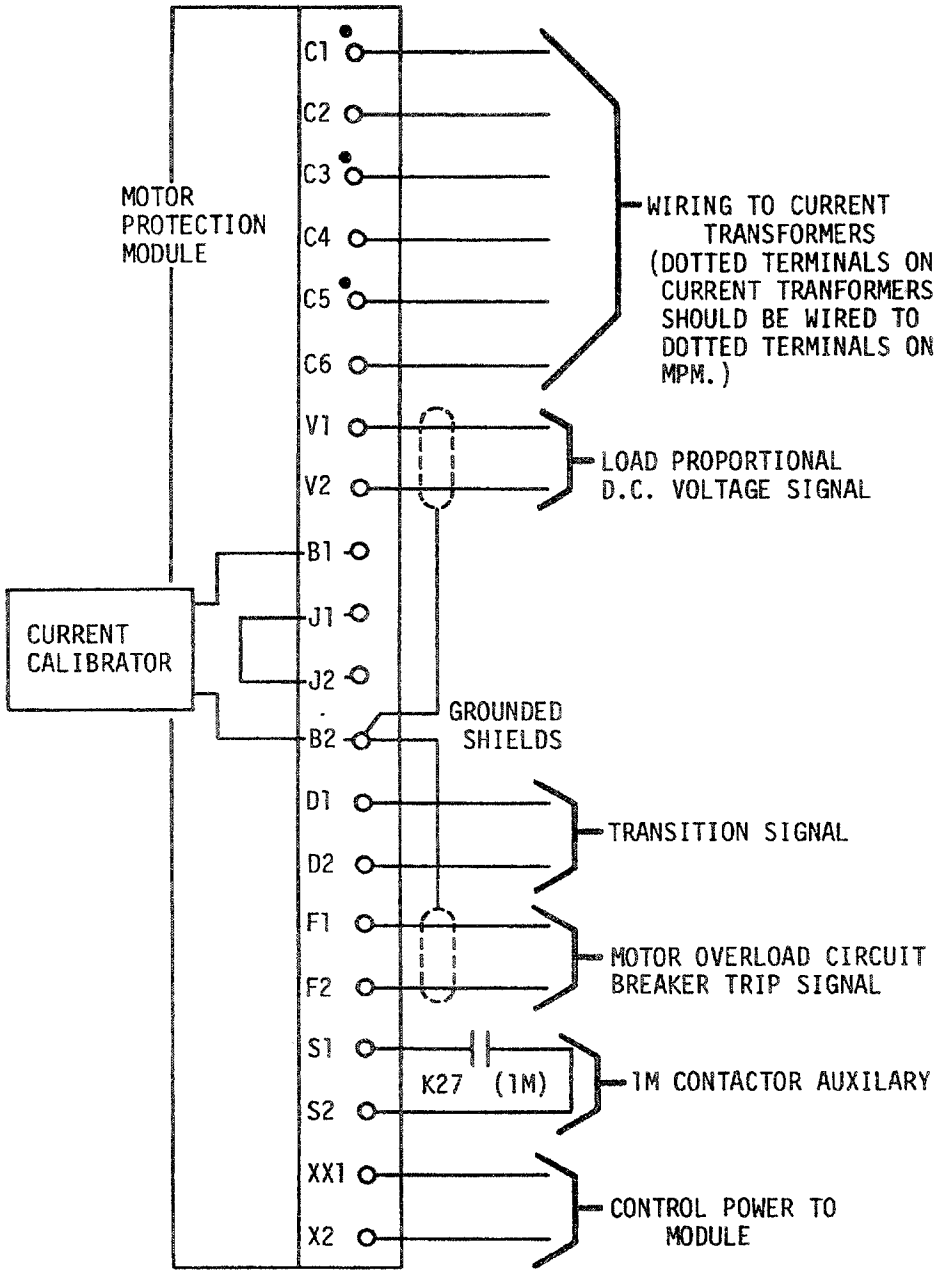

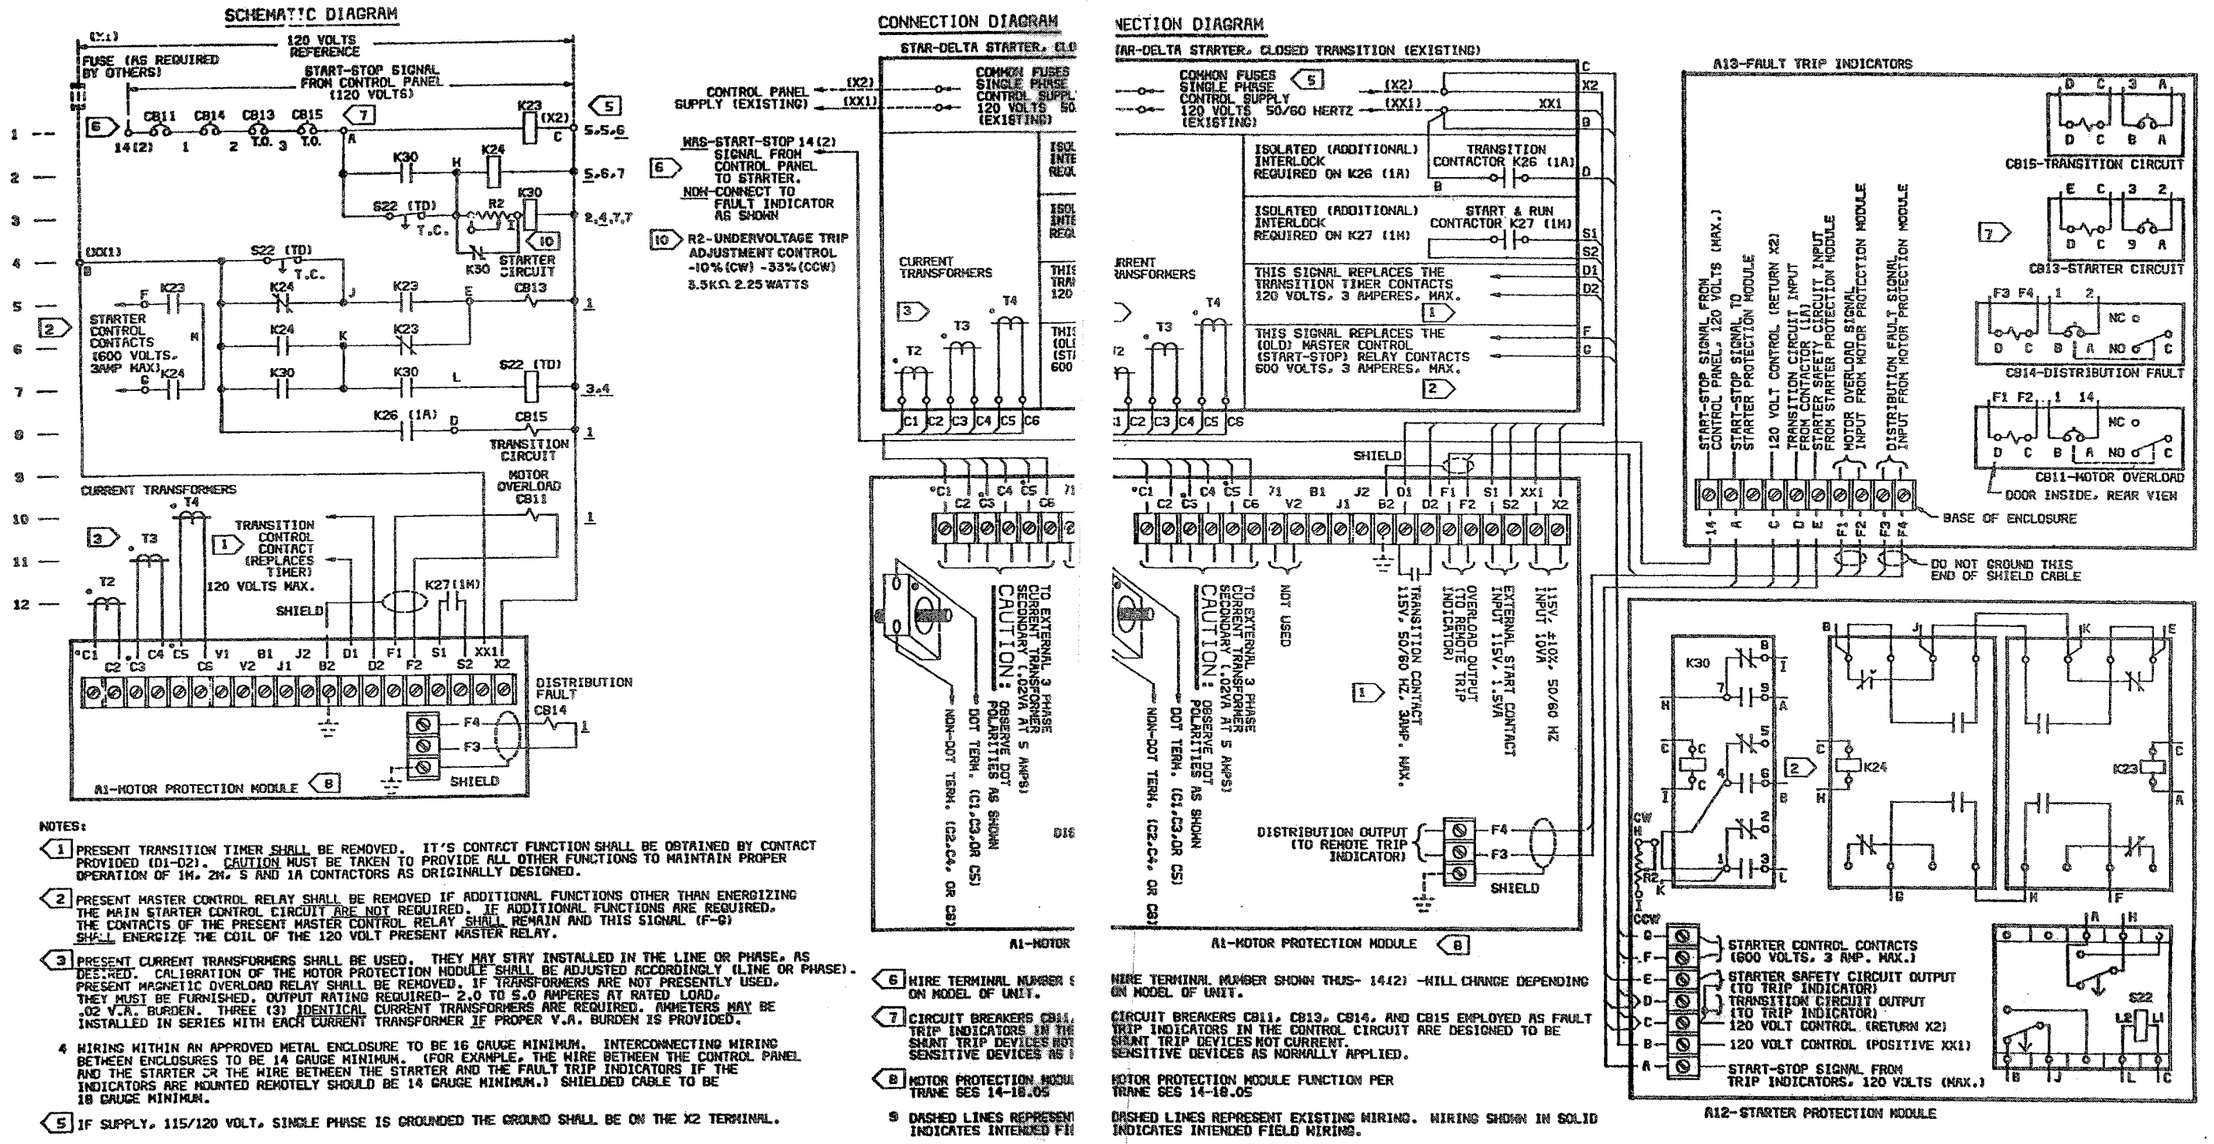

FIGURE 8 - MOTOR PROTECTION MODULE INTERCONNECTIONS

NOTES:

1. PRESENT TRANSITION TIMER SHALL BE REMOVED. IT'S CONTACT FUNCTION SHALL BE OBTAINED BY CONTACT PROVIDED (D1-D2). CAUTION MUST BE TAKEN TO PROVIDE ALL OTHER FUNCTIONS TO MAINTAIN PROPER OPERATION OF 1M, 2M, S AND 1A CONTACTORS AS ORIGINALLY DESIGNED.

2. PRESENT MASTER CONTROL RELAY SHALL BE REMOVED IF ADDITIONAL FUNCTIONS OTHER THAN ENERGIZING THE MAIN STARTER CONTROL CIRCUIT ARE NOT REQUIRED. IF ADDITIONAL FUNCTIONS ARE REQUIRED, THE CONTACTS OF THE PRESENT MASTER CONTROL RELAY SHALL REMAIN AND THIS SIGNAL (F-G) SHALL ENERGIZE THE COIL OF THE 120 VOLT PRESENT MASTER RELAY.

3. PRESENT CURRENT TRANSFORMERS SHALL BE USED. THEY MAY STAY INSTALLED IN THE LINE OR PHASE, AS DESIRED. CALIBRATION OF THE MOTOR PROTECTION MODULE SHALL BE ADJUSTED ACCORDINGLY (LINE OR PHASE). PRESENT MAGNETIC OVERLOAD RELAY SHALL BE REMOVED. IF TRANSFORMERS ARE NOT PRESENTLY USED, THEY MUST BE FURNISHED. OUTPUT RATING REQUIRED- 2.0 TO 5.0 AMPERES AT RATED LOAD, .02 V.A. BURDEN. THREE (3) IDENTICAL CURRENT TRANSFORMERS ARE REQUIRED. AMMETERS MAY BE INSTALLED IN SERIES WITH EACH CURRENT TRANSFORMER IF PROPER V.A. BURDEN IS PROVIDED.

4. WIRING WITHIN AN APPROVED METAL ENCLOSURE TO BE 16 GAUGE MINIMUM. INTERCONNECTING WIRING BETWEEN ENCLOSURES TO BE 14 GAUGE MINIMUM. (FOR EXAMPLE, THE WIRE BETWEEN THE CONTROL PANEL AND THE STARTER OR THE WIRE BETWEEN THE STARTER AND THE FAULT TRIP INDICATORS IF THE INDICATORS ARE MOUNTED REMOTELY SHOULD BE 14 GAUGE MINIMUM.) SHIELDED CABLE TO BE 18 GAUGE MINIMUM.

5. IF SUPPLY, 115/120 VOLT, SINGLE PHASE IS GROUNDED THE GROUND SHALL BE ON THE X2 TERMINAL.

6. WIRE TERMINAL NUMBER SHOWN THUS- 14(2) -WILL CHANGE DEPENDING ON MODEL OF UNIT.

7. CIRCUIT BREAKERS C811, C813, C814, AND C815 EMPLOYED AS FAULT TRIP INDICATORS IN THE CONTROL CIRCUIT ARE DESIGNED TO BE SHUNT TRIP DEVICES NOT CURRENT SENSITIVE DEVICES AS NORMALLY APPLIED.

8. MOTOR PROTECTION MODULE FUNCTION PER TRANE SES 14-18.05

9. DASHED LINES REPRESENT EXISTING WIRING. WIRING SHOWN IN SOLID INDICATES INTENDED FIELD WIRING.

SUBJECT: CENTRAVAC OPEN ROTOR DIAGNOSTIC PROCEDURE

INTRODUCTION:

This service bulletin provides the recommended procedure for diagnosing an open rotor bar condition in a CenTraVac motor.

DISCUSSION:

Each rotor bar in a CenTraVac motor is an electrical conductor intended to carry an electrical current between the two rotor end rings. When the rotor bar material is no longer metallurgically continuous due to a break, an open rotor bar condition exists. Partial separation of a rotor bar results in an increase in resistance which leads to localized heating in the rotor bar. If this condition is not corrected, the rotor bar(s) will continue to overheat and eventually burn open to the point where other damage to the motor bearings or stator may result.

When a CenTraVac motor has an open rotor bar, it will exhibit the following symptoms in varying degrees depending on the severity of the failure.

1. Fluctuating amperage under steady operating conditions.

   The magnitude and frequency of the current fluctuations will increase as the unit load increases. The frequency change results from rotor slip at high loads.

2. Oil pressure fluctuation.

   An open rotor bar may cause fluctuation of the unit oil pressure. This is a result of movement of the rotor within the journal bearing, which is caused by the disrupted current flow in the rotor as it passes around the stator fields.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be

3. Mechanical vibration and noise.

A motor with an open rotor has a definite beat to the sound level of the unit which follows the current fluctuations. There will also be an increased amount of machine vibration as the condition worsens.

To properly diagnose an open rotor, the unit must be operated at a steady condition and be observed for the symptoms previously described. Control stability and machine operation without carryover or surging are absolute requirements for properly diagnosing an open rotor condition.

A simple field test using a variac can also be performed to aid in confirming an open rotor. This test is very limited due to its low current output and should not be used as the only basis for determining a defective rotor.

Variac Test Procedure

The following items are necessary to field test a rotor:

- Multi-amp relay tester or an amperage source with a maximum output of 110/60/1 volts and fused for a maximum of 5 watts output. This is the variac.
- An accurate A.C. voltmeter.
- An accurate low scale ammeter.

1. Open the unit disconnect switch and verify that there is no power available to the unit starter.

   WARNING: OPEN AND LOCK UNIT DISCONNECT TO PREVENT INJURY OR DEATH FROM ELECTRICAL SHOCK OR CONTACT WITH MOVING PARTS.

2. Remove the refrigerant charge and evacuate the unit. Break the vacuum with dry nitrogen to bring the unit to atmospheric pressure.

3. Remove the compressor suction elbow or second stage suction cover as required to gain access to the motor windings.

4. Connect the test equipment as shown in Figure 1.

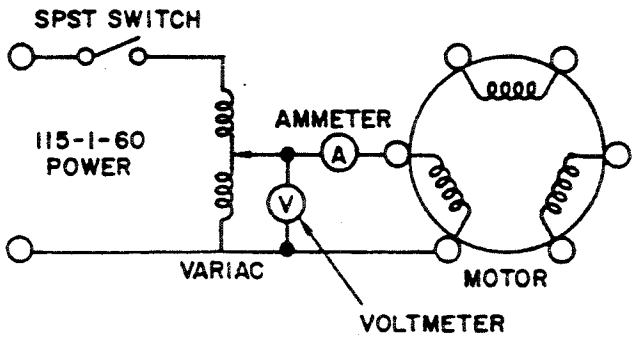

Figure 1
Test Circuit
With Variac

La Crosse, Wisconsin 54601
Printed in U.S.A.

5. Apply 5 to 100 volts across one winding of motor. Control the output at 4 amps.

6. Slowly rotate the rotor by hand.

7. An amperage fluctuation of greater than 1/4 amp indicates an open rotor.

A more accepted test for confirming rotor defects requires the use higher voltage and current levels. The equipment needed to perform these tests is only available in a large motor rebuild shop or test facility. For this reason, the test will not be discussed in this bulletin.

Subject: CenTraVac© Refrigerant Charges

Introduction:

The purpose of this service bulletin is to define the refrigerant charge needed to insure reliable CenTraVac© operation. The models covered by this bulletin are CTV, CV, LCV, LOCV, OCV, PCV, CVHA, CVHB (standard and heat recovery versions), CVHE and CVHF.

Discussion:

Points to consider when determining the charge level of a CenTraVac© unit:

1. The refrigerant charge for a standard (non-heat recovery or free-cooling) machine is always based on evaporator size.

2. A typical heat recovery CenTraVac© with a split bundle condenser uses 50 pounds more refrigerant than a standard evaporator/condenser version of the same machine.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

3. CVHA and CVHB machines with auxiliary heating condensers use a standard evaporator charge.

4. CVHE CenTraVacs with auxiliary condensers use 50 pounds additional refrigerant.

5. Early model machines have a number and/or letter combination that identifies the compressor, evaporator and condenser, in that order.

6. Standard combinations of CVHA and CVHB compressors, evaporators and condensers are listed in the tables of this bulletin.

7. The evaporator size of "pre-PDS" CenTraVacs are identified in the unit model number. Refer to appropriate table in this bulletin.

Exception: PCV and CV-style machines that shipped after November 1, 1971, require a smaller refrigerant charge. Changes were made in the evaporator design that are not reflected in the machine model number. Refer to the original start-up record to determine optimum refrigerant charge.

8. When certain machines are converted to motors that have a liquid refrigerant-cooled rotor, the refrigerant charge must be increased.

9. As of January 1, 1990, for CVHE units and May 14, 1991, for CVHB units, the evaporator shell size (CVSZ) and evaporator tube bundle sizes (EVBS) are identified in the Product Description Block of the unit nameplate. Unit refrigerant charge information is also included on the unit nameplate.

The following tables list refrigerant charge recommendations for typical chillers, including current production models. Variations are also listed where applicable.

CTV-SB-61 - Original service bulletin
CTV-SB-61A - General Update
CTV-SB-61B - Bulletin revised to include information for units equipped with MOV surge protectors.

Subject: CenTraVac Motor Insulation Resistance Testing

Introduction:

The purpose of this service bulletin is to discuss and clarify the recommended procedures for insulation resistance testing of CenTraVac motors. Also discussed are three procedures which are commonly used in the field, but which are subject to a wide range of interpretations.

Discussion:

There are a number of reasons why it is important to be able to determine a motor's insulation resistance value prior to operation of the motor. The following critical areas are where motor insulation resistance values are needed:

1. Upon start-up of a new machine installation.
2. At time of motor replacement due to repairs.
3. Routine checkout for preventive maintenance purposes.
4. When a machine has become contaminated with moisture.

Generally, a 500-volt DC megohm insulation tester is recommended for all resistance testing of CenTraVac motor windings. The use of a megger with a voltage output of more than 500 volts is not recommended for insulation systems of 600 volts or less because of the potential insulation damage due to the higher than normal operating voltage. A 1000-volt megger can be used on motors with insulation systems rated for 2300/4160 volts.

WARNING: Since the motor acts like a capacitor when voltage is applied, the motor winding terminal studs should be grounded to the motor frame after the testing has been completed. This will discharge any residual voltage in the motor that could result in severe electrical shock.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

High potential (Hi-Pot) testing should not be conducted on CenTraVac motors in the field. High potential testing involves applying twice the motor rated voltage plus 1000 volts and then measuring the leakage to ground. This check is intended to verify integrity of windings during the assembly process. This test is not intended for field use and can be destructive to the motor. An example of the test voltage used for a 460-volt motor would be 2 x 460 = 920 volts + 1000 volts for a total of 1920 volts.

Caution: Do not attempt to measure insulation resistance on a centrifugal unit under a deep vacuum. The unit should be charged with refrigerant, a nitrogen holding charge, or be open to the atmosphere before a megohm insulation test can be performed. Megging a motor under a deep vacuum could result in a to ground condition even with extremely low voltages which can cause carbon tracking and damage to the motor windings. When this occurs, reapplication of normal motor voltages could cause a leakage path to ground which could result in extreme motor damage.

In October 1988, Trane began factory-mounting MOVs on each unit. The MOVs provide voltage surge protection on all 600-volt and less CenTraVac motors. When megging a motor with MOVs attached, the reading can vary from what would be expected for a good motor.

A normal megohm reading across a MOV is between 1.1 - 3.5 megohms. Manufacturing variations of the MOV disc itself will cause the different readings. Because of this, The Trane Company recommends that the MOVs be disconnected in order to get a true motor megohm reading.

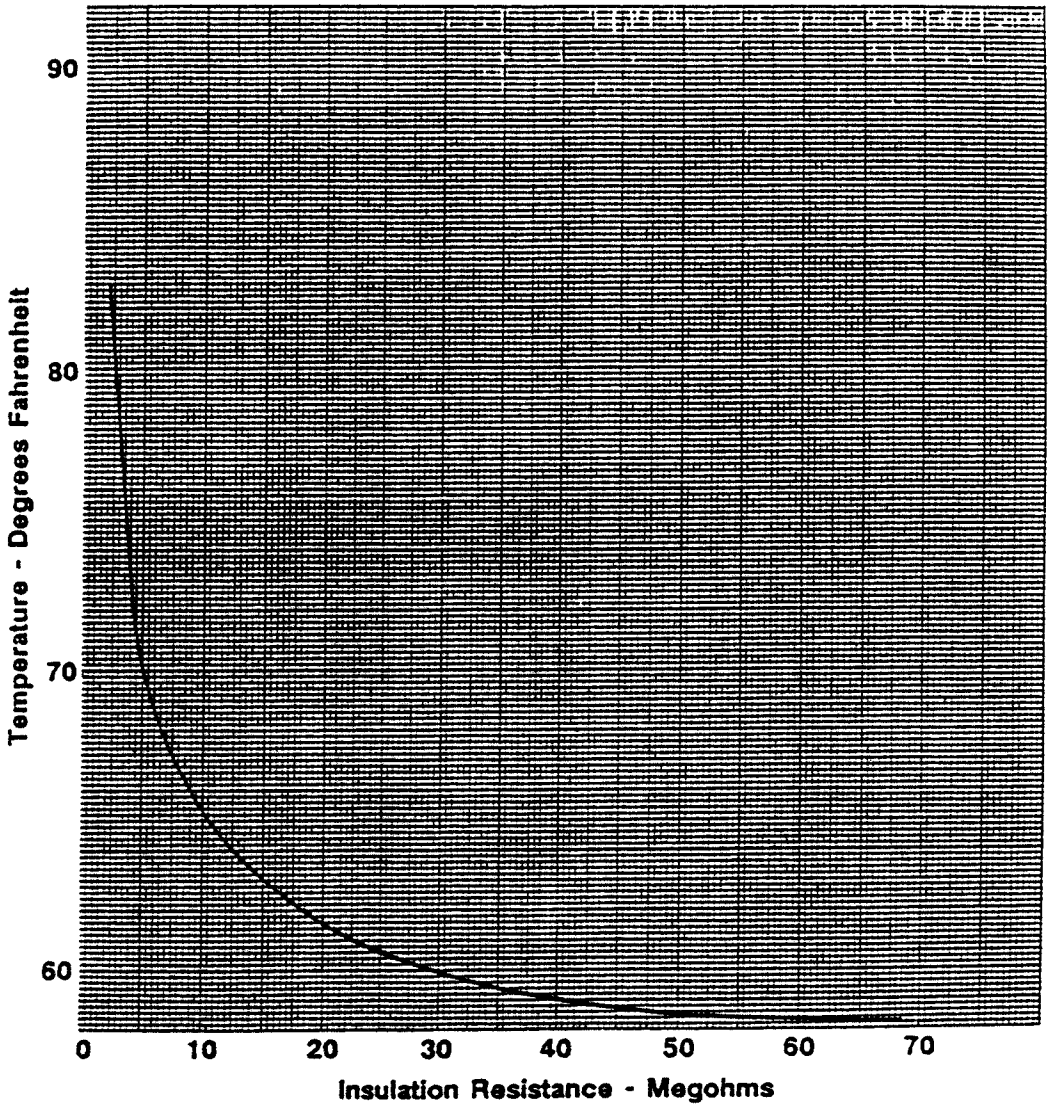
A zero megohm reading will indicate a shorted MOV. If this happens, physical evidence of extreme heat should be seen. Also, tripped safety devices (circuit breakers or fuses) should be present. A MOV's primary mode of failure is shorted. The short will eventually result in an open, with physical evidence of damage.

An infinity reading or possible infinity reading, depending on the megohmeter scale, indicates an open circuit internal to the MOV. This type of failure is more than likely caused by a manufacturing defect rather than by a voltage surge.

Insulation Test Procedures:

1. Megohm One-Time Value/Comparison Curve

The megohm one time resistance value test versus a comparison curve simply provides a comparison of the megohm reading obtained when megging a motor as compared to the temperature and an acceptable megohm limit as shown in the curve (Figure 1). Any motor with a megohm resistance value to the right of the curve (Figure 1) is acceptable and can be started and operated.



It is important to note that in most cases the megohm value of a motor will be above the 50 megohm value. Motors with less than 50 megohms may have contamination on the windings, which will cause a lower than expected megohm value. As long as the insulation resistance of the motor falls to the right of the curve, the motor may be started. It is suggested that on any motor where the megohm reading appears to be lower than normal, but not less than 4 megohms, that the motor be run for a period of time (1/2 to 1 hour) to normally dissipate any moisture or other contaminates which may have accumulated on the motor windings and generally will show an increase in the megohm value. If the megohm value of a motor continues to drop, a problem may be indicated and further checks are in order. The following steps should be taken if the readings are still low or are continuing to drop:

[ ] Remove motor leads and megger test the motor at the motor terminals.

[ ] Wash entire terminal board with clean refrigerant or denatured alcohol.

[ ] Remove terminal board and megger test directly on the motor leads. The unit's refrigerant charge must be removed prior to removal of terminal board.

Figure 1
Insulation Resistance

Notes:
1. If test value of insulation resistance is to the right of the curve, the motor is acceptable.
2. If test value is to the left of the curve, the motor must be operated with caution. The insulation resistance should be checked hourly until it has definitely been established that the insulation resistance is increasing. If it is decreasing, the motor should not be operated.
3. The motor should not be started if the insulation resistance is less than 4 megohms.

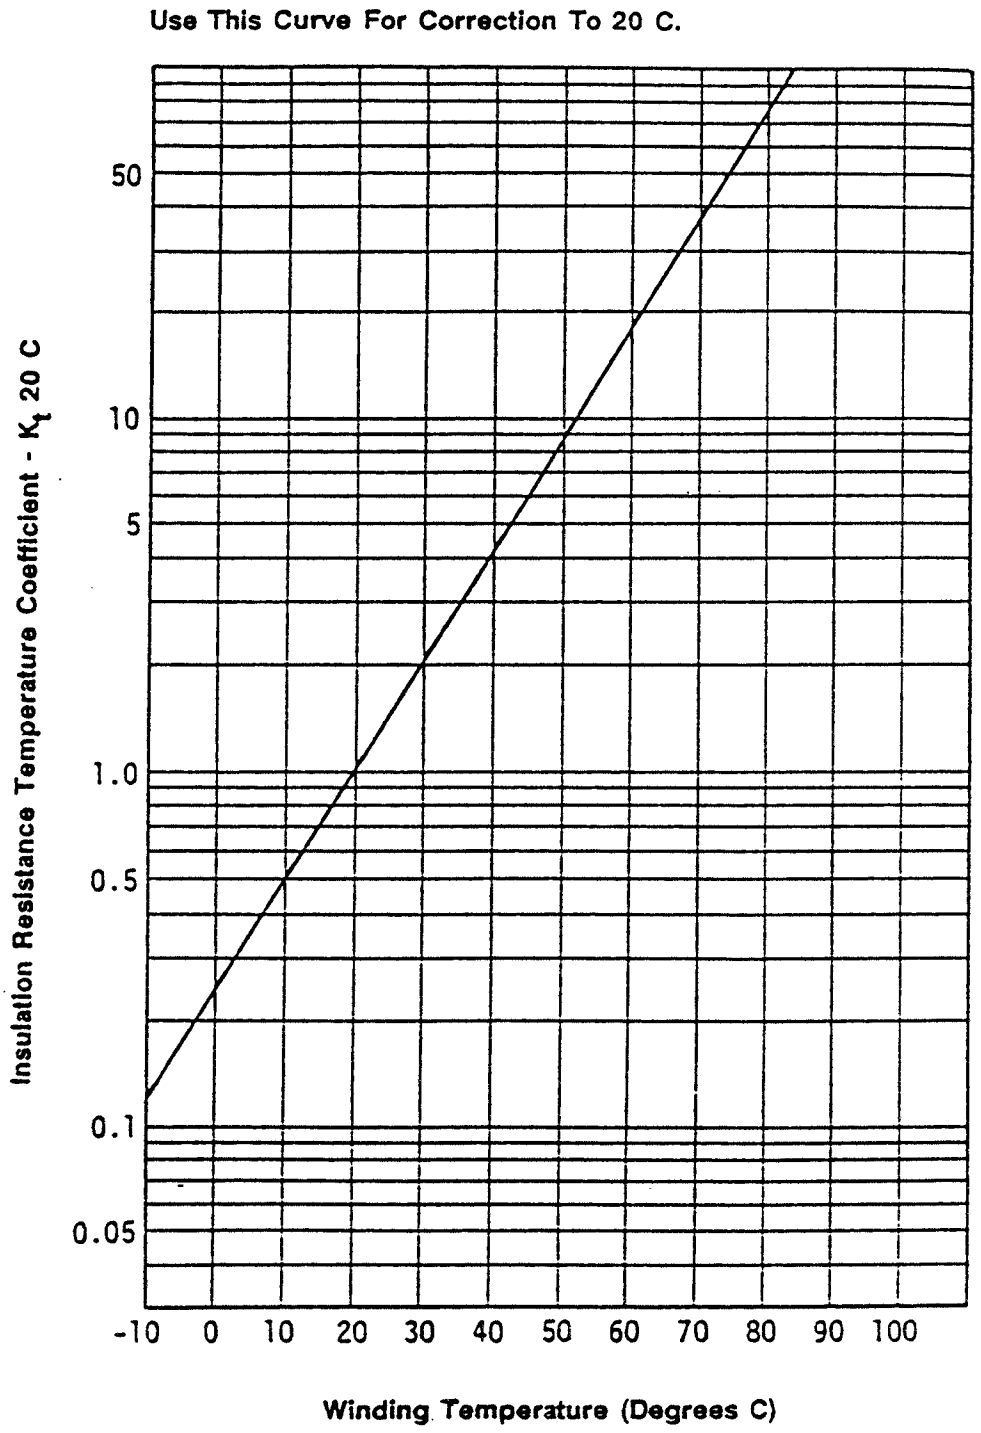
If comparisons between successive readings are to be made, they must all be corrected to a standard temperature. Figure 2 gives a winding temperature versus correction factor for 20 C. Newer motors are equipped with internal sensors which can be used to determine the winding temperature. If the motor is not equipped with internal sensors, it will be necessary to allow the motor to cool to room temperature before readings can be taken for comparison purposes.

2. Dielectric Absorption Ratio (60/30-second ratio)

To perform this test, a motor-driven or hand-crank type megger must be used to obtain megohm readings at specific intervals of time. The megger is used to provide a continuous voltage to the motor for a period up to 60 seconds. At intervals of 30 seconds and 60 seconds a megohm reading should be taken.

To determine the dielectric absorption ratio, which can then be compared to Table 1, the 60-second reading must be divided by the 30-second reading. The readings obtained using the 60/30-second absorption ratio method must be interpreted properly to determine the actual insulation integrity of the motor. This will be discussed later in the Service Bulletin.

Table 1 - Insulation Results



Insulation Condition	Polarization Index (10/1 Minute Ratio)	Absorption Ratio (60/30 Seconds)
Dangerous	Less than 1	Less than 1
Poor	Less than 1.5	Less than 1.1
Questionable	1.5 to 2	1.1 to 1.25
Fair	2 to 3	1.25 to 1.4
Good	3 to 4	1.4 to 1.6
Excellent	Above 4	Above 1.6

3. Polarization Index (10/1-minute ratio)

The polarization-index test method is similar to the dielectric absorption ratio method except that readings are taken at time intervals of 1 minute and 10 minutes respectively. The 10-minute reading must be divided by the 1-minute reading to determine the polarization-index ratio. The motor insulation quality can then be compared to Table 1.

The dielectric absorption ratio and polarization-index methods were originally specified in accordance with ANSI/IEEE (Standard #43, Recommended Practice for Testing Insulation Resistance of Rotating Machinery). The recommended tests were for all types of motors and were not specifically written for hermetic motors in a refrigerant atmosphere. The continuous application of a test voltage to a motor can cause some winding contaminates, such as moisture, to be driven from the windings which results in higher megohm readings after continued application of voltage. For this reason, the ratio figures were applicable to motors which had windings and leads with the ability to absorb moisture. Some of the older generation CenTraVac motors, prior to the newer designs, used insulation materials that could absorb moisture. The newer motors, however, are now using higher quality insulating material such as Daglas and Mylar, etc., which will not absorb moisture as the older cloth (cotton) type insulating materials would. Newer-style motor designs and their related insulating materials become charged more quickly, under similar conditions, than older motors. This affects the results of the electric-absorption and polarization-index test methods. It is possible that a polarization-index test on a good hermetic motor could show a high megohm value at both 10 and 1-minute intervals and yet not establish a large enough differential (ratio) to be considered acceptable as indicated in Table 1.

Figure 2
Winding Temperature Versus Correction Factor

To convert observed insulation resistance (R_t) to 20 C, multiply by the temperature coefficient K_t 20 C.

$$R_{20}\ C = R_t \times K_t\ 20\ C$$

Test Recommendation:

The most generally accepted field method for determining winding insulation integrity is the one-time megohm test as compared to the curve shown in Figure 1.

The dielectric-absorption and polarization-index test methods are subject to a wide range of interpretation and should not be used solely to determine insulation quality of a CenTraVac motor.

The following guidelines should be used for field testing of CenTraVac motor windings:

1. The use of dielectric and absorption testing is subject to misinterpretation.

2. The one-time megohm reading versus the curve (Figure 1) is the most generally accepted field test method for measuring the megohm readings of all CenTraVac motors.

3. Do not high potential test CenTraVac motors in the field.

4. Under no circumstances should any voltage be applied to a motor while it is under a deep vacuum.

SUBJECT: CENTRAVAC SOLID-STATE OVERLOAD NUISANCE TRIPOUT

INTRODUCTION:

The purpose of this Service Bulletin is to discuss nuisance tripouts of the solid-state overload (Motor Protection Module) used on CVHA/CVHB CenTraVacs. Module modification may be required to prevent nuisance motor overload tripouts at starter transition. This bulletin applies only to CVHA and CVHB low voltage machines shipped prior to July 1982. Units shipped after July 1982 have SSOLs which have been modified to prevent nuisance tripouts.

Other CenTraVacs which have the motor protection module system field installed may also be affected.

DISCUSSION:

Some CVHA and CVHB CenTraVacs have exhibited a nuisance motor overload trip which may occur at transition on star/delta starters. This is caused by high transient currents produced during transition. These transient currents do not occur on all units. The occurrence is dependent upon the speed of starter operation (contact closure during transition), motor construction (manufacture of stator) and unit load at start-up.

A starter which transitions slowly (takes a relatively long time for the contactors to complete transition once it has been initiated) may allow the motor to slip out of phase with incoming power. The resulting slip then can produce a transient current as the starter connects to delta. Because of this, older style units on which motor/starter protection retrofit kits are being installed, may also be susceptible to these nuisance tripouts.

The original manufacturing tolerances inherent in stator windings also influence the transition transient currents. Therefore, even with two identical motors it is possible that one may experience nuisance tripout and the other may not. It is not possible to predict which machines may experience nuisance tripouts until the unit is actually operating under field conditions.

A heavy evaporator load at start, (warm evaporator water) will typically cause longer acceleration times. High starting load causes transient currents which are higher and of longer duration. Therefore, a unit which starts normally with cool evaporator water, may experience a nuisance tripout under an extremely hot start condition.

Overload Identification:

As stated in the Introduction section of this Bulletin, units shipped after July 1982 are equipped with SSOLs which have been modified.

Before proceeding to the corrective action section of this bulletin, the overload module should be inspected to determine if it is the earlier version. Examine the terminal strip as shown in Figure 1. When looking into the SSOL with the terminal strip toward the top, as it is mounted in the starter, the fifth and sixth terminals from the right in an unmodified SSOL are labeled F1 and F2. Terminals 5 and 6 in a modified SSOL are labeled E1 and E2. The upper two screw terminals on the swing out of an unmodified SSOL circuit board are labeled F3 and F4. The modified SSOL terminals are labeled E3 and E4 (see Figure 2).

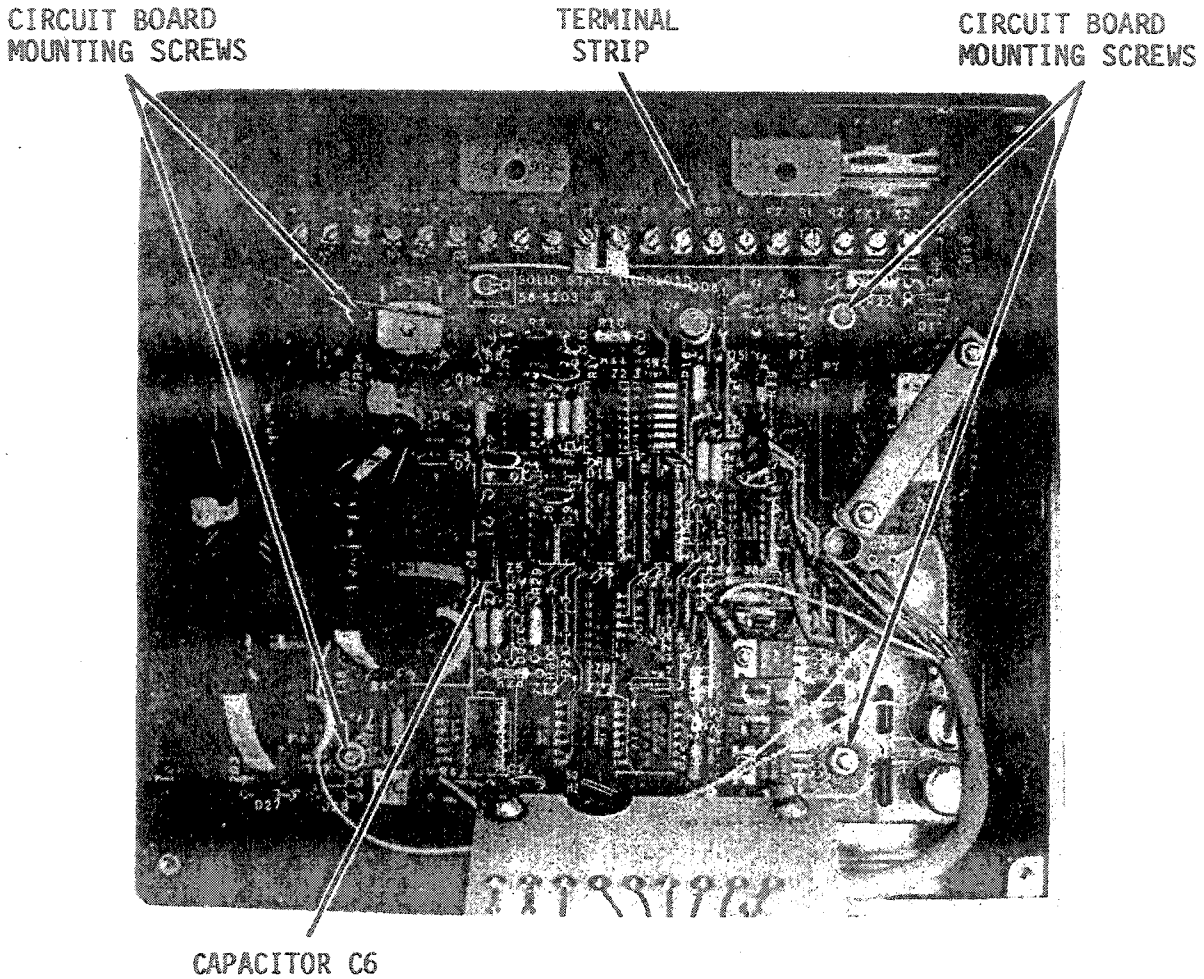

FIGURE 1 - Solid State Overload Circuit Board

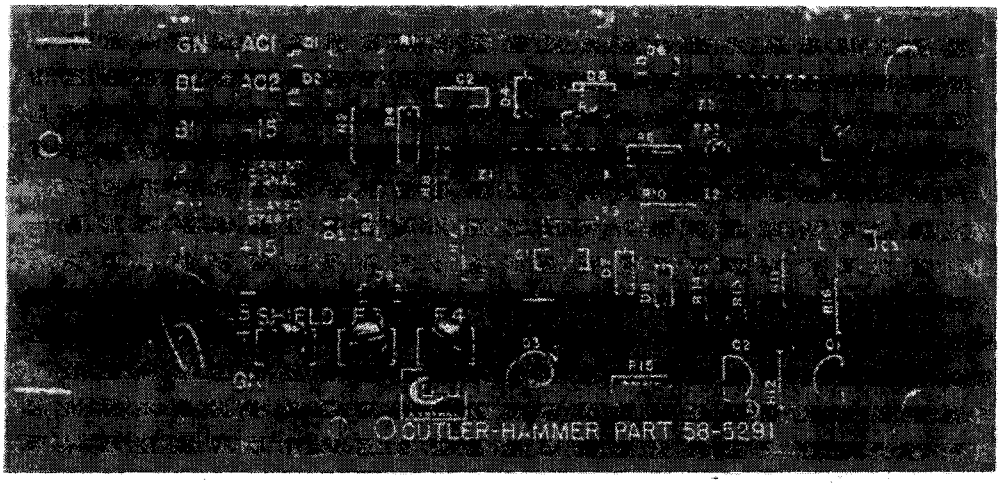

FIGURE 2 - Solid State Overload Swing Out Circuit Board

Any SSOL without the swing out circuit board is an unmodified model.

The modified SSOL has the changes described in this bulletin incorporated into its circuitry. Therefore, the modification described here is not applicable to a modified SSOL.

Tripout Diagnosis:

Proper identification of the exact time of the tripout occurrence is very important. The corrective action described in this bulletin applies only to tripouts which occur precisely as the contactors finish transition from start to delta. The motor will accelerate normally, transition will occur as the current drops to 80% of RLA as normal, but as soon as the contactors can be heard transitioning the "Motor Overload" fault trip indictor on the starter door will trip. If the nuisance tripout does not occur precisely at transition as described, the following corrective action does not apply.

CORRECTIVE ACTION:

Corrective action involves replacement of the C6 capacitor on the main circuit board in the SSOL. The C6 capacitor originally supplied on all SSOL's provides approximately an 8 cycle delay after transition before the module begins to sense running current. The addition of a larger capacitor increases the delay time preventing nuisance tripouts. The C6 capacitor that needs to be replaced is shown in Figure 1. This designation is written on the circuit board next to the capacitor. The capacitor has a flat rectangular shape and is orange in color.

For replacement, a 40 to 70 mf (micro farad) electrolytic capacitor rated between 35 and 50 volts should be used. Such capacitors are available at most electronic supply stores.

To remove the old capacitor, it will be necessary to remove the main circuit board. It is held in place by four screws located near the corners of the circuit board. See Figure 1. The board is held in place with electrical isolating washers and star lockwashers. Care must be taken to note the location of these parts while the board is being removed, so that they are replaced correctly.

Once the circuit board has been removed, the capacitor can be desoldered and removed.

NOTE: A soldering pencil of no larger than 35 watts should used when soldering electronic components. Higher power soldering irons may overheat the components causing failure.

Excess solder will often be left in the mounting holes when the old capacitor is removed. This may make installation of the new capacitor difficult. The excess solder may be removed with a desoldering tool or "solder sucker". This is a tool which sucks melted solder from the soldered joints. This tool is available at most electronic supply stores.

Once the old capacitor has been removed, the new one may be installed. The original capacitor was a non-polarized type while the new one is polarized and must be installed correctly.

NOTE: The new capacitor must be installed with the correct polarity to prevent failure of the SSOL.

The correct polarization of the capacitor is with the positive (+) end toward the terminal strip.

Insert the new capacitor into the circuit board and solder in place. Be careful not to use too much solder. Excess solder can cause a short circuit on the circuit board. Clip the excess wire off the capacitor leads. Bolt the circuit board back into the black box. Be careful to-reinstall all spacers and insulators in the correct position. Carefully reinstall the SSOL in the starter making sure it is wired correctly.

NOTE: The F1-F2 terminals of the unmodified SSOL are <u>not</u> 115 VAC power inputs. XX1-X2 are the 115 VAC power inputs. The control voltage wiring in the starter, which is used to power the SSOL, may be labeled F1 and F2. These wires do not go to F1 and F2 in the SSOL, they go to XX1 and X2. The F1 and F2 terminals of the SSOL should be wired to the "Motor Overload" fault trip indicator. Follow the unit wiring diagram when reinstalling the module.

<u>PARTS ORDERING INFORMATION:</u>

All parts should be purchased locally.

<u>NEW PRODUCTION:</u>

CenTraVac starters (direct ship and unit mounted) shipped after July 1982, are equipped with the modified SSOL which eliminates the nuisance tripout.

Literature History:
CTV-SB-66D - 3/29/85 Added additional size Gasket Eliminator 515
CTV-SB-66E - Changed Trane Part Number for Chisel in Table 3
CTV-SB-66F – Added information for units built without o-rings

Subject: CenTraVac™ O-Ring and Flange Sealant

Introduction:
This service bulletin recommends the sealant and sealing methods to be used when installing new o-rings on Trane centrifugal liquid chillers using R11, R113 and R123. This bulletin also discusses recommendations for installing o-rings on Trane medium pressure centrifugal chillers using R12, R22 and R134a. The sealing of chiller components designed and assembled without the use of o-rings or gaskets is also covered in this bulletin.
Note: The information in this bulletin does not apply to sealing applications for flat rubber gasketed surfaces or other sealing methods and designs.

Discussion:
Trane recommends using Loctite Gasket Eliminator 515 on all refrigerant to atmosphere o-ring connections (except CVHE, CVHF, CVHG, CDHF and CDHG suction elbows to suction cover connection) on all centrifugal liquid chillers using R11, R113, R123, R12, R134a. The o-ring and its material properties along with the design of the casting mating surfaces are intended to provide a leak free joint without the aid of additional sealing compounds. However, providing an additional sealing mechanism with the use of Gasket Eliminator 515 extends the sealing design life of the joint and helps seal some of the minor surface imperfections in the casting and machined surfaces. These surface defects can occur due to nicks and gouges that occur due to disassembly and cleaning or due to rust and corrosion that can occur in some installations.

Minute leaks often show up at the jack-bolt holes on castings. Electronic leak detectors can often sense an intermittent refrigerant leak at the jack-bolt holes since this is a captive area where refrigerant will collect. An intermittent leak does not indicate the amount of actual leakage at that connection and additional methods should be used to verify the leak quantity. One such method is to evaluate the amount of purge time required to remove air from the unit. Another method is to plug the jack-bolt holes and use a soap solution to confirm a leak at the flange edges. Check the leak at the jack-bolt holes with a Halide leak detector and observe for a continuous leak indication. Make sure that any leak indication is properly evaluated to determine if further observations, unit testing or repairs are necessary.

© 2002 American Standard Inc.

Since Trane has a policy of continuous product improvement, it reserves the right to change design and specification without notice. The installation and servicing of the equipment referred in this document should be done by qualified, experienced technicians.

Trane recommends the use of Loctite Gasket Eliminator 515 to insure all R11, R113, R123, R12, and R134a centrifugal chiller refrigerant to atmospheric o-ring and flange connections are as leak free as possible after field repairs. This discussion may not apply to reciprocating or helical rotor compressor designs.

⚠ CAUTION

Chemical Irritant!

Loctite Gasket Eliminator 515 has been shown to be a skin, eye and respiratory irritant. Always wear proper eye protection, plastic or rubber gloves, long sleeves and pants and avoid prolonged inhalation of vapors. Obtain a copy of the vendors Material Safety Data Sheet (MSDS) and follow all safe handling practices provided. Failure to follow all safety instructions could result in minor to moderate injury.

Recommended Application:
Loctite Gasket Eliminator 515 is a relatively fluid substance that will not harden in the presence of air. It will set up to form an effective seal between the o-ring and the mating surface, or between the mating surfaces, in the absence of air after the flanges or castings have been properly torqued. Loctite should not be applied to any o-ring mating surface where excessive amounts of it can extrude or seep into undesirable areas, making removal of additional components difficult. An example of this would be the suction elbow o-ring to the suction cover on CVHE, CVHF, CVHG, CDHF and CDHG units. See Figure 3. See the section for installation of the suction elbow.

To insure a leak free joint after rebuild, apply Loctite Gasket Eliminator 515 to grooved o-ring joints as follows:

Check the fit of the o-ring in the flange or casting groove to insure the correct size o-ring is being used. See the section entitled "Determining Maximum Allowable O-Ring Stretch".

1. Inspect the o-ring groove for nicks and scratches. Minor surface scratches or nicks can be repaired by filling the imperfections with a soft soldering material, then filing or sanding the surface to a acceptable finish as described in the "Flange Surface Preparation" section.

2. Remove all high spots or burrs that may have occurred on the flange faces because of the use of the jack bolt holes. File the high spots and burrs to obtain a flat surface.

3. Check the expiration date on the tube of Loctite. Important! Do not use Loctite beyond the expiration date.

4. Apply a bead of Loctite 515 (1/8" diameter max) to the entire circumference of the bottom inside diameter (I.D.) of the o-ring groove as shown in Figure 6.

5. Place the o-ring into the groove and gently press it into sealant.
   Note: O-Rings should not be stretched more than 5 % of their inside diameter dimension once seated in the groove. See section on determining the maximum amount of allowable stretch.

6. Apply a bead of Loctite 515 (1/8" diameter max.) to the entire circumference between the o-ring and top outside diameter (O.D.) of the groove as shown in Figure 6.

7. A final smaller bead (1/16" diameter maximum) should be applied around the flange-mating surface between the o-ring groove and the bolt holes as shown in Figure 6.

8. Assemble the mating surfaces and install and properly torque all bolts. Ideally, Loctite recommends that no more than 3 minutes be allowed to elapse between the mating of the flanges and the application of the final bolt torque.

9. In standard conditions (plant room temp 21°C (70°F) or above) allow the Loctite to cure for a minimum of 8 hours before adding refrigerant to the unit.

The use of Loctite Primer N® or Loctite Primer T® accelerators will reduce the effective cure time of the Loctite 515 to as little as 15 minutes, thereby increasing the risk of the product partially curing before assembly and final bolt torque. If the Loctite partially cures during assembly it may act as a shim and prevent a proper seal. Because of this risk the use of accelerating primers is not recommended as a standard service procedure.

Determining Maximum Allowable O-Ring Stretch:
In general, o-rings used by Trane in sizes larger than 20.0" inside diameter (I.D.) are furnished in one-inch increments. The actual inside diameter of o-ring machined grooves may vary depending on the application, which may require a standard size o-ring to be stretched to fit the groove I.D. For instance an o-ring with a 60.0" I.D. will have an inside circumference of 60.0 x 3.14 (Pi) or 188.4". When used in a groove with a 60.75" I.D. (60.75 x 3.14 = 190.75" inside circumference) the o-ring will need to be stretched approximately 190.75" – 188.4" or 2.35".

O-rings may be stretched up to 5% of their inside diameter per the manufacturer's recommendations. In the example above, the 2.35" of stretch is well within the allowable tolerance for an o-ring with a 60.0" I.D.

Before installing an o-ring with Loctite hold it up to the groove and determine the amount of stretch that will be required. To do this place the o-ring in the top of the groove and work it around the groove until the bottom portion of the o-ring becomes horizontal. See Figure 5. Do not stretch the o-ring at this point. Measure the distance (Dimension "A") from the bottom of the horizontal o-ring to the bottom inside diameter of the o-ring groove. Determine the actual inside diameter of the o-ring machined groove and find the groove diameter closest to the actual measured value in Table 1. Compare the measured dimension "A" to the value shown in the table +/- 1/4" to determine if the required stretch will be less than the maximum allowable 5%. The following table shows the maximum allowable dimension "A" for all o-ring sizes from 20.0" to 60.0" inches. Any o-ring where the dimension measured is greater than the "A" dimension shown in Table 1 should not be used as the amount of stretch required will be greater than the 5% allowed by the o-ring manufacturer. Dimension "A" for any groove inside diameter can be determined by multiplying the measured groove inside diameter x .2204.

Example: Groove measured at 36.75" I.D. x .2204 = 8.1" "A" dimension.

Table 1 – Shows Maximum Allowable "A" for All O-Ring Sizes

Groove I.D.	Dim. "A"	Groove I.D.	Dim "A"	Groove I.D.	Dim. "A"
20	4.4	34	7.5	48	10.6
21	4.6	35	7.7	49	10.8
22	4.8	36	7.9	50	11.0
23	5.1	37	8.2	51	11.2
24	5.3	38	8.4	52	11.5
25	5.5	39	8.6	53	11.7
26	5.7	40	8.8	54	11.9
27	6.0	41	9.0	55	12.1
28	6.2	42	9.3	56	12.3
29	6.4	43	9.5	57	12.6
30	6.6	44	9.7	58	12.8
31	6.8	45	9.9	59	13.0
32	7.1	46	10.1	60	13.2
33	7.3	47	10.4		

Suction Elbow To Evaporator Flange:
The lower suction elbow to evaporator flange joint can be assembled using Loctite as described above.

The upper suction elbow connection to the compressor suction cover should be installed with no Loctite sealant on the o-ring and a back up Gore-Tex (GKT-2694) tape installed between the o-ring groove and the inner suction connection opening in the elbow. See Figure 4.

Installing the Gore-Tex tape:

1. Remove the adhesive backing strip from the Gore-Tex tape and install the material approximately 1/8" inboard of the o-ring groove I.D. This should be done before installation of the o-ring to avoid contaminating the surface with petroleum jelly, which could prevent the Gore-Tex from adhering to the flange surface.

2. Overlap the ends of the Gore-Tex as shown in Figure 4.

3. Lightly coat the o-ring with petroleum jelly to help it stay in the o-ring groove during installation.

Units Without Jack-Bolt Holes:
In any application using Loctite 515 as a sealant, jack-bolt holes should be present for future disassembly. If jack-bolt holes are not present refer to Figure 7 and the following procedure to tap the casings. The procedure is for CVHE units but can be modified for all other units.

Note: Model CVHE CenTraVacs built prior to November 1983 do not have jack-bolt holes. Some of these units were assembled with Loctite and will need jack-bolt holes. Casings should not be forced apart without the use of jack-bolts. Follow the procedure below. Uneven force could cause the casings to crack□

1. Remove three of the 5/8-11 bolts (120 degrees apart) that hold the casings together. The bolt clearance hole opening will be 3/4"-inch diameter.

2. Refer to Table 2 and select the proper tap for the 3/4" inch bolt hole opening. For this example, use a 7/8"-9 tap.

Table 2 – Shows Proper Tap for 3/4" Bolt Hole

Bolt Hole Opening	Tap Size	Threads Per Inch
5/16"	3/8"	16
27/64"	1/2"	13
17/32"	5/8"	11
3/4"	7/8"	9

3. Tap the holes with a 7/8"-9 tapered tap, which will allow several threads to be started easily. The remaining tapping should be done by using a 7/8"-9 bottoming tap. This will allow the maximum number of threads to be formed without damaging the 5/8"-11 threads in the adjoining casting.
   Note: When tapping, a cutting oil should be used to minimize the possibility of tap breakage or thread damage.

4. To separate the casings, insert the 5/8"-11 bolt as shown in Figure 7. Insert a 1/2" steel ball and the 7/8"-9 bolt. By removing the remaining 5/8"-11 bolts and inserting the rigging and guide pins as necessary to remove the casing, the 5/8"-11 bolts can be tightened until they exert force on the steel balls and the 7/8"-9 bolts. This force, when uniform at all three points, will separate the casings.

5. With proper rigging the casing can be removed safely.

When Loctite 515 has been used, field clean-up of the casings can be difficult. Loctite offers gasket-removing compounds called "Chisel" and "Chisel MC Free," which are available in aerosol cans. When using "Chisel," "Chisel MC Free," or any other solvent, the manufacturer's safety recommendations should always be followed completely.

The use of Loctite on flat rubber gaskets is not recommended.

⚠ WARNING

Hazardous Chemicals!

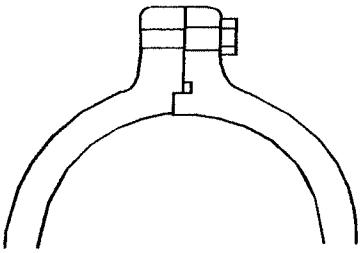
Some gasket removal compounds (such as Loctite #790 Gasket Remover- Chisel) may contain chemicals that are known be skin, eye and respiratory tract irritants. Always wear proper eye protection, plastic or rubber gloves, long sleeves and pants and avoid prolonged inhalation of vapors. Obtain a copy of the vendors Material Safety Data Sheet (MSDS) and follow all safe handling practices provided. Failure to follow all safety instructions may result in death or serious injury.

CenTraVac Flanges Assembled Without O-Rings:

Beginning in late 1999 Trane began eliminating the use of some o-rings and gaskets in motors and compressors on CVHE/F/G, CDHF/G, and CVGF units. Loctite 515 Gasket Eliminator® is used alone to seal flanges designed and constructed without o-rings or gaskets. In the early stages of the program only the inspection covers and end shields of the CenTraVac motors were affected, later results of the program will include other various motor and compressor flange assemblies. Various CVGF motor and compressor joints are also assembled using this new technology and may be without o-rings or gaskets. This section will provide the proper service procedure to be used when servicing a motor or compressor flange assembly that does not have an o-ring groove, an o-ring, or a gasket.

Note: Components designed and assembled without o-rings use a new flange design that eliminates the o-ring groove. The procedures described in this section do not apply to components that were originally assembled with o-rings. Units originally constructed with o-rings should be properly repaired using o-rings in conjunction with Loctite 515 sealant. Refer to the preceding sections of this bulletin for information regarding the servicing and repair of CenTraVac flanges and joints constructed with o-rings.

Figure 1: Typical original flange design with o-ring groove.



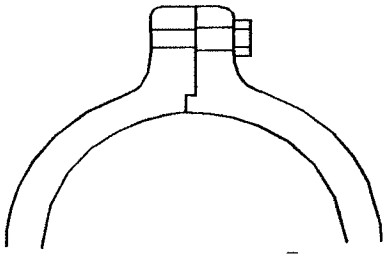


Figure 2: Typical new flange design with o-ring groove removed.

Flange Separation:

Unit flanges constructed without the use of o-rings or gaskets will have adequate jack-bolt holes to allow the separation of the sealed flanges. Insert the appropriate size bolts into the jack-bolt holes, and install the rigging and guide pins that are necessary to safely remove the part. Remove the remaining bolts and apply a uniform tightening force to all jack-bolts and the flanges will separate.

Flange Surface Preparation:

Surface preparation prior to the reassembly of a joint constructed without o-rings will first require the removal of the old Loctite 515.

Cured Loctite 515 may be removed with a scraper, such as a putty knife or gasket removal tool, if care is taken to not seriously scratch or gouge the flange. Wire or abrasive bristle brushes, either hand or powered, may also be used but care must be taken to ensure that you do not polish the flange. Do not use solid grinding wheels or disks or powered sanding tools because of the excessive damage they may cause to the flange surface.

Remove all high spots or burrs that may have occurred on the flange faces because of the use of the jack bolt holes. File the high spots and burrs to obtain a flat surface.
Loctite 515 is not effective on polished or "glass-smooth" surfaces. If a flange surface does get extremely smooth (mirror-like), use some 80 to 120 grit sandpaper on a hand-sanding block to rough up the surface and complete the removal of the cured Loctite.

If using a gasket removal chemical such as Loctite Chisel® or Chisel MC Free®, read and follow all of the manufacturers' directions carefully. Review the product MSDS sheet and be aware of and follow any safety requirements for eye, face, and hand protection, space ventilation, respirator use, waste disposal, etc.

⚠ WARNING

Hazardous Chemicals!

Some gasket removal compounds (such as Loctite #790 Gasket Remover- Chisel) may contain chemicals that are known be skin, eye and respiratory tract irritants. Always wear proper eye protection, plastic or rubber gloves, long sleeves and pants and avoid prolonged inhalation of vapors. Obtain a copy of the vendors Material Safety Data Sheet (MSDS) and follow all safe handling practices provided. Failure to follow all safety instructions may result in death or serious injury.

During Loctite removal, use cloth or plastic to cover any openings in the parts or the chiller. Avoid the uncontrolled use of compressed air or nitrogen to blow sealant debris from the part, as it may push the debris into inaccessible areas. Take all possible actions to keep the internal chiller parts clean and free of debris.

After the flange surfaces are free of any cured Loctite and the surface finish is acceptable, wipe the flanges clean with industrial quality Isopropyl Alcohol applied with a clean towel or rag. Do not contaminate the flange surface by using a dirty or oily rag. Do not use a rag that deposits fibers on the surface. Do not use Isopropyl Alcohol wipes that contain lanolin or other oils. Avoid touching the cleaned flange surface with bare hands as body oils can affect the adhesion of the sealant.

Sealant Application:
With both mating flanges fully cleaned and ready, select one of the flanges and apply 2 continuous beads of Loctite 515 in a crossing pattern as shown in Figure 8. The approximate thickness of each bead of sealant is given in Table 3. The thickness of the bead that is applied can be adjusted by trimming the tip of the applicator tube and by varying the pressure that is applied to the sealant container. Practice on a different surface may be desirable before applying Loctite to the actual flanges.

Ensure that all process holes and jack-bolt holes have sufficient Loctite 515 applied directly around them. A process hole is a hole that was used during the factory machining process, it may be unused or open on the final assembled product.

Table 3: Loctite 515 bead size when no o-ring is applied

Flange Face Width (inches)	Sealant Bead Size (inches)
1 1 ¼	3/32
1 ½ 1 ¾ 2 2 ¼	1/8
2 ½ 2 ¾ 3 3 ¼ 3 ½	5/32
3 ¾ 4	3/16

After the sealant is applied, quickly assemble the flanges and properly torque all fasteners.

Loctite 515 is an anaerobic sealant and very little curing will occur until the sealant is pressed between the flanges and air can no longer contact it. However, Loctite 515 will begin to cure very quickly once the flanges are assembled. Because of it's fast cure rate it is recommended that the time between Loctite application, flange assembly, and final bolt torque be kept as short as possible. Ideally, Loctite recommends that no more than 3 minutes be allowed to elapse between mating of the flanges and applying the final bolt torque.

Typical effective cure times for Loctite 515 will range from 1 to 12 hours depending on surrounding temperatures and flange gaps. For our typical applications and in a plant room with a surrounding temperature of 21°C (70°F) or higher we recommend that a minimum of 6 to 8 hours be allowed before pressure testing, evacuation, or charging of the unit. For plant room temperatures below 21°C (70°F) a minimum time of 12 hours is recommended before pressure testing, evacuation, or charging of the unit.

Application of Loctite 515 at ambient temperatures below 8°C (46°F) is not recommended.

⚠ CAUTION

Chemical Irritant!

Loctite Gasket Eliminator 515 has been shown to be a skin, eye and respiratory irritant. Always wear proper eye protection, plastic or rubber gloves, long sleeves and pants and avoid prolonged inhalation of vapors. Obtain a copy of the vendors Material Safety Data Sheet (MSDS) and follow all safe handling practices provided. Failure to follow all safety instructions could result in minor to moderate injury.

The use of Loctite Primer N® or Loctite Primer T® accelerators will reduce the effective cure time of the Loctite 515 to as little as 15 minutes, thereby increasing the risk of the product partially curing before assembly and final bolt torque. If the Loctite partially cures during assembly it may act as a shim and prevent a proper seal. Because of this risk the use of accelerating primers is not recommended as a standard service procedure.

Parts Ordering Information:
Loctite Gasket Eliminator 515 and Gore-Tex tape are available from Trane as follows.

Table 4 – Shows Gasket Eliminator 515 and Trane Information

Description	Trane Part Number
Gasket Eliminator 515 (50 ml tube) (Carton 10 pieces)	SEL00489
Gasket Eliminator 515 (300 ml caulking tube)	SEL00376
Gore-Tex (.03 + K x .12W x 150 inches)	GKT02694

Note: Loctite 515 Gasket Eliminator® should ideally be stored in a cool, dry location in unopened containers at a temperature that is between 8° to 28°C (46° to 82°F). Do not use previously opened sealant. Loctite 515 Gasket Eliminator® has a limited shelf life, SEL00376 300ml caulking tubes have a "use by" date marked on each individual tube. Smaller SEL00489 50ml tubes have the "use by" date marked on the bulk carton the tubes are shipped in, so be sure to note this date when removing tubes from the carton for individual sale or use.

Review the Loctite 515 Gasket Eliminator® MSDS sheet and be aware of and follow any safety requirements for eye, face, and hand protection, space ventilation, respirator use, waste disposal, etc.

SUBJECT: CENTRAVAC® MOTOR CURRENT IMBALANCE

INTRODUCTION:

The purpose of this Service Bulletin is to discuss the causes and effects of CenTraVac motor current imbalance, define imbalance limits and provide troubleshooting methods.

DISCUSSION:

Motor current imbalance causes a general decrease in unit performance, which increases motor heat and reduces motor torque, power factor and motor speed. Motor current imbalance should be avoided as much as possible. A CenTraVac motor which has balanced voltage at the motor terminals should not have significant current imbalance, when measured at the supply leads.

The main cause of unbalanced motor amperage is voltage imbalance. Another cause is winding resistance imbalance, which is very rare due to the stringent specifications employed by the motor manufacturer during the winding and testing of new motors.

The following jobsite conditions can cause voltage variations which result in amperage imbalance:

1. Extreme difference in either line to starter or starter to motor terminal lead lengths.
2. Different conductor sizes between phases.
3. Unequal phase representation of conductors in a conduit. This will also cause excessive conductor temperatures, due to unbalanced magnetic flux.
4. Unbalanced single phase loads within the customer or power company distribution system.
5. Loose starter and/or motor terminal stud connections.

Motor Amperage And Voltage Imbalance

The following formula may be used to convert voltage and current readings taken on a motor, to a percentage unbalance.

* THE TRANE COMPANY 1983
COMMERCIAL SYSTEMS GROUP
LA CROSSE, WISCONSIN 54601-7599

For example, on a 208-volt system, the readings at the motor terminals are 219, 213 and 220 volts. To find the percentage of imbalance, use the following formula:

$$\frac{219 + 213 + 222}{3} = 218 \text{ (average)}$$

$$\frac{(218 - 213)}{218} \times 100\% = 2.29\% \text{ imbalance}$$

Use Chart 2 to obtain a derating factor of 0.93. The unit safety settings (overloads, etc.) which are based on nameplate RLA, should be set for 0.93 x RLA due to the voltage imbalance of 2.29 percent.

If there is a current imbalance with no measureable voltage imbalance, the cause (either a motor or line problem) must be determined. This can be done by rotating the motor leads to find out if the current imbalance stays with one particular motor winding or if it follows one set of phase leads as the wires are rotated. The motor should be operated only long enough to obtain current measurements. Since some motors have uni-directional bearings, rotate the motor leads twice to keep the proper motor rotation.

Example: The following current measurements were taken from a unit:

Line Lead Numbers	1	2	3
Line Phase Designation	A	B	C
Current Measurement	200	182	208

Using the formula, there is a current imbalance of 5.8 percent. This would be an excessive imbalance for a motor running, with balanced voltage near its full load current.

If the voltage imbalance on the system is negligible, switch two sets of leads around. This applies the phase voltages across different motor windings as shown in the following example:

Line Lead Numbers	1	2	3
Line Phase Designation	B	A	C
Current Measurement	155	148	165

The readings taken before and after rotating the leads shows that the current imbalance follows the incoming lead change. The "C" phase is high and the "A" phase is low, which indicates that incoming power is causing the current imbalance. If voltage imbalance is not the cause, it could be the result of unbalanced impedance or resistance somewhere in the power system. Contact the local power company or correct the problem.

If the current imbalance remained with the motor phases (high current on 3 and 6 windings), contact the La Crosse Service Department with complete motor nameplate information.

SUBJECT: INSTALLATION OF THE DISTRIBUTION FAULT AUTOMATIC RESET OPTION USED ON CENTRIFUGAL UNITS

INTRODUCTION:

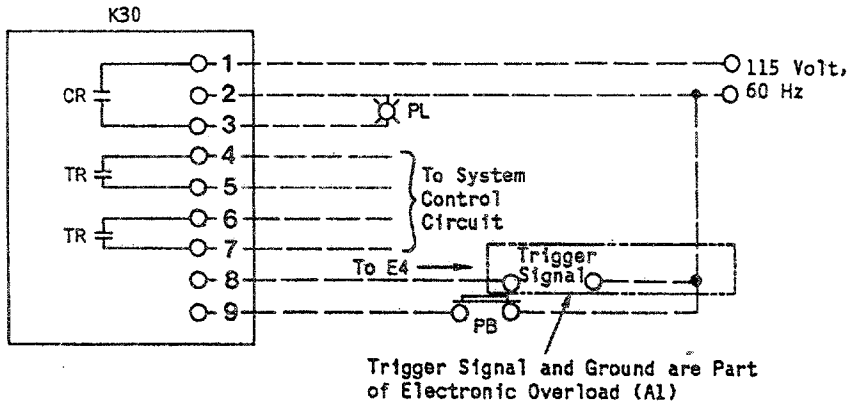
This service bulletin provides instructions for installing a distribution fault automatic reset option on centrifugal units that use the Cutler Hammer solid state overload. This option is designed to automatically restart the unit after line power has been restored following a power loss.

Also discussed is a possible nuisance condition with the timing relationship between the Model CVHE oil pump, the anti-recycle timer, and the distribution fault timing.

DISCUSSION:

This section explains the function of the standard distribution fault option and the need for automatic reset.

A distribution fault is defined as a loss of three-phase line voltage due to a distribution system failure. When a power failure occurs during unit operation, the solid state overload senses the immediate drop in line current while the starter remains energized. The overload responds by tripping the distribution fault breaker to stop unit operation. The breaker must be manually reset to restart the unit. Since some buildings require continuous cooling, it is not practical to manually reset the breaker every time the power is interrupted. To eliminate the manual reset, an automatic reset module can be installed to restart the unit within two minutes after the main supply power is restored.



Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Manual Reset Operation

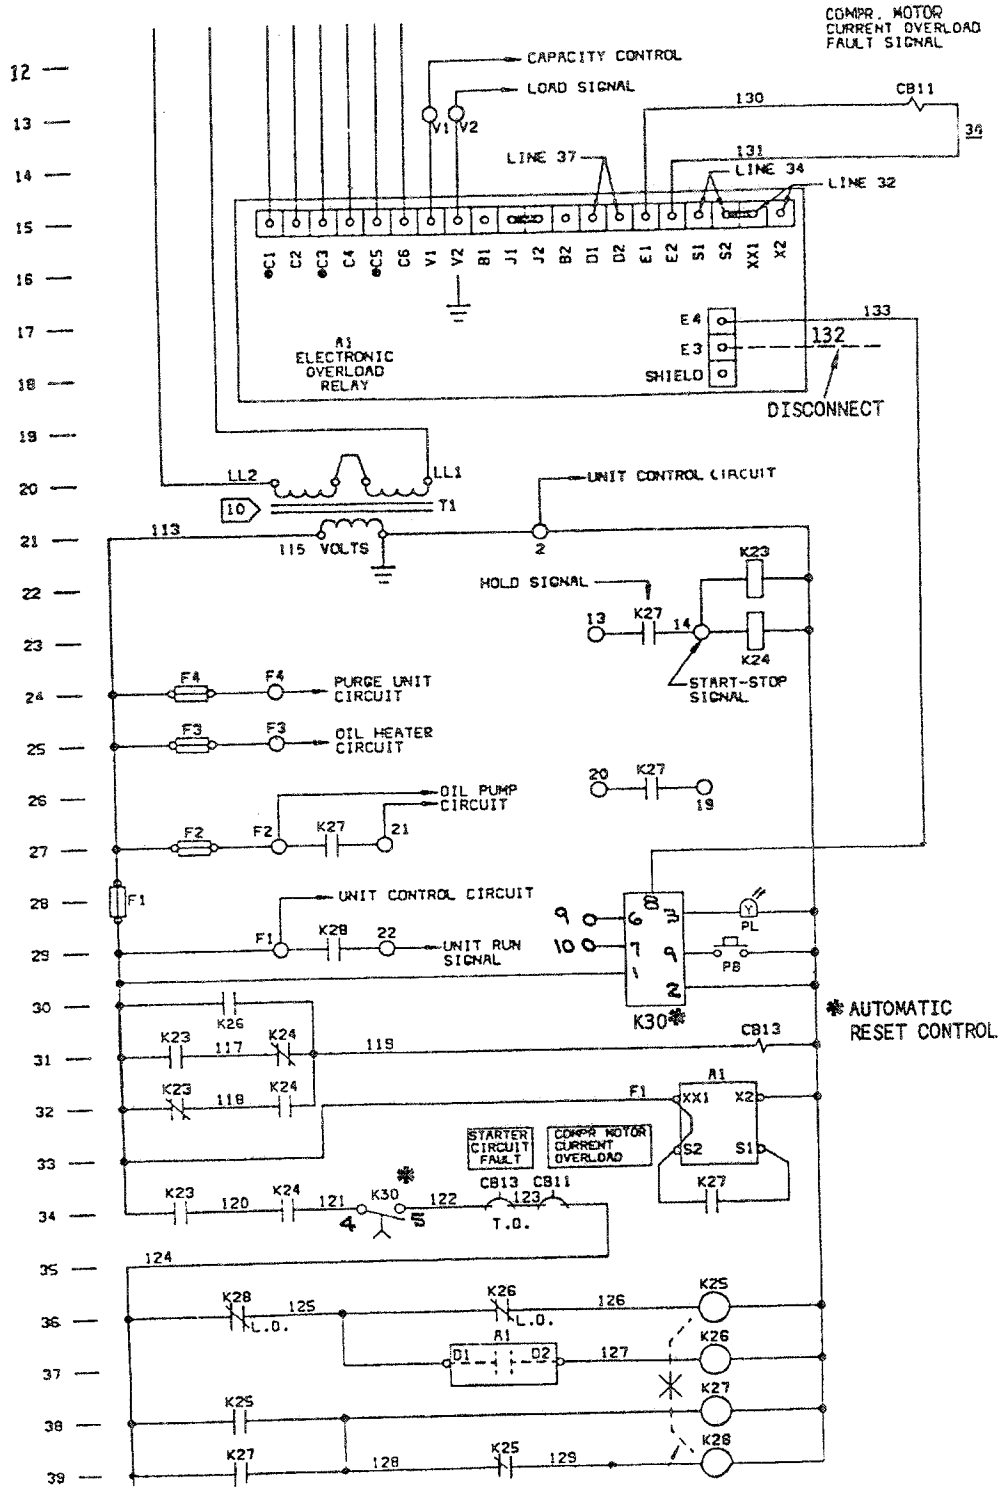
As soon as line voltage is lost, a trigger voltage generated by the solid state overload (A1) is applied to Terminal 8 of the reset control. This 28 VDC signal causes the normally closed TR contacts (Terminals 4 to 5 and 6 to 7 of K30) to open. When these contacts open, the unit shuts down. Two minutes after the trigger voltage has disappeared and line voltage has been restored, the TR contacts will reclose, allowing restart of the unit, provided the 30-minute anti-recycle timer has timed out.

Simultaneously with the generation of the trigger signal, the CR contacts will close, applying power to Terminal 3 which activates a pilot light. This CR is a latching relay which means that the pilot light will remain energized as long as the 115 volt supply power is on. Closure of the push button contacts will reset this CR circuit and extinguish the pilot light. The push button may have to remain depressed for two or three seconds to allow the capacitor in the latching circuit to completely discharge. See Figure 1.

Figure 1
Automatic Reset Control
Wiring Connections

AUTOMATIC RESET INSTALLATION:

To install the automatic reset option, use the following procedure:



CVHE Control System

1. Remove the jumper from Terminals 9 and 10 of the unit control panel.
2. Connect the leads from Terminals 6 and 7 of the automatic reset control (K30) to Terminals 9 and 10. See Figure 2.
3. Disconnect wires 121, 122, 132 and 133 from the distribution fault circuit breaker (CB15) which is mounted on the starter panel door.
4. Remove CB15 from the starter panel door.

Figure 2
Typical Starter
Schematic Diagram

5. Mount the automatic reset control (K30) in an easily accessible location inside of the starter panel.

   To install the automatic reset control, two 3/16-inch diameter holes must be drilled as shown in Figure 3. Mount the control using two #8-32 screws with washers and nuts.

6. The push button pilot light assembly (PB/PL) should be mounted in the location that was occupied by CB15. A hole must be cut in the panel as shown in Figure 4. A ring is provided for mounting the assembly to the starter panel door.

   Figure 5 illustrates the push button pilot light assembly and Figure 6 shows the wiring connections for the assembly.

7. Wire the automatic reset control according to the schematic diagrams shown in Figures 2 and 7. Wires 121 and 133 that were removed from CB15 can be reused. Connect wire 121 to K30 (Terminal 4), wire 122 to K30 (Terminal 5) and wire 133 to K30 (Terminal 8). Additional 16 gauge wire may be required. Remove or insulate wire 132.

"A" and "B" Design Motor/Starter Protection System (MSPS)

1. Mount the automatic reset control (K30) in the upper right-hand corner of the MSPS. The mounting holes are pre-drilled on the "B" design MSPS.

2. Remove the knockout in the MSPS panel door and install the pilot light and push button switch. When the installation is complete, this light will indicate that automatic reset has occurred.

3. Run the two wires from the pilot light to terminals 2 and 3 of the automatic reset control.

4. Run one wire from the push button to the ground side of the pilot light. Run a second wire from the push button to terminal 9 on the automatic reset control.

5. Remove the jumper between terminals 2 and 2A on the MSPS. Run wires from terminals 2 and 2A to terminals 6 and 7 respectively on K30.

6. Disconnect the shielded wires E3 and E4 from the distribution fault circuit breaker (CB14). Reconnect wire E4 to terminal 8 of the automatic reset control (K30). Wire E3 is not needed, so it should be well insulated and tucked out of the way.

7. Run a 120 volt wire from terminal XX1 of the MSPS to terminal 1 of the automatic reset control.

8. Connect terminal 2 of the automatic reset control to terminal X2 of the MSPS.

Terminals 4 and 5 of the automatic reset control are not used. Refer to Figure 1 for wiring details.

Nuisance Tripping of the Low Oil Pressure Fault Indicator

Nuisance tripping of the low oil pressure fault indicator can occur due to improper timing between the automatic reset control, the anti-recycle timer and the oil pump timer of Model CVHE units. This condition can occur when unit attempts to restart after a distribution fault has occurred. The automatic restart control allows for a two minute delay after power has been restored, during which time the oil pump timer is in the post-lube timing cycle. If the anti-recycle timer has timed out, it will begin its normal timing cycle after the two minute lockout cycle of the automatic reset control. In some cases, the post-lube timing cycle of the oil pump timer is completed before the anti-recycle timer can initiate a restart. As the oil pump timer recycles, it interrupts the low oil fault indicator.

To insure that the automatic reset control does not interfere with the timing of the oil pump, the timing of the automatic reset control should be changed from two minutes to thirty seconds, which allows the start signal to be received before the oil pump timer has timed out.

To change the timing of the automatic reset control (Figure 8) to thirty seconds, remove the four cover screws and lift out the panel. The control components are located on the back side of the panel. Remove the resistor shown in Figure 9 and replace it with a 1/2-watt, 120K ohm resistor.

Literature Changes:

Added clarification that this bulletin only applies to "Version 1" and "Version 2" of the Cutler-Hammer SSOL.

Subject: CUTLER-HAMMER SOLID-STATE OVERLOAD (SSOL) UPGRADE

Introduction:

This service bulletin outlines several recommended changes and additions to "Version 1" and "Version 2" of the Cutler-Hammer solid-state overload ("SSOL"; Trane part no. RLY-765). Built from 1981 through December 1986, the affected SSOLs were used in CVHE, CVHB, CVAC and MSPS retrofit kit applications.

Note: By March 1st, 1987, 4 different versions of the Cutler-Hammer SSOL (electrically designated as "A1") will be available in the field. However, **only "Version 1" and "Version 2" are affected by the upgrade described in this bulletin since these improvements are completed by the factory on "Version 3" and "Version 4" of the SSOL!** To distinguish one version of the SSOL from another, look for the following identifying characteristics:

a. "Version 1". The original—and most familiar—version of the Cutler-Hammer SSOL was introduced in 1981 and manufactured until September 1986.

b. "Version 2". Built from September 1986 through December 1986, this variation of the SSOL is most readily identified by the "REV A" that appears on the front cover of the module. It can also be distinguished from Version 1 by comparing the p.c. board assemblies: Version 2 does not include the 50/60-Hz frequency adjustment switch, and all of the IC chips are soldered into place.

c. "Version 3". Identified by a "REV B" on the module's front cover, this SSOL variation is scheduled for production from January 1987 until March 1987, and includes these modifications: removal of the locked rotor potentiometer; a different transformer; removal of the J1-J2 jumper; and factory installation of the "new style" transition relay, MOV, capacitor and surge suppressor described in this bulletin.

d. "Version 4." Scheduled for initial production in March 1987, Version 4 of the SSOL will be known as the "AG-5". In addition to all of the modifications described for Version 3, the AG-5 includes a redesigned p.c. board. You will also notice that the terminal strip and acceleration time DIP switches are relocated to the outside of the SSOL module.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Discussion:

Testing and evaluation of "Versions 1 and 2" of the Cutler-Hammer solid-state overload module revealed areas where improvements can be made to increase reliability. The following sections discuss each of these areas in detail.

1. Intermittent Transition

The plug-in style transition relay originally provided in the overload module was an American Zettler Model AZ420-70-4HUS, while an AMF Potter-Brumfield Model R10-E1-X2 replacement relay was used for La Crosse service stock. Both of these relays have contacts made from a cadmium-oxide/silver-type material.

Cycle testing has shown that intermittent closures occasionally occur as a result of cadmium build-up between the surfaces of the relay contacts. A material specification change was made that requires the use of all-silver contacts in the transition relay.

2. Nuisance Tripping Due to Current Imbalance

The SSOL module senses the 3 current phases of the motor and converts them to a proportional DC voltage output at Terminals V1-V2. The resulting VDC signal is then used by the capacity control module to current-limit the chiller. When a significant amount of current imbalance exists in the system, the Cutler-Hammer SSOL may trip on the highest of the 3 current legs while the capacity control module is trying to current-limit based on the average. This type of nuisance trip only occurs when the unit's running load current is near 100%.

Installation of a capacitor wired in parallel with the current calibrator (Terminals B1-B2) in the SSOL will eliminate these nuisance trips.

3. Electrical Component Failures Due to Voltage Transients

High voltage spikes in the 120 VAC control circuit can cause SSOL module failure. This particular problem was discussed in Service Bulletin CVHE-SB-12A, which recommended field installation of a surge suppression device (metal oxide varistor, or "MOV") in the control circuit to protect the 120 VAC input portion of the overload module.

Further inspection of failed overload modules also verified that voltage transients can be introduced into the low voltage circuit (V1-V2) and cause the failure of operational amplifier Z1. This type of failure is usually the result of improper wiring in the V1-V2 circuit between the SSOL in the starter panel and the capacity control module in the chiller control panel. Remember that interconnecting wiring for V1-V2 must be 18 AWG, shielded wire. When properly installed, the shielding is only grounded at the starter panel.

Caution: Voltage from external sources may be induced into the V1-V2 circuit and damage the SSOL module if the wiring is improperly grounded.

Transient voltage suppression can be obtained with the addition of a bipolar surge suppressor—or "TRANS ZORB"—across the SSOL's V1-V2 terminals. The addition of this device is not only recommended for all installations without proper shielding, but can also be added to any installation with shielded wire for increased voltage-transient protection.

Note: Shielded cable was not used in some Trane-built, unit-mounted starters manufactured between January 1985 and January 1986. Be sure to review all succeeding installations of Model CVHE and CVHB units with free-standing starters to verify that the V1-V2 wiring conforms to the specifications outlined in this bulletin.

4. Electrostatic Discharge (ESD)

Because of the "metal oxide semiconductor" (MOS) component technology used in the construction of the SSOL module, the electronic components on the p.c. board are susceptible to damage caused by electrostatic—or "static" —discharge. Static discharges are most often transmitted by a person touching the SSOL's electronic components or the p.c. board itself.

To prevent electrostatic discharges, always wear static control wrist straps (i.e., 3M Model 2071 wrist straps, or equivalent) whenever working inside the overload module.

Corrective Action:

When service is required on a unit with "Version 1" or "Version 2" of a Cutler-Hammer SSOL, be sure to complete the modifications described below.

1. **Intermittent Transition.** Install a new transition relay (RLY-849) in place of the existing relay.

After February 1st, 1986, all relays ordered from La Crosse service stock are the new style. The model number of the new-style transition relay is R10-E1-Y2 (Potter-Brumfield). ("Y2" indicates that the relay contact material is all silver, rather than cadmium-oxide/silver.) Be sure to check your office stock of RLY-849 to ensure that all relays are the new style.

2. **Nuisance Tripping Due to Current Imbalance.** Install an electrolytic capacitor (22 to 26 MFD, rated for 25 to 100 VDC) across SSOL Terminals B1-B2; Trane part no. CPT-335 is recommended for this application.

Wire this capacitor in parallel with the existing current calibrator in the SSOL module. Since CPT-335 is nonpolarized, it can be installed without regard to the polarity of Terminals B1-B2. However, if a locally-supplied capacitor is used, be sure to install it so that the positive (+) side is on Terminal B1 and the negative (-) side is on Terminal B2.

3. **Electrical Component Failures Due to Voltage Transients.** Install a metal oxide varistor—Trane part no. SPS-11—in the unit control panel if one is not already there; refer to Service Bulletin CVHE-SB-12A for installation details.

Then, wire a "TRANS ZORB"—Trane part no. SPS-14—between SSOL Terminals V1-V2 to protect the Z1 output operational amplifier in the low voltage circuit.

4. **Electrostatic Discharge.** Whenever the cover of the SSOL module is removed for service, static discharge must be avoided! Wear static-control wrist straps to eliminate any possibility of electrostatic discharge.

For further information on this product or other Trane products, refer to the "Trane Service Literature Catalog", ordering number IDX-IOM-1. This catalog contains listings and prices for all service literature sold by Trane. The catalog may be ordered by sending a $20.00 check to: The Trane Company, Service Literature Sales, 3600 Pammel Creek Road, La Crosse, WI 54601.

SUBJECT: NUISANCE "DISTRIBUTION FAULT" TRIPS FOLLOWING UNIT SHUTDOWN

INTRODUCTION:

Centrifugal units equipped with Cutler-Hammer solid-state overloads (SSOLs) may experience nuisance "distribution fault" trips when the starter de-energizes during the normal shutdown sequence. This service bulletin explains why these nuisance trips occur, and what can be done to prevent them.

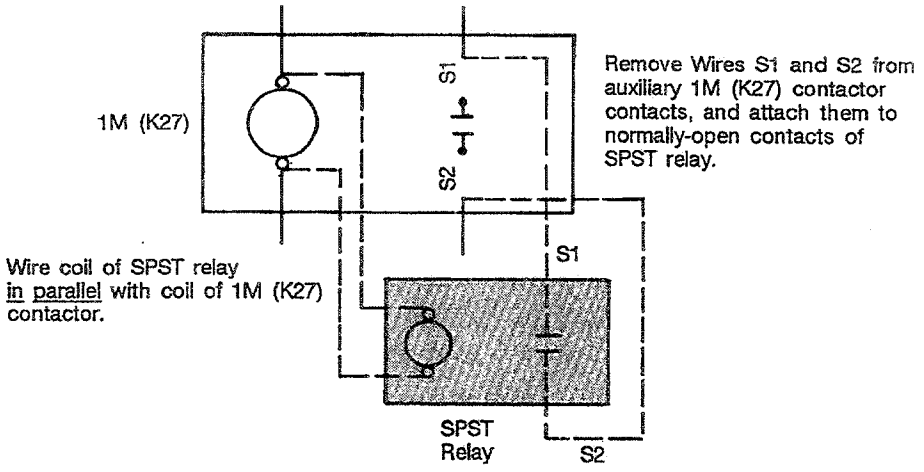
DISCUSSION:

To better understand why nuisance "distribution fault" trips occur, let's first review what a distribution fault is. "Distribution fault" is defined as the total loss of line voltage for a period lasting less than 60 electrical cycles. In this situation, the compressor motor remains on-line and acts as a generator; often, the motor is capable of generating enough voltage to allow the control circuit to remain energized for up to 1 second (i.e., 60 electrical cycles).

By contrast, during a normal shutdown (i.e., when the ON/OFF switch is adjusted to the OFF position), the compressor motor is instantly disconnected from the line. This simultaneously de-energizes the control circuit, dropping out all of its relays and contactors--and effectively eliminating the likelihood of a distribution fault trip.

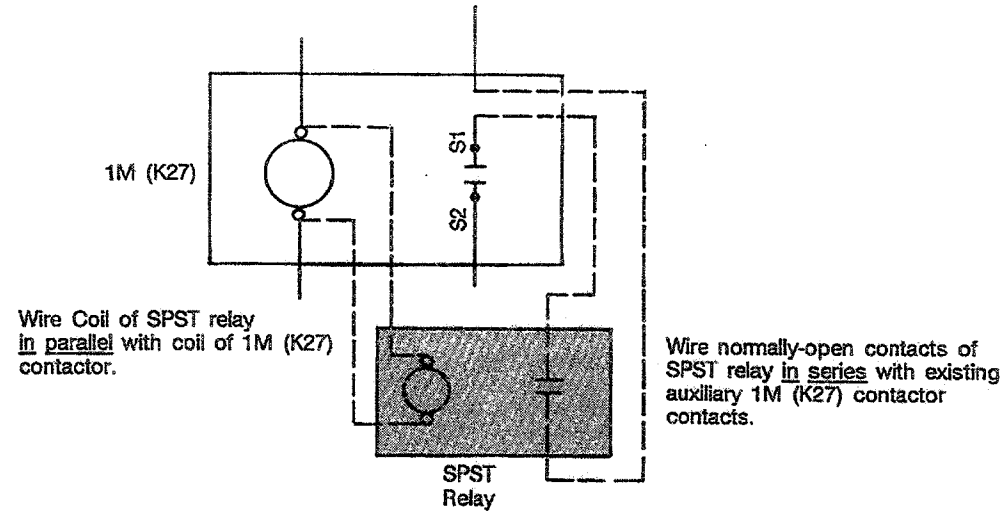
When a unit is protected by the Cutler-Hammer SSOL motor/starter protection system, existence of a distribution fault condition is detected within 1-1/2 electrical cycles; within 6 electrical cycles, the motor is off-line. SSOL recognition of a distribution fault is based on the status of the S1-S2 circuit (auxiliary on 1M) and motor amp draw: If the S1-S2 circuit remains closed while line current is less than 15% of RLA, a distribution fault exists.

In star-delta starter applications, this situation can occur if the 2M (K28) contactor opens, interrupting current to the motor, while a sluggish 1M (K27) contactor--or unresponsive auxiliary 1M contacts in the S1-S2 circuit--remains closed. As a result, the SSOL interprets what should be a normal, scheduled shutdown (i.e., one initiated with the unit ON/OFF switch) as a distribution fault, and trips the distribution fault indicator.



Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

CORRECTIVE ACTION:



Starter vendors interface their auxiliary contacts with the main contactor in a variety of ways. Depending on the method used, some auxiliary contacts can be adjusted to improve their responsiveness, while others are more easily changed out. In all situations where nuisance distribution fault trips are a problem, however, be sure to determine whether the presence of debris or corrosion is responsible for the sluggish reaction of the 1M (K27) contactor (or auxiliary contacts).

In the event that the 1M (K27) contactor is found to be in good condition and neither adjustment nor replacement of the auxiliary contactor contacts eliminates the nuisance trip problem, wire a single-pole, single-throw relay into the distribution fault circuit. The addition of this relay ensures that the S1-S2 circuit opens as soon as the coil of the 1M (K27) contactor is de-energized (even though the auxiliary 1M contacts may still respond slowly).

Examples A and B illustrate two alternative methods for adding the SPST relay to the distribution fault circuit.

Subject: CUTLER-HAMMER SOLID-STATE OVERLOAD (SSOL; "A1") OPERATION, CALIBRATION AND TROUBLESHOOTING

Introduction:

This service bulletin describes the operation of the Cutler-Hammer solid-state overload module (electrically designated as "A1"), as well as appropriate procedures for SSOL calibration and trouble analysis. This module is provided in all current-production starter panels built to Trane specifications for CVHE and CVHB CenTraVacs (excluding those designed for use with the microcomputer-based UCP695 chiller control system).

It is important to note that by March 1st, 1987 4 different versions of the Cutler-Hammer solid-state overload (electrically designated as "A1") will be available in the field. Identifying characteristics that will enable you to distinguish one version from another are described below.

[ ] **"Version 1".** The original---and most familiar---version of the Cutler-Hammer SSOL was introduced in 1981 and manufactured until September 1986.

[ ] **"Version 2."** Built from September 1986 through December 1986, this variation of the SSOL is most readily identified by the "REV A" that appears on the front cover of the module. It can also be distinguished from Version 1 by comparing the printed circuit (p.c.) board assemblies: Version 2 does not include the 50/60-Hertz frequency adjustment switch, and all of the IC chips are soldered into place.

[ ] **"Version 3."** Identified by a "REV B" on the module's front cover, this SSOL variation is scheduled for production from January 1987 until March 1987, and includes these factory modifications:

a. removal of the locked rotor potentiometer;
b. a different transformer;
c. removal of the J1-J2 jumper;
d. a transition relay (RLY-849) with all-silver contacts; and,
e. factory-installation a metal oxide varistor (SPS-11), an electrolytic capacitor (CPT-335), and a TRANS ZORB surge suppressor (SPS-14). (Because these components are now installed at the factory, service bulletin CTV-SB-75---which describes field installation of these components---is not applicable.)

[ ] **"Version 4."** Scheduled for initial production in March 1987, Version 4 of the SSOL will be known as the "AG-5". In addition to all of the modifications described for Version 3, the AG-5 also includes these changes:

a. a redesigned p.c. board; and,
b. relocation of the terminal strip and acceleration time DIP switch to the outside of the SSOL module.

Since The Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Discussion:

Following is a list of the SSOL's operational functions and features:

1. provides precise compressor motor overload protection;
2. protects against excessive locked rotor (inrush) current draw;
3. limits the length of time that inrush current is drawn;
4. protects the chiller from damage that could be caused by an electrical distribution fault;
5. initiates starter transition when compressor motor current drops to 85% of RLA;
6. provides a DC voltage signal that is proportional to the load;
7. can be adjusted to compensate for high line voltage; and,
8. can be adjusted for either 50- or 60-Hertz operation.

SSOL Calibration Procedure

WARNING: To prevent injury or death due to electrical shock, lock unit disconnect switch open before servicing SSOL module (A1).

The adjustments and calibration procedures itemized below---and detailed on the following pages of this bulletin---must be completed before the chiller is started. Remember to use a grounding strap whenever working on a SSOL module!

1. Adjust line frequency (SSOL Version 1 only).
2. Calibrate the motor overload resistor.
3. Adjust locked rotor current (SSOL Versions 1 and 2 only).
4. Set the maximum motor acceleration time.
5. Adjust for high-voltage compensation.

If the unit is equipped with the distribution fault function, the small circuit board mounted in the center of the SSOL must be tilted outward to calibrate the module. To move this circuit board out of the way, gently pull on the 2 black tabs located at the top of the board, and tilt it down on its hinges.

Note: To verify that the existing---or new---SSOL is operational, use Trane service tool TOL-90 to perform a functional checkout of the module. TOL-90 is available from Trane ServiceFirst, and is provided with operating instructions (TOL-OM-1). If you are using TOL-90 to test the module's integrity while it is still mounted in the starter panel:

a. remove the high voltage power supply from the starter panel;
b. connect a separate 115 VAC source to power up the SSOL; and,
c. disconnect the fuses on the primary side of the transformer.

Line Frequency Adjustment (SSOL Version 1 Only)

"Version 1" of the Cutler-Hammer SSOL module can be adapted to operate in either 50- or 60-Hertz electrical systems. To select the appropriate line frequency for a specific application:

1. Determine the line frequency of the installation. (Remember that all U.S. installations are 60 Hz.)

2. Position the SSOL's frequency adjustment switch at the appropriate setting. Refer to Figure 1 for the location of this switch on the SSOL's p.c. board; Figure 2 indicates the appropriate switch position for both 50 Hz and 60 Hz settings.

3. Check the appropriate box on the SSOL's nameplate (Figure 3) to record the line frequency switch setting selected in Step 2.

Note: Versions 2, 3 and 4 of the SSOL can also be used in 50-cycle applications. Though a specific line frequency adjustment is not necessary for any of these SSOL versions, the maximum acceleration time setting must be readjusted by multiplying the 60 Hz maximum acceleration time setting by "5/6". (For instance, if the maximum acceleration time setting is 30 seconds for a 60 Hz application, the corresponding 50 Hz setting is "30 x 5/6", or 25 seconds.)

Compressor Motor Overload Setup (SSOL Verions 1, 2, 3 and 4)

Compressor motor overload calibration is accomplished by adjusting the resistance of the current calibrator (shown in Figure 1). When the current calibrator is adjusted properly, the SSOL will trip at 107% of the compressor motor's RLA value. (This particular "trip" point prevents nuisance full-load lockouts, while still protecting the compressor motor from potentially damaging overloads.)

Follow the instructions outlined below to correctly set the SSOL's current calibrator:

1. Determine the chiller's RLA value and current transformer ratio; be sure to consider the conditions described below when arriving at these values:

a. If the job site voltage is equal to--or lower than--the specified voltage rating stamped on the chiller nameplate, base the current calibrator setting on the nameplate RLA value. However, if the actual voltage is higher than the specified voltage, refer to the instructions provided under "High Voltage Compensation" later in this bulletin.

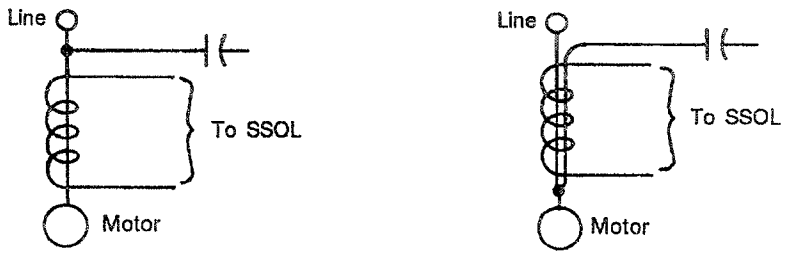
b. If the chiller is equipped with power factor correction capacitors (PFCCs) that are connected to the load side of the overload current transformers, the RLA value shown on the unit nameplate must be recalculated in order to correctly set the current calibrator.

This "adjusted" RLA value is already calculated for those units with factory-installed PFCCs, and it is marked on the cover of the solid-state overload (SSOL).

To determine the "adjusted" RLA value for other units, run the unit at full load; then take amperage readings on the load and line sides of the capacitor terminal points. Multiply the line-to-load-side ratio of these amp readings by the nameplate RLA to arrive at an "adjusted" RLA value.

Example

100 amps = Motor Rating (RLA Value) from Nameplate
84 amps = Line-Side Current Reading
92 amps = Load-Side Current Reading



$$\text{Nameplate RLA} \times \frac{\text{Line-Side Current}}{\text{Load-Side Current}} = \text{"Adjusted" RLA}$$

$$100 \text{ amps} \times \frac{84 \text{ amps}}{92 \text{ amps}} = 91.3, \text{ or } 91 \text{ amps}$$

If the PFCCs are connected on the line side of the SSOL current transformers--or if the capacitor leads are run through the current transformers with the motor leads (Figure 4), do not recalculate compressor RLA; use the RLA value stamped on the chiller nameplate to establish the current calibrator setting.

Note: For additional information and recommendations regarding field additions of power factor correction capacitors, refer to Trane Engineering Bulletin EB-CTV-44. Remember, too, that the PFCCs must be installed on Leads T1, T2 and T3--not on Leads T4, T5 and T6!

Figure 4
Current Transformers

2. Once the appropriate RLA value is determined (Step 1), calculate the rated load secondary current ("Isec") using 1 of the two methods described below. Notice that the calculation method selected---and the resulting Isec value---are dependent on the location of the current transformers (CTs).

a. CTs Monitoring Line Current. If the CTs are located to monitor line current, determine the Isec value by dividing the appropriate RLA value by the CT ratio.

Example
RLA Value = 91 amps
CT Ratio = 100:5 (or 20)

$$\frac{\text{RLA}}{\text{CT Ratio}} = \text{Isec}$$

$$\frac{91 \text{ amps}}{20} = 4.55$$

b. CTs Monitoring Phase Current. If the CTs in a wye-delta starter are positioned to monitor phase current, the Isec value is calculated by dividing the appropriate RLA value by the CT ratio, and then multiplying the result by 0.58.

Example
RLA Value = 91 amps
CT Ratio = 100:5 (or 20)

$$\frac{\text{RLA}}{\text{CT Ratio}} \times 0.58 = \text{Isec}$$

$$\frac{91 \text{ amps}}{20} \times 0.58 = 2.639, \text{ or } 2.64$$

Note: Where donut-type CTs are used, the wires routed through them are sometimes wrapped around and passed through the CTs more than once; this alters the "actual" CT ratio. To determine the CT ratio in this situation, divide the CT ratio by the number of times that the wire passes through the CT; in other words, the "actual" ratio for a 200:5 CT with a wire passed through it twice is 100:5.

3. Using Table 1 and the rated load secondary current ("Isec") value calculated in Step 2, determine the appropriate current calibrator and its potentiometer setting.

For example, if the "Isec" value is 4.55, the correct current calibrator is H818 and the potentiometer should be adjusted to 82.6 ohms; this adjustment will result in an overload trip point that is 107% of the nameplate RLA.

4. To adjust the current calibrator to the setting determined in Step 3, remove it from the SSOL module. Use a digital ohmmeter with a minimum accuracy of 3-1/2 places to obtain the desired resistance setting.

5. Return the current calibrator to the SSOL module. Be sure to record the calibrator number and setting on the SSOL nameplate.

Locked Rotor Current Lockout Adjustment (SSOL Versions 1 and 2 Only)

The SSOL is designed to protect the compressor motor from excessive LRA current draw during start-up by tripping the motor overload circuit breaker any time the set LRA is exceeded. Remember that the LRA current trip point value depends on the type of starter used with the CenTraVac compressor motor. It is set with the "LRA Setpoint" potentiometer found near the lower right-hand corner of the SSOL p.c. board. (See Figure 1.)

To properly set the LRA setpoint potentiometer:

1. Insert a screwdriver in the potentiometer adjusting slot; then turn the pot to the fully-counterclockwise (CCW) stop to establish a reference point.

2. Refer to Figure 5; then rotate the pot clockwise (CW) to the position that corresponds to the type of compressor motor starter used.

Note: The LRA setpoint pot positions illustrated in Figure 5 represent approximate settings for various starter types. To calculate a specific potentiometer setting, see Step 5.

Figure 5
LRA Setpoint Potentiometer Settings for Various Starter Types

	2.66	2.70	140.0 ohms		4.31	4.35	86.5 ohms
	2.71	2.75	138.0 ohms		4.36	4.40	85.5 ohms
	2.76	2.80	135.0 ohms		4.41	4.45	84.5 ohms
	2.81	2.85	133.0 ohms		4.46	4.50	83.5 ohms
	2.86	2.90	130.0 ohms		4.51	4.55	82.6 ohms
	2.91	2.95	128.0 ohms		4.56	4.60	81.7 ohms
	2.96	3.00	126.0 ohms		4.61	4.65	80.8 ohms
	3.01	3.05	124.0 ohms		4.66	4.70	79.9 ohms
	3.06	3.10	122.0 ohms		4.71	4.75	79.1 ohms
	3.11	3.15	120.0 ohms		4.76	4.80	78.2 ohms
	3.16	3.20	118.0 ohms		4.81	4.85	77.4 ohms
	3.21	3.25	116.0 ohms		4.86	4.90	76.6 ohms
	3.26	3.30	114.0 ohms		4.91	4.95	75.8 ohms
	3.31	3.35	113.0 ohms		4.96	5.00	75.1 ohms
	3.36	3.40	111.0 ohms				
	3.41	3.45	109.0 ohms				
	3.46	3.50	108.0 ohms				
	3.51	3.55	106.0 ohms				
	3.56	3.60	105.0 ohms				
	3.61	3.65	103.0 ohms				

3. Initiate the chiller start sequence. If the motor overload circuit breaker trips as soon as (within 1 second) the starter energizes, the LRA current trip point may need to be set higher. (This will not harm the operation of the SSOL module or the compressor motor.)

4. Record the LRA and RLA values from the chiller nameplate on the SSOL's nameplate.

5. Use the following procedure to calculate the "RATIO _____%" value; then record this value on the SSOL nameplate.

$$\text{Ratio \%} = \frac{\text{Motor LRA*}}{\text{Motor RLA}} \times 100\% ,$$

*where LRA (locked rotor amperes) is the reduced value determined by starter type. See Table 2.

Example
Motor LRA = 200 amps
Motor RLA = 100 amps

$$\text{Ratio \%} = \frac{200 \text{ amps}}{100 \text{ amps}} \times 100\% = 200\%$$

Maximum Acceleration Time Setup (SSOL Versions 1, 2, 3 and 4)

Designed to limit the time allowed for transition to occur, the SSOL trips---and shuts down the unit---whenever the compressor motor fails to transition within the time period established with maximum acceleration time switches (Figure 1). This prevents the motor from drawing LRA for an excessive period of time which, in turn, prevents the motor from overheating.

To set the maximum acceleration time switches properly:

1. Determine the appropriate maximum acceleration time---between 1 and 63 seconds---for the unit; refer to Table 3 for typical settings by starter type.

Keep in mind that the type of unit and starter, as well as job site conditions, will determine how much the actual maximum acceleration time setting varies from the typical settings shown in Table 3.

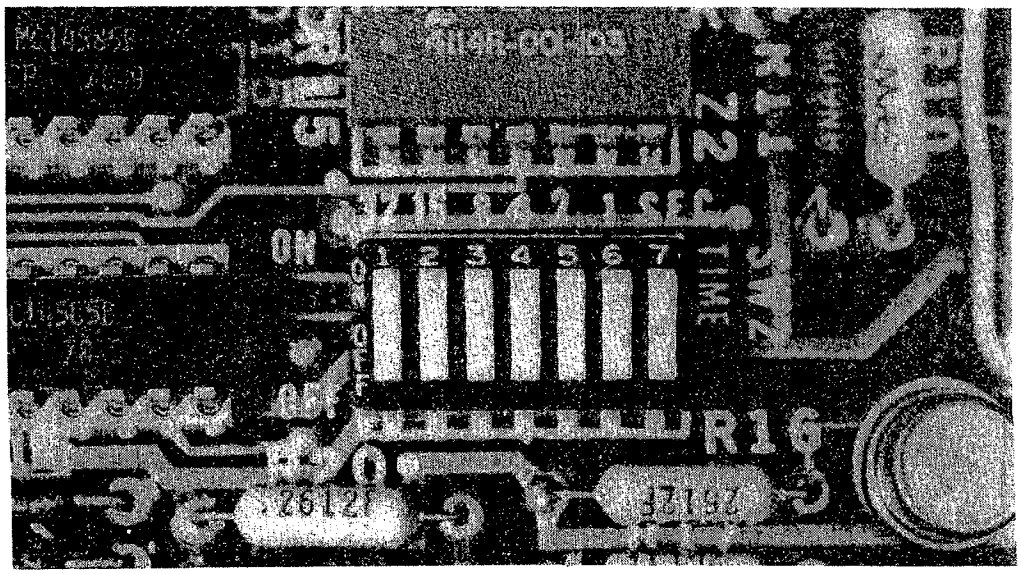
2. Locate the maximum acceleration time DIP switches on the SSOL p.c. board; refer to Figures 1 and 6. Notice that each DIP switch represents a specific number of seconds (e.g., DIP switch no. 1 is 32 seconds, no. 2 is 16 seconds, etc.). Determine what DIP switch "seconds" values can be added to yield the maximum acceleration time found in Step 1; then flip these DIP switches to the ON position. (For instance, if the desired maximum acceleration time setting is 27 seconds, flip DIP switch nos. 2, 3, 5 and 6 to ON.)

Note: If none of the DIP switches is set at ON, the unit will not start. (The SSOL will not allow any time for motor acceleration in this situation, so the motor overload circuit breaker trips as soon as a start-up is attempted.)

3. Record the maximum acceleration time setting on the SSOL nameplate.

For 50 Hz Applications w/SSOL Versions 2, 3 or 4. When determining the appropriate maximum acceleration time, remember to compensate for the difference in line frequency. Multiply the appropriate 60 Hz maximum acceleration time by "5/6" to arrive at the proper setting for 50 Hz applications. (For instance, if the maximum acceleration time setting is 30 seconds for a 60 Hz application, the corresponding 50 Hz setting is "30 x 5/6", or 25 seconds.)

Table 2
Starting Characteristics of Various Types of Motor Starters



Starter Type	Starting Characteristics--- % of Rated Value			
	% Tap	Motor Voltage	Motor LRA	Motor Torque
Full-Voltage Type				
Magnetic, Across-the-Line	n/a	100%	100%	100%
Reduced Voltage Types				
Auto-Transformer	80%	80%	64%	64%
	65%	65%	42%	42%
	50%	50%	25%	25%
Primary Reactor	80%	80%	80%	64%
	65%	65%	65%	42%
	50%	50%	50%	25%

Wye-Delta	n/a	100%	33%	33%
Open- or Closed-Transition	n/a	100%	33%	33%

Table 3
Typical Maximum Acceleration Time Settings

Starter Type	Recommended Max. Acceleration Time Setting
Wye-Delta	27 seconds
Auto-Transformer	16 seconds
Across-the-Line	6 seconds

Figure 6
Maximum Acceleration Time DIP Switches

Example
12 seconds = 8 seconds + 4 seconds; therefore, flip DIP switch nos. 3 and 4 to ON.

High-Voltage Compensation Adjustment (SSOL Versions 1, 2, 3 and 4)

While the RLA value shown in the chiller nameplate represents the design nominal voltage, actual job-site voltage often varies from this value. Therefore, it is possible that a higher-than-nominal line voltage condition will cause the motor to generate excessive horsepower without exceeding the current draw shown on the nameplate.

To prevent motor overloading resulting from higher-than-rated voltage, recalibrate the SSOL module in 1 of 2 ways:

[ ] SSOL Versions 1 and 2 Only. Remove the 10% current reset jumper from Terminals J1-J2 in the SSOL (Figure 1); removal of this jumper automatically recalibrates the SSOL so that approximately 90% of the motor nameplate current rating is the new "rated" current for that application.

Note: SSOL setup does not change if the J1-J2 jumper is removed since all SSOL functions are automatically recalibrated.

[ ] SSOL Versions 1 thru 4. Reset the current calibrator. To arrive at a new current calibrator setting, multiply the Isec. value (calculated in "Compressor Motor Overload Setup") by the ratio of the rated line voltage to the actual line voltage.

$$\text{"New" Isec} = \text{Original Isec} \times \frac{\text{Rated Line Voltage}}{\text{Actual Line Voltage}}$$

Example

Original Isec = 4.55
Rated Line Voltage = 460V
Actual Line Voltage = 485V

$$\text{"New" Isec} = 4.55 \times \frac{460V}{485V} = 4.32$$

Using the "new" Isec value, the current calibrator number and Table 1, determine appropriate potentiometer setting; then readjust the pot to this value. (Remember that readjusting the current calibrator not only compensates for the high-voltage condition, but also recalibrates all other SSOL functions.)

* * * * * * *

Note: Whenever the SSOL is recalibrated for high voltage—whether by removing the J1-J2 jumper or by readusting the current calibrator, turn the LRA potentiometer 1 dial setting higher than that indicated in Figure 5 to prevent nuisance "trips" at start-up (since higher-than-nameplate LRA current draw will occur). Also, be sure to record the method—and reason for—high-voltage compensation on the cover of the SSOL module!

Dry-Running Starters w/SSOL Modules

Starter panels equipped with the SSOL module can be dry-run at start-up in the same manner as starters without the SSOL. However, 2 important differences must be noted:

1. The distribution-fault circuit breaker must be disconnected before the starter can be dry run. To disconnect the distribution-fault circuit breaker, simply remove a wire from it. If the breaker is not disconnected, the starter will not sequence, and the SSOL module will lock out on distribution fault as soon as the start sequence begins. (Lockout occurs because the distribution fault trip is initiated when motor current drops below 15% of the RLA with the M1 contactor energized; see "Distribution-Fault Circuit Breaker Operation". This situation will only occur during an actual distribution fault or during a starter dry-run.)

2. The starter will transition as soon as the dry-run is initiated. This immediate transition occurs because the SSOL initiates transition on the basis of motor current draw. During a normal start-up, motor current draw falls from the LRA value to one that is below the RLA because the inlet vanes are closed; when motor current draw falls to 85% of RLA during the start sequence, the SSOL initiates transition.

However, during a dry run, there is no current draw so the SSOL initiates transition immediately (within 1 second).

Note: The starter dry-run procedure is a good way to test the SSOL's distribution fault function; if it is working properly, the distribution-fault circuit breaker will trip as soon as the start sequence is initiated (provided that the breaker was not disconnected).

Operation of the Distribution-Fault Circuit Breaker

"Distribution fault" is defined as the total loss of line voltage for a period lasting less than 60 electrical cycles. This type of short-duration power interruption can be damaging to many types of induction-motor-driven equipment since an induction motor acts as a generator for several seconds after power is disconnected. The voltage generated by a water-cooled CenTraVac motor, for instance, is often sufficient to "hold in" control relays and starter contactors for approximately 60 electrical cycles---or 1 second---when a voltage-loss occurs.

If line voltage is re-established while the contactors are held in by motor-generated voltage---and the two voltages are out of phase, motor torques that are 6 to 10 times greater than the normal running torques can occur. These torques occur as the motor is pulled into phase and may be in either direction (forward or reverse). Such excessive torques severely overload the impeller hub area and may, in turn, upset the impeller keyway or---in severe cases---crack or destroy the impellers.

SSOL modules detect a distribution fault by monitoring current draw and the status of the M1 contactor. The distribution-fault circuit breaker is designed to trip when motor current draw is less than 15% of RLA while the M1 contactor is energized. The SSOL detects the existence of a distribution fault within 1-1/2 electrical cycles, and---within 6 cycles (1/10 of a second) ---trips the distribution-fault circuit breaker to take the compressor motor off line.

Normally, this situation will only occur during an actual distribution fault (or during a starter dry run) since: (a) an induction motor will typically draw more than 15% of RLA---even when completely unloaded, and (b) when the M1 contactor is energized, the motor is running.

Troubleshooting the SSOL

Note: The information presented in the following troubleshooting chart is only applicable for the SSOL; use of this chart alone will not verify the integrity of other starter panel components.

SSOL Troubleshooting Chart

Symptom	Recommended Action
Distribution-fault circuit breaker trips . . .	
1. while the chiller is running.	1. If this fault becomes a nuisance problem, use TOL-90 and the checkout procedures described in TOL-OM-1 to verify that the SSOL is functioning properly. If the results of this checkout indicate that the SSOL is defective, replace it.
2. during the start sequence, at the point when transition should occur.	2. Check for: a. installation of power-factor correction capacitors (PFCCs) on the start contactor (K27, or "1M"). If the PFCCs were incorrectly wired to the run contactor (K28, or "2M") instead of K27, the PFCCs will be placed in parallel at start-up, and the change in capacitance could drive the available current down to 15% of RLA. b. bouncing contacts---especially the auxiliary contacts on the starter contactors.
3. when the starter de-energizes during the normal chiller shutdown sequence.	3. This symptom is usually <u>not</u> the result of a SSOL problem; see service bulletin CTV-SB-76 for corrective action. However, if the suggestions described in CTV-SB-76 do not eliminate this problem, replace the SSOL.
Motor-current-overload circuit breaker trips . . .	
1. at start-up.	1. Check the: a. locked rotor setpoint potentiometer to make sure that it isn't turned too low. To properly set this pot, follow the instructions under "Locked Rotor Current Lockout Adjustment" in this bulletin. **Note:** The locked rotor setpoint pot is <u>only</u> found on Versions 1 and 2 of the SSOL. b. acceleration time setting. See "Maximum Acceleration Time Setup" in this bulletin. c. SSOL with TOL-90 and the instructions provided in TOL-OM-1. If this check indicates that the SSOL is defective, replace it.
2. at transition.	2. Check the SSOL module's terminal strip; <u>if Terminals 5 and 6 are labeled "F1" and "F2"</u>, complete the corrective action described in service bulletin CTV-SB-65.

(Continued on next page . . . . .)

SSOL Troubleshooting Chart (concluded)

Symptom	Recommended Action
Motor-current-overload circuit breaker trips . . . (continued)	
3. immediately after chiller loads up.	3. Check the: a. polarity of the V1-V2 wires connected to the capacity control module in the chiller control panel. b. voltage at V1-V2 in the SSOL. If the voltage measured at V1---with respect to V2---is positive, replace the SSOL.
4. at a value less than 100% of RLA.	4. Check: a. the balance of the 3-phase current. It may be necessary to add the electrolytic capacitor (CPT-335) described in CTV-SB-75. **Note:** The check just described in 4a is only applicable for SSOL Versions 1 and 2. b. for phase loss or phase reversal at the SSOL. To do this, connect the positive (+) lead of an oscilloscope to SSOL Terminal B1 and the negative (-) lead to Terminal B2. The oscilloscope should display a normal sine wave, as shown in Figure 7. If 1 phase is missing, the sine wave will appear as shown in Figure 8; Figure 9 shows the the type of sine wave produced if 1 phase is reversed.
Chiller does not transition.	1. Check for closure of the auxiliary K27 contacts in the SSOL's S1-S2 circuit. 2. Use TOL-90 to perform the "transition level" functional test described in TOL-OM-1. If test results verify that the transition relay on the SSOL is "pulling in", use an ohmmeter to check for closure of the transition relay contacts. If these contacts fail to close, replace the SSOL's transition relay (RLY-849).
Chiller transitions as soon as the start sequence is initiated.	1. Check the 3-phase current signals with an oscilloscope; see Item 4b under "Recommended Action" above. 2. Use TOL-90 and the checkout procedures described in TOL-OM-1 to check SSOL operation. If test results indicate that the SSOL is defective, replace it.

Subject: CenTraVac® Conversions and Reselections

Introduction:

This general service bulletin describes the required procedure for receiving same day quotations for Engineered Conversions℠ or requesting La Crosse-run selections for existing centrifugal chillers. These reselections are typically necessary when chillers are being evaluated for energy efficiency, ice storage or when the operating parameters change due to waterflow or temperature conditions.

Engineered Conversions quotations and estimated performance on HCFC-123 can be supplied on the same day requested if the form is completed. There will be some limitations on this same day response. These include high voltage, special units. TriStar™ selections or units that do not have standard Louis Allis motor types of RCS, RPS, RVS, RVX and DRV. Also, if the form is incomplete, the response will NOT be the same day.

Discussion:

To request an Engineered Conversion quotation for an existing CenTraVac:

1. Complete a copy of the "Engineered Conversion Request for Quote" form; an example of a completed form is shown on page 2. This form can be ordered from Literature Services using order no. 1-30.156.
2. FAX the completed form to:
   The Trane Company
   Existing Building Services
   Chiller Evaluation Group
3. As an alternative, you can use the PROFS miniform, CONVQTE, Engineered Conversion Request for Quote. Complete this electronic form as above but send it to PROFS ID: EBS — Existing Building Services printer.

To request a La Crosse-run selection for an existing CenTraVac:

NOTE: You will be charged $250.00 for an initial selection request on an existing chiller; additional reselection runs performed for the same chiller will cost $50.00 per run. A purchase order number is required before any work will be done.

Reselections are completed on a "first-come, first-served" basis, the anticipated turnaround will be within five days of receipt. You will be notified immediately if we cannot complete the reselection within this timetable.

1. Complete a copy of the "CenTraVac Reselection Request" form; an example of a completed form is shown on page 3. This form can be ordered from Literature Services using order no. 1-30.156.
2. FAX the completed form to:
   The Trane Company
   Existing Building Services
   Chiller Evaluation Group
3. As an alternative, you can use the PROFS miniform, CTVREQ, CenTraVac Reselection Request. Complete this electronic form as above but send it to PROFS ID: EBS — Existing Building Services printer.
4. The field should be aware that the existing CenTraVac Selection program in the office can be used to reselect any CVHE or CVHB155 within reasonable limits to answer most questions. Typically, this is within 2% of actual.
5. Any reselection charges that result in the sale of a new chiller or an Engineered Conversion will be credited to the appropriate commission account.

An example of a completed "CenTraVac Reselection Request" form is provided below for your reference.

To run the requested reselection(s), these blanks must be filled in completely.

General Service Bulletin

CTV-SB-82D

Library	Service Literature
Product Section	Refrigeration
Product	Centrifugal Liquid Chillers
Model	CVHB, CVHE
Literature Type	Confidential Service Bulletin
Sequence	82D
Date	April 26, 1994
File No.	SV-RF-CTV-CTV-SB-82D-494
Supersedes	CTV-SB-82C dated 1/31/92

Literature Changes:
CTV-SB-82 (4/91)--Original issue of bulletin.
CTV-SB-82A (5/91)--Bulletin revised to incorporate cautionary statement on mixing of refrigerants.
CTV-SB-82B (7/91)--Bulletin revised to incorporate changes required due to revised AEL for HCFC-123.
CTV-SB-82C (1/92)--Bulletin revised to update information to include motor winding insulation and cation" section.
CTV-SB-82D (4/94)--Revised to incorporate new information regarding safe handling of CFC-11 and HCFC-123 and additional guidelines.

Subject: HCFC-123 For Centrifugal Water Chillers

Introduction:

HCFC-123 is the acceptable alternative refrigerant to CFC-11 for application in low-pressure centrifugal water chillers which have been designed or retrofitted for use with this refrigerant. There are a great number of similarities and some differences between HCFC-123 and CFC-11. This service bulletin will discuss these similarities and differences so personnel conducting start-up and service work on HCFC-123 chillers are familiar with the proper procedures for handling HCFC-123.

Discussion:

A comparison of Material Safety Data Sheets (MSDS) for HCFC-123 and CFC-11 will show many similarities. Obtain and review the MSDS for HCFC-123 prior to handling this new refrigerant. All Trane Commercial Sales Offices have copies of the MSDS for HCFC-123 and CFC-11. A comparison of some of the characteristics of HCFC-123 and CFC-11 is made in Table 1 on the next page.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Table 1
Physical Data Comparison for HCFE-123 and CFC 11

Physical Data	HCFC-123	CFC-11
Boiling Point	27.6 C (81.7 F @ 760mm Hg	23.9 C (75 F) @ 760mm Hg
Vapor Pressure	13 psia @ 25C (77F)	15.3 psia @ 25 C (77 F)
pH Information	Neutral	Neutral
Color	Colorless	Colorless
Odor	Slight Ethereal	Slight Ethereal
Flash Point	Will Not Burn	Will Not Burn

Hazardous Reactivity:

Both HCFC-123 and CFC-11, as well as many other commonly used fluorocarbon-based refrigerants. can be decomposed by high temperature (open flames, glowing metal surfaces, etc.) forming hydrochloric and hydrofluoric acids, and possibly, carbonyl halides.

Health Hazard Information:

Exposure Limits

Safe handling is essential for all refrigerants. The specific requirements for HCFC-123 are provided in "Refrigerant Handling Guidelines" (CFC-GUIDE-2). A consideration in using HCFC-123, is the AEL (Allowable Exposure Level) of 30 parts-per-million. The AEL for HCFC-123 dictates specific handling requirements and practices when using HCFC-123 in centrifugal water chillers, to insure safe and environmentally sound operation. In the case of a major spill, resulting in accidental exposures above the AEL, the short-term toxicological effects of HCFC-123 are quite comparable to those seen with CFC-11. See Table 2 for a safe handling comparison of CFC-11 and HCFC-123. Present agency-established and manufacturer-recommended personal exposure levels to HCFC-123 and CFC-11 are given in Table 3.

Table 2
Shows Safe Handling Table comparing CFC-11 and HCFC-123

Safe Handling For the HVAC Industry the Danger is Acute not Chronic		CFC-11	HCFC-123
Chronic	AEL	1,000 ppm	30 ppm
Accute	EEL	1,000 ppm	1,000 ppm
	LC_{50}	26,000 ppm	32,000 ppm
	Cardiac Sensitization	5,000 ppm	20,000 ppm
	Anesthetic Effect (10 Min)	35,000 ppm	40,000 ppm

©American Standard Inc. 1994

Table 3
Allowable Personal Exposure Levels for HCFC-123 and CFC-11

Exposure Level Acronym	Source	HCFC-123	CFC-11
PEL (1)	OSHA (5)	Not Established	Not Established
Ceiling (2)	OSHA (6)	Not Established	1,000 ppm
AEL (3)	DuPont (6)	30 ppm	1,000
EEL (4)	DuPont (6)	1,000 ppm	1,000

Notes:
1. PEL = Permissible Exposure Limit. OSHA time-weighted average. The employee's average airborne exposure in any 8-hour workshift of a 40-hour workweek, which shall not be exceeded.
2. Ceiling = The employee's exposure level which shall not be exceeded for any time period.
3. AEL = Acceptable Exposure Level. An employee's average, airborne exposure in any in any 8-hour workshift of a 40-hour workweek, which shall not be exceeded.
4. EEL = Emergency Exposure Level. Maximum exposure-level ceiling during emergency situations, such as a spill or accidental chemical release. Exposure duration shall not exceed one hour. Escape is feasible without suffering any escape-impairing or irreversible effects on employee health.
5. OSHA = Occupational Safety and Health Administration.
6. DuPont = DuPont Chemicals.
7. ppm = Parts-per-million.

Personal Protection Requirements:

The minimum personal respiratory protection equipment requirements at various exposure levels are listed in Table 4.

Table 4
Minimum Respirator Protection for HCFC-123

PPM	Exposure Time	Minimum Equip. Required
Less than 30 as a TWA*	8 or 12 Hours per day	None
In the event of unusual/non-routine tasks or when work place levels may exceed 30-PPM for other than the above exception:		
30-100		1/2 Mask - Organic Vapor Cartridge or Canister
100-500		Full Mask - Organic Vapor Cartridge or Canister
Greater than 500		SCBA or Full Face Air Line

* Instantaneous Spikes may occur during breaking of charge lines, tapping of drums etc. When factored into the Timed Weighted Average, these excursions have not resulted in exceeding the AEL during ROUTINE servicing.

Service Requirements:

The refrigerant handling guidelines detailed in Trane's "CTV-SB-81B", in "CFC-Guide-2" and in DuPont's "PUSH-123", must be followed. Particular attention must be given to the purge system and the unit relief vent lines. HCFC-123 can collect in these locations in a liquid state and must be properly drained prior to servicing. Do not open the unit to atmosphere for service work until the refrigerant charge is fully removed or recovered. Avoid spills while charging and removing charge from machines. Drain refrigerant from hoses and charging equipment into acceptable containers. Seal all containers after use. As with any fluorocarbon-based refrigerant, a self-contained breathing apparatus (SCBA) is highly recommended in the event of a large spill.

CAUTION: When adding refrigerant to a chiller operating on HCFC-123, use HCFC-123 only. Use of other types of refrigerant (i.e., CFC-11, CFC-113) may affect unit performance, deteriorate gaskets, seals, motor winding insulation or varnish, and will render the refrigerant charge unsalvageable.

All personnel performing service work on an HCFC-123 centrifugal water chiller must:

- Before performing service, activate customer's equipment room ventilation system and maintain ventilation flow at highest possible level during service procedures.

- Verify the presence and proper calibration of the customer's equipment room refrigerant monitor. It is possible to release traces of refrigerant gas during normal service procedures (i.e., refrigerant charging, removing or reclaiming refrigerant, opening the chiller to atmosphere, etc.). This device must detect levels of HCFC-123 that insures the AEL of 30 ppm is not exceeded. Above 30 ppm concentration, the monitor must activate an automatic alarm.

Air Monitors For Service Personnel:

A refrigerant monitor must be installed that has the capability of detecting HCFC-123 in the range of 0-200 ppm and activate an alarm above 30 ppm. Since HCFC-123 vapor is heavier than air, the air monitor sensing device should be located 12"-18" above the floor, and in close proximity to the HCFC-123 chiller location, to provide adequate sensing and early warning indications for safety. Typically, an equipment room refrigerant concentration level of 30 ppm during normal unit operation would indicate a leak condition that requires corrective service procedures. Long-term exposures (continuous 8 hrs/day; 5 days/wk; for an entire working career) to levels over 30 ppm could provide the potential for health hazards. For additional protective directives refer to Trane manual RF-AM-3. Contact the CenTraVac Technical Service Department in La Crosse to identify a recommended air monitor. Additional sources of refrigerant monitoring devices are listed in various HVAC-industry publications and in the Thomas Register.

Typical refrigerant levels present in equipment rooms with HCFC-123 chillers have been reported below one part-per-million during normal operation and up to 8 ppm during normal maintenance, after all refrigerant has been properly removed or recovered from the machine.

Safe Application of HCFC-123:

Trane, York, DuPont, Allied Signal, and even the United States Environmental Protection Agency (EPA) have publicly stated that HCFC-123 can be used safely in centrifugal chillers with equipment room concentrations being held well below one part-per-million during normal operation, providing a margin of safety of at least 30-to-1, as long as the equipment room guidelines established in ASHRAE "Standard 15" are followed.[1] Refrigerant vapor concentrations found during servicing of equipment are normally held below two ppm, on a time-weighted average, as long as the recommended refrigerant handling procedures in Trane's "Refrigerant Handling Guidelines" (CFC-GUIDE-2) are followed.[2] Now that all the facts are known, the primary concern over the safety of HCFC-123 is a matter that can easily be handled through proper design of the equipment room and by adherence to established refrigerant handling practices.

1. Data supported by two detailed reports; a Trane/DuPont HCFC-123 equipment room concentration report "CFC-Report-1", October 1991, and the United States EPA equipment room concentration report (both available from The Trane Company).
2. For a report relating actual measured HCFC-123 concentration levels in various equipment rooms, contact the CenTraVac Technical Service Department of the La Crosse Business Unit at (608) 787-3943.

Literature Changes:
CTV-SB-83 (6/90) --Original issue of bulletin.

Subject: CenTraVac Voltage Surge Arrestors (MOV's)

Introduction:

A potential safety problem has been identified with the voltage surge arrestors (MOV's) that are factory-installed on Model CVHE and CVHB centrifugal chillers with a voltage rating of 600 VAC (nominal) or less. These surge arrestors are mounted on the side of the CenTraVac motor terminal junction box. The CenTraVac technical service department has received three separate reports of explosive failure of an MOV. This bulletin affects any CVHE or CVHB units equipped with these voltage surge-protection devices.

Discussion:

In 1988, a special engineering team identified several design improvements for CenTraVac low-voltage motors that were intended to provide motor voltage-surge protection. Most of the recommended changes applied to the motor internal wiring and motor-stator manufacturing procedures. All of these changes have been implemented since that time. To provide surge protection during the interim period when these changes were being implemented, the team also recommended factory installation of voltage surge arrestors on the motor terminal junction box.

Recent vendor tests indicate that under certain conditions, these devices can fail in a manner that propels the top of the MOV forcefully out of the MOV body. No injuries have resulted from this situation. Because The Trane Company feels that the motor design changes that have been intitiated recently, in themselves provide sufficient motor surge protection, a decision has been made to discontinue the use of MOV's.

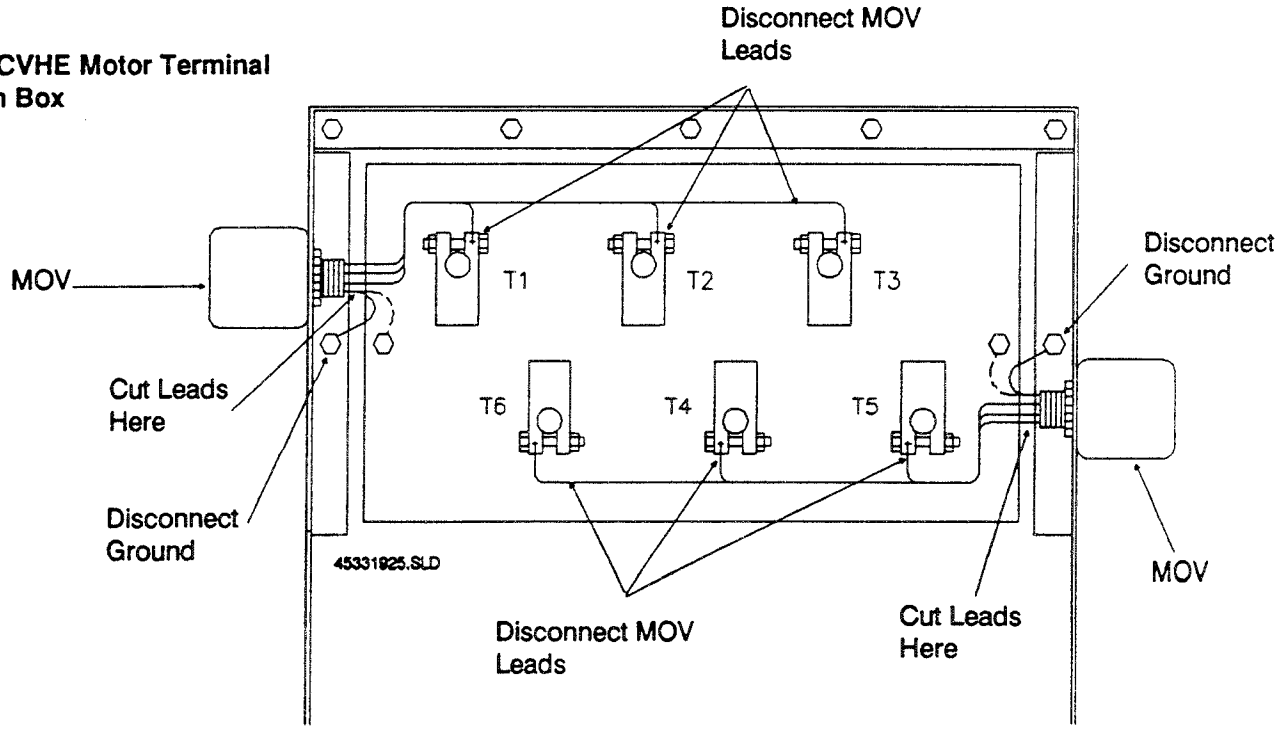
Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Since MOV failure can potentially result in personal injury, all units equipped with MOV's must be identified and repaired. All operating units must be repaired immediately. Repair of units that have not been started must be accomplished at the time of start-up.

Units Affected:

All CVHE units, 600 VAC or less, manufactured August 18, 1988 and after and all CVHB units, 600 VAC or less, manufactured April 4, 1989 and after are affected. A manufacturing design change has been implemented to remove the MOV's. No CVHE or CVHB units shipped after May 31, 1990 are equipped with MOV's. A complete list of unit shipments for the dates indicated was provided to each office involved. Since all affected units are low voltage, the 8th digit of the unit model number will be a letter, A thru J.

Corrective Action:



The MOV's on all units affected by this bulletin must be disabled. To accomplish this, disconnect and discard the MOV electrical leads as follows:

1. Follow the procedures provided in the CVHE Service Guide (CTV-SG-2) to shut the unit down and secure it for service.

WARNING! To prevent injury or death due to electrical shock, lock unit disconnect in open position while servicing unit.

2. Remove the cover from the motor terminal junction box (remote-mounted starter) or open the starter panel access door (unit-mounted starter).

Figure 1
Typical CVHE Motor Terminal Junction Box

 © American Standard Inc.

3. Disconnect the MOV electrical leads at the motor terminals (T1-T6) and at their ground connections in the motor terminal junction box or in the unit-mounted starter connection box. Refer to Figure 1.

Note: There are two MOV's on each CenTraVac motor.

4. Cut off the four MOV electrical leads as close to the MOV as possible and discard the leads.

Note: Do not remove the MOV's from the motor terminal junction box or starter panel connection box. They are to be left in place on the terminal box.

5. Follow the procedures provided in the CVHE Service Guide (CTV-SG-2) to place the unit back into operation.

Parts Information:

No parts should be ordered for this procedure.

Literature Changes:
CTV-SB-85 (5/20/92) -- Original date of bulletin - Correct solid-state load limit control and current transformer mismatch.

Subject: Solid-State Load Limit Control CNT1064 and Current Transformer Mismatch

introduction:

The purpose of this informational service bulletin is to provide general information related to what appears to be a functional problem with the CNT1064 solid-state load limit control system.

The CNT1064 is a direct replacement for the old style pneumatic load limit relay RLY0023. Instructions for this changeout are contained in CTV-SB-80.

Discussion:

The problem with this control is that; even if the control is properly installed, on some machines it will not properly unload the machine at load limit settings of 60% and below. It will, however, work properly at the 100% and 80% taps.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Problem Identification:

The malfunction of control CNT1064 is caused by the current transformer which drives it; it is not a problem with the CNT1064. However, the CNT1064 requires calibration.

In January of 1991, production of the previously used current transformer installed in older CenTraVacs was discontinued by the vendor. These current transformers are shown in Table 3 by part number. To meet the needs of customers who may experience a current transformer failure, replacement kits were created. These replacement kits were part number KIT1942 through KIT1948 (Table 3).

The current transformer contained in KIT1942 through 1948 is rated at 10 VA maximum. At that VA rating, the transformer will not drive the CNT1064. It may function properly at the 100% and 80% taps. However, once the load setting is reduced to 60% or less, the 10 VA current transformer contained in the kit becomes saturated and cannot overcome the high input impedance of the CNT1064.

Units Affected:

Units potentially affected by this bulletin include any unit from Table 1 or Table 2 which may have experienced an original current transformer failure after May 1991.

Table 1
Models and Design Sequences Which May Have Experienced An Original Current Transformer Failure

If a current transformer with a TRR number from Table 3 failed and was replaced with a KIT # from Table 3, the CNT1064 may not work properly. As stated earlier, this is due to the low VA rating of the current transformer included in the kit.

Table 3
Shows TRR, Rating and KIT Numbers
Affected by Voltamp Rating (10 VA max)

TRR#	Rating	KIT
TRR0275	100:5	1948
TRR0276	150:5	1948
TRR0111	200:5	1942
TRR0112	300:5	1943
TRR0113	400:5	1944
TRR0114	500:5	1944
TRR0115	600:5	1944
TRR0277	800:5	1945
TRR0379	1000:5	1946
TRR0773	1200:5	1946
TRR0774	1500:5	1946
TRR0775	2000:5	1947

Units Not Affected:

If the CNT1064 is installed in any machine listed under "Units Affected" or in Table 1 that has a current transformer rated at 35 VA or more, the CNT1064 will work properly. However, it may require calibration.

Corrective Action:

To correct this problem the current transformer in KIT1942 through 1948 will be replaced with a larger-burden transformer. The new kits will be part numbers KIT2120-2124. See "Parts Ordering Information". To determine if this problem is occurring, the CNT1064 should be calibrated and tested for proper operation as follows:

CNT1064 Check Out

To determine proper operation of CNT1064, complete the following procedures:

Setup:

1. Determine maximum input current from line current transformer to CNT1064 at machine full load amperage.

$$\frac{\text{FLA}}{\text{CT RATIO}} = \text{Maximum Input Current to CNT1064}$$

$$\text{CT RATIO} = \frac{\text{PRIMARY}}{\text{SECONDARY}}$$

Note:
Input current to the CNT1064 should not exceed 7.0 amps.

Example: Machine has 100:5 current transformer and the FLA (full load amps) is 90.

$$\text{CT RATIO} = \frac{100}{5} = 20$$

$$\text{Maximum input current to CNT1064 at full load} = \frac{90}{20} = 4.5 \text{ amps}$$

2. Install current probe on current transformer primary (motor line current).

3. Install current probe on current transformer secondary at input terminals of CNT1064.

4. Install voltmeter on terminals 9 and 10 on TB1 of CNT1064. Set for VDC.

5. Remove plastic cover of CNT1064. Turn band width potentiometer (R7, B.W.) fully CCW. Then 1/8 turn CW.

6. Set percent load potentiometer to:

$$\frac{\text{Maximum input current to CNT1064}}{5} \times 100$$

Example: $\frac{4.5 \text{ amps}}{5} \times 100 = 90$

7. Set machine load selector switch to 100%.

Setup is complete. Proceed to calibration procedure.

CNT1064 Calibration:

1. Start machine. Monitor motor line current using current probe installed on current transformer primary. Run machine to full load.

2. Monitor current on current transformer secondary. At full load, this current should equal maximum input current to CNT1064 ± 1/2 amp.

3. Measure voltage on terminals 9 and 10. This voltage should be 18 VCD ± 1. Note the measured voltage.

4. With unit running at full load, monitor voltage on terminals 9 and 10. Reduce percent load potentiometer setting until voltage at terminals 9 and 10 decreases 10% from voltage noted in Step 3.

System Test:

With unit running at full load, reduce unit load selector switch to 80%. Line current should decrease to 80% of full load current ± 5%. Repeat at 60% and 40%. The current transformer system will automatically compensate for the change of desired load and maintain the maximum input current to the CNT1064.

If line current does not equal proper percentage when selector switch is reduced, additional equipment checkout may be required. Check wiring from current transformer through selector switch to CNT1064. Check contacts in selector switch for excessive wear, contamination or failure.

Parts Ordering Information:

Order one transformer replacement Kit for each affect unit from Table 4 below. This is an informational service bulletin. No parts or labor are authorized.

Table 4
Shows Current Ratio And Kit

Current Ratio	KIT #
100:5 - 150:5	2120
200:5 - 400:5	2121
500:5 - 800:5	2122
1000:5 - 1500:5	2123
1800:5 - 2500:5	2124

Subject: 2K5B Relay Fail Safe Circuit Kit for Cutler Hammer Wye-Delta Starters With UCP695 Control Panels. (This is an informational bulletin only)

Introduction:

To understand the intent of this informational service bulletin, a brief review of the 2K5 pilot relay in a wye-delta starter follows.

During the starting sequence, the 2K5 pilot relay in a wye-delta starter is energized by the momentary closure of the K4 contacts in the 1U3 micro module. The 2K5 pilot relay coil is held in electrically by a holding circuit through one set of 2K5 contacts. A second set of 2K5 contacts close to energize the 2K3 contactor, and so on through the remaining wye-delta start sequence.

During the shut down sequence the 2K5 pilot relay is de-energized when one of the K1, K2 or K3 contacts in the 1U3 micro module is open. Once the 2K5 coil is de-energized, the holding 2K5 contacts open, a second set of 2K5 contacts open, and the run contactor is de-energized, stopping the compressor.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Discussion:

The 2K5 pilot relay is a pivotal component in starting and more importantly stopping the compressor if a problem should arise. In the current micro starter design there is one 2K5 pilot relay. In previous pre-micro starter designs two 2K5 pilot relays with a circuit breaker were incorporated in a fail safe arrangement.

In response to customer concerns Trane Company Engineering working with Cutler Hammer have developed a 2K5B relay fail safe circuit kit. This kit may be installed in any Cutler Hammer wye-delta starter where the customer requires the added insurance of the fail safe circuit. In the unlikely event one of the two 2K5 pilot relays fail a circuit breaker will trip and open the control circuit to the run contractor.

The intent of this bulletin is not to suggest adding a fail safe kit to all starters, but to provide information on the availability of the fail safe 2K5B relay kit for those customers who may require it.

Units Affected:

Any CVHE, CVHB or CVHF unit with a Cutler Hammer Starter that incorporates one 2K5 pilot relay.

INSTALLATION INSTRUCTIONS

Hardware Installation

The 2K5B fail safe relay kit (Figure 1) may be installed in any Cutler Hammer wye-delta starter. For all unit mounted starters refer to Figure 2 for proper location. For Size 3-5DP direct ship starters refer to Figure 3. For size 6 - 8 direct ship starters refer to Figure 4.

Figures 2 through 4 show the approximate locations of one pre-drilled hole in the back panel of the starter. This is the required location where the 2K5B relay is to be installed. A second hole must be drilled in the back panel in the appropriate location. Fasten the 2K5B relay kit to the back panel of the starter with 2 - #10 -32 self tapping screws.

Wiring Instructions

Wire 2K5B relay kit per drawing in Figure 5. Also refer to Table 1 for wire termination's.

Parts Ordering Information:

The 2K5B Fail Safe Circuit kit may be ordered through Trane Service Parts using a direct ship method from Cutler Hammer. The Cutler Hammer part number is 800612-206.

This service bulletin is informational only. No parts or labor are authorized.

Literature History

CTV-SB-89 (7/29/92) -- Original issue of bulletin - Update on handling and shipping refrigerant samples for analysis.

Subject: Handling and Shipping Refrigerant Samples for Analysis

Introduction:

This service bulletin presents general guidelines for proper handling and shipment of refrigerant samples submitted for laboratory analysis.

Discussion:

While the issue of proper refrigerant handling has always been a concern, it is especially timely, given the increased interest of the Environmental Protection Agency (EPA).

To ensure safe, legal handling and shipment of refrigerant samples submitted for laboratory analysis, it is important to recognize and address the potential safety hazards involved as well as the governmental regulations that apply.

In an attempt to clarify the requisites for proper refrigerant sample handling and shipment, this bulletin covers the following topics:

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

-- Safety Precautions for Handling Refrigerant
-- Cylinders Recommended for Refrigerant Sample Containment
-- Trane Laboratories Designated for Refrigerant Analysis
-- Labeling Requirements for Refrigerants for Refrigerant Sample Shipping Packages
-- Sources of Additional Information on Refrigerant Handling and Shipping

Safety Precautions for Handling Refrigerant

Before handling any refrigerant, it is important to become familiar with the appropriate Material Safety Data Sheet (MSDS).

In general, MSDS are to be in English and must include material identity (chemical and common names); ingredients in mixtures, if they are hazardous; physical and chemical characteristics; physical hazards (fire, reactivity); health hazards (signs and symptoms of exposure); medical conditions aggravated by exposure; primary route(s) of entry into the body; OSHA, ACGIH, and vendor exposure levels and TLVs; carcinogenicity statement per NTP, IARC, or OSHA; general precautions for safe handling and use; emergency-response procedures and first aid; and appropriate work practices. You should acquire a copy of the law and read it.

Under Occupational Safety and Health Administration Act (OSHA) Hazard Communication Rule, Title 29 Code of Federal Regulations (CFR) 1910.1200 MSDS sheets are to be supplied by the refrigerant manufacturer. The MSDS sheets must be available for review by all persons handling and/or using the refrigerants.

The following warnings are provided to alert you to potential hazards associated with handling refrigerant that could result in personal injury or death. Your personal safety depends upon the strict observance of these precautions.

WARNING! Breathing high concentrations of refrigerant vapor can sensitize the heart to adrenaline. This type of sensitization -- in conjunction with a large amount of adrenaline produced within the body (as can happen under stress)-- could result in arrhythmia, ventricular fibrillation, and -- ultimately -- death due to cardiac arrest.

WARNING! Skin or eye contact with the extremely cold, liquefied form of refrigerants with low boiling points, (R-12, R-22) can cause frostbite. Contact with refrigerants characterized by higher boiling points (R-11, R-113) dissolves the natural oils of the skin and may cause dermatitis.

Note: Wear lined butyl gloves and chemical splash goggles whenever handling refrigerant to avoid skin/eye contact and prolonged or repeated exposure. Normally, respiratory protection is not required unless a large release of refrigerant occurs.

WARNING! Use a suitable receptacle to ship refrigerant samples destined for laboratory analysis; see "Cylinders Recommended for Refrigerant Sample Containment". Remember that refrigerants expand significantly when heated.

To allow for refrigerant expansion, do not fill the cylinder to more than 3/4 of its capacity! If the cylinder is completely filled with refrigerant and sealed, any increase in temperature will cause an abrupt rise in refrigerant liquid pressure; in some instances, the rise in pressure may be high enough to deform or burst the cylinder. Such an explosion is extremely dangerous, and can result in serious personal injury or death.

WARNING! DO NOT UNDER ANY CIRCUMSTANCE SHIP REFRIGERANT SAMPLE CYLINDERS WITHOUT A SAFETY RELIEF DEVICE.

There are three general types of relief devices commonly used: fusible plug, rupture member, or pressure relief valve. Make sure the sample cylinder is equipped with a relief device before using.

 © American Standard, Inc.

Cylinders Recommended for Refrigerant Sample Containment

An important aspect of safe handling and shipment of refrigerant samples is selection of the cylinders used to store the refrigerant. Trane's Chemistry Laboratory, located in La Crosse, recommends the use of any of the cylinders identified below (or an equivalent receptacle). For general sampling, aluminum or stainless steel cylinders are suitable. However, if a refrigerant sample is taken from a unit with a motor burnout, use only stainless steel. The acidic components that result from a motor burn will attack the aluminum cylinder material. Steel sample cylinders are not recommended for laboratory test sampling due to the possibility of internal rust contamination.

Also, listed here is a pressure-regulating valve. Each refrigerant sample cylinder must include a pressure-relief valve!

Recommended Cylinders:

[ ] 500 cc cylinder
Source: Minnesota Valve & Fitting Company
15901 W 78th Street
Eden Prairie, MN 55344
Phone -- (612) 937-1160
Order No. 304L-HDF4-500

[ ] 1,000 cc cylinder
Source: Minnesota Valve & Fitting Company
Order No. 304L-HDF4-1000

[ ] 10-oz. Aluminum Lecture Bottle
Source: Cliff Impact Division
Parker Hannifin Corp.
33800 Lakeland Blvd.
East Lake, OH 44094
Bottle order No. AL440 No. 1749
Valve order No. Cliff Part # VI

Note: Cylinders used to transport refrigerant must be manufactured in accordance with Department of Transportation (DOT) regulations. All of the cylinders identified above comply with these regulations.

Recommended Pressure Relief Device

[ ] Pressure regulator
Source: Minnesota Valve & Fitting Company
Order No. SS-16DKM4-F4-A-1

WARNING: Reusing refrigerant sample cylinders for other types of refrigerants is not recommended since refilling and repressurizing the cylinders can be dangerous. If reuse of the cylinder is unavoidable, be sure to clean the cylinder thoroughly before refilling it with any other substance.

To insure accurate analysis of a refrigerant sample, use only clean and standardized sample bottles. The use of unorthodox or homemade sample bottles is not recommended; the use of such a bottle may result in a contaminated sample and/or skewed test results.

To aid the laboratory in conducting an accurate refrigerant analysis, the refrigerant sample bottle should be labeled with its evacuated TARE weight.

[ ] Recommended Cylinder Cleaning Procedure:
Remove valve from sample bottle.
Flush bottle with suitable solvent numerous times to remove all contaminants.
Visually inspect the bottle side walls and bottom to ensure all contaminants as well as solvent are removed.
Flush bottle valve with solvent to remove any contaminants that may be present in the valve seat area.
Ensure bottle and valve are free of any residual liquid solvent.
Re-install valve on cylinder following the manufacturer's instructions.
Evacuate sample bottle for one-minute minimum.

Trane Agencies Designated for Refrigerant Analysis

Once a refrigerant sample is obtained and stored in a suitable cylinder (with pressure regulator), it must be sent to the appropriate Trane agency for laboratory analysis. At present, refrigerant analyses are performed at two locations based on refrigerant type:

1. CFC-12, CFC-22. Trane's Chemistry Laboratory, located in La Crosse, WI, performs in-warranty chemical analyses of high-pressure refrigerants (e.g., CFC-12 and CFC-22) only. Out-of-warranty analyses of CFC-12 and CFC-22 are also conducted as time permits. (The cost associated with an out-of-warranty analysis is determined when the analysis is completed.)

Chemical analyses for HCFC-123 are also done in the La Crosse Chemical Laboratory.

Use the following "ship to" address to submit CFC-12 and CFC-22 refrigerant samples for analysis:

The Trane Company
Chemistry Lab - Building 11
2313 South 20th Street
La Crosse, WI 54601-7599

2. CFC-11, CFC-113. Chemical analyses of low-pressure, refrigerants only (e.g., CFC-11 and CFC-113) are performed by Trane ServiceFirst. The "ship to" address is:

Trane ServiceFirst
Attn: Chemistry Lab
4500 Morris Field Drive
Charlotte, NC 28208

Labeling Requirements for Refrigerant Sample Shipping Packages

To comply with DOT regulations, special identification requirements must be met on all shipped packages containing refrigerant cylinders - - and on the associated shipping papers and bills of lading. Basic labeling requirements for shipment of CFC-11, CFC-12, CFC-22 and CFC-113 samples over domestic highways are outlined below. (If some other method of transportation is used, contact a local carrier for shipping information.)

Note: Besides using the proper nomenclature on the shipping package and accompanying paperwork, it is also necessary to include a copy of the appropriate "Material Safety Data Sheet" (MSDS) with each shipment of refrigerant. Copies of the current safety data sheets for CFC-11, CFC-12, CFC-22 and CFC-113 are included at the end of this bulletin for your convenience. As you prepare a refrigerant sample for shipment, be sure to xerox a copy of the appropriate MSDS and attach it to the bill of lading.

[ ] **CFC-11 Sample Identification.**
Bill of lading must be marked with the following:

Compressed Gas, N.O.S.;
nonflammable gas;
Trichlorofluoromethane (CFC-11);
UN No. 1956

Shipping package must be marked as follows:

Compressed Gas, N.O.S.;
Trichlorofluoromethane (CFC-11);
UN No. 1956

A green **"NONFLAMMABLE GAS"** label must also be applied to the package exterior.

[ ] **CFC-12** Sample Identification.
Bill of lading must be marked with the following:

Dichlorodifluoromethane (CFC-12);
nonflammable gas;
UN No. 1028

Shipping package must be marked as follows:

Dichlorodifluoromethane (CFC-12);
UN No. 1028

A green **"NONFLAMMABLE GAS"** label must also be applied to the package exterior.

[ ] **CFC-22** Sample Identification.
Bill of lading must be marked with the following:

Chlorodifluoromethane (CFC-22);
nonflammable gas;
UN No. 1018

Shipping package must be marked as follows:

Chlorodifluoromethane (CFC-22)
UN No. 1018

A green **"NONFLAMMABLE GAS"** label must also be applied to the package exterior.

[ ] **CFC-113** Sample Identification.
Bill of lading must be marked with the following:

Compressed Gas, N.O.S.;
nonflammable gas;
Trichlorotrifluoroethane (CFC-113);
UN No. 1956

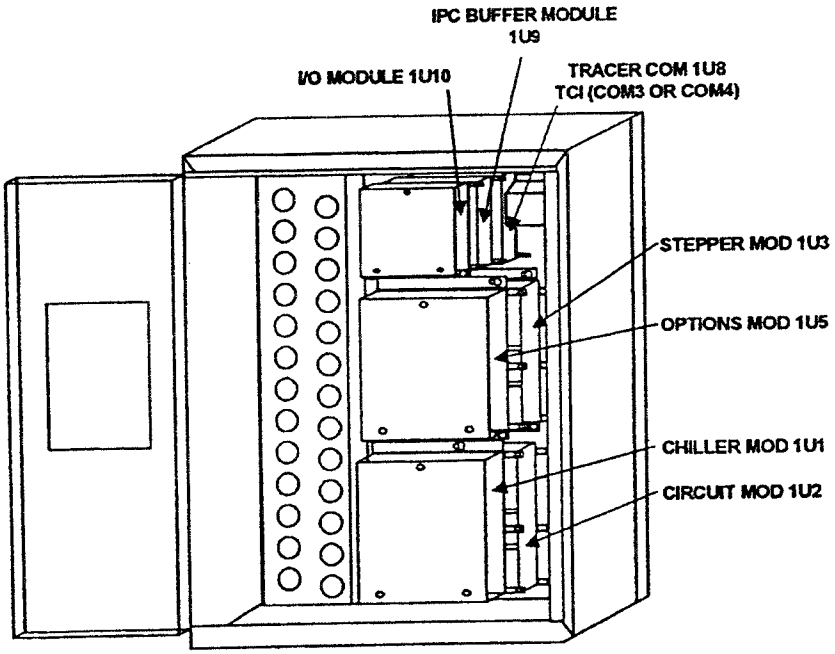
Related problem description and corrective action information are also contained in this Confidential Service Bulletin, a General Service Bulletin will not be published.

Subject: CVHE/CVHF UCP2 Module Update

Introduction:

The purpose of this service bulletin is to provide information concerning UCP2 chillers that shipped without one or more UCP2 modules, and the requirement to order and install the modules.

Discussion/Units Affected:



Units that shipped between August 9, 1993 and December 31, 1993 may have shipped without an options module, TCI Com 3 module, or I.O. module. Additional units will be shipping without the I.O. module until April of 1994. This bulletin covers units that shipped short one or more of the above modules. A list of units affected and the material that needs to be ordered by the office parts department will be sent to the office service manager under seperate cover.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Module Update Procedure

All factory wiring and connectors have been provided in the control panel by the factory. Mount the new modules in the space provided in the control panel as shown in Figure 1. We are requesting that all work be completed at startup or as soon as possible, before the June 30, 1994 cut-off date. The required modules should be ordered through Trane Service Parts using the normal parts ordering procedure.

Figure 1
Control Panel

Parts Ordering Information and Authorization:

Following is a breakdown of the modules that are required for the affected units.

1. Units requiring a TCI Com 3 (Tracer 100 Interface) module (MOD 0073) to be installed, also require a new chiller module (MOD 0091), and a new clear language display module (MOD 0092). These modules are available now to order and install. The TCI Com 3 module mounts to the backplate with #8-32 x 1/2 thread rolling screws.

2. Units that are not free cooling that shipped short an options module, require a new options module (MOD 0093) only. This module is available now to order and install.

3. Free cooling units that are either short or have an options module (MOD 0093) require a new options module (MOD 0093), chiller module (MOD 0091) and clear language display module (MOD 0092).

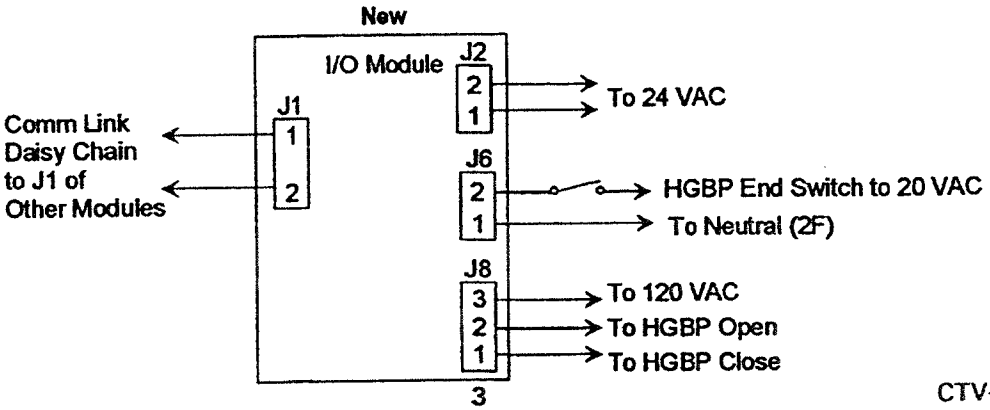
   Note: These modules will be available May 1, 1994 to order and install.

© American Standard Inc.

4. Hot gas by-pass units with an I.O. module, will require a new I.O. module (MOD 0074), clear language display (MOD 0092) and a chiller module (MOD 0091). Units that shipped from August 9, 1993 through December , 1993, will require the modifications shown in Figure 2 to install and hook-up the new I/O module.

   Note: These modules will be available May 1, 1994 to order and install.

Note: The reason for changing additional modules when a unit shipped short only one module is for software compatibility.



Modifications Required to install the new I.O. module.

1. **J1 Terminal:** With existing wire and connector, connect from J1 of the New I.O. module to J1 terminal of one of the other modules in the daisy chain, such as the stepper module.
2. **J2 Terminal:** Existing wire and connector plugs into J2 of the new module.
3. **J4 Terminal:** of the old module connects to J8 of the new module using existing wire and connector.
4. J28 of the old module connects to J6 of the new module. You will need to splice in an extra length of 16 AWG, 600V, 105°C, wire to reach.

Figure 2 I/O Module Wiring from August, 1993 to December, 1993

I/O Module Wiring from January, 1994 to present.

CTV-CSB-90

5. Mounting Plates

5.1 A large mounting plate is required to mount the options module to the stepper module. The plate should have shipped with the unit. However, if required order part number PLT 2153.

5.2 A small mounting plate is required to mount the IO module. The plate should have shipped with the unit. However, if required order part number PLT 2154.

6. Wire Connectors

All factory wiring has been provided with the required Phoenix wire connectors. Field wiring will require appropriate connectors to be ordered and installed.

Mnemonic Part Number	Code Number	Connector
CON 0429	X19220085-01	2 pin
CON 0430	X19220085-02	3 pin
CON 0431	X19220085-03	4 pin
CON 0432	X19220085-04	5 pin
CON 0433	X19220085-05	6 pin

Labor and Travel Authorization:

This service bulletin authorizes 1.0 man hour per unit on affected chillers, plus actual travel time for each unit. Authorized hours and actual travel time will be paid at approved Commercial Systems Group rates. All claims must be submitted on the "Service/Warranty/Sales Allowance Claim" (Form No 1-30.09-2), within 30 days of repair. To receive proper credit check the "Retrofit Box" on the claim form and refer to this service bulletin.

Material Disposition:

Upon completion of the upgrade, the original UCP2 modules must be returned to La Crosse per the following instructions.

1. Return all modules to:
   The Trane Company
   Plant 4 Salvage
   2411 East Avenue
   La Crosse, WI 54601
2. Return all modules on a job by job basis. Do not wait to complete all updates before returning replaced modules.
3. Mark the outside and inside of each box **"Per CTV-CSB-90"**
4. On units that have not yet been started mark the modules **"NEW"**.
   On units that have previously run mark the modules **"USED"**.

Cut-Off Date

To acquire credit for this bulletin, all claims must be received in La Crosse no later than June 30, 1994. Any exceptions to these guidelines require written authorization of La Crosse Technical Service.

General Service Bulletin

CTV-SB-91A

Library	Service Literature
Product Section	Refrigeration
Product	Centrifugal Liquid Chillers
Model	CTV
Literature Type	General Service Bulletin
Sequence	91A
Date	May 4, 1994
File No.	SV-RF-CTV-CTV-SB-91A-594
Supersedes	CTV-SB-91

Subject: HCFC-123 Engineered Conversion Requirements

Introduction:

The purpose of this bulletin is to provide general guidelines for the proper completion of a HCFC-123 "Engineered Conversion".

Recommended Action:

WARNING: To prevent injury or death due to electrical shock or contact with moving parts, lock unit disconnect switch in open position.

1) Close all chilled water and condenser water supply and return valves and drain the water boxes. Open all electrical disconnects and verify the power has been removed.

WARNING! To avoid injury or death due to inhalation of, or skin exposure to refrigerant, closely follow all safety procedures described in the Material Safety Data Sheet for the refrigerant and to all labels on refrigerant containers. Certain procedures common to refrigeration system service may expose operating and/or servicing personnel to liquid and/or vaporous refrigerant.

2) Remove all of the refrigerant charge using UL approved recycling equipment and follow proper handling procedures. Once the refrigerant charge has been removed to the required vacuum level established for low pressure refrigerant recovery, continue to evacuate chiller to 2.5 millimeters.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

3) Bring unit pressure back to atmosphere using dry nitrogen.

4) Set up proper rigging and begin unit disassembly. As components are being removed record all tolerances and match mark them so they may be reassembled in their original position. Make sure all items removed from the unit are properly covered and protected from rusting.

Note: CVHE Units
a) The casing parts should be scribed on both sides so they can be realigned properly during reassembly. This will insure the suction elbow will fit properly without causing misalignment of the compressor.

b) If the third stage volute (CVHE's) was not originally doweled it will be necessary to add dowel pins in order to insure proper realignment. See service bulletin CVHE-SB-10 for details.

5) Meggar test the new motor, check shaft runout, and end play (if appropriate) before proceeding with the compressor rebuild.

Note: CVHE Units
a) Particular attention should be given to the original tolerance of the oil seal assembly. The allowable (total) clearance between the shaft and the oil seal should be between .004 - .007". The clearance radially should be no more than .002 - .0035". Clearance in excess of this may lead to oil loss problems. If the seal is beyond the allowable clearance it should be replaced!! See Service Bulletin CVHE-SB-26.

Note: PCV or CV Units
a) When converting a PCV or CV unit from an old style motor to the newer liquid cooled rotor designs it will be necessary to make piping modifications. This applies when changing from a RCS style motor to a RPS or RVS style or from a RCC to the RVX style. Refer to service bulletins PCV-SB-3 and CV-SB-4.

b) The excess refrigerant drain line on the RPS and RVS style motors should have a filter screen installed per service bulletin CVHA-SB-11 or as explained in section 8.10.1 of Service Guide CTV-SG-1.

6) Drain the oil sump thoroughly and dispose of the waste oil in a manner consistent with all state, federal and local regulations for disposal of oil. Disassemble the oil sump head and clean the inside of the sump. The oil sump at this point should be modified to provide the necessary fittings to add an eductor assembly if necessary to insure proper oil return. See the section of this bulletin that describes Unit Modifications and Enhancements. Replace the oil pump motor if required and rebuild or replace the oil regulating valve. Reassemble the oil sump.

7) Drain oil from the oil filter assembly and remove the filter. Place used oil filter in resealable container. Follow all state, federal and local regulations for disposal of filter. Clean the filter holder and install a new filter or element. At this point you may want to install ball valves similar to the current CVHE's to help facilitate future oil filter changes. See service bulletin CTV-SB-19.

8) Reassemble compressor making sure all components are installed properly. Record all tolerances. Clean all casing parts thoroughly to remove all previous o-ring sealing compound. The compressor o-rings should be coated with Loctite 515 Gasket Eliminator, except the elbow to compressor joint. Gortex joint sealant (1/8" width) should be used for this joint. See service bulletin CTV-SB-66 for information on using and applying the sealant.

9) Always replace the existing oil drain hoses with the new ones provided in the conversion package. It is recommended that the hose clamps be inspected and new ones used when necessary. Using two clamps for the bottom connection on the oil drain line is advised.

© American Standard Inc.

10) It is probably advisable to disassemble all threaded pipe joints while doing a major overhaul or conversion on an older chiller. The joints should be cleaned and resealed using a thread sealing compound compatible with either refrigerant CFC-11 or HCFC-123. Threaded pipe joints on current production chiller units use either Loctite 277 or La-Co Slic-Tite paste with Teflon, except where the joint is close to a braze connection and may be subjected to extreme heat. Where heat is a major concern Teflon tape is currently being used. The Loctite 277 thread locker compound has been approved for use as a pipe sealer in this application and requires approximately 24 hours set time before being exposed to refrigerants. Set time before exposure will likely be a requirement for most of the pipe sealing compounds available today. There are undoubtedly many other pipe sealing compounds that are compatible in this type of application with refrigerants CFC-11 and HCFC-123. Before using other thread sealers check with the manufacturer of the compound to verify compatibility and reliability through laboratory testing and field experience in use.

11) Motors should be air run without impellers to measure oil flows and check for vibration. Refer to service bulletin CTV-SB-13. Run motors at reduced voltage if the starter type will allow. Do not run motors more than 10-15 minutes. The motor should be allowed to cool before additional runs are made.

Note: Units with factory or field installed electrically actuated hotgas bypass or free cooling valves may require rebuild or replacement. Prior to 1994 the Trane Company used four different valve manufacturers.

A. Valves manufactured by Posi-Seal (1), will in most cases require rebuild kits in order to be made compatible. There were a few Posi-Seal valves manufactured with resilient internal seats that will require complete valve replacement since new seats are not available in a compatible material.

B. Valves manufactured by Keystone(2) and Jamesbury (3) are compatible.

C. In a very limited number of units Dover-Norris (4) valves were also used. The Dover-Norris valves are not compatible and must be replaced since rebuild kits are not available.

In all cases the unit should be inspected to determine the valve manufacturer and their model numbers. This information is necessary in order to insure the correct material or valves are furnished and to determine what work will be required.

Note: Units with pnuematically actuated hot gas valves have stem seals and other internal components that are compatible. In all cases we recommend new flange gaskets be used.

12) ORIFICE REPLACEMENT:

a) PCV,CVHA,CV,CVHB:
When a new set of orifices are required for these model units the conversion package will include a new set of distributor plates for installation in the condenser and evaporator liquid lines. The package also includes a drawing that highlights the new well rounded orifice diameter that will be required. The well rounded orifice (both) should be enlarged by using a proper diameter steel Hawg cutter, a tapered reamer or a die grinder with carbide bur to increase the size to the new specified diameter. Discard the old distributor plates and install the new ones provided.

b) CVHE: When orifices are required new orifice assemblies will be provided for the condenser liquid line, evaporator liquid line, and the economizer. For units which do not have the removable orifice option it will be necessary to remove the entire liquid sump from the bottom of the economizer. Once the sump is removed the orifice welds must be ground away so the new orifice can be installed. Make sure the new orifice is welded into the economizer to the same depth as the original to insure there will be no restrictions to flow. The sump should be welded back onto the economizer.

13) ADDITIONAL UNIT MODIFICATIONS AND ENHANCEMENTS:

a) All Units: It is advisable to add the necessary fittings so that an InterClean system can be added to the chiller to remove any small amounts of debris (typically rust) or old compressor oil etc., that may still be left in the unit after the conversion is completed. Once a system is clean and there is no concern about contaminating the oil sump with the old oil or other debris an oil return eductor may be connected direct to the sump if oil loss becomes a problem. Oil loss can occur in some chillers due to unusual operating conditions such as cold tower water temperatures and light loads etc. The fittings that are added for connection of an InterClean system can also be used as access points for future use of recovery equipment etc. when servicing the chiller.

b) PCV,CVHA,CV,CVHB: If an oil return eductor system is to be installed follow the procedures in service bulletin CTV-SB-68.

Note: For units with the older RCS style motor an additional oil sump vent line to the evaporator will be required.

c) CVHE: Older style CVHE's that had the oil sump vent line connected to the suction elbow should be repiped per service bulletin CVHE-SB-26 to include a vent line solenoid valve and a larger 1-1/8" line. The larger vent line, solenoid valve, and timer should be installed on all units. CVHE units should be modified to have two eductors similar to new production units. One is used to return oil from the suction cover and the other returns oil directly from the evaporator. Make sure that the system is clean so that debris does not get into the sump as indicated above.

d) CV,CVHB: The oil sump vent line valve should be located on the suction elbow per service bulletin CVHB-SB-2. An oil return line from the suction cover to the oil sump as described in this bulletin should also be added.

Note: For CVHE's which use the DRV 5 1740 frame motors a larger motor cooling orifice should be used as per service bulletin CVHE-SB-29.

14) Make sure that all other field added components such as liquid level indicators, head pressure controls, etc. have been reviewed for compatibility.

Note: CVHE Units
At this point CVHE units should be air run with and without the suction elbow to insure proper balance. See service bulletin CVHE-SB-18 for additional information on vibration testing CVHE chillers.

15) Once the unit has been reassembled it should be pressure tested using dry nitrogen and soap solution. All leaks should be repaired, the unit should be evacuated to 2.5 millimeters. Once evacuated the chiller will be required to pass a standing vacuum rise test.

16) Inspect the equipment room to insure the requirements of ASHRAE Standard 15 have been met. This will require:
    1. A refrigerant monitor
    2. Self Contained Breathing Apparatus (SCBA)
    3. Ventilation
    4. The purge relief be piped into the rupture relief vent line to outside the building.

17) Refill the chilled and condenser water systems.

18) Charge the chiller with the new refrigerant. Refer to service bulletin CTV-SB-60 for proper refrigerant charge. Make sure vapor only is charged until the unit pressure is above the vapor pressure equivalent to the freezing point of water. Always run the evaporator pump while charging the unit to prevent freeze-ups from occurring.

19) Run the unit and log it for proper operation. If an InterClean has been installed the refrigerant angle valve on the liquid supply line should be adjusted to maintain a proper level in the tank. If an eductor has been connected directly to the oil sump it may be necessary to adjust the volume of flow to insure the oil sump temperature does not drop too low from excessive refrigerant flow. After cleanup the InterClean or the eductor system can be turned off and only used if future oil migration occurs due to unusual operating conditions etc.

20) Instruct the facilities operating personnel on proper procedures to follow when operating the chiller, the requirements for safely handling refrigerants, and the maintenance of the chiller and ancillary equipment such as the monitor etc.

Note: Always refer to the latest revisions of the service bulletins referenced.

Supersedes	New

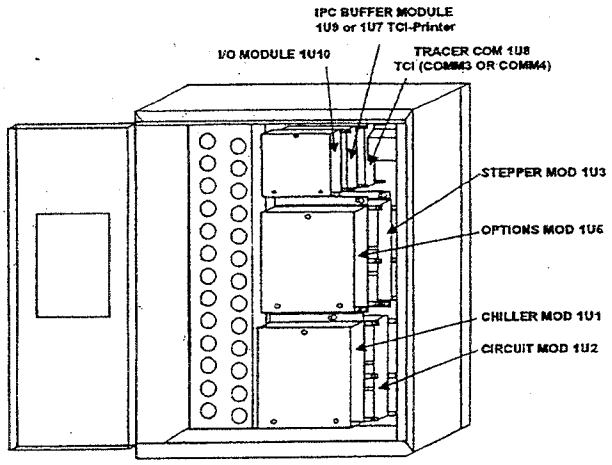
Literature Changes:
CTV-CSB-92 (7/94)--Original issue of Confidential Service Bulletin.
No General Service Bulletin Published.

Subject: CVHE/CVHF UCP2 PHASE C MODULE UPDATE

Introduction:

The purpose of this confidential service bulletin is to provide information concerning UCP 2 chillers requiring Phase C software.

Discussion/Units Affected:



Phase C software has now been released for the following options: Hot Gas By-pass, Free Cooling, Tracer Comm4, TCI-Printer Module and Evap/Cond. GPM & Chiller Tons Option (WFCH or WFCL). This bulletin covers units that shipped short one or more of these modules. A list of affected units and the material that needs to be ordered by the office will be mailed to each appropriate service manager under separate cover letter.

Module Update Procedure:

All factory wiring and connectors have been provided in the control panel by the factory. Mount the new modules in the space provided in the control panel as shown in Figure 1. We are requesting that all work be completed as soon as possible, before the **October 31, 1994** cut-off date. The required modules should be ordered through Trane Service Parts using the normal parts ordering procedure.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Figure 1
Control Panel

Parts Ordering Information And Authorization:

Following is a breakdown of the modules required for the affected units.

1. **Hot Gas By-Pass**——See Service Bulletin CTV-CSB-90 for installation.
   Modules required are CLD (MOD-0155), IO (MOD-0074) Chiller (MOD-0126)

2. **Free Cooling**————See Service Bulletin CTV-CSB-90 for installation.
   Modules required are CLD (MOD-0155), OPT (MOD-0170), Chiller (MOD-0126)

3. **Printer Interface Option:** Order TCI-Printer Module MOD-0152, Clear Language Display Module MOD-0155and Chiller Module MOD-0183.

4. **TCI-Comm4 to support Tracer Summit:** Order TCI-Comm4 Module MOD-0173 and a Clear Language Display and Chiller Module based on the following information:

   (A) If the unit is a Phase B shipment, Dec 13, 1993 to July 19, 1994 with a Clear Language Display Part Number X13650448-02 or newer and a Chiller Module with Part Number X13650450-03 or newer, then you do not require new Clear Language Display and new Chiller Module (Only Comm4 MOD-0173).

   (B) If the unit is a Phase A shipment, August 9, 1993 to December 13, 1993, then you need to order a new Clear Language Display Module MOD-0155 and a new Chiller Module MOD-0183 in addition to the Comm4 MOD-0173.

5. Units with Evap/Cond. Gpm & Chiller Tons Option (WFCH or WFCL) require a new Chiller Module MOD-0183 and a new Clear Language Display Module MOD-0155.

6. **Mounting Plates:**

   6.1 A large mounting plate for mounting the Chiller Module shipped with the original panel. However, if required, order Part Number PLT-2153.
   6.2 A Small mounting plate is required to mount the TCI-Printer Module. Order Part Number PLT-2154.

©American Standard Inc. 1994

7. **Wire Connectors:**
   All factory wiring has been provided with the required Phoenix Connectors. Field wiring will require appropriate connectors to be ordered and installed.

Mnemonic Part Number	Connector
CON-0429	2-PIN
CON-0430	3-PIN
CON-0431	4-PIN

Labor and Travel Authorization

This service bulletin authorizes 1.0 Man Hour per unit on affected units, plus actual travel time for each job. Authorized hours and actual travel time will be paid at approved commercial systems group rates. All claims must be submitted on the "Service/Warranty Sales Allowance Claim" (FORM NO. 1-30.09-2), within 30 days of the repair. To receive proper credit, check the "Retrofit Box" on the claim form and refer to this service bulletin.

Material Disposition:

Upon completion of the Phase C upgrade, any original UCP2 modules must be returned to La Crosse per the following instructions.

1. Return all modules to:

   The Trane Company
   Plant 4 Salvage
   2411 East Avenue
   La Crosse, WI 54601

2. Return all modules on a job by job basis. Do not wait to complete all updates before returning replaced modules.
3. Mark the outside and inside of each box "Per service bulletin CTV-CSB-92."
4. On units that have not yet been started, mark the modules "New".

Cutoff Date

To acquire credit for this bulletin, all claims must be received in La Crosse no later than October 31, 1994.
Any exceptions to these guidelines, require written authorization from La Crosse Technical Service.

Literature History: CTV-SB-97 - Original issue of bulletin - October 1996

Subject: Redesigned Lubrication System for CVHE/F/G

Introduction:

A redesigned lubrication system is being used in production for the CVHE,F, and G centrifugal machines. (See Figure 2 & Figure 8).

Units Affected:

Beginning with design sequence 2K for the CVHE, L0 for the CVHG and U0 for the CVHF machines, the redesigned lubrication system is incorporated.

Discussion:

Lube System Overview

The new lube system incorporates the following features:

- One rotary valve is used to allow the following operation modes: run, filter drain, and filter change. (See Figure 1).
- The oil pressure regulator and oil filter is integral to the tank cover assembly. See Figure 2.
- Only two joints to the lubrication system and they are bolted, gasketed, flanged joints.
- Better visual display of the oil level indication through the use of aluminum balls incorporated in the sight glass which float when oil is present. See Figure 3.
- Better access through the oil tank cover to allow removal and/or replacement of the oil mist eliminator.
- Reduced number of manufactured joints will reduce field leaks.

©American Standard Inc. 1996

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

Operating the New Lube System

The operation of the new system is identical to the old system. Oil is pumped from the oil tank (by a pump and motor located within the tank (see Figure 4) through an oil pressure regulating valve designed to maintain a net oil pressure of 12 to 18 psid. It is then filtered and sent to the compressor motor thrust bearing and to the motor journal bearing through the oil cooler (if so equipped). The oil filter assembly incorporates a rotary valve to isolate the oil filter from the unit during filter replacement. (See Figure 1).

Lube System Maintenance

Reference service bulletin CTV-SB-19D for recommendations for oil analysis and oil sampling procedures. Replace the oil filter annually, at each oil change, or anytime erratic oil pressure is experienced during chiller operation.

Oil Filter Replacement Procedure

Use the following procedure to service the oil filter. (Refer to Figure 8):

1. Run the oil pump for two to three minutes to insure that the oil filter is warmed up to the oil sump temperature.

2. Turn the oil pump motor off.

3. Pull the "D" handle on the rotary valve locking pin out of its detent and rotate the valve to the "DRAIN" position. (See Figure 5). An offset pointer is located on the top of the valve with wrench flats to allow turning. The spring force on the locking pin should allow the pin to drop into a detent at this position. (See Figure 6).

4. Allow at least 15 minutes for the oil to drain from the filter back into the oil sump.

5. Pull the "D" handle to unlock the pin and rotate the valve to the "CHANGE FILTER" position. (See Figure 7). This isolates the filter from the unit. The locking pin should drop into a detent in this position.

6. Remove and replace the filter as quickly as possible. Place the used filter in a resealable container. Follow all local, state and federal regulations to dispose of the filter.

7. Pull the "D" handle to unlock the pin and rotate the valve to the "RUN" position. The locking pin should drop into a detent in this position. (See Figure 1). The chiller is now ready for operation.

Lubrication of the Rotary Valve

The rotary valve uses dual o-rings to seal to atmosphere. A small pipe plug located above the oil filter is provided to allow manual lubrication to these o-rings. To prevent o-rings from drying out and leaking, at least once a year or more often if desired, remove the pipe plug and place a few drops of Trane Oil-0022 in the cavity. This will provide proper lubrication to the o-rings. **Be sure to reinstall the pipe plug when lubrication is completed.**

Adjusting the Oil Pressure Regulator

The oil pressure regulator is identical to the previous design oil system except that it is located on the oil tank head directly. To adjust the oil pressure, remove the seal cap to this valve and turn the stem clockwise to increase pressure or counter-clockwise to decrease the net oil pressure. Make adjustments as quickly as possible. A slight amount of refrigerant leakage/air leakage may occur when the cap is not sealing the valve. **Be sure to secure the cap tightly on the valve when adjustment is completed.**

Optional Dual Oil Filter System

As an option, a dual oil filter assembly is available. This is essentially two complete oil filter assemblies each with its own oil pressure regulator and rotary isolation valve. The following procedure should be followed:

1. Both valves should normally be in the "RUN" position.

2. After the operator throws the toggle switch to switch the active valve assemblies, the following action should be taken on the inactive valve assembly (clogged filter):

   a) Pull the "D" handle on the rotary valve locking pin out of its detent and rotate the valve to the "DRAIN" position. Release the "D" handle and the locking pin should engage a detent in this position.

   b) Allow at least 15 minutes for the oil to drain from the filter into the oil sump.

   c) Pull the "D" handle to unlock and pin and rotate the valve to the "FILTER CHANGE" position. Release the "D" handle and the locking pin should engage a detent in this position.

   d) Remove and replace the filter as quickly as possible. Place the used filter in a resealable container. Follow all local, state and federal regulations to dispose of the filter.

   e) Pull the "D" handle to unlock the pin and rotate the valve to the "RUN" position. Release the "D" handle and the locking pin should engage a detent in this position.

Subject: Color Markings on O-Ring and Gasket Material

Introduction:

The purpose of this service bulletin is to provide information related to the color markings of the rubber o-rings and flat gaskets furnished as service replacement parts for the Trane CenTraVac® products.

Discussion:

The o-rings and gaskets used by the Trane Company have an identifying mark on them designating the specific type of material. These markings are generally a small colored dot used on o-rings and for gaskets, either a small dot on the edge or a thin stripe on the face of the gasket. **The information in this bulletin does not apply to paper, Teflon, red rubber, or fiber reinforced type gaskets.**

The following information is intended to assist the installing service technician in identifying the type of rubber o-ring and gasket materials that are acceptable for use in the different refrigerants. Also included is general information on water box o-rings and gaskets. Use of an improper rubber o-ring or gasket in a refrigerant application can result in premature failure of the material and subsequent equipment leaks.

R11 and R113 Water Cooled Centrifugal Units:

The low pressure R11 and R113 centrifugal units use a material with a yellow or white marking. For some high temperature applications (commonly the discharge flange and second stage volutes to motor housing or volute to volute o-rings on heat recovery units) the material will have an **orange** mark indicating its suitability for the higher operating temperatures.

The **yellow** and **white** marked materials for use in these refrigerants are still available and may be supplied as service parts for replacements. There will be many instances where the replacement part will be an alternate material with a **brown** mark. The **brown** marked material is completely compatible with R11 and R113 in all temperature applications and can be used in refrigerants R11 and R113. The substitution of the alternate material has occurred on some o-ring and gasket sizes where low usage and increased costs of the original material (**white**, **orange** or **yellow**) has warranted the change to reduce inventories of stocked parts.

Since the Trane Company has a policy of continuous product improvement, it reserves the right to change specifications and design without notice. The installation and servicing of the equipment referred to in this booklet should be done by qualified, experienced technicians.

©American Standard Inc. 1998

R123 Water Cooled Centrifugal (Including Converted) Units:

All refrigerant side R123 o-rings and flat rubber gaskets must have a **brown** mark indicating their compatibility with this refrigerant.

⚠ **CAUTION**
DO NOT USE YELLOW, WHITE OR ORANGE MATERIAL IN REFRIGERANT R123 APPLICATIONS. USE MATERIAL WITH A BROWN MARKING. Failure to do so will result in material failure and subsequent equipment leaks.

R12 Air Cooled or R12 Water Cooled Centrifugal Units:

The original refrigerant side o-rings and gaskets used for the air and water cooled CenTraVac® units built by The Trane Company are marked with either a **red** or **green** dot depending on the application. These o-rings are still available as service parts in many cases. In some cases the replacement service part for one of the original o-rings or gaskets (**red** or **green**) may be the material with the **brown** marking as indicated in the section above. The substitution of the **brown** material is related to usage and cost as previously discussed. It should be noted that the o-rings and gaskets with the **brown** marking are fully compatible with R12 in all applications.

Note: The only R12 water cooled centrifugal chillers manufactured by The Trane Company were the large hermetic model CVHD units.

R134a (Converted) Air Cooled Centrifugal Units:

The material used today in the conversion of units in the United States and Canada from R12 to R134a is the same material used on the R123 low pressure refrigerant units and has the **brown** markings. All of the rubber gaskets and o-rings used in these conversions and any replacement service parts ordered after the conversion must be the **brown** marked material. This applies only to units converted in the US and Canada.

Water Box O-rings and Gaskets:

In general, the most widely used o-rings and gaskets installed on water boxes has been the **yellow** or **white** material. Many water boxes also use a thin tape (**red**) type of gasket which is supplied in a roll for field replacement. The replacement material (excluding tape) most often supplied today will be the **white** or **yellow** marked material. It may be possible to receive an alternate **brown** or even a **red** or **green** marked material as a replacement part. All of these materials are acceptable for use in a water box application.

In summary the following general rules apply to the use of Trane's o-rings and gaskets for the various refrigerant applications in the CenTraVac® product.

Application	Approved Material	Possible Substitute Material
R123 CenTraVacs All Temperatures	Brown	None Approved
R11 and R113 CenTraVacs Standard temperatures and heat recovery non-discharge areas.	Yellow or White	Brown
R11 and R113 CenTraVacs High temperatures (heat recovery) in discharge areas only.	Orange	Brown
R12 CenTraVacs Air and Water Cooled All temperatures.	Red or Green	Brown
R134a Converted Air Cooled CenTraVacs All temperatures.	Brown	None Approved
Water Box O-Rings and Gaskets	Yellow or White	Brown, Red, Green

It should be noted that the small painted marks on the o-rings and gaskets after being subjected to refrigerant and oil over time may no longer be visible.

It is hoped the information in this bulletin will help the installing servicemen quickly identify and confirm the suitability for use of the replacement gaskets and o-rings supplied for Trane CenTraVac® equipment. This may avoid inadvertent use of an o-ring or gasket material that is not compatible with the refrigerant being used in the unit. This is especially important as many units today are being converted to alternative refrigerants.

Labor, Material and Travel Authorization

This is an informational bulletin only and there is no labor, material or travel authorized.

Replacement of Relay RLY00765 with KIT07406

⚠ Warning
Hazardous Voltage!

Disconnect all electric power, including remote disconnects before servicing. Follow proper lockout/tagout procedures to ensure the power can not be inadvertently energized. Failure to disconnect power before servicing could result in death or serious injury.

RLY00765, the Trane Motor Protection Module, is no longer available. KIT07406 is a functional replacement. KIT07406 includes the MP-3000 (SHD00334) motor protection relay, a signal conditioner (TRR01622), a terminal block (BLK00285), and a mounting adapter (PLT03427) to allow the MP-3000 to be mounted through the existing cabinet door.

SHD00334 provides most of the functionality of the existing Motor Protection Module.

Note: *The new SHD00334* ***Does Not*** *provide distribution fault protection. A distribution fault is defined as a complete loss of line voltage for a period of less than 60 cycles. If distribution fault protection is still desired, a FastPak or full UCP2 controls retrofit can provide that functionality.*

Setting Proper CT Ratio

RLY00765 is designed for use with current transformers (CTs) having a nominal or rated secondary current of either 5 amps or 1 amps. Typical Trane CTs are 5 amp.

When CT ratios are set, the value entered is the numerator of the main CT ratio. The denominator then is assumed to be 5.

For reliable motor protection, the CT must deliver between 2.5 and 4 amperes at 100 percent of the chiller motor FLA.

For optimal metering accuracy at low loads, the CT should deliver between 3.5 and 4 amperes at 100 percent FLA. **Attempt to achieve 3.75 A.**

© American Standard Inc. 2002

Since Trane has a policy of continuous product and product data improvement, it reserves the right to change design and specifications without notice. Only qualified technicians should perform the installation and servicing of equipment referred to in this publication.

For example, if the motor has an FLA value of 300A and the existing CT is 400:5, the CT will supply:

300 x 5/400 = 3.75 amps (an ideal value) This parameter is set in Page 1, Line 5. See the enclosed vendor literature, page 47, for more details.

If the existing CTs do not deliver acceptable values, new CTs will be required. Once the correct CT ratio is determined, see Table 3 for part numbers to order the correct CTs.

On some CVHA models with pneumatic load limit relays, the CTs were located on the leads (T1, T2, T3, T4, T5, T6) going to the motor rather than on the line side of the starter ("phase amp monitoring"). These CTs do not read full current drawn by the motor. In these cases, the CTs must be relocated to the line side of the starter so they read full current drawn by the starter. These CTs may have to be replaced if they do not fall in the range mentioned above. If new CTs are required, see Table 3 for part numbers to order the correct CTs. A wiring diagram is included in this manual.

Wiring Notes

Because some of the functionality of the old RLY00765 is contained within the SHD00334 module, some of the existing wires are no longer required. The following table describes where the wires from the old relay, RLY00765, are to be placed on the new SHD00334 module and TRR01622.

The terminal block will not be required for every installation. It is included for situations where existing wiring is not long enough to reach from the existing RLY00765 location to the through-door location of the new SHD00334. Figures 1 and 2 show the existing RLY00765 connections and the SHD00334 terminals. Figure 4 shows the TRR01622 connections.

Because the existing capacity control module expects a 0 to -8.25 volt DC signal and the MP-3000 outputs only a 4 to 20 mA signal, a signal processor is required (TRR01622). Wire TRR01622 to SHD00334 and the existing RLY00765 as shown in Table 1.

Installation

1. Install the SHD00334 through the panel door using the mounting flange, hardware, and gasket provided. See figure 3 for panel cutout and mounting details. Figure 5 is a full size cutout template.

Installation

***Note**: SHD00334 does not have to be mounted through-the-door. That would mean the display will not be able to be read and all programming must be done with the door open.*

2. Move wires from existing RLY00765 to new SHD00334 and TRR01622 as shown in Table 1 and Figures 1, 2 , 4 and wiring diagram. Terminal block BLK00285 is included if required to splice in additional wire.

***Note**: RLY00765 does not have to be removed if it does not present a space problem in the starter cabinet.*

3. SHD00334 must be programmed correctly to ensure proper operation and protection of the chiller.
   See the installation manual included with SHD00334 and Table 2 for proper settings. Table 2 shows values that need to be changed from the default values. If no value is shown in "Selected Value" column in Table 2, the default value should be used. Verify default settings match what is shown in Table 2.

***Note:** The security door located on the bottom left of the operator panel covers two pushbuttons: Program and Emergency Override. The door will accept a lead seal to prevent unauthorized set point changes and the overriding of start lockout functions.*

4. Consult enclosed Cutler-Hammer literature I.L.17562 for details about specific parameters, operation, and troubleshooting.

New Connection TRR01622								1	3			

From new connection TRR01622	6	5
To new connection SHD00334	24	25

Notes:

Terminals 7 and 9 must be jumpered together on SHD00334.

For wires not used, wire nut and tape wires, coil up, and place out of the way.

* Shut trip circuit breaker CB11 no longer used. Wire terminals 12 and 13 directly into circuit as shown on wiring diagram.

** TRR01622 terminals 7, 8 and Capacity Control module terminals V1 and V2 are polarity sensitive. If polarity is reversed, chiller will run fully loaded and will not unload.

Service Alert

Subject: CenTraVac Thrust Bearing Alignment Mark Removal

ORDER NO: CVHE-SVA07A-EN DATE: June 10, 2002

To: Field Office Managers, Field Service Managers and Parts Managers

From: La Crosse CenTraVac Technical Service

Introduction

The purpose of this Service Alert is to inform the field that a change is being implemented that removes the alignment (high spot) markings on the duplex ball bearings for the CenTraVac® thrust bearings.

Discussion

In the past, all CenTraVac duplex ball bearing sets were marked for high spots and had specific alignment marks to allow proper installation (a half of a "V" or small circles for the outer race and a straight line or small circles for the inner race). The procedure for bearing installation is covered in Service Bulletin CVH-E-SB-33A and PART-IN-43. Beginning in 2002, the bearing vendor will be shipping duplex ball bearing sets without the high spot markings (no alignment marks present). In the past, when bearing sets were received

without the alignment marks, they were rejected for installation on the CenTraVac®. Today, if the bearing set arrives with no alignment markings, this is perfectly acceptable. No special alignment of the duplex ball bearings is required for these bearings except that they are mounted on the shaft in a back to back arrangement. This means that the oil grooves in the outer race must face each other when they are installed on the shaft. No special orientation of the oil grooves is necessary. If the bearing set has alignment marks, then follow the procedure given in Service Bulletin CVHE-SB-33A and PAFT-IN-43.

Units Affected

All direct drive CenTraVac machines that use the duplex ball bearing thrust bearings (Models CVHE, CVHF, CVHG, CDHF and CDHG).

Expiration Date

This service alert does not expire until further notice.

General Service Bulletin

Tracer CH530

Electronic Modules (LLID) Failures

Order Number: CTV-SVB05A-EN DATE: September 10, 2003

NOTICE: Warnings and Cautions appear at appropriate sections throughout this literature. Read these carefully.

⚠ WARNING: Indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

⚠ CAUTION: Indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury. It may also be used to alert against unsafe practices.

CAUTION: Indicates a situation that may result in equipment or property-damage only accidents.

Introduction

The purpose of this bulletin is to explain the corrective action of suspect or failed CH530 Electronic modules, also known as Low Level Intelligent Devices (LLIDs). Suspect electronic modules are identified in table 1 by description and date codes.

This is a Chiller reliability issue, not SAFETY HAZARD because the Main Processor (Dyna View) and Starter module are not included.

Product Models

CVHE, CVHF, CVHG, CVGF, CDHG, CDHF

Symptoms

- Loss of communication with a specific LLID.
- Loss of communication to most or all LLIDs (where the failed LLID is pulling down the entire communication buss).
- Service LED went on with magnet, but did not stay on when removed magnet.

© 2003 American Standard Inc. All rights reserved.

- Unable to bind device.
- Bound okay, but then lost binding. May or may not rebind.
- If rebound, possible loss of binding at a future time (check date code).
- Service LED or output goes on and off on its own.
- A power cycle seems to make the failure go away for a while. It will most likely fail again with time. Could be a non-recoverable failure at some point.
- Corrupted memory data such as a hardware part number or LLID date code with all zeros or random data (as viewed using TechView).

  Previous experience shows that the microprocessor most often fails on initial startup, of the controls, typically within the first few hours after power application. If you experience these symptoms follow the troubleshooting procedures below.

Sales Orders Affected

Potential affected Chillers shipped during March of 2003 through June of 2003.

⚠ WARNING

Live Electrical Components!

During installation, testing, servicing and troubleshooting of this product, it may be necessary to work with live electrical components. Have a qualified licensed electrician or other individual who has been properly trained in handling live electrical components perform these tasks. Failure to follow all electrical safety precautions when exposed to live electrical components could result in death or serious injury.

Corrective Action

- Determine if your unit has symptoms.
- Is it an affected sales order/serial number?
- Review LLID Date Codes via Binding View.
- Identify which LLIDS meet the criteria.

Two criteria must be met in order for a LLID to be considered suspect.

1. First the LLID date code must be within the range shown in Table 1. If this is true then continue with step 2.
2. The microprocessor date code must have a date code of 0305.

   Note: That there are large quantities of microprocessors with a date code of 0305 that are perfectly okay. Again, both the LLID date code and the microprocessor date code must be looked at to determine if this is a suspect LLID.

Table 1: LLIDs and Corresponding Date Codes

Trane X Code found on device(LLID)	Pride Part #	Description	TechView Min Date Code	TechView Max Date Code	LLID Date Code Label (White Sticker on LLID)

Replacing Suspect LLIDs

Use TechView version 7.02, and JAVA JRE 1.4.1_02

- LLIDs with red status in binding view are not communicating and need to be checked for proper IPC buss connections and replaced as necessary.
- LLIDs with Green status: Check the date code using the service tool.

If a LLID is currently communicating, and has the suspect date code/serial number, we will have you UN BIND it first, then remove from the BUSS and replace it.

NOTE: If you fail to UN BIND the LLID before installation of the replacement LLID, the new LLID date code will not be shown in TechView.

Those parts **not** affected include:

DynaView, Starter, pressure transducers, Rockwell/Trane AFD communications card, Triple winding temperature input, Comm 4, Comm 5, Inlet Guide Vane Actuator, and power supply.

TechView

If the component has suspect LLID code then check the microprocessor part for date code 0305 and replace the LLID only if it has both (suspect LLID and 0305 microprocessor). If the suspect LLID meets this criteria then:

1. Note the device name (function in this application)
2. UNBIND the LLID
3. Power down IPC buss
4. Remove and replace LLID
5. Power up buss
6. Reconnect (boots DV to Converter mode and rebuilds BV)
7. Bind installed LLID
8. Note the new date code for replacement LLID

Figure 1: Tech View - Binding View

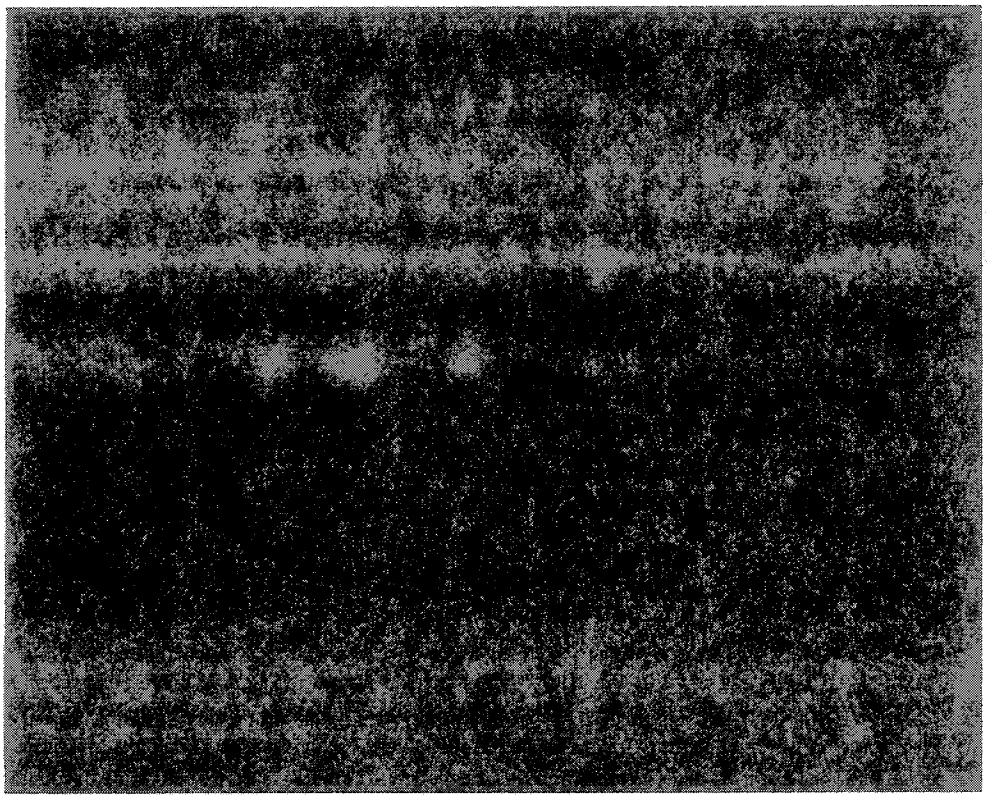

Figure 1 provides an example of TechView Binding View using the device information button (?).

Note that the date code is viewable. Check this date code with Table 1 to determine if LLID is suspect.

Parts Ordering Information

- Obtain the required parts from your local Trane Parts Center.
- Temperature sensors will require an IPC buss kit KIT 07957 to facilitate the installation of the new temp sensor. (This kit consists of two connector assemblies, a 2 foot section of unit wiring bus cable, four buss end caps and adhesive.)
- After June 3, 2003 all parts that have been shipped from the La Crosse warehouse are outside of the suspect date codes.

Questions

For general questions contact the CTV Technical Service department in La Crosse at 608-787-3943 or e-mail at TechService@trane.com.

Service Bulletin

Direct Drive CenTraVac Thrust Bearing Oil Feed Orifice Size Change

Order Number: CTV-SVB11C-EN DATE: October 8, 2004

Introduction

A production change has been made as a product enhancement to enlarge the oil feed orifice to the thrust bearings. We are asking that this enhancement be incorporated in all CenTraVac direct drive chillers with the center oil feed system to the thrust bearings whenever service work is performed that requires refrigerant removal.

Units Affected

All CVHE/F/G and CDHF/G chillers with center oil feed system to the thrust bearing. The design sequence (digits 10 and 11 of model number) for the units affected by this bulletin are as follows:

- CVHE — 3B through, but not including 3Y
- CVHF — 1J through, but not including 2J
- CVHG — 1B through, but not including 2B
- CDHF — J0 through, but not including 1A
- CDHG — H0 through, but not including Z0

As a note, all units with the refrigerant pump have a center feed system and will require this enhancement for the design sequences listed above.

Discussion

As a product enhancement, a production change has been made to increase the size of the thrust bearing oil feed orifice from 0.082 inches to 0.116 inches (number 32 drill size). The orifice will have a ".116" scribed on one of the flats of the hex if so equipped. This may be covered with paint and be hard to read without removing the

© 2004 American Standard Inc. All rights reserved.

paint. If service work is being performed on a center oil feed machine that requires refrigerant removal and the larger size orifice is not present, then the oil feed orifice should be removed and either drilled out to the new size or replaced with the new orifice (Trane Part Number ORF01388, which consists of the orifice brazed to a 5/8 inch copper tube with a protruding length of tubing of 3 inches).

For field modification, removal of the orifice will require cutting the 5/8 inch oil feed line with a tubing cutter and carefully removing the orifice from the bearing bracket. This pipe joint uses Loctite 242 for sealing and can be removed without the application of heat to the joint. After removing the orifice, drill out the hole to 0.116 inches using a number 32 drill bit. Be sure to check the hole for any burrs or debris after drilling and remove them if present before installation. Also, after drilling the orifice out, stamp or scribe/engrave one of the hex flats of the orifice with the number 116 to indicate the new orifice size.

Before installing the new or reworked orifice, be sure to flow dry nitrogen through the oil line if brazing is used to reconnect the line. If soft soldering with Stay-Bright silver bearing solder or equivalent, be sure not to use excessive flux at the joint. Another option is to use a 5/8 inch compression (such as Swagelock) straight connector to join the tubing, which will only require deburring the copper tubing before installation. This method will allow easy disconnection and reassembly should future work be required where the oil feed line must be disconnected.

When the chiller has been leak checked, evacuated, and charged with refrigerant; run the oil pump and check the differential oil pressure before starting the chiller. Adjust the oil pressure to maintain between 18 and 22 psid. After starting the chiller, check the oil pressure again and adjust as necessary to maintain between 18 and 22 psid.

After completing this enhancement, please be sure and contact Bob Gollnik of the Product Quality Department in La Crosse by either phoning 608-787-4110, faxing 608-787-3024 or e-mailing *Bgollnik@Trane.Com* with the unit serial number, date of completion and whether or not the unit had a thrust bearing failure or replacement during this service work.

General Service Bulletin

Re-torquing of flat gaskets before start-up

Order Number: CTV-SVB17C-EN DATE: October 2005

Introduction

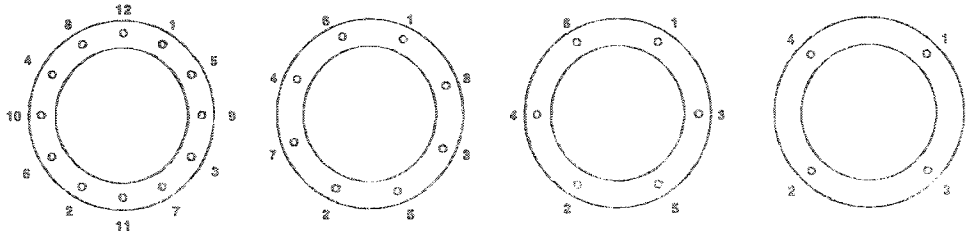
The purpose of this bulletin is to remind all service technicians of the importance of checking the flat gasket bolt torque's before charging and starting the chiller.

NOTICE: Warnings and Cautions appear at appropriate sections throughout this literature. Read these carefully.

⚠ WARNING: Indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

⚠ CAUTION: Indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury. It may also be used to alert against unsafe practices.

CAUTION: Indicates a situation that may result in equipment or property-damage only accidents.



Discussion

During the installation of any of the below listed La Crosse-built chillers, all economizer flange bolts should be re-torqued to current factory specifications as follows.

Torque all bolts using a calibrated, good quality torque wrench. All bolts shall be tightened in three stages and in a star pattern as shown in Figure 1.

© 2005 American Standard Inc. All rights reserved.

Figure 1.

Stage 1 - Cordless Drill - Driver to 5 ft-lbs.
Stage 2 - Hand torque wrench to 15 ft-lbs.
Stage 3 - Hand torque wrench to final torque as per Table 1.

Table 1.

Flange Family Size	Torque in Ft-lbs.
4 inch	33 ± 3
5 inch	25 ± 3
6 inch	25 ± 3
8 inch	33 ± 3
10 inch	25 ± 3
All other sizes	33 ± 3

Note: Factory uses a cordless drill-driver tool to provide initial tightening of bolts. Other means can be used for this stage. Second stage and final torque values should be accomplished with torque wrench for best results.

This service should be performed once the holding charge has been removed from the unit. Once the unit is charged and or running the re-torquing procedure discussed in this bulletin may not prevent the leak from occurring.

The following flanged economizer joints are included in this bulletin:

- Compressor inter-stage (1 connection-2 stage, 2 connections-3 stage)
- Evaporator connection (orifice)
- Condenser connection (orifice)/Condenser connection sump (032 & 050 shells)

Units Affected

- CVHE
- CVHF
- CVHG
- CDHF
- CDHG

Future work being done on flat gasket leaks

There will be additional design and process changes that will be completed within the next several months. This work will supplement the refrigerant leak issues at these joints.

Labor Authorization

There will be no authorized labor given.

Questions

For general questions contact the CTV Technical Service department in La Crosse at 608-787-3943 or e-mail at *TechService@trane.com*.

General Service Bulletin

CVHE/F/G and CDHF/G Thrust Bearing Center Race Retention

Order Number: CTV-SVB19C-EN DATE: June 2006

Introduction

The purpose of this informational service bulletin is to advise service and maintenance persons of a service parts change to the direct drive CenTraVac thrust bearing center race retention, and to describe the new procedures for the proper service of the assembly.

NOTICE: Warnings and Cautions appear at appropriate sections throughout this literature. Read these carefully.

⚠ **WARNING:** Indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

⚠ **CAUTION:** Indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury. It may also be used to alert against unsafe practices.

CAUTION: Indicates a situation that may result in equipment or property-damage only accidents.

Units Affected

All CVHE/F/G or CDHF/G chillers with compressors of 1280 NTON or less.

The design of the thrust bearing center race retention on CVHF or CDHF extended capacity chillers with 1470 or 1720 NTON compressors is not changed, so this discussion does not apply to extended capacity chillers.

Discussion

There have been some reported cases where field installation of the tab washer, while the motor is in a horizontal plane, has resulted in a tab washer that is not properly centered on the shaft. If this occurs an uneven pre-load may be applied to the bearing center races.

© 2005 American Standard Inc. All rights reserved.

Beginning Dec. 1, 2005, an upgraded self-locking thrust bearing retaining nut will be available from Trane.

The self-locking nut eliminates the use of the tab washer and the associated field service issues it can cause.

If you are installing new duplex ball thrust bearings onto a CVHE/F/G or CDHF/G compressor of 1260 NTON or less, it is recommended that you discard the older style lock nut and tab washer, and order and install the new style self-locking nut instead.

Application

Assembly procedure for the self-locking nut

1 If during a thrust bearing replacement an old type lock nut and tab washer are present, they should be discarded and a new style self-locking nut installed.

2 Verify the new style self-locking nut has a counter bore on one end and that the nut is labeled either SNSH-11 (for the small diameter shaft) or SNSH-18 (for the large diameter shaft).

Note: Only self-locking nuts sourced directly from Trane will have the necessary counter bore that allows the nut to fit properly onto the Trane motor shaft. Lock nuts purchased from other sources may not have this counter bore.

3 After the new bearings have been properly mounted and hydraulically seated onto the shaft, as per the latest revision of service bulletin CVHE-SB-33, assemble the self-locking nut to the shaft threads. The nut should be placed onto the shaft with it's finished face against the bearing. The face with the part # visible will be away from the bearing.

- Avoid the use of a hammer and spanner wrench to tighten the locknut. Use the proper size socket tool and follow the procedure as described below.

4 Torquing of the self-locking nut. Ideally, a torque wrench should be used to apply the required torque to the self-locking nut. This may be possible for the small diameter shaft units. For the large diameter shaft, a pneumatic impact wrench will be required to provide the torque required without allowing the rotor to turn in the stator. The following torque value is required:

- Small diameter shaft with SNSH-11 nut - 60 to 80 Ft.-Lb.
- Large diameter shaft with SNSH-18 nut - 160 to 200 Ft.-Lb.

Use the following method to obtain an accurate torque value and bearing pre-load when a torque wrench cannot be used:

a Torque the nut to 10% of final torque value using a torque wrench and socket tool. This will require a torque of 6 to 8 Ft.-Lb. for the small nut and 16 to 20 Ft.Lb. for the large nut. Visually inspect the nut to confirm it has seated against the bearing inner race.

b Mark the nut and inner race in a straight line to act as a reference point. Use a fine tipped marker pen or equivalent.

c Mark the inner race in a clockwise direction the following distance from the first mark:

- Small SNSH-11 nut: 0.3" to 0.5" range. (7.62mm to 12.7mm range)
- Large SNSH-18 nut: 0.5" to 0.7" range. (12.7mm to 17.78mm range)

This will provide a degree of rotation method for torquing the self-locking nut.

d Use the appropriate socket tool for the size of nut and a pneumatic impact wrench to rotate the self-locking nut until the mark on the nut falls in the range stated in step c. If an air source is not available, a large cylinder of dry nitrogen with a regulator adjusted to 120 psi (827 kpa) can be used to power the pneumatic impact wrench. A 3/4" drive wrench is required for the large self-locking nut.

Important: When the nut is fully torqued against the bearings, the brass shoes of the nut must NOT align with the keyway of the shaft. If this occurs you must loosen the locknut, then re-torque it to a value that is still within the specified range. Contact LBU technical service if you are unable to achieve a position where the locknut shoes properly clear the keyway.

e After the self-locking nut has been correctly pre-loaded, begin to secure the nut by tightening each of the set screws to a value that is 1/2 of the recommended torque. Then tighten each set screw to it's full recommended torque.

- Small SNSH-11 nut: Tighten the 3 set screws to 17.5 in-lb of torque, then tighten the 3 set screws to 35 in-lb (2.92 ft-lb) of minimum torque. The set screws provided with the SNSH-11 nut will be either allen type or TORX-Plus. If allen type, use a 3/32 allen socket. If TORX-Plus, use a 10-IP socket.
- Large SNSH-18 nut: Tighten the 3 set screws to 80 in-lb of torque, then tighten the 3 set screws to 160 in-lb (13.3 ft-lb) of minimum torque. The set screws provided with the SNSH-18 nut will be either allen type or TORX-Plus. If allen type, use a 5/32 allen socket. If TORX-Plus, use a 25-IP socket.
- Use only socket tools that are in good condition to avoid stripping out the set screws.

f Complete the thrust bearing and motor assembly following the remainder of the procedures as shown in the latest revision of CVHE-SB-33.

Removal Procedure for the Self-Locking nut:

1 Remove the torque on the 3 set screws of the self-locking nut by loosening them ½ turn. Use the proper allen or TORX-Plus socket, ensure it is in good condition to avoid stripping out the set screws.

2 Re-set the internal brass keys of the self-locking nut by tapping on the nut at the 3 set screw locations. Use a non-marring hammer. Use great care to avoid damage to the motor coils, shaft threads, etc.

3 Using a spanner wrench and hammer, carefully loosen the self-locking nut ¼ turn to remove the bearing pre-load, then repeat step 2.

4 Using a spanner wrench and hammer, carefully remove the self-locking nut from the shaft. If the self-locking nut does not begin to rotate freely you may need to repeat steps 2 and 3 several more times. Extra force on the spanner wrench or socket may be needed to help wear and release the internal brass keys.

5 After removal the self-locking nut must be discarded. The self-locking nut cannot be reused, always install only new self-locking nuts.

Parts Identification

- NUT01056, Self-Locking Nut SNSH-11 for the small diameter shaft, use with thrust bearings: BRG00913, BRG00609, BRG01209, BRG01507, BRG01583, and BRG01585.
- NUT01057, Self-Locking Nut SNSH-18 for the large diameter shaft, use with thrust bearings: BRG00914, BRG00610, BRG01210, BRG01508, BRG01584, and BRG01586.

In addition to being available separately, beginning in 1st qtr 2006 the self-locking nut will be included in thrust bearing sets ordered from Trane parts. The standard locknut and tab washer will no longer be included with thrust bearing sets.

Service Tools

- For small nut NUT01056, use socket tool TOL02826
- For large nut NUT01057, use socket tool TOL02827

Material and Labor Authorization

No material or labor is authorized.

Material Disposition

There are no materials to return.

Recommended Action

Discard the older design locknut and tabwasher when changing or installing thrust bearings onto CVHE/F/G and CDHF/G chillers with compressors of 1280 NTON or less. Use only the new self-locking nut.

Expiration Date

There is no expiration date for this bulletin.

General Service Bulletin

Vibration Analysis for CVHE, CVHF & CVHG

Order Number: CTV-SVB29A-EN DATE: August 2006

NOTICE: Warnings and Cautions appear at appropriate sections throughout this literature. Read these carefully.

⚠ **WARNING:** Indicates a potentially hazardous situation which, if not avoided, could result in death or serious injury.

⚠ **CAUTION:** Indicates a potentially hazardous situation which, if not avoided, may result in minor or moderate injury. It may also be used to alert against unsafe practices.

CAUTION: Indicates a situation that may result in equipment or property-damage only accidents.

Introduction

This service bulletin outlines the proper method for checking vibration levels on model CVHE, CVHF, CVHG, CDHF, and CDHG compressors, and also discusses the interpretation of vibration levels or signatures that may be encountered.

Discussion

This bulletin describes typical routine vibration analysis processes that can be performed to evaluate thrust bearing condition, or to determine if a rotational imbalance is present.

This bulletin does not directly address the determination of inboard or sleeve bearing condition in centrifugal chillers, as this is best done by an oil analysis program. This bulletin also does not address vibration or noise caused by aerodynamic, aero-acoustic, or structural resonance issues within the chiller, and it does not address the use of current analysis to determine motor or bearing faults.

© 2006 American Standard All rights reserved

Thrust Bearing Condition Analysis

While it is not a requirement for the proper routine maintenance of a CenTraVac chiller, vibration analysis is recommended as a valuable non-destructive method of determining the condition of the compressors bearings and for detecting any imbalance of the rotating components. Vibration analysis is often incorporated into the chiller's periodic maintenance program or "service contract" terms.

The thrust (or "outboard") bearing used in CVHE/F/G and CDHF/G chiller compressors is an anti-friction type, "duplex" ball bearing. As a result of this bearing's properties, the classic oil analysis program - successfully used to evaluate the condition of the babbitted inboard bearing - does NOT reliably indicate the condition of the thrust bearing.

"AUDIO" CHECK. The simplest and least expensive method of checking for thrust bearing failure is to listen to the bearing during operation and coastdown. A failed bearing will "howl" while the unit is running and "click" during coastdown. While the howling noise is readily apparent, the best way to listen for "clicking" during coastdown is to place a stethoscope against the thrust bearing inspection cover; the "clicking" sound will be most noticeable just before the rotor stops turning.

Mechanics stethoscopes for listening to machine noises are commonly available from automotive supply stores. If necessary, a screwdriver can be used in lieu of a stethoscope; simply place the tip of the screwdriver against the inspection cover, then press your ear lightly against the handle.

If the "audio" method of bearing evaluation indicates that the thrust bearing is bad, but unit vibration is not severe, the bearing will usually continue to be operable for several months before failing.

VIBRATION ANALYSIS. Another method to determine thrust bearing condition is by the use of a "vibration analyzer". There are several popular makes of analyzer equipment, and this discussion will try to remain general in nature in order to provide the best coverage.

Important!: While vibration analysis results indicating high vibration levels may be symptomatic of a potential bearing problem, it may not be necessary to change out the thrust bearing unless the audible symptoms described above are also present. View Figure 1, for example, a chiller with bearing vibration in the yellow caution range may continue to provide valuable service life if it does not also have audible symptoms.

It is sometimes difficult to define "good" or "bad" readings for a vibration analysis, since bearings of identical quality in similar units may well show different levels of vibration output. Most commonly, vibration analysis is used to monitor changes in the bearings quality over its entire life.

To correctly monitor a thrust bearing, it is important to record vibration levels when the chiller is fairly new; this establishes a "baseline" vibration level that can be used for comparison with future vibration level checks. It is also recommended that vibrations readings be taken with the chiller operating as fully loaded as is possible. Readings taken on a lightly loaded chiller (running less than 50% of capacity) can be misleading. Always check at higher loads if possible.

Note that it is important for the unit to be operating at similar conditions each time the bearing condition is checked. For this reason it is advisable to record vibration level readings at various operating load points.

Once the "baseline" is established, vibration analysis can be used to periodically check for bearing deterioration.

For units equipped with variable speed motor drives, it is recommended to manually override the motor speed command to 60Hz during the recording of vibration data. Readings taken at the same speed will be easier to use for trending, and will allow for the easier interpretation of data.

Equipment Recommendations

The vibration recording equipment used should be capable of recording or plotting vibration data or signatures, on single or on multiple channels. Equipment with the ability to plot "spectrums" and "waveforms" to allow the easiest review of data is highly desirable. NOTE: There is a great range of vibration analysis equipment available for purchase on the market, some with greater ability than others. Equipment should be selected based on the results expected, the amount of investment required, and the amount of expertise needed to operate it and to understand the result. Simpler less expensive equipment may be acceptable in many cases.

Any equipment used should, at a minimum, be capable of:

- Recording data in the frequency ranges of 0-3,000 Hz.
- Be capable of recording and displaying data at a minimum resolution of 1600 lines.
- Recording and plotting (as a spectrum) velocity in in/sec and mm/sec, in the range listed above.
- Recording and plotting (as a waveform) acceleration in g's.

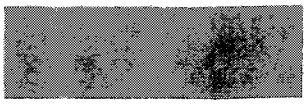
La Crosse CenTraVac Product Support presently uses CSI vibration equipment.

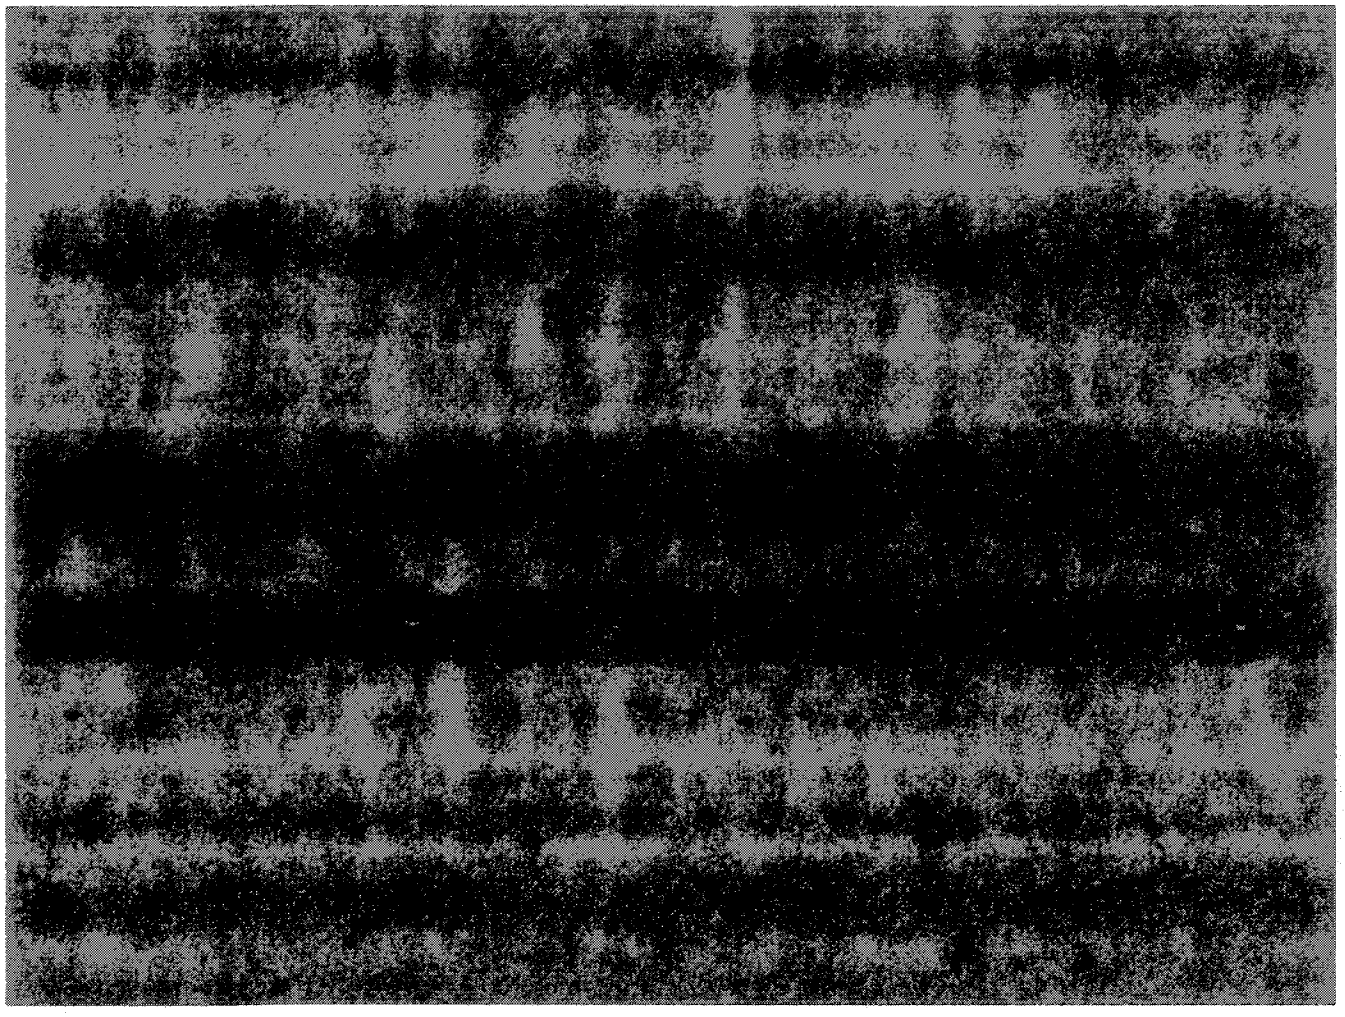
Data Collection Points

Data should be collected from the appropriate transducers placed on the equipment in the locations described below. The transducers may be magnetic mounted if desired, though a more securely mounted (bolted, epoxied, etc.) transducer may provide better results for bearing analysis. Be aware that transducers are generally very limited in accuracy at the higher frequency ranges, and some higher frequency results can be misleading if care is not taken.

Collect data from:

- Axial - Point A on Figure 1. Thrust bearing end of the compressor motor. Axial data can be very helpful in the determination of thrust bearing issues. Because bearing fault frequencies may be very high it is recommended that magnetically mounted transducers be avoided when taking axial readings. If possible, use the transducer mounting stud that is present on most bearing inspection cover bolting systems. Also, do not take axial readings near the center of the bearing inspection cover since it can act as a "drum head" and provide erroneous readings.
- Vertical Motor End - Point B on Figure 1. Place the transducer on the motor cover at the 6 o'clock position, close to the bearing inspection cover. May indicate thrust bearing condition or rotational imbalance.
- Radial Motor End – Point C on Figure 1. Place the transducer on the motor cover at the 4:30 o'clock position, close to the bearing inspection cover. May indicate thrust bearing condition or rotational imbalance.
- Horizontal Motor End - Point D on Figure 1. Place the transducer on the motor cover at the 3:00 o'clock position, close to the bearing inspection cover. May indicate thrust bearing condition or rotational imbalance.
- Vertical Compressor End - Point E on Figure 1. Optional. Generally used to determine rotational imbalance rather than thrust bearing issues. Readings affected by electrical noise.
- Horizontal Compressor End - Point F on Figure 1. Optional. Generally used to determine rotational imbalance rather than thrust bearing issues. Readings affected by electrical noise.





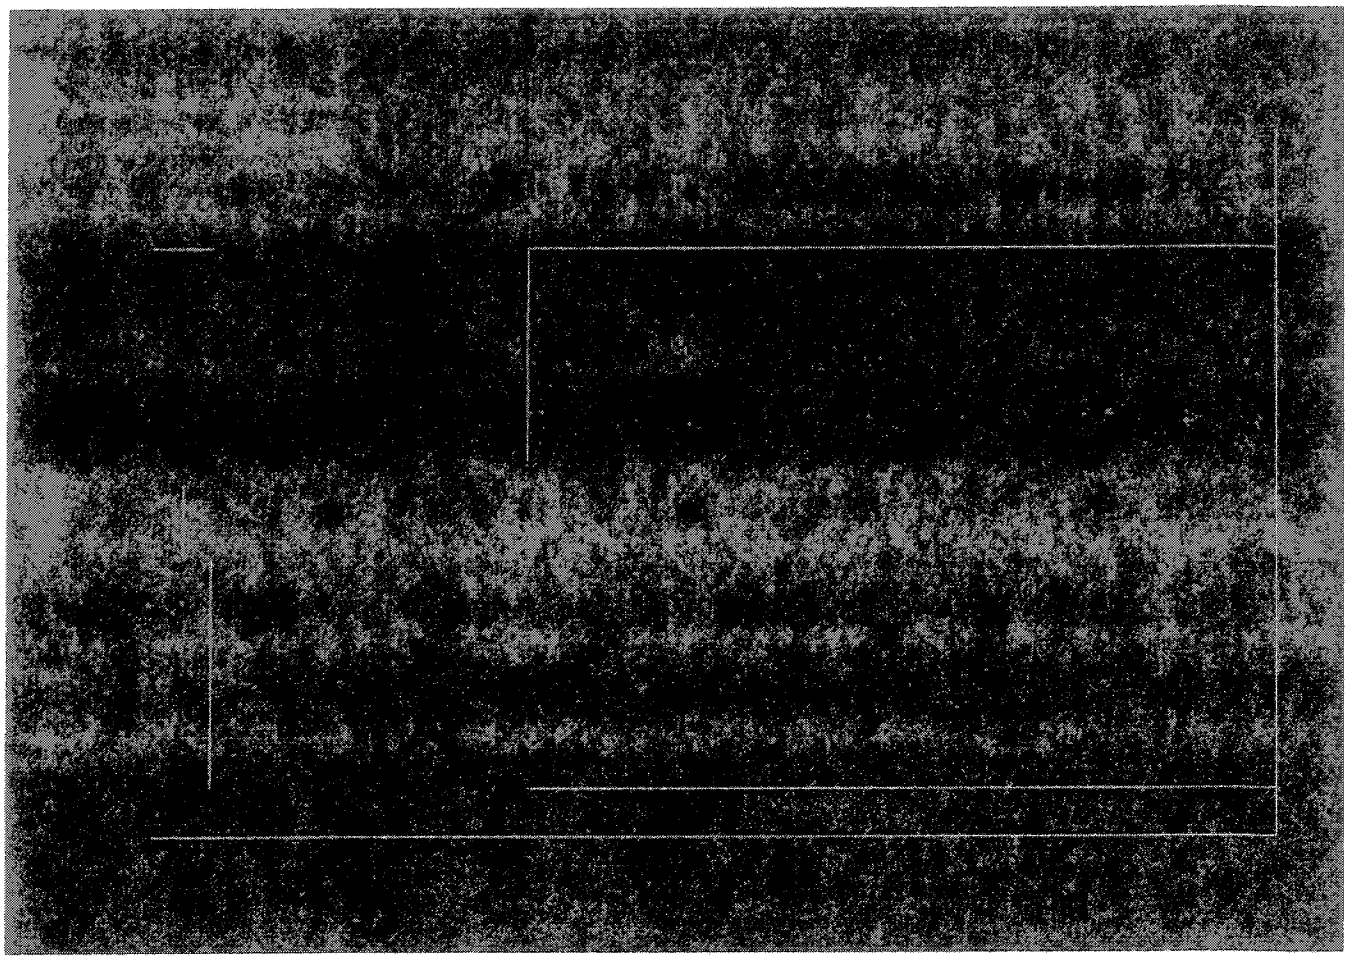


Figure 1. Recommended Vibration Data Collection Points

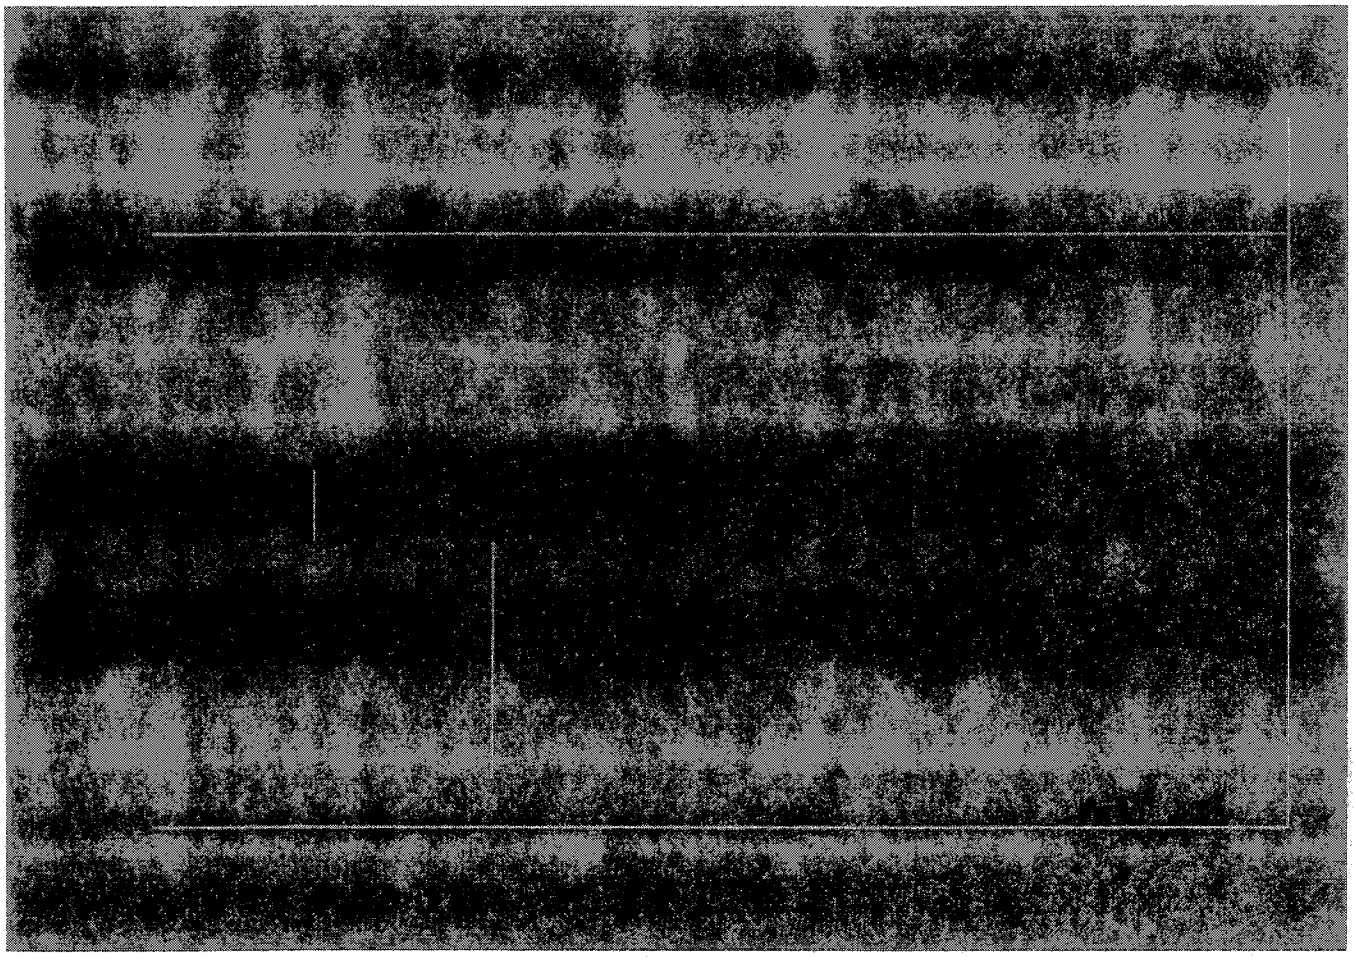
Thrust Bearing Acceptance Criteria - Velocity

While it is difficult to define pass/fail criteria for rolling element bearings, operation of any centrifugal chiller with a vibration level in excess of 0.25 in/sec (6.35 mm/sec) peak at rotational speed (50 or 60 Hz) is not recommended. The chiller should be secured and the cause of the vibration determined and corrected. For vibration limits at other frequencies refer to figure 2 & figure 3.

Figure 2. Recommended Limits



Green – acceptable vibration levels, no action recommended

Yellow – caution, closer monitoring of trends recommended

Red – warning, a bearing failure or rotational imbalance may be present

Figure 3. Recommended Limits

Green – acceptable vibration levels, no action recommended

Yellow – caution, closer monitoring of trends recommended

Red – warning, a bearing failure or rotational imbalance may be present

Thrust Bearing Characteristics

The data below is intended to assist a vibration analyst when identifying sources of thrust bearing vibration energy. Refer to tables 1 and 2.

Table 1. Ball Bearing Geometry

Bearing	Pitch Dia.(In)	# Of Balls	Ball Dia.(In)	Alpha (Contact Angle Deg)
BRG00913 BRG00609 BRG01209 BRG01507 BRG01583 BRG01585	3.4488	11	0.8437	40

Table 1. Ball Bearing Geometry

Bearing	Pitch Dia.(In)	# Of Balls	Ball Dia.(In)	Alpha (Contact Angle Deg)
BRG00914 BRG00610 BRG01210 BRG01508 BRG01584 BRG01586	5.5118	12	1.25	40
BRG01258	5.8071	12	1.3125	40

Table 2. Common Ball Pass/fault Frequencies
As orders of shaft turning frequency.

Bearing	Cage	Inner Race	Outer Race	Roller Spin	Roller Defect
BRG00913 BRG00609 BRG01209 BRG01507 BRG01583 BRG01585	0.4063	6.5307	4.4693	1.9721	3.9442
BRG00914 BRG00610 BRG01210 BRG01508 BRG01584 BRG01586	0.4131	7.0424	4.9576	2.1382	4.2764
BRG01258	0.4131	7.0424	4.9576	2.1382	4.2764

*values are approximate

Common Fault Indications

The CenTraVac product line has a lot of variation, the guidelines provided in this discussion are of a general nature and should be applied with caution

Loss of Thrust Bearing Preload - High radial vibrations at 1x operating speed. Loss of pre-load can reduce the 1st natural frequency of the shaft to running speed, resulting in excitation of the critical speed and very large shaft orbits.

Bearing Misalignment – May see high axial indications at 2x operating speed.

Electrical or line issues, may see indications at 2 x line frequency, if increasing over time consider electrical testing.

Thrust Bearing Damage - High axial vibrations at the ball pass frequencies and their multiples may be an indication of possible internal bearing damage.

Outer race clamping or distortion, may see indications or mounding at 500-600 Hz?

Motor eccentricity – High vertical and horizontal indications at 1x or 2x operating speed.

Open Rotor – Indications sometimes seen at ~44x (will vary due to rotor configuration or # of bars) operating speed. Sidebands may appear at 1x line frequency plus/minus 2x slip. To determine possible rotor bar defects using a vibration analyzer it will be necessary to set the analyzer for an 80Hz maximum scale and with a minimum of 1600 lines of resolution and preferably 3200 lines, to properly observe for the sideband frequencies around rotor shaft turning speed. Current analysis is a better indicator of rotor bar issues. Also be observant for other indicators of rotor issues (fluctuating oil

pressure, fluctuating amps, noise, longer acceleration times, more slip, etc.). Refer to CTV-SB-48 (latest revision)

Operating Imbalance – High vertical and horizontal indications at 1x operating speed.

Compressor Component Rub – 1/2x

Copper Plating - Indicated by higher frequency faults at all reading points. High g's overall. High energy at 8-12 kHz. May see an indication appear at the cage fault frequencies.

Definitions

Acceleration. the rate of change of velocity of a mechanical system. Commonly measured in units of "g" in English units. 1g = 386.4 in/s squared.

CPM. Cycles Per Minute. 60 cycles per minute = 1 cycle per second = 1 hertz.

Displacement. The distance that an object moves when vibrating.

Frequency. the number of times that an event repeats itself in a unit of time. Units commonly used are hertz (cycles per second) and CPM (cycles per minute).

Fundamental Frequency. the first frequency in a series of harmonic frequencies. Shaft turning speed is generally used as the fundamental frequency for bearing analysis.

Harmonic. an integer multiple of a fundamental frequency.

Hertz, or Hz. a unit of frequency equal to cycles per second.
1Hz = 1 cycle per second = 60 cycles per minute.

Mil(s). a unit of displacement equal to 1/1000 of an inch.

Order. a multiple of the shaft turning frequency.

Resolution. the number of lines displayed in a spectrum, for a given frequency range.

Spectrum. The frequency domain representation of a signal. Generally represented as magnitude against frequency, over a defined frequency range.

Velocity. the rate of change of displacement of a mechanical system. Typical units are inches per second.

Waveform. analog or digital representation of a signal displayed as a plot of level against time.

8

Tech Notes
Black Classic Panel

All of the panel circuit breakers have a 30 millisecond time delay so the U-2 gets power first.

K-5 – Oil pump time delay

K-6 – Oil pressure prove relay

K-3 – A back around relay to provide power for CB-1 coil

K-4 – Relay to start condenser water pump

Starter fault indicator breaker on panel front – trips if the starter opens when it has a run or start command. Possible causes:

loose control wires in control panel or starter panel
overload trip (causes breaker on starter to tip also)
loss of three phase (causes breaker for distribution fault to trip also)

A-3 – Vane close switch in vane operator motor

Wire points 8 to 9 – Flow switch wired in here, recommend time-delayed switch

Computer start/stop should be wired in at 9 to 10

Condenser water flow switch time-delay type wired in 11 to 12

Motor sensors 265°F = 115 ohms

Original U-1 temperature controller – It's sensor is polarity sensitive. Make sure you wire it correctly. Sensor cable should not be in a conduit with other power wires.

U-1 – Receives a voltage signal from solid-state overload. If current calibrator in the solid-state overload is set up correctly, you should see 8.25 VDC at U-1 at RLA – V1 to V2 on U-1.

Freestat is two stage – First stage causes had unload terminal 84 on U-1 – line 40. Second stage shuts chiller down!
This freestat is not ambient compensating. Therefore, if the equipment room is real cold or hot, the set point may drift. You can cover the capillary tube with insulation to reduce the bad effects.

K-5 – N.O. contacts on line 43 – Pre-lube
K-5 – N.C. contacts on line 44 – Post-lube

Terminal 31 – S on oil pump
30 – R
2 – C

K-15 – Oil pump current relay
Remember relay position sensitive

If you replace the oil pressure switch, don't use any switch with cap tubes. This causes sluggish response.

During evacuation service, pull F2 fuses so the oil pump can't try to start and burn out the motor because of the deep vacuum. This can occur if the post-lube time was not complete when the unit had the main power turned off.

During stop inspection, don't forget to check the little gears and hold down the wire on the vane operator. Lube the gears with a little grease.

Tech Notes
UCP-1
1985 - 1994

1 - U-1	Relay Output Board
1 - U-2	Power Output Board
1 - U-3	Micro Module
1 - U-4	Option Module - added in late production years (chilled water reset, etc. on this board

When you have a failure code, don't forget to write it down before you reset. If you don't and you reset, the code is gone!

If the oil pump switch is in the on position not automatic, the chiller will not start.

Pre-lube	15 seconds to 48 seconds
Post-lube	2 minutes

To check service setting, the vane position switch on the Micro must be in the "hold position to read items".

A-70 Anti-recycle time ranges from 4 minutes to 30 minutes based on winding temperature sensors

A-72 Start must occur and get to code A-74 by 27 seconds or a lock out will occur.

A-78 Look at current for swings - 15 minute time frame

A-100 Later unit code, see page 36 of CVHE-SB-22A

1-U-3 Chilled water reset module has three more knobs than the standard unit, see page 19 of CVHE-SB-22A. Must be in auto remote to enable reset.

Motor sensors can be removed from circuit with 75 ohms at 75°F one half watt. Watch out, don't jump out more than one without looking for some motor problem. i.e. grounding out, wet refrigerant, etc.

Starter prove contacts must report back to 1-U-3 in 2 seconds or starter failure code will result. Check auxiliary contacts on contactor. Must be mounted on the contacts near the coil. These contacts close a few milliseconds sooner than the other contacts in the auxiliary stack.

1-P4 on 1-U-3 is labeled from left to right 1 to 11 →
1-P5 on 1-U-3 is labeled from left to right 1 to 21 →
1-P1 on 1-U-2 is labeled from right to left (backward) 10 to 1 ←

Low voltage only in top of panel!! Nothing over 30 VAC

TECH NOTES

Balance Nuts
CVHE Chillers

There is quite an issue with balance nuts for CVHE units. I hope this data supplied by American Chiller will help clear up what is needed for these units.

For units built 1992 and after: NUT-838 for size 058 -125. NUT-839 for size 025 - 050.

For units prior to 1992: NUT-392 for size 056 - 125. NUT-393, NUT-394 and NUT-396 for size 020 - 050. So, if we are doing balance work on size 020 - 050, we will need all 3 nuts.

CVHE Tech Notes

When retrofitting a CVHE to a UCP 2 control panel, Trane has found that the old flat style oil heaters that are 1000 watts total are too much wattage for the contact in the microprocessor relay module. The contact will only handle a maximum of 750 watts. The fix is to install a pilot relay on the oil heater contact relay output and wire the heater to the contacts of the new relay.

When replacing an oil pump on a CVHE or CVHF without the refrigerant pump, the amperage has changed. The original oil pump pulled 4.9 amps. The replacement pump pulls 6.25 amps. The new motor is a part # MOT-2989. If you had the original CVHE with the screw in fuses, it will blow the fuses. To fix this, you need to add a fuse holder and fuses to the circuit. The Trane part number for the holder is HLD-87 and the fuses are FUS-547. Please be aware of the amperage change. You may come upon a unit that has the new style pump yet the nametag shows 4.9 amps as full load.

Bryan

Tech Notes

When we do stop inspections on CVHE/CVHF units, there is an allen screw on the first stage vane arm. Don't forget to remove it and put a couple drops of compressor oil in it. This lubricates the o-rings on the shaft and may increase their life and reduce refrigerant leaks caused by dry worn o-rings. (CVHE-OM-8B pg. 79)

CVHE/CVHF motor shafts have a step down on them where the first stage impeller sets. The impellers have been redesigned to be more aerodynamic.

Impellers on the CVHF extended capacity (i.e. single compressor large tonnage around 1470 to 1720 tons) have internal splitter vanes like the Carrier 19X series, but of course it is a closed face impeller.

The large extended capacity units (CVHF 1470 - 1720 single compressors) have two stepper motor vane actuators. It is currently required for equal vane movement. But other options may occur. One motor is not strong enough and two motors provide more accurate vane movement without slop due to linkages.

Impeller locking nuts are balance type nuts on all CVHE and CVHF's, etc.

Oil coolers are required on units over 350 tons.

Leaving chilled water and refrigerant sensors should be checked annually in an ice bath. These two sensors can be calibrated by software up to 2°F on UCP-2. (CVHE-OM-8B pg. 77)

The two eductors on the CVHE/CVHF should have the vanes set 1 ½ to 2 turns open on the evaporator and suction cover lines. If they are open all the way, they could cause cold oil sumps. Eductor lines may frost therefore they are insulated. (CVHE-OM-8B pg. 18)

Bearing sensors are standard on all units that have lower oil sump with refrigerant motor cooling pump which returns the refrigerant back to the condenser.

Oil pressure transducers are good for -15 psig to 35 psig. If you exceed 35 psig you may damage the sensor.

Minimum chiller pressure differential between the condenser saturation pressure and the evaporator saturation pressure is:

Older units with basic motor cooling - 5 psid
New units with refrigerant pumps - 3 psid

Refrigerant pump motor cooling units do not have or need the vent line solenoid.

The UCP-2 units have evaporator and condenser limits that may cause the chillers to run unloaded. If the chiller is in a big central plant where the elevated water out of one chiller is not noticed. You could lose oil because of the light load to a point that you may have to put oil back in the chiller to get it on line.

A couple of the guys in the class indicated they had units that developed leaks on the supply and return lines on the purge. It could be caused by maintenance stepping on the lines while cleaning or by vibration.

A few drops of compressor oil needs to be put on the o-rings on the oil block rotating valve. You will need to remove the small pipe plug at the valve to do this. Replace the plug. (CVHE-OM-8B pg. 79)

Trane has current tests to replace o-rings with new seal technology. This is loctite - 515 instead of o-rings. (Note small comment in CVHE-OM-8B pg. 78)

Trane service support recommends test running stepper motor during stop inspection and putting a few drops of compressor oil on the shaft and coating it. This reduces rust and internal damage. (Minor note CVHE-OM-8B pg. 77)

There were three designs of purges:

PRG-A purge with filter in cooling coil
PRG-B purge with regular canister style drier
PRG-C purge with replaceable one time drier with an o-ring

There are different charcoal replacement schedules for this based on the purge. See pg. 52 of the PRG-OM-6A. The normal purge rate seems to be about 3 minutes in a 24-hour period. Default setting in the micro is 20 minutes in a 24-hour period. If it purges that often, you probably have a leak.

Enhanced oil protection program on the UCP-2 must be enabled to run on units with refrigerant pump Just in case the refrigerant pump seal leaks refrigerant into the oil sump. Minimum oil sump temperature is evaporator saturation temperature +30°F or 100°F whichever is higher.

As most of you know, the UCP-2 can dry run the starter. But, remember to turn off 3 phase incoming power. You may need to supply 120V control from another source to do this.

Service Alert - Cutler Hammer size 4 and 5 contactor could stick closed. Trane offices are checking out units in their area. The contactors are called Cutler Hammer "Freedom Contactor".

CVHE/CVHF in very humid areas have had terminal condensation issues. Some of the units have had heaters installed in the terminal box cover to address this. This is another advantage of the refrigerant pump system - motor temperature runs higher than the old motor cooling system. (CVHE-OM-8B pg. 79)

New recommended net oil pressure for CVHE/CVHF is 18 to 22 psid. Low oil pressure cutout should be set for 12 psid. (CVHE-OM-8B pg. 30)

If keypad is locked for no access, the auto stop and panic stop on the UCP-2 is also locked out! To unlock the keypad, push previous and enter at the same time.

If you have a unit that has higher motor sensor reading and you would like to try and cool them down a little quicker for restart, try running the oil pump for 2 or 3 minutes.

The solid-state starters may not have any lower inrush than the normal Star-Delta starter. Don't tell a customer that as a sales tool, it may be wrong.

Some of the older and even some of the new Trane Purifiers had an issue with the TXV getting hung up. Ths caused excessive pump out due to low suction sensor temp. The older units had the TXV mounted upside down. The newer units were CVHE's 4 to 6 years old.

12% to 15% of the centrifugals leaving the Trane plant have frequency drives.
